Here, our question has been clarified. Why is it that KT disclosure grounds the anchored legitimacy of public universities?

The administrators of public universities, especially in generalist universities, must be able to draw a whole picture of all stakeholders (Freeman, 1984), as they in a sense represent them all (Leydesdorff 2012). However, thousand-year-old institutions may be deeply embedded in the DNA of their territories, representing norms, values, and beliefs. So-called anchored institutions, for instance civic universities, represent inner society and go beyond their missions, becoming deeply committed to the sustainable development of that areas (Goddard et al. 2016). Petruzzelli (2008) alone has taken account of how relational attributes can affect the KT between economic actors as is also treated here, although that study takes its data from a technical university, which is devoted to formal KT and does not consider informal KT, which pertains to departments of the social science and humanities more than to the more technical subjects. Moreover, Petruzzelli's study does not consider any implication in terms of legitimacy theory. Legitimacy theory, in its moral, cognitive, and pragmatic applications, does not provide an answer to the legitimacy problem of anchored institutions. While all organizations are driven by the search for legitimacy (Suchman, 1995, p. 574), anchored institutions already have secular social contract, which in the long run can be taken for granted, but must be supported by a communication policy (Dowling and Pfeffer 1975; Suchman 1995).

As anticipated by Dumay's work (Dumay and Guthrie 2017), despite the proliferation of IC reports (Agyemang and Broadbent, 2015; Ceulemans et al., 2015a; Sangiorgi and Siboni, 2017), the real decision points are found in the disclosure of information (Ferlie et

al., 2008): how to disclose and to whom. Our paper, which takes the University of Torino (UniTo) as its case will show the way in which disclosure adds value to anchored legitimacy.

3 Methodology

UniTo is taken as a case study, due to its particular features and its experience with KT. Using a qualitative methodological approach, the method of a case study allows the presentation of a situated examination of the problematic under investigation, with vivid illustrations from actually operating organizations and projects, offering insights into relations of cause and effect beyond what can be achieved from the quantitative analysis (Denzin and Lincoln 1994). Descriptions of meanings and relations are presented to understand how reality is put together, from the how events unfold of (Gephart, 2004). This methodology follows an accepted approach, in its design and execution (Yin 2003), involving the following: a criterion-sampling strategy, data collection from multiple sources, a strategy of analysis intended to obtain the greatest possible completeness of the targeted information (Patton and Appelbaum 2003). The rationale for this methodological choice are related to the exploratory nature of this study: UniTo is chosen as revelatory case of the generalist Italian public university, and the choice of a single-case study design is due to this method's capability of describing the existence of a phenomenon (Siggelkow 2007).

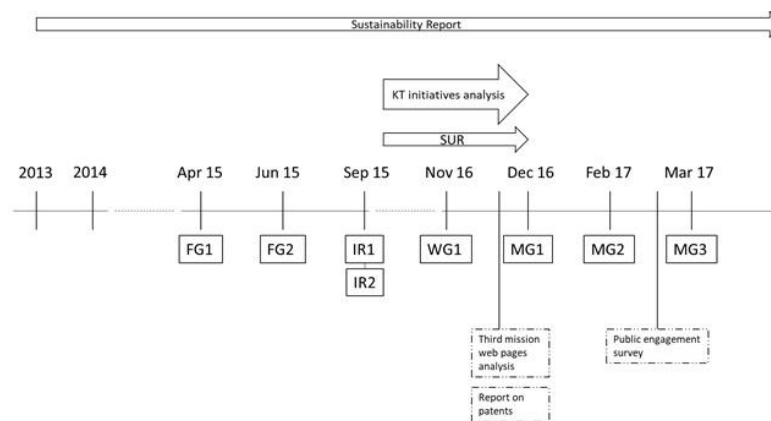

This case represents a unique opportunity to observe and interpret how a generalist public university addresses KT disclosure. UniTo is a large Italian public university, founded in 1440, and in addition to these historical roots, it has trained the winners of three Nobel Prizes and two presidents of Italy. Located in the Piedmont, UniTo is a city within the city of Torino, with 120 buildings in different areas of the city, as well as in key urban locations of the entire region. It includes a botanical garden and five university museums, and it is responsible for half of the medical services of the entire region through its university hospital. Nearly 75,000 students, professors, researchers, and staff members engage with UniTo each day. Teaching goes on in all of its 27 departments, and it does research in all academic fields (excluding engineering and architecture, which are taken by the local polytechnic university).

UniTo is a relevant case study, because it is one of the largest and most ancient Universities in Italy in 2018, 23 out of its 27 departments were officially lauded by the Ministry of Education as excellent departments and received additional funding, and in 2018, it was awarded first place in the public engagement ranking of the ministry.

The use of UniTo as a case study also granted the possibility of the use of primary data collected in a field where our participants had not been previously briefed on our study, allowing them to depict reality as it is, not as researchers may influence them to portray it. For most of the project, the researchers acted as impartial spectators, bearing in mind the methodologies used in active studies. Our work was interventionist to the extent that one researcher participating in the research group was the editor of the university sustainability report. We account for our approach by citing Dumay and Baard (Dumay

and Baard 2017), who affirm that “the knowledge of academics is useful in practice to enhance organizations and the way they operate rather than remaining in inaccessible ivory towers.” We firmly believe that our approach is justified as being part of interventionist research.

To address the complexity of the case of UniTo and to achieve a complete picture and a deeper understanding of the phenomenon, a mixed method was adopted for the collection of data (Johnson et al. 2007). This mixed method is largely qualitative and required active participation of the organization, taking place in meetings and focus groups (FGs), interviews, questionnaires, documentary reviews, and analyses of web pages. Data collection took place over a period of several years, allowing a longitudinal analysis. Data were been collected from April 2015 to March 2017 from the aforementioned sources and a review of internal and external information sources, such as documentation of the organization, internet sources, and publicly available studies and reports (see Appendix A). Appendix A shows the hermeneutic units and stakeholders involved in each stakeholder engagement event related to KT accountability and the input and the output of each event. All the events incorporate specific interesting features with regard to KT accountability related to its enhancement of university legitimacy. Figure 1 provides a timeline of events.

The recordings of meetings were transcribed and coded by two different researchers. Where there were inconsistencies, the researchers revised the transcripts, using with meeting notes, and reached consensus. Data analysis used open and axial coding techniques (Strauss and Corbin 1990) for the identification and linking of the data collected to the research question. Objective descriptive data and interpretative data based on perceptions were coded separately. Data were analyzed with different tools, both manual and software-aided ones, such as Gephi and QCMap.

The materials for interviews and focus groups were analyzed and triangulated with data collected through other sources. To assess the validity of our work, the data were triangulated through the connection of different kind of data, bearing on the same

phenomenon (Jick 1979). We connected data from multimedia sources, such as recording videos, photos, and minutes and notes of events. Finally, the case study was given written form through iteration of the concepts present in the theoretical framework.

4 Findings

4.1 Context of KT in UniTo

UniTo is considered bureaucratic. Departments have complete administrative autonomy, but the management of financial resources is centralized. As a result of the system of performance management that was imposed by the ministerial reform of 2010, UniTo began to publish budgets, a consolidated budget, financial statements, a consolidated financial statement, and a reclassification of the financial statement, according to ministerial guidelines (called missions and programs), as well as a performance plan (PP). The PP resembles an annual report of IC on the achievements of teaching, research, and the third mission. These documents were each 100 pages long, on average. All top administrators have access to a 24/7 online dashboard monitoring IC Key Performance Indicators (from university dropout rates to number of spin-offs created, number of foreign students and visiting professors attracted, and other indicators). The rector once began his speech at the ceremony inaugurating the academic year:

Italian Public Universities are one of the most controlled and transparent organization of the Italian market, which constantly make a great amount of data publicly available, even though external institutional stakeholders always ask to present UniTo again and again. (Rector, Convocation Address)

In his address, he expressed the frustrations of an anchored institution, wherein its legitimacy seems questioned. During the 2013/2014 academic year, a of mixed group of people, including professors, administrators, and students were given the task report information to external stakeholders in a more discursive and less bureaucratic manner. This was done to create a document able to report measures of performance and social, environmental, and economic sustainability to stakeholders. This strategy came about due to the increased perception among administrators that the university's grasp of local actors and the university was deteriorating, due to the intention of beginning a new discourse on sustainable development and the role of the university. Unfortunately, in spite of the adoption of the Global Reporting Initiative as a framework for reporting sustainability-related information, the report did not cover the main outcomes of the business model of the university. Despite this, during a meeting in April 2015 involving stakeholders of UniTo both internal and external, one professor judged the report to be "a nice stylistic effort that will not guarantee any extra funds to my research" (professor of philosophy, FG1).

Another meeting with multiple institutional stakeholders (FG2), UniTo was described as "nebulous" (municipal representative) an "ensemble" (association of public communicators) and a talented professor was described as training an "enormous number of students that need to be employed" (representative of an industrial association). This

image of vagueness and non-specificity emphasized a criticism of the legitimacy of the institution, not for its values or its rigor, but due to the lack of disclosure of its business models and the outcomes it derived. A manager said, “Compared to Torino Polytechnic, it is difficult to define UniTo, to engage it in a dialogue, to co-create policies. We have difficulty finding the right interlocutor, in knowing [your KT’s] exact firepower” (municipal manager, FG2). This how difficult it is for the institution to dialogue with stakeholders. This was largely due to the difference between the representatives of the university (whose behavior can be questioned) and the university itself (which is anchored). People were worried “about doing business with UniTo, as we have no clear perception of it. We perceive the name of a professor or an expert in a niche research field with more clarity, reading about his research output in the newspaper. The bonds we have with UniTo are personal, one to one” (company representative, FG1). The external stakeholders suggested that organizations like UniTo should not only be at the top of the rankings for research but must also be recognized as leader and a pioneer by the public at large, due to the coherent and coordinated communication of its affairs (environmental communicator, FG1).

4.2 KT reporting to KT disclosure

KT contents were drafted mostly to show existing relations between IC budget allocations. The greater part was missing, as information related to IC, such as the number of publications, research projects awarded, and external grants awarded, were silent about the impact of the third mission of the overall university, hidden in multiple different documents. At the organizational level, infrastructural disparities were found among departments, where certain department managers were able to account for their third-mission activities and department managers who completely ignored such practices. This point emerged from the results of a survey composed of 24 closed- and open-ended questions taken by the KT referent of each department. Each department’s feedback showed interest in the issue. The results of the survey depicted the university as a body with various animating spirits: for example, scientific departments tended to show more institutionalized and structured KT processes, while humanistic departments required deeper support in the development and disclosure of their KT, such as hiring professional experts in public engagement or in intellectual property rights and innovation. Most departments had adopted uncoded approaches (54.5%) or declarations of intent (27.3%), and only the scientific and medical departments had formal documentation. Almost all departments declared that they transferred to the outside (output) more knowledge than they received from the outside (input). This illustrated that the state of the art did not reflect the mission statement of the university, where it is characterized as a promoter of “scientific and technological KT to economic and social systems; the university supports the founding of new corporations or other entities, as well as sustaining new corporations able to exploit the results derived from research” (UniTo Statute, art. 5).

After this survey was complete, the Vice Rector of Public Relations created a taskforce framing the KT state of the art of KT in UniTo. The taskforce analyzed the

“third mission” web page created by each department, finding a great disparity between those that detailed all of the third mission activities undertaken and those with only a blank page containing no more than rhetoric.

It was thought that this was a consequence of the lack of a bureaucratic definition of KT. Furthermore, it also emerged a locus of the problem was to be found in the researchers “as primary source of data” (Director of the Research Department). After financial data and survey results were triangulated, our findings showed that in medical and hard sciences departments, KT and innovation generally coincided with the presence of formal research agreements (especially for legal and ethical motivations, such as privacy protection and the ethical implication of the experiments); for this reason, these agreements have been always considered more “research” than “third mission”. They raise greater amounts of money and they disclose less. Social sciences and humanities departments did not to formalization, especially concerning local SMEs, associations, and third sector partners, and they raised less money from local actors.

The outcomes of UniTo KT are shown in Table 1.

Table 1 Amounts of KT between department types in formal and informal activities, as well as external funds raised

<i>Areas</i>	<i>Formal KT</i>	<i>Informal KT</i>	<i>External funds raised</i>
Medical and hard sciences	90%	38%	95%
Social sciences and humanities	10%	62%	5%
Total	100%	100%	100%

Our findings suggest that formal KT occurred with less external engagement and more focused commitment and that it pays more. One hard science professor, during the internal roundtables (IRs) of September 2015, stated that:

We are trying to overcome the prejudice that we are not involved in the world. We work every day with people, we engage local communities, here and in developing countries, we engage with schools, but we must know if such arguments are of importance for people beyond the university (Professor, IR1).

Also during IR2, a social science professor stated that

The social sciences are often treated as second-level disciplines, and asking us to produce data on KT implies the prejudice that we are not really working (Professor, IR2).

These statements reported are essential for determining what KT disclosure is. Is KT disclosure just accounting of KT performances? Then the answer is not. Our findings suggest that KT disclosure means divulging the results derived from a scientific project, engaging citizens and in reasoning together about the findings of specific research and benefitting from it.

4.3 KT disclosure in practice

Disclosure of KT depends on the nature of the given KT. In 2016, a new institutional website, called FRidA, was launched, with the function of presenting the research of UniTo to the general public, using popular language; this tactic embodies informal KT. Each professors and researchers who wished could voluntarily share with the general public the results of their research by uploading a summary of her/his projects. The same database contains a description of more than 3,000 events of public engagement performed in 2011–2015. The most-used form of disclosure was found to be the participation of a researcher in a public event, such as a festival, science café, or fair. In public engagement, the researcher presents him- herself and his or her research without laying an emphasis on the role of the institution.

Taking a semantic analysis of the KT initiatives depicted by departmental representatives, our paper here presents a visual network. Figure 2 was created to visibly show the links between KT accountability and the content itself, giving the links between stakeholders, the topics of the KT, and UniTo departments.

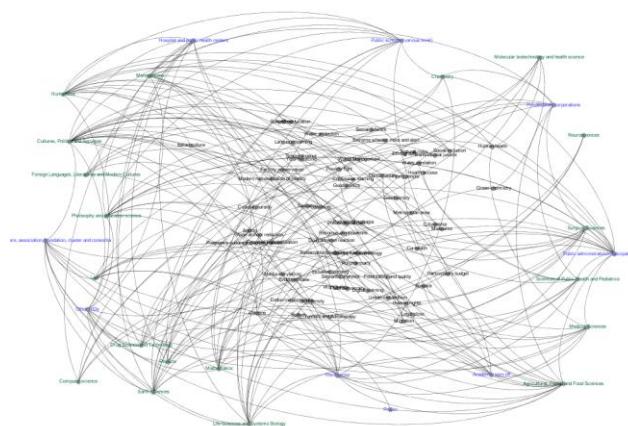

Figure 2: Social network-analysis of projects collected, departments involved, and stakeholders

Figure 2 was created using social network and semantic analysis of the project presentations collected by departments, where the blue represents the stakeholders involved, green nodes represent departments, and black nodes reflect project contents. Social sciences and humanities, hard sciences, life sciences, and health sciences are equally distributed in the top ten departments according to numbers of weighted nodes. Stakeholders are labelled in homogeneous categories. The most common categories are public administration departments, municipalities, and governments; third-sector

organizations; other research institutions and universities; public schools; and hospitals and public health centers. Our study found that projects covered a wide range: from water sanitation to innovative agricultural techniques in Saharan rural villages, from projects supporting vulnerable people (migrants, disabled, newly poor, addicts, and inmates) to financial literacy, from pregnancy care to the early diagnosis of rare diseases, dysphagia, endometriosis, and oncology related to DNA risk. The legitimacy obtained by educating people on such topics is priceless, overwhelming any business strategy that a public organization could put in place.

Formal KT on patents was located in five different databases, which were merged and controlled by researchers. The final results showed 175 patents (2011–2015), which should be considered far from final, because they accounted only for patents traced by university offices (excluding those created by researchers personally). We found more patents than those reported in notes to financial statements or IC reports. Further, our initial hypothesis about formal KT, that it pays more and means reduced external engagement, was overturned.

UniTo's legitimacy is anchored in the territory of the hard science departments. This was confirmed by an administrator, who said, "For us, it is relevant to have updated information on partners and the work that has been done, along with its territory" (representative of a hard science department, MG2). The problem of stolen legitimacy can be perceived in the words of a research director: "among the hard sciences, there is the challenge of marketing strategy and negotiation with private corporations. [Companies] start from the assumption that when they pay for something, it is then their property. We feel that our role is unbalanced role. They presume that the output of a public university could be privatized, but we must defend our role and territory" (director of central research department, MG3).

The problem of legitimation is closely linked with the production and transfer of knowledge. Our findings demonstrate that "the value of KT is a question of reputation: if UniTo presents itself in a certain way, then large corporations will concede it more space, to create a dialogue and to deal with favorable contractual duties. Companies, in general, consider us to be a supplier and not as a partner" (Professor 1, MG3).

However, at the organizational level, all tools examined in this project are institutionalized, and with emphasis placed on creating engagement events with the surrounding territory, not simply to ensure the role of the university as a researcher, but to affirm again UniTo's status quo. This is risky, but being anchored means that

"Innovation may come through the work of companies the university efforts: the desirable future of the economy and the society relies on the dialectic role more than on mechanical adjustment, as explained by supply and demand numbers" (vice rector, Strategic KT Report).

5 Discussion and conclusions

This study investigated KT disclosure at the university level and how these strategies influence and are influenced by stakeholders. Related with the theoretical framework presented earlier, UniTo illustrates the complexity of an anchor institution (Howard 2011) that perceived potential conflict undermining its legitimacy and the social contract with its stakeholders. As Dumay and Baard (2017) found, the problems of a university must be addressed and resolved using intervention strategies. This has been executed in UniTo through a protracted process of organizational and communication changes. Our study of how the development and implementation of the new strategy exhibits a new notion of anchored legitimacy. The complexity connected to the development of this new concept is especially apparent, given the long-term existence of the institution, rooted in its territory for centuries, subjected to a centralized public control influencing the implementation of changes.

One challenge linked to KT disclosure is from KT that may vary from the source field of knowledge and its inclination, relative to stakeholder interactions and communications. Opening the black box of generalist knowledge through public universities means disentangling various legitimacy issues that are interlinked. With the aim of educating and informing the external public (Lindblom 1994), the relation between the nature of knowledge and the generalist approach takes first place. The first proposition of our study is to consider the nature of knowledge when ministries are called to develop politics and incentives in terms of KT.

The second challenge relates to the hierarchy of needs. University managers are often more concerned with following the law than they are with ensuring the effective use of the data they produce. Universities as data factories are myopic, in that university managers do not recognize the importance of translating data into comprehensible information. In anchored legitimacy, the adhesion to the general norms and values of the larger society are taken for granted, while the disclosure of new, secret, and unknown information has the potential to reveal new aspects of an institution that everyone thinks they know (Dumay 2015; Ntim et al., 2017; Deegan, 2002). The second proposition is to apply anchored legitimacy to different knowledge intensive public institutions such as research centers, schools, museums, to understand similarities and differences in its generalization.

The third challenge, which may be more of a risk, is the disclosure of data and the communication of information that internal stakeholders do not approve. This disaffection might can birth to a legitimacy crisis (Ntim et al., 2017). KT disclosure is perceived to be individual-centric, deinstitutionalizing the university and its legitimacy for the benefit of personal legitimacy. Myopic managers and directors may come to take university legitimacy for granted (Suchman, 1995; Dumay et al., 2015a), focusing their attention more on the bureaucracy than on the message that is being communicated (Vagnoni and Cavicchi 2015). At third, anchored legitimacy should be framed by stakeholder management theory in understand how to engage internal stakeholder on KT.

Our study also suggests the importance of elevating third mission activities to a strategic level. To recognize KT means identifying the producer and receiver of KT, as well as having the ability to clearly communicate the outcome of research to the right stakeholder and to capitalize on them. This means to propose organizational changes such as creating a culture of public engagement where researchers have the soft skills to valorize the contribution of the social sciences and humanities, as well as giving a value to scientific and medical formal KT on the market. Adoption standardized procedures and the simplification of the institutionalized processes, as well as the timely answer given to external interlocutors, impact its external reputation, as when public universities performs well, companies legitimize them (Deegan 2002).

Finally, the attempt to implement KT generates an image of an anchored institution that is engaged and bonded among its central administration and departments, as well as the external public. Our study clearly revealed that large-scale spaces of public knowledge are composed by the constellation of competencies that generate internal KT coopetition (such as between the scientific and humanities departments), and disclosure managed at a central level can serve as tool to deflect donations from one area to another. This final proposition affects the area of anchored institution management.

This study showed the practical implications that reinforce the need for KT disclosure as a process of anchored legitimacy, using new communication strategies and media. This can result in clearer and more transparent external communication with the policy makers, who both govern higher education systems and may play the role of partners in triangulation among the university, private industry, and public government. Responding to the call of Dumay and Rooney (2011), our work emphasizes the literature on the disclosure of knowledge in public sector organizations. The social implications are many, and this study shows the potential for disclosing KT through unlocking and offering new relational opportunities between universities and territories (Massaro et al., 2015), by sharing goals and becoming a public leader in a territory. Continuous learning can contribute to reciprocal local development and reinforce the university as outstanding nationally and internationally. Due to exogenous pressure creating a changing role for universities in societies, this paper presents a broad framework for the adoption of disclosure of the KT as a strategy to ensure that the legitimacy of the institution is still anchored.

Abstract

"Each company has the customers it deserves" said one day a Ceo to his management. This is a very strict statement that forces companies to question the reasons why they have a specific customer portfolio and to distinguish strategic customers from tactical ones.

The mapping of the customers, focus of this article, has the dual objective to measure objectively the level of "strategicity" of the customer portfolio and the level of business reciprocity between the company and its customers, in order to appropriately orient the decision processes of the company.

In order to achieve the aforementioned dual objective, three sets of information are required: the economic and financial quality of the client, the level of utility of the client for the company and the level of utility of the company for the client.

The combination of the two first set of information allows to evaluate the level of "strategicity" of each single customer, that is if the customer is strategic or tactical and why. The questions to be answered are: how much competitive are the strategic customers for the company? How many customers are at the same time competitive but tactical for the company? The company's goal is to select strategic customers that are at the same time competitive and useful for the company over time.

A second combination between the above strategic level of the customer and the level of utility of the company for the client allows to measure the degree of business reciprocity of the customer relationship. The questions to answer are: how much is strategic the company for the strategic customers? How many are the strategic customers for whom the company is considered tactical? The company's goal is to be strategic for strategic customers.

Each set of information is based on key performance indicators that allow not only to map the customer portfolio in terms of customer strategicity and business reciprocity of the customers, but above all to identify the priority business figures in terms of

management decisions and actions and therefore to plan and control the customer portfolio quality and through the latter the economic value creation.

Paper type – Academic Research Paper

1 Introduction

How do you identify a competitive company? Which are the determinants that let the company gets and preserves the competitive advantage? The determinants of the competitive company are connected to the superior ability to operate with clients, suppliers, process, resources, know-how, markets, etc. each one useful for the business continuity (Krapfel et al., 1991; Turnbull and Zolkiewski, 1995; Kotler et al., 1996; Lars Grønholdt et al., 2015). In order to identify as strategical what is essential for the company, those previous determinants are detected as strategical dimensions.

There are many scientific contributions regarding the customer portfolio models or supplier portfolio models that suggest managerial decision tool to support the right customer portfolio composition (Fiocca, 1982; Campbell and Cunningham, 1983; Shapiro et al., 1987; Krapfel et al., 1991; Olsen and Ellram, 1997; Turnbull and Zolkiewski, 1997; Browne, 2000).

According with many papers regarding the study of the Customer Relationship Management (Park et al., 2003; Rado Kotorov, 2003; Chor-Beng Anthony Liew, 2008) and many theory of strategic relationship management (Donaldson and O'Toole, 2002; Klink and Sjöberg, 2003; Aihie Osarenkhoe and Az-Eddine Bennani, 2007) the aim of the company is to increase and maintain for a long time a profitable relation with the customer (Weinstein, 1994; Mulhern, 2003; Jonker et al., 2004).

The goal of this article is the quality measurement and, more precisely, the strategic level of the client's portfolio. It is based on an original model created by the authors, the so-called Customer Portfolio Mapping (CPM from now on). The added value of this approach is to provide company management with a clear tool in the logic and definition of the criteria that make it possible to distinguish strategic and tactical customers and evaluate the quality of customer business relationship. The entrepreneurs achieve this goal thanks to the integration of two knowledge: the methodology of university scientific research and the applicative one connected to the dynamics of the competitive context. The Customer Portfolio Mapping methodology is oriented to the companies with a business-to-business approach who believe that the good quality of the business relationship with the customer is an element of competitive advantage (Elliott, 1998; Conlon et al., 1987; Derrick 2006; Henry Lau et al., 2016). In particular, the management should be answer to these questions: which is the share of the revenues and of the operating profit realized by the company with the strategic clients? Which are the clients with whom the company has a non-strategic relationship of trade? Which are the

management area where the company can operate to improve the strategy relevance and the reciprocity of the revenue and the operating profit? (Porter, 1996; Bennett Stewart, 2013).

In 2009, the authors of the article created within the department of Management and Production Engineering (DIGEP) of the Politecnico di Torino, a research group with the aim of developing metrics for measuring economic, financial, competitive and strategic business performance and sharing it with the companies. Today the research group is recognized from many companies as a studies centre where to get knowledge to transfer to the management and where to find the competence to develop new management tools. The strong collaboration of the research team with companies operating in the sector of the Italian automotive independent aftermarket (IAM) (the research group is totally financed by the companies) allowed the realization of a model consistent with the dynamics of the business and understandable to those who make the decisions (McDonald et al., 1997) useful to create economic value for the company (Porter, 1980, 1985; Rappaport, 1998; Besanko et al., 2000; Guelfi, 2013). The Italian Automotive IAM is composed of Manufacture, Distributors and Spare Parts Dealers (in Italy almost 500 manufacturers, 150 distributors and 5.000 dealers).

2 Three set of integrated information and three set of key performance indicators

The methodologic path of the Customer Portfolio Mapping is based on three set of information which are continuously integrated and where each one of these set gets inputs from logical performance indicator already evaluated.

The first set of information is referred to the Customer's Company Quality (Guelfi et al., 2016): the goal is to measure the level of the economic/financial and competitive/strategic balance and where you it is possible distinguish the following methodologic steps:

1. identify the best key performance indicators (KPIs);
2. choose the criteria and the evaluation scale.

About the identification of the best key performance indicators, it is possible to determine:

- a. indicators about economic balance to highlight the attitude in realizing a good economic profit in their business (for example, the contribution margin's percentage, the level of operating gross margin or the added-value for each euro of internal and external labor cost);
- b. indicators about assets and liabilities balance in order to evaluate the attitude to operate in balanced conditions of use and procurement of capital (e.g. warehouse turnover rate, relationship between equity and net fixed assets, relationship between the days sales outstanding and the days purchases outstanding);
- c. indicators about financial balance to distinguish the attitude in generating correct cash-flow (e.g. the percentage of operative cash-flow generated by the revenues, the relationship between ebitda, earnings before interests taxes depreciation and amortization

and the variation of the operating net working capital and the relationship between new investments and current cash-flows);

d. indicators about competitive balance in order to highlight the attitude of managing the direction and the intensity of their own competitive risk (e.g. operating leverage, the intensity of competitive cost advantage and the level of concentration of the revenues in terms of clients and/or markets and/or products);

e. indicators of strategic balance to evaluate the coherence between strategic goals and resource and competence (e.g. relationship between the rate of revenue's growth and investments in process and/or product, development rate of investments in distinctive competences, company size and development rate).

In order to identify the criteria and the evaluation scale of each indicator, the next steps have to be followed:

a. the evaluation criteria are three: positivity or negativity, improving or worsening, stability or volatility. For each indicator, the comparable companies were chosen and therefore the related average value (median value, if the companies are far different) was calculated. These calculations have to be done in term of punctual value of the period, variation and volatility over the previous period.

b. the evaluation scales are five: far over the average (represented by the 15 percentile), over the average (between 15 and 40 percentile), average (between 40 and 60 percentile), under the average (between 60 and 84 percentile), far under the average (85 percentile and more).

In order to be as much synthetic as possible, the performance highlighted by an indicator is better evaluated as it is positive and has stable improving, all conditions being the same.

The economic/financial and competitive/strategic balance measurement is declined in five judgement states with decreasing positivity of the customer's company:

1. Strong;
2. Consistent;
3. Normal;
4. Mediocre;
5. Weak.

The second level of information deals with the Client's Level of Strategical Coherence for the mapped company: the goal is to objectively measure how much is the client strategic, using the most coherent indicators. The criteria and the measurement scale are the same as for the first level, while it can be distinguished a particularly difficult step and indicators linked with the company strategic goals. About the first step, in order to identify a strategic client, the company has to have clearly in mind which are his strategic goals and then build the client's strategic indicators. Strategic goals are synthetized as:

a. profitability: in this case the main goal is to get a consistent profit, implying that the more important indicators to qualify a client as strategic in both absolute value and percentage are those one related to client's profitability;

b. cash-flow: the logic is the same as point a) but focused on the client's cash-flow: indicators about the cash flows generated by the client are the best in order to define the latter's strategic level;

c. development: the logic behind is the same as point a) and b), and it can be split in terms of revenues, organization, processes, competences, diversification, relationship, etc. and how the client can be functional/coherent in the identified development strategy: indicators related to continuity and to client's dimension rather than to the level of territorial control and to the attention/trust degree about the mapped company;

The Client's Level of Strategic Coherence is declined in five judgement states with decreasing positivity in terms of strategic attitude of the client:

1. Vital client;
2. Valuable client;
3. Proper client;
4. Mediocre client,
5. Weak client.

The first three typologies (vital, precious and proper) allow the company to be in good health and improve, the last two clusters bring negativity to the company.

The third level is referred to the Strategic Coherence level of the Mapped Company for the Client: this analysis reverses the traditional point of view of the client's utility for the mapped company and has the goal of evaluating how much is the company strategic according the client's utility curve. The quality of the information is in function of how deep is the knowledge of the client, of its priorities and what leads his decisions in terms of suppliers. Also in this case:

- a. criteria and measurement scale are the same as the previous level of information;
- b. the indicators to select are those related to the client's strategic goals, also in terms of profitability, cash-flow and development: between all the indicators, there are some particularly relevant such as the substitution time of the mapped company with the competitors, the utility recognized by the client in terms of price/value relationship (reliability, responsiveness, service, etc.), the percentage of the mapped company's revenue over client's purchases, financial condition agreed with the client, etc (Campbell and Cunningham, 1983).

3 Strategic customer. Customer's Strategic Map

The second step of the methodologic path of Customer Portfolio Mapping is based on the integration of first two set of information: Customer's Company Quality and the Customer's Strategic Coherence Level. The result is the distinction between the strategical clients of first and second level, valuable, tactical and harmful. In particular, for the mapped company (fig.1):

1. the strong first level client, so the one who are in economic-financial and competitive-strategic balance, are strategic and vital/valuable for the company itself;
2. the consistent second level client are strategic and vital/precious for the company itself;

3. the normal clients are valuable and proper for the company itself;
4. the mediocre clients are tactical in terms of economic/financial and competitive/strategy and mediocre for the company itself;
5. the weak clients are harmful, that means that they are economic/financial and competitive/strategic unbalanced, and also harmful for the company itself.

Customer's Level of Strategic Coherence for the Mapped Company	Economic/Financial and Competitive/Strategic Customer's Profile				
	Strong	Consistent	Normal	Mediocre	Weak
Vital	Strategic 1	Strategic 2	Precious	Tactical	Harmful
Valuable	Strategic 1	Strategic 2	Precious	Tactical	Harmful
Proper	Precious	Precious	Precious	Tactical	Harmful
Mediocre	Tactical	Tactical	Tactical	Tactical	Harmful
Harmful	Harmful	Harmful	Harmful	Harmful	Harmful

Fig. 1 – Strategic Customer. Customer's Strategic Map

It's particularly interesting looking at two different combination about the harmful clients for the mapped company:

- a) the harmful client, even if they are strong, are dangerous because of the incoherence of strategic utility: those clients are healthy and competitive, but dystonic looking at the strategic goals of the mapped company;
- b) the harmful clients because they are weak in terms of economic/financial and competitive/strategic, but at the same time they are proper for the mapped company.

For the harmful clients like point a), the mapped company has the competitive duty and the economic convenience of understanding the reason why the strong clients are not strategically useful and it has to identify some operating solutions that can increase the strategic utility. As it was outlined before, this methodology requires a deep knowledge of the strong/harmful client's business model by the mapped company.

The harmful clients like point b) are different because the mapped company has not the right or the possibility to act in the economic/financial and competitive/strategic choices. This constraint implicates a particular fragility condition, because the client's revenue/profit is vital, precious and proper for the mapped company.

Customer's Portfolio Mapping allows to:

- a) quantify the punctual and the trend effect, in relation to the past, of the revenues and margin realized by the mapped company with different client's segment: strategic, valuable, proper, mediocre and harmful;
- b) identify in a strict way, for different client's segments, the more appropriate policies to improve the strategic quality of its customer's portfolio.

3.1 The strategic exchange relationship. Strategic Reciprocity/Equivalence Map

The third step of the methodologic path of the customer's portfolio mapping is based on the integration of the first map results (concerning the distinction between the Strategic/Precious/Tactical/Harmful Clients) with the third set of information (connected to the Strategic Coherence of the Mapped Company recognized by the Customer). The connected result is the exchange relationship's distinction based on positive coherence rather than negative incoherence as well as other possible combinations: the positivity of the former is contrasted by the negativity of the latter. Particularly, it is possible to distinguish for exchange relationships for the mapped company (fig.2):

1. positive coherences the ones that occur between strategic / valuable customers for the company that in turn recognize the company as strategic / valuable: the goal is to preserve and strengthen these relationships by operating appropriately on the rationales that feed them;
2. negative incoherences the ones that occur between tactical/harmful clients that recognizes the mapped company as strategic/valuable, as well as the relationship with the strategic/valuable clients, which recognize the mapped company as tactical/harmful: the goal is to change those harmful relationship towards a positive coherence;
3. useless coherence for those with tactical clients that recognize the mapped company as tactical and vice versa;
4. harmful coherence for those with harmful clients that recognize the mapped company as harmful as vice versa.

Strategic Coherence Level of the Mapped Company for the Customer	Customer's Strategic Level for the Mapped Company			
	Strategic	Valuable	Tactical	Harmful
Strategic	Positive Coherence	Positive Coherence	Negative Incoherence	Negative Incoherence
Valuable	Positive Coherence	Positive Coherence	Negative Incoherence	Negative Incoherence
Tactical	Negative Incoherence	Negative Incoherence	Useless Coherence	Useless Coherence
Harmful	Negative Incoherence	Negative Incoherence	Useless Coherence	Useless Coherence

Fig. 2 – The Strategic Exchange Relationship. Strategic Reciprocity/Equivalence Map

The positive coherence exchange's relationship of point 1) are the healthy one, where the mapped company and its clients are mutually strategic/valuable and the company's decisions/actions have the duty of preserve and reinforce them, after reaching that relationship level. The incoherence negative relationships of point 2) highlight two different company's policies:

a) when the company is tactical/harmful for the strategic/valuable clients is required that the mapped company has to modify its decisions/actions in order to improve the dispensed contents in that client's segment;

b) when the company is strategic/valuable for the tactical/harmful clients, it is always the mapped company that has to modify decisions/actions, in order to reduce the dispensed contents to the tactical/harmful clients or increasing the gained advantage (e.g. prices, profitability) or deciding to stop serving that client.

The useless coherence exchange's relationships are not interesting for the competitive company that has only two choices: increase the two-strategic level from the tactical condition to the valuable one or increase, in a short-term vision, the gained advantage becoming harmful for a tactical customer.

The harmful coherence exchange's relationships have only one possible way, identify the most convenient exit strategy.

The under-discussion mapping allows to:

a) measure, in punctual and trend terms, the percentage of revenues and profit realized in a reciprocity/equivalence strategic condition;

b) highlight, for every client's strategic level for the mapped company, the positive coherence's or negative incoherence's degree, referring to the strategic/valuable clients. Highlight the negative incoherence's and useless coherence's degree, referring to the tactical clients. Highlight the harmful incoherence's degree, referring to the harmful clients;

c) objectively distinguish the strategic reciprocity level of the exchange relationship for each client, in punctual and trend terms;

d) accurately identify, for every client's segment, the more appropriate policies in order to improve the customer's portfolio strategic quality;

e) increase the knowledge of the customer's business model and to ask oneself on what are the determinants of their economic value creation in order to build a competitive price/value offer different from the competitor's one (Homburg, 2002).

4 Conclusions

To conclude, the Customer Portfolio Mapping model allows the competitive company to, by using the appropriate key performance indicators, to objectively measure the strategic level of its customer portfolio and the reciprocity/equivalence strategic level of the exchange relationship with their own customers.

How much are the revenues and the strategic profit of the mapped company? Is the mapped company strategic for the strategic customers? With which client and for what reasons are there imbalances in the exchange relationship? The information derived by the structured and methodical analysis of the customer's portfolio quality are essential conditions in terms of awareness, development and managerial communication and they all operate as a real distinctive competitive leverage in order to drive the company towards its strategic goals.

Abstract

This paper aims to uncover the determinants of University-Industry Cooperation (UIC) from an individual perspective, to identify which entrepreneurs' characteristics affect the emergence of UIC and, more specifically, affect the selection of cooperation channels. To this purpose, we employed the Corporate Entrepreneurial Intention (CEI) model (Fini et al. 2012), which allowed to assess the effect of both individual and contextual factors in UIC dynamics, whether no previous attempts have jointly considered both types of variables in UIC literature. After applying structural equation modelling techniques to a sample of 130 entrepreneurs in the Region of Campania (South of Italy), our results show that corporate entrepreneurial behaviour is positively related to forms of UIC with an average and high level of complexity

Keywords – university-industry collaboration, Campania region, structural equation modelling, channels of UI cooperation; entrepreneurial perspective

Paper type – Academic Research Paper

1 Introduction

University – Industry Cooperation (*hereinafter* UIC) is defined as “*the interaction between any parts of the higher educational system and industry aiming mainly to encourage knowledge and technology exchange*” (Ankrah and Al-Tabbaa 2015). There has been a growing interest in university–industry relationships as made evident by the abundant literature on the topic (D’Este and Patel, 2007; Lai, 2011; Liefner and Schiller, 2008; Tether and Tajar, 2008) grounding on the common belief that collaborative research by academia with industry may be a powerful source of innovation (Ambos et al., 2008; Mansfield, 1998). Literature on UIC generally focuses on a few general aspects of analysis, including the determinants underpinning U-I collaborations, the barriers to cooperation and the selection of main channels of interaction (Perkmann et al. 2013). In most cases, the factors affecting UIC dynamics have been investigated from the academic perspective, at both institutional and individual level, while less attention has been given to the firm’s perspective and, most specifically, to that of the entrepreneur (Ankrah et al. 2013). Our paper instead, tries to explore the factors affecting the UI cooperation from the perspective of the company. Extant literature that studies UI relationships from a firm’s perspective, is generally focused on the analysis of the factors affecting this collaboration by considering the effect of the contextual factors and the effect of firms’ characteristics influencing or inhibiting the emergence of firms’ cooperation with academia, the propensity of firms to cooperate with university, the intensity of the cooperation itself and finally, the selection of UIC channels (Fontana et al, 2006; Moraes Silva et al, 2019; Segarra-Blasco and Arauzo – Carod 2008; Maietta 2015; Eom, K. Lee 2010; Thune, 2007)). However, most scholars focus on the typical firm variables (size, industry, absorptive capacity, R&D intensity) and neglect to consider the perspective of the entrepreneur. In other words, to the best of our knowledge, there are no studies that try to identify which are the entrepreneur’s characteristics that may eventually affect the choices of cooperation with academia. Conversely, if we look at the academic counterpart of the UI relationship i.e., the *researcher* or *scientist*, we find abundant empirical evidence about which individual attributes of researchers explain the UIC dynamics, suggesting the importance of considering the individual perspective in this field (Abramo et al, 2012, Rasmussen, 2011; Fini et al, 2009; Visintin and Pittino, 2014). In order to fill this gap, we position ourselves within the literary strand focused on the determinants of UI Cooperation from the perspective of firms, to explore how the individual characteristics of entrepreneurs affect firms’ propensity to cooperate with university and their selection of UIC channels. To this purpose, we adopt the Corporate Entrepreneurial Intention (CEI) model (Fini et al. 2012), which allows to assess the effect of both individual and contextual factors in UIC dynamics, whether no previous attempts have jointly considered both types of variables in UIC literature from the perspective of the entrepreneur. We apply structural equation modelling techniques to a sample of 130 entrepreneurs in the Region of Campania (South of Italy). The Region of Campania represents an interesting case of study since, despite the presence of a relative high number of academic and research institutions, innovative firms and a set of target regional policies to incentivize

UIC R&D, UIC is still considered uncommon from the industrial side. Our results show that attitude toward entrepreneurial behaviour is positively related to forms of UIC with a greater level of complexity. This study makes a contribution to the literature focused on the determinants of UIC from the firm's perspective, by considering the entrepreneurs' individual characteristics. The remainder of the paper is organized as follows. Section 2 reviews main studies exploring the determinants of UIC from a firm perspective. Section 3 develops research hypotheses. Section 4 examines the specific context of firms in Campania and presents data and methodology used in this study. Section 5 discusses main results, before concluding (Section 6).

2 Theory

From a firm's perspective, scholars consider the main determinants to UIC at the organizational level (ex. firm's size; experience; R&D intensity; absorptive capacity) or at the industrial level (characteristics of the firm's main sector of activities). Among the studies that analyse the determinants at the firm level, the role of firm size in affecting the propensity of firms to collaborate with PROs is one of the most recursive topics (Mohnen and Hoareau, 2003; Cohen et al., 2002; Arundel and Geuna, 2004; Laursen and Salter, 2004). One of the basic assumptions is that the larger the firm, the larger is the amount of resources available to establish relationships and engage effectively in more complex strategies, such as cooperation with research institutions (Tether, 2002; Miotti and Sachwald, 2003; Negassi, 2004). However, recent studies provide mixed results regarding the role of firm size on UIC. On the one hand, it has been shown that the propensity to engage in an alliance with an academic partner depends on the *absolute size* of the industrial partner (Fontana et al. 2006) and that conversely, for small and innovative firms - especially in manufacturing and service industries - it is very difficult to find R&D partners (Segarra-Blasco and Arauzo – Carod 2008). On the other hand, the positive link between firm size and UIC has been questioned by a few scholars arguing that the role of firm size is not particularly significant to UIC dynamics and that, in contrast, small firms would be more prone to cooperate with academic partners given the shortage of internal resources, as R&D capacity, facility and financial resources (Eom, K. Lee 2010). However, according to some scholars, firm size does not determine the intensity of UIC, but rather the purpose of the cooperation. As a way of illustration, Santoro e Chackrabarti (2002) show that large firms chose types of UI channels that involve higher intensity knowledge transfer and research support to have access to university facilities and advance their non-core technologies. In contrast, small firms rely more on those types of cooperation that allow them to reinforce their knowledge and gain access to academic infrastructure to advance core technologies. Firms' sectoral characteristics represent another key variable in the study of the industry–university cooperation (Meyer-Krahmer and Ulrich Schmoch, 1998; Santoro and Chakrabarti, 2002; Schartinger et al., 2002). In general, it has been shown that the likelihood of establishing U–I linkages increases with the strength of the firms' knowledge base (Giuliani and Arza 2009). Moreover, empirical evidence shows different trends when comparing the behaviour of

high tech and low tech firms. By way of illustration, Segarra-Blasco and Arauzo – Carod (2008) find out that low-tech firms show a lower propensity to cooperation with academia in general, by taking evidence from on a sample of 4.150 Spanish innovative companies. Additionally, a recent article by Moraes Silva et al. (2019) observes that the sector has a moderator effect in the relationship between firms' propensity to UIC and their barriers to innovation. By using the Brazilian Innovation Survey (PINTEC) on a sample of technology-based SMEs, the authors show that, while knowledge service firms cooperate with university to overcome financial obstacles to their innovation activities, in high tech manufacturing sectors the propensity to UIC is mainly motivated by the possibility to mitigate knowledge barriers to innovation. Finally, it has been demonstrated that firm's sectoral characteristics shape the selection of UIC channels. For example, Cohen et al. (2002) show that patents and licenses are key channels of information transfer from research institutions to industry in pharmaceuticals, more than in any other manufacturing industries. Firm's experience of collaboration is also recognized as an important driver of UIC. This is explained by the fact that cooperating with academic institutions on research projects demands not only that firms learn how to work across the company's boundaries, but also that they build the skills necessary to work with partners with a different system of incentives. Starting from this assumption, Bruneel et al. 2010 demonstrate that prior experience of collaborative research alleviates the barriers related to differences in the orientations of industry and universities. These findings are supported by a large-scale survey including more than 3000 firms participating to research projects funded by the UK Engineering and Physical Sciences Research Council (EPSRC). Similarly, Eom, K. Lee (2010) during a study conducted on more than 3000 Korean firms, finds that the formation of new relationships between university and industry, is positively related to firm's participation to public R&D projects. Firm geographical location is among the firm characteristics that are identified as drivers of university–industry R&D collaboration, with specific regard to firm's location in innovative clusters and ecosystems (D'Este et al., 2013; Fernández-Esquinas et al 2016; Eom, K. Lee 2010 ; Scandura 2016). Indeed, it is well established among the studies on systems of innovation that firms' proximity to universities favours the development of research partnerships. This is generally based on the assumption that short distance facilitates interaction and the exchange of tacit knowledge, while embeddedness contributes to the development of trust mechanisms that positively affects the emergence of collaboration (Granovetter 1983; Boshma 2005; Lundvall and Johnson, 1994). In this vein, Maietta (2015) while exploring the drivers of U-I R&D collaboration in low-tech industries, observe that long co-location contributes to explaining the relationships among firms and universities, especially when the relationship involves IP exploitation activities. Other variables are customarily included in literature on UIC. These include firms' absorptive capacity (Fernández - Esquinas et al. 2016) and R&D intensity (Schartinger et al., 2001; Arundel and Geuna, 2004). Specifically, firms with high levels of absorptive capacity (usually measured by the presence of staff with PhD degrees), are particularly prone to cooperate with universities through knowledge generation and the creation of new organizations, which require a high intensity of exploitation or exploration activities (Fernández - Esquinas et al. 2016).

On the other hand, firm's R&D intensity is considered to increase the probability of UIC (Schartinger et al., 2001; Arundel and Geuna, 2004) because firms that invest heavily in R&D are likely to possess a high technological capability that also allows them to absorb the knowledge developed outside the firm (Segarra-Blasco and Arauzo – Carod 2008; Maietta 2015; Eom, K. Lee 2010). The presence of prior ties between managers and researchers, is one of the few UIC determinants to be considered at the individual level. In this regard, Thune (2007) explored collaborative UI R&D projects from the perspective of both researchers and R&D managers to show the important role of social capital and network embeddedness in providing opportunities and resources needed to stimulate collaboration in both application and process innovation. Despite the rich literature devoted to understanding the determinants of UIC from a firm's perspective, there are still some research gaps. First, while there is evidence about the firms' characteristics affecting UIC dynamics, too little is known about the characteristics of the entrepreneur that may influence the emergence of UIC. Secondly, most studies tend to focus on the determinants of UIC intensity, while only a few scholars have deepened what determines the selection of channels of UIC from an entrepreneurial perspective. In order to fill these gaps, our study aims to uncover the determinants of UIC from an individual perspective to identify which entrepreneurs' characteristics affect the emergence of UIC and, more specifically, the selection of cooperation channels.

3 Research hypotheses

In order to analyse the characteristics of the entrepreneur affecting UIC, we use the Corporate Entrepreneurial Intention (CEI) framework (Fini et al. 2012). CEI grounds on the "Theory of Planned Behavior" (Ajzen, 1991), which states that intentions are the result of individual attitudes, subjective norms, and perceived behavioural control. Specifically, CEI refers to the entrepreneurs' "*willingness to create new value in their firms by engaging in innovative, risky, and proactive actions*" (Fini et al., 2012 p. 397). Specifically, the actions' innovativeness refers to an entrepreneur's intention to take part in experimentation and creative processes leading to the creation of new products, services, or technological processes. Actions' proactiveness is defined as an entrepreneur's forward-looking perspective, that foresees the trends of future demand and contributes to re-shape the surrounding environment. Finally, actions' riskiness refers to the entrepreneurial willingness to commit to risky projects in order to achieve the firm's goals (Covin and Slevin, 1989). CEI is considered to be the result of both personal characteristics and perceptions of the external environment. On this basis, the conceptual model considers three main determinants of CEI (Fini e Toschi 2016) including psychological characteristics, individual skills, and perceived environment support. The first determinant i.e., psychological characteristics includes the *entrepreneurial risk-taking propensity* (Keh et al., 2002) and *entrepreneurial self-efficacy* (Zhao et al., 2005), this last defined as the entrepreneur's confidence in his ability to influence the environment and to successfully achieve business-related goals (McGee et al., 2009). The second determinant i.e., individual skills, refers to the idea that both technical and

managerial skills (such as planning, organizing, staffing, leading, and controlling) would help the entrepreneur to identify opportunities and, more broadly, stimulate the entrepreneurial process (Shane, 2000), by fostering the development of specific mindsets and developing the ability to commit to value-creation in their organizations (Baum et al., 2001). Finally, the third CEI determinant, refers to the perception of government support through initiatives as tax incentives (Munari et al., 2014) or mechanisms put in place by governments to support entrepreneurial activities (e.g. business incubators, science parks, business-plan competitions, potential financial incentives) that shape the environment in which the entrepreneur takes his decisions, thus affecting positively his CEI (Feldman, 2001; Foo et al, 2005; Marlow and McAdam, 2012). As long as CEI increases the level of entrepreneurs' engagement in innovative and proactive actions, we assume that CEI would also affect the level of engagement in cooperation with academia, which is a powerful source of innovation (Ambos et al., 2008; Mansfield, 1998). However, not all types of cooperation require the same level of engagement and do not necessarily lead to value and innovation generation. Therefore, the importance of CEI can vary according to the complexity of the UIC channel. Indeed, the classification proposed by Philpott et al. (2011) illustrates a soft-hard spectrum of UIC according to the level of entrepreneurial sophistication of the individual channel (Klofsten and Jones-Evans, 2000). More specifically, these forms of UIC differ for the level of complexity, including the level of both parties' engagement and new value generation. Less complex forms of interaction, such as human resources mobility; financing of PhD scholarship by industry; teaching activity's externalization, align better with the traditional academic mission (Klofsten and Jones-Evans, 2000; Louis et al., 1989) and are not generally viewed as entrepreneurial activities. These activities are usually associated to the traditional educational mission of university that is seen by companies mainly as a source of skilled labour. The "teaching mission" of university is generally recognized by all the entrepreneurs without particular distinctions. Therefore, the level of CEI of the entrepreneur concerned, should not be particularly relevant in determining these types of UI cooperation channels. Hence, we hypothesize that:

H1. CEI is not significantly related to the development of low-complex UI cooperation channels.

The greatest part of UIC channels are characterized by average levels of complexity and generally refer to academic participation to firm's organizations; co-affiliation to professional associations; temporary exchange of academic staff with industry; board interlocks; sharing facilities (e.g. laboratories, equipment, housing). These channels even if they are not necessarily aimed at producing innovation, are generally characterized by a greater level engagement of the parties that co-participate to the realization of the activity, compared to the low complexity channels. On the other hand, these activities are mostly related to the exchange of complementary capabilities and assets, but do not require a real knowledge transfer among the parties. In light of this, we assume that an entrepreneur needs to present a certain level of CEI.

Therefore, we expect that:

H2. CEI is positively related to the development of average- complex UI cooperation channels

Finally, UI Cooperation channels with high levels of complexity usually include contract research; co-patenting consultancy of university staff members the industry; licensing agreements; university spin-offs; specific knowledge transfer activities organized by the university's technology transfer office (TTO). These activities are often considered as being more entrepreneurial in nature and more compatible with the so called *university third mission* (Louis et al., 1989). These types of collaboration are often at the core of entrepreneurs' businesses and require an high level of engagement of both parties that have to work together to realize an effective knowledge exchange and develop innovations. From a firm perspective, we expect that entrepreneurs have to be very open-minded to implement such forms of cooperation with universities. Hence, we expect that:

H3. CEI is positively related to the development of high -complex UI cooperation channels.

Figure 1 summarizes the proposed model of the micro-foundation of UIC.

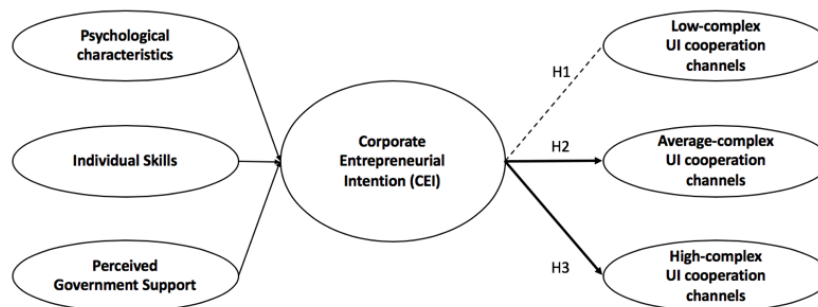

Figure 1. Conceptual model

4 Research design

4.1 Sampling strategy

In order to test our hypotheses, we collected evidence on the determinants of UIC from a firm's perspective, at the individual level. To ensure internal validity, we selected a specific regional context to control for normative environment, contextual munificence, and entrepreneurial opportunities (Beckman and Burton, 2008). Specifically, we locate our study in the Campania region, in the south of Italy. The Region of Campania represents an interesting case of study as it is characterized by a dynamic entrepreneurial landscape and a large number of universities and research centres. More specifically, Campania hosts 7 Universities (6 public and 1 private); 40 advanced research centres focused on technology transfer and innovation services; 30 business support structures

(incubators, accelerators). Campania is the 5th Italian region for the number of innovative start-ups (726 in October 2018) and 24,000 employees in Research & Development activities (above the national average). Furthermore, in the last decade the Regional Government has been taking initiative in implementing plans and ad-hoc interventions to stimulate UIC. In order to build our sample, we contacted the five provincial sections of the *Confindustria Campania* (the Campania regional section of the Italian National Industrial Association) and we asked them to provide us with contact information about all of their affiliated firms. We contacted all of them and we sent them an online structured questionnaire addressed to each firm's founder or, in a few cases, to the CEOs (in case of large companies). After three rounds of e-mails and phone calls, we collected a total number of 133 questionnaires. The data collection started in November 2018 and was completed by the end of February 2019. Our final sample counts 133 enterprises, distributed as follows: large firms (11,7%); medium firms (30,1%); small firms (28,2%) and micro firms (30,1%)¹. Sampled firms' innovation activities include the use and/or development of new technologies (40,8%); application and/or use of new business models (12,6%); use and/or development of both new technologies and business models (32%).

4.2 Questionnaire

We gathered data both at individual and at firm level. Specifically, we developed a survey to collect primary data directly from entrepreneurs. We gathered information on entrepreneurs' personal characteristics as age, gender, professional experience, level and type of education, future investment orientations, perception of the regional environment through a questionnaire that counts 39 closed questions. The questionnaire is divided in different sub-sections: firm profile; entrepreneur profile and individual skills; entrepreneur psychological characteristics; university cooperation; government support. The questionnaire has been realized by using Google form and has been filled online. To the purpose of data triangulation we also verified the validity of firm-level information about the sector, size, year of foundation, type of innovation activities, number of employees; R&D expenditure by using the Aida Database. Finally, we conducted a small-scale field pre-test to collect feedback about question phrasing, time needed to respond, and coverage with respect to the object of research. To this purpose, the questionnaire has been addressed to a panel of 10 entrepreneurs, that provided valuable feedback to improve the clarity of the questions. No major inconsistencies emerged.

4.3 Independent Variable

We characterize the CEI, our independent variable, in terms of the entrepreneur's (i) psychological characteristics (i.e. *entrepreneurial risk-taking propensity* and *entrepreneurial self-efficacy*); (ii) individual skills (technical and managerial) and (iii)

¹ Large firm (> 250 employees and > 50 M revenues); Medium firm (250 - 50 employees and 50 - 10 M revenues); Small firm (50 - 10 employees and <10 M revenues); Micro firm (< 10 employees and < 2 M revenues)

perceived government support (Fini e Toschi 2016) to ultimately measure the entrepreneur's willingness to create new value in the firm by engaging in innovative, proactive, and risky behaviors (Fini et al. 2012). For all measures, we used scales already tested in the existing literature. As for the psychological characteristics, we relied on Baum et al. (2001) and Ajzen (1991), while for the individual skills we adapted Gupta and Govindarajan (2000) and Roberts and Fushfeld (1981). Finally, to measure the perceived government support we used the scales proposed by Fini et al. (2009).

4.4 Dependent Variable

Our dependent variable, the type of channels of UIC implemented, have been operationalized by using the classifications proposed by Shartinger et al. (2002) of 17 types of U-I knowledge interactions, classified in three groups according to their level of complexity (Philpott et al. 2011). For each type of interaction, respondents were asked to indicate the frequency of use for each channel on a four-point scale (i.e. not used; occasionally; often; very often) (Table 1).

Table 1- Structural Model Variables

	Item	Scale format	Research reference
Psychological characteristics			
Entrepreneurial risk-taking propensity	d36	0 to 7 scale	Baum et al., 2001
Entrepreneurial self-efficacy	d28 d30	1 to 7 Likert-like	Gomez-Mejia & Balkin, 1989
Individual skills			
Technical skills	d5	1 to 7 scale	Gupta & Govindarajan, 2000
Managerial skills	d8	1 to 7 Likert-like	Roberts & Fushfeld, 1981
Perceived government support	d33 d34	1 to 7 Likert-like	Fini et al., 2009
Low-complex UIC (y1)			
Human resources mobility (students and researchers to industry)	d24_i4	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Funding of PhD scholarship by industry	d24_i10	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Industry externalization of teaching activity to university	d24_i12	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Average-complex UIC (y2)			
Academic participation to industry organizations	d24_i2	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Co-affiliation to professional associations	d24_i3	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Academic staff commitment within industry organizations	d24_i5	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Temporary exchange of academic staff with industry	d24_i6	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Board interlocks	d24_i7	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011
Sharing facilities (e.g. laboratories, equipment, housing)	d24_i17	1 to 4 scale	Shartinger et al. 2002; Philpott et al. 2011

High-complex UIC (v3)			
Contract research	d24_i9	1 to 4 scale	Sharteringer et al. 2002; Philpott et al. 2011
Consultancy services by university staff members to the industry	d24_i11	1 to 4 scale	Sharteringer et al. 2002; Philpott et al. 2011
Co-patenting	d24_i13	1 to 4 scale	Sharteringer et al. 2002; Philpott et al. 2011
Licensing agreements	d24_i14	1 to 4 scale	Sharteringer et al. 2002; Philpott et al. 2011
University spin-offs	d24_i15	1 to 4 scale	Sharteringer et al. 2002; Philpott et al. 2011
Specific knowledge transfer activities organized by the university's TTO	d24_i16	1 to 4 scale	Sharteringer et al. 2002; Philpott et al. 2011

4.5 Analyses

The hypotheses are tested using a structural equation model. The choice of a structural equation modeling approach (SEM) has been made because SEM is the most suitable analytical tool when the constructs composing the conceptual model are latent in nature and are operationalized through a vector of observed, error-laden, empirical variables. Also, SEM can trace causal paths to multiple dependent variables within the same model, by estimating measurement and structural paths at the same time, instead of than one at a time.

5 Results and Discussions

Figures 2 to 4 show main results from the structural model. Our findings show no significant effect of CEI with regard to Low-Complex UI cooperation channels (Figure 2), which confirms our first hypothesis (H1).

Figure 2. Structural model – CEI effect on Low-Complex UI Cooperation channels

On the other hand, we observed a significant and positive effect of CEI on Average-Complex UIC channels (Figure 3) and, to a greater extent, on High-Complex UIC (Figure 4). Hence, both hypotheses 2 and 3 are confirmed.

Figure 3. Structural model – CEI effect on Average-Complex UI Cooperation channels

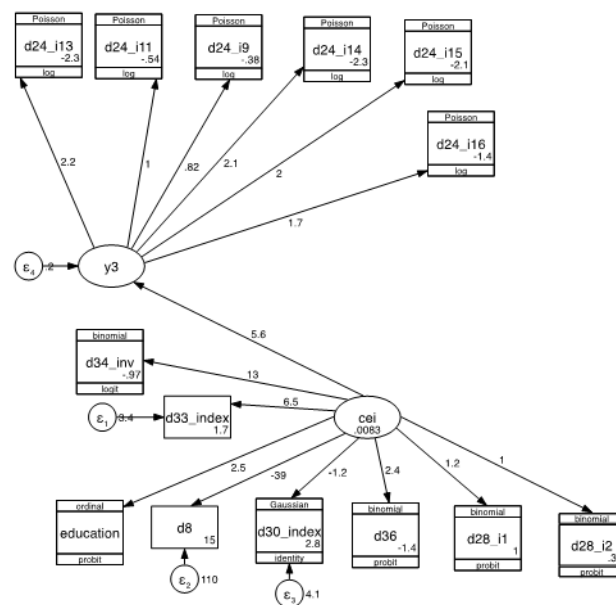

Figure 4 Structural model – CEI effect on High-Complex UI Cooperation channels

More specifically, we found a stronger effect on CEI on High-Complex UIC compared to Average-Complex UIC. This result may be explained by the fact that UIC channels with high levels of complexity are considered more entrepreneurial in nature. More specifically, with regards to CEI's dimensions, these activities, that are likely to be at the core of entrepreneurs' businesses, would necessarily involve higher levels of engagement and risk propensity, as well as a greater extent of technical and managerial activities. Also, these activities may be more vulnerable to external environment factors,

as funding in case of R&D projects or regulations, in case of IP commercialization. Hence, the entrepreneur's perception of the Government support may also be more relevant for these types of activities.

6 Conclusions

This paper aims to uncover the determinants of UIC from an individual perspective to identify which entrepreneurs' characteristics affect the emergence of UIC and, more specifically, the selection of cooperation channels. To this purpose, we employed the Corporate Entrepreneurial Intention (CEI) model (Fini et al. 2012), which allowed to assess the effect of both individual and contextual factors in UIC dynamics, whether no previous attempts have jointly considered both types of variables in UIC literature. After applying structural equation modelling techniques to a sample of 130 entrepreneurs in the Region of Campania (South of Italy), our results show that corporate entrepreneurial behaviour is positively related to forms of UIC channels with average and high levels of complexity. This study makes an original contribution to the literature focused on the determinants of UIC from the firm's perspective, by considering the entrepreneurs' individual characteristics, while most studies tend to limit their analysis to the identification of firm's organizational and sectorial characteristics to UIC. Also, while most scholars tend to focus on the determinants of UIC intensity, this study also contributes to explore what determines the selection of channels of UIC from an entrepreneurial perspective. Our study has also important implications for entrepreneurs willing to increase their engagement in cooperation with universities, by suggesting which types of channels would fit them best according to their individual characteristics. However, our results suffer from some limitations. First, the sample could be expanded to include a greater number of entrepreneurs within the Region in order to gain a deeper exploration of the industry variety effect on patterns of U-I cooperation. Second, a comparative study with other regions would contribute to a greater extent of validation of the results.

Abstract

The aim of this paper is to examine the role of entrepreneurial experiences of heads of departments and their impact on the ability to acquire external funds and the commercialization of research results measured by patents. The study is based on data from 208 Austrian university departments and combines data from different sources encompassing the CVs of the heads of departments, the commercial register, funding data and performance data intellectual capital reports. The results show a positive relationship between entrepreneurial experience and the third-party funding and patent output of the departments.

Keywords: Entrepreneurial university, third-party funds, entrepreneurial experience, patent output

Paper type: Academic research paper

1 Introduction

In recent decades, a number of concepts and strategies, such as the entrepreneurial university (Etzkowitz, 2003), new public management (Leisyte and Kizniene, 2006), the third mission of universities (Zomer and Benneworth, 2011), the Triple-Helix (Etzkowitz and Leydesdorff, 2000), and the mode 2 of knowledge production (Gibbons *et al.*, 2002) have been proposed to progressively transform universities into entrepreneurial institutions. These universities are closely linked to the demands of industry, society and governments (Etzkowitz, 2016), they are often required to diversify their funding streams (Tijssen, 2006; Slaughter and Leslie, 2001), and they are characterized by the

implementation of management tools primarily known from the private sector (Peus *et al.*, 2015). As a consequence, the role of scientists has changed from truth-seeking academics to entrepreneurial actors capable of considering the practical implications of their research and matching their knowledge with innovation (Elia *et al.*, 2017; Etzkowitz and Viale, 2010).

This study aims to take a closer look whether entrepreneurial experience of the heads of departments might influence the ability to acquire external research and the department's commercialization activities by patenting. Entrepreneurial experience is assessed by prior industry or leadership experience of the heads of departments. While previous studies have mainly investigated the role of the scientific experience of academic leaders in the research performance of their institution in later decades (Goodall, 2006, 2009; Goodall *et al.*, 2014), research on other non-scientific experiences of academic leaders is still in its infancy. By adding this 'entrepreneurial' perspective, our research contributes to the literature by understanding of how entrepreneurial universities can improve their performance to fulfill the increasing demands by industry, society and governments. Entrepreneurial experiences of the heads of departments can also be considered as important form of human capital of entrepreneurial universities (Secondo *et al.* 2017).

Our research methodology has been organized in several phases: First, we analysed the literature on entrepreneurial universities and leadership of universities to understand the relationship between different scientific and non-scientific experiences and other key performance indicators. Then, we captured data from 208 Austrian university departments in the natural and technical sciences and combined data from different sources. We have collected data about the heads of departments from CVs and the commercial register, used funding data from the biannual survey by Statistics Austria and collected data from publication databases of the universities (intellectual capital reports). We conducted OLS, logistic and negative binomial regression analyses to test our hypotheses.

In the next section, we review the relevant literature and propose testable hypotheses. The method and data used are described in section 3 and the results are presented in section 4. In section 5, we discuss our results in the context of the literature.

2 Theoretical background and hypotheses development

Today's universities play a central societal and economical role and the effort to adapt policies and practices to better translate knowledge into economic activities has increased worldwide (Etzkowitz, 2016). In contrast to traditional universities, which focused mainly on teaching (first mission) and/or research (second mission; for a concise overview of the evolution of universities since the first industrial revolution, see Elia *et al.*, 2017), entrepreneurial universities and their members need to collaborate more strongly with industrial and governmental partners to mutually create new innovations and to foster the development of a region (Elia *et al.*, 2017).

As noted by Etzkowitz (2016), key elements of an entrepreneurial university include the endeavor to move research out of the university as protected intellectual property, to

organize firms within the university, and to integrate academic and business elements into new formats such as university–industry research centres. According to Tijssen (2006), entrepreneurial universities embrace an entrepreneurial and innovative spirit, promote an entrepreneurial culture, foster relationships with industry, transfer knowledge and technologies, and integrate managerial and market-related practices and tools.

Within the university, several levels exist on which entrepreneurial patterns occur. These levels either concern the university itself, the members of the university, or the interaction with the environment of the university (Röpke, 1998). Many universities have taken various actions to raise awareness for an entrepreneurial approach among students (Secundo *et al.*, 2017; Packham *et al.*, 2010), but also among staff members. These universities promote managerial and attributional changes toward the commercialization of research findings because the entrepreneurial orientation of universities relies largely on cultural determinants, such as the managerial culture at universities, the governance culture of the higher education sector or the overarching socio-economic culture of a country (Tijssen, 2006).

In this changing process, academic leaders play a crucial role, particularly when managing severe changes and merging the individual scientific autonomy with new organizational goals (Bergner, 2015). Changing governance structures, greater autonomy, the need to diversify funding streams and the increasing request to transfer knowledge in collaboration with different partners will require new capabilities from academic leaders (Rybníček, 2015).

In the light of the new challenges, tasks and strategies that come together with the entrepreneurial university, it is evident that a more entrepreneurial mindset and business-oriented culture is needed at universities. Therefore, different management tools, more commonly used in the private sector, have already been transferred to public universities (Peus *et al.*, 2015; Rybníček, 2015). Similar to the implementation of new management tools, it is also to be expected that the necessary leadership skills at universities will converge with those observed in the private sector. Thus, scientists in leading positions will have to take over similar roles and duties as those leading in the private sector (Peus *et al.*, 2015).

In the context of changing funding patterns, heads of departments have to increasingly acquire research funds from various sources. In the literature, it is argued that industry experience and leadership experience are of importance for budgeting and the acquisition of external research funds. Scholars studying entrepreneurial universities, for instance, stress the role of leadership capabilities and inter-sectoral mobility in the success of acquiring third-party funds and managing research departments.

Regarding industry leadership experience, scholars recently delivered empirical evidence about the effect of leadership capabilities and management practices on the performance of universities. McCormack *et al.* (2014), for instance, investigated 248 heads of departments in UK universities, revealing a direct link between management practices and performance in research and teaching.

Regarding industry experience, previous studies reported that inter-sectoral mobility can facilitate the building of competencies and relationships that are important for the

acquisition of research projects. Concretely, industry experience expands the social capital, which again helps to develop and acquire research grants in collaboration with various partners. The network of the head of department represents an important resource the entire department can benefit from (Harvey *et al.*, 2002). In addition, industry experience helps to build up trust in collaboration with non-academic partners and to establish a cooperative culture. Social capital of the head of department developed in previous jobs also facilitates the emergence of a common language and a better understanding of collaborative research work (Rouse *et al.*, 1992).

Based on these arguments we state:

Hypothesis 1a: Industry experience of heads of departments has a positive impact on the level of third-party funding.

Hypothesis 1b: Leadership experience of heads of departments has a positive impact on the level of third-party funding.

Apart from traditional forms of technology transfer by means of collaborative research projects and contract research, the commercialization of research results has become increasingly important in many countries in recent years. With the implementation of the Bayh–Dole Act in 1980, US universities are allowed to file patents on inventions they elect to own for almost four decades. In the 1990s a number of European countries started to establish Bayh–Dole-type regulation to foster academic patenting, aiming to enhance the utilization of industry-relevant scientific research, contribute to economic development and job creation and to improve resource generation (Weckowska *et al.*, 2018). Promoting the commercialization of research by the university through patenting is a key pillar of the entrepreneurial university.

In Austria, the University Act 2002 changed the legal framework and allowed universities on the institutional level to claim the intellectual property (IP) of their inventions. Prior to that, it was solely the professor's privilege to apply for patents, although this rarely occurred. In recent years, as in many other European countries (Pinheiro *et al.*, 2015), a number of specific promotion programmes and initiatives with targeted funding schemes have been established, supporting universities in their commercialization activities. Austrian universities established Technology Transfer Offices, created IP policies and established long-term plans and goals to become more entrepreneurial (BMWWF, 2016).

We claim that industry and leadership experience both have a positive impact on the likelihood of generating patents as both types of occupational engagement facilitate or enable the identification of business and market opportunities. This can be argued based on the diversity hypothesis (Dietz and Bozeman, 2005), reasoning that more diversity in work experience allows researchers to develop stronger network ties, skills and access to enhanced knowledge gatekeepers, which, in turn, enables the commercialization of innovative research outputs.

In a related vein, recent studies suggest that third-party funding is also correlated with the generation of patents (Gulbrandsen and Smeby, 2005). Interestingly, Hottenrott and

Thorwarth (2011) found that while a higher share of industry funding has no effect on the *number* of patents generated by professors, it has a positive impact on *citations* per patent.

Based on these arguments we propose the following hypothesis:

Hypothesis 2a: Industry experience of the heads of departments is positively associated with the patent output.

Hypothesis 2b: Leaderships of the heads of departments is positively associated with the patent output.

Hypothesis 2c: There is a positive relationship between third-party funding and the patent output.

3 Methods and data

The study is based on a sample of 208 university departments in natural and technical sciences from ten public Austrian universities. We thus covered all public universities apart from medical universities and arts universities. We focused on natural and technical sciences as in both disciplines external funding has grown considerably in the last two decades and plays a crucial role (BMWWF, 2014). Therefore, we assume that in these disciplines academic research is relevant to industry and, vice versa, industry experience is relevant to the university departments and their heads. Considering the organizational and governance structure of Austrian universities, departments can be considered as relevant units of observation.

We considered the development of the departments over a period of three years between 2013 and 2015 and selected those departments that had the same head of department over this period of time, which was the case for 77% of in total 270 natural and technical sciences departments from the ten universities. As the turnover is rather small, we did not take into account those departments that changed their heads. Today many universities consider leadership or managerial experience in the appointment of professors (e.g. Vienna University of Technology, University of Graz), following the trend to integrate these qualifications and experiences already in the job specifications of a professorship (Rybníček *et al.*, 2016).

We collected data from various sources to determine our dependent and independent variables. The measurements for industry and leadership experience are not overlapping and capture different aspects, qualities and qualifications of the CVs and the commercial register: To determine industry experience, we analysed mainly the CVs from the heads of departments. For the analyses, we developed a coding system to collect data regarding industry experience (excluding positions at universities, non-governmental organizations or public institutions). Additionally, we included board responsibilities from the Austrian commercial register. For leadership experience we analysed the Austrian commercial register and focused here on the functions ‘managing director’, ‘owner of the company’ and ‘authorized representatives’ of the company. In this context, we determined the type and duration of position. Leadership experience is measured in months (reporting day was 31st July 2017), while industry experience is a binary variable as it was not possible to extract the number of years from all CVs.

In addition, we collected separately the number of publications of the heads of departments and calculated a dichotomous variable with those heads that belong to the top 25% in terms of the publication output investigating the impact of the top performers. It is argued that the publication output of the head of departments has also an impact on the various forms of outputs, the variable is included as control factor.

Data about R&D funding are collected by Statistics Austria, which biannually conducts an obligatory survey about the public and private third-party funding sources among the university departments. We used the amount of third-party funding as a percentage of the total funding. In addition, we distinguished between public and private third-party funds as the percentage of total funding. Third-party public funding includes funding from national and international public science and research promotion funds. Funds from the European Commission and the Framework Programmes are included as well. Third-party private funds cover funds from private organizations, with enterprises as the most important source.

In addition, Statistics Austria collects data about R&D personnel, which is used to determine the number of researches, measured as full-time equivalent, at department level. We used the data for the survey in 2013 and 2015 and calculated the mean for the three-year period.

Considering the different types of variables, we conducted OLS, logistic and negative binomial regression analyses. We analysed residuals, error terms and outliers to check for heteroscedasticity and normality of the residuals. The private third-party funds did not meet the assumption of normality to conduct an OLS regression and we hence used a binary variable, distinguishing between the top 25% and employing a logistic regression. In addition, the number of patents, which serves as dependent variable in one hypothesis test, had a highly skewed count data and revealed over-dispersion. We thus ran a negative binomial regression model for studying the patent output.

We controlled for size, discipline and age, which should have an impact on the output according to the literature (Carayol and Matt, 2006). For the variable size and age, we also calculated the squared value in order to control for any possible non-linear effects (Bolli and Somogyi, 2011). In addition, we used the location of the university (= Vienna) as control, took into account the discipline (natural science versus technical sciences) and checked whether the departments belong to a technical university.

4 Results

With regard to our main variables of interest, industry and leadership experience, the data show that among the 208 heads of departments, 118 had prior industry experience and 64 had leadership experience lasting, on average, 60 months. Fifty-four heads of departments belong to the top 25% group in relation to their publication output. Overall, 100 departments are engaged in natural sciences and 108 departments belong to technical sciences and engineering. A total of 125 departments belong to one of the three technical universities and 77 departments are part of the three universities in Vienna.

To test hypotheses 1a and 1b dealing with the effect of industry and leadership experience, we conducted a regression model with the share of total third-party funds (Table 1). We first analysed the effect of industry experience (Table 1, Model 1) and then investigated the role of leadership experience (Table 1, Model 2) including different controls. For all models we checked outliers and heteroscedasticity, which raised no concerns of them violating any assumptions. Model 1 revealed a low positive coefficient for industry experience. Leadership experience revealed no effect (Table 1, Model 2). However, size, discipline and the location of the department had an effect on the amount of acquired third-party funds. Larger departments and departments in technical sciences and engineering have a higher likelihood of acquiring third-party funds. Universities in Vienna have lower levels of third-party funds, which is partly explained by a lower share of private third-party funding and fewer industrial companies. In both models we also included the publication output of the heads of departments, which revealed no influence either. Thus, we found support for hypothesis 2a, but have to reject hypotheses 2b.

Table 1: Dependent variable: third-party funds total (in %) of the department 2013–2015 (standardized beta)

Independent	Model 1	Model 2
Industry experience of the head of department	0.167**	
Leadership experience of the head of department		0.029
Size	0.329***	0.322***
Technical sciences	0.210***	0.243***
Vienna	-0.189***	-0.212***
Technical university	-0.101	-0.119
Age	0.597	0.637
Age squared	-0.601	-0.656
Publication output of the head of department (top)	-0.007	0.026
N	207	207
F-value	6.060***	5.967***
Adj. R ²	0.164	0.140

+ p < 0.10; * p < 0.05; ** p < 0.01; *** p < 0.001

In addition, we tested the effect of industry and leadership experience on the amount of third-party funding from private sources by separate models. As the private third-party funding variable was skewed and did not meet the requirements to run an OLS regression, we conducted a logistic regression, splitting the departments into two groups. We compared the departments that had private third-party funding of more than 20% of total funding with the reference group below 20%. We were particularly interested to explain the determinant for the success of the top performing departments and thus cut at 20%. Table 2 (Models 1 and 2) depicts the results of this analysis. We found a positive coefficient for the effect of industry experience on private third-party funding, which was not significant, though. We found no evidence for an effect of leadership experience on acquiring private third-party funds. The discipline again explains the level of private third-party funding, showing that technical sciences and engineering departments have higher levels thereof. In contrast, size, age of the head of department and type of university had no significant effect. The variable location (Vienna) reveals a strong magnitude but the term was not significant.

Table 2: Dependent variable: private third-party funds of the department 2013–2015 (> 20%), logistic regression (coefficient beta)

Independent	Model 1	Model 2
Constant	-5.146	-3.863
Industry experience of the head of department	0.407	
Leadership experience of the head of department		0.003
Size	0.009	0.013
Technical sciences	3.372**	3.559**
Vienna	-19.107	-19.234
Technical university	-0.454	-0.584
Age	-0.551	-0.610
Age squared	0.005	0.005
Publications of the head of department (top 25%)	-0.273	-0.212
N	208	208
Chi-square	40.049***	39.953***
Log-likelihood	82.444	82.541
Cox & Snell R ²	0.175	0.175

+ p < 0.10; * p < 0.05; ** p < 0.01; *** p < 0.001

Hypotheses 2 deals with the patent output of university departments and the role of entrepreneurial experience of the heads of departments. Due to the nature of the dependent variable number of patents, which was skewed, we ran a negative binomial regression model.

Table 3, depicts the results with the main effect variables and control factors. Leadership experience was entered as a binary variable in this model. The regression analysis shows that both industry and leadership experience had positive coefficients, with leadership experience being significant on the 1% significant level. The leadership coefficient is 0.778. Thus, heads of departments with leadership experience are more likely to publish patents, which provides support for our hypothesis 2b. However, hypothesis 2a has to be rejected.

In addition to industry and leadership experience we also investigated the impact of third-party funding on the likelihood of generating patents. However, we found no support for the assertion that there is a positive relationship between third-party funding and the patent output. Both, private and public third-party funds showed no significant impact. Therefore, hypothesis 2c has to be rejected.

The discipline and location of the university had no effect on the patent output either. However, we found that the age of the head of department had a negative significant effect and the size of the department a weak positive impact on the patent output. The publication output was positively correlated with the patent output of departments revealing that the top-performing heads of departments are able to convert ideas that can be commercialized. Technical universities were less likely to generate patents, which might be explained by specific patent policies within some universities and a weaker position in negotiating arrangements on how to deal with intellectual property rights in third-party-funded research projects.

Table 3: Dependent variable: Patents 2013–2015, negative binomial model (coefficient beta)

Independent	B	Exp(B)

5 Discussion and Conclusion

Today's universities are confronted with increasing demands from economy and society. To meet these new requirements, universities have to reconsider their research focus, to adopt their funding sources, and to adjust their internal rules and organization. These changings are also influencing the necessary qualities and characteristics of university leaders. Our study contributes to the literature by investigating the role of industry experience, leadership experience and research output of the heads of departments on key aspects of entrepreneurial universities like third-party funding and the patent output.

Leaders play a crucial role in this transition as they are responsible for the implementation of changes (Peus *et al.*, 2015) and serve as entrepreneurial role models, and they must be able to identify business opportunities (Kirby *et al.*, 2011). Hence, we assumed that industry and leadership experience of the heads of departments should impact scientific and entrepreneurial key aspects such as the departments' potential to acquire third-party funds and the generation of patents.

With regard to the impact on third-party funding our investigation revealed a low positive effect for industry experience. However, leadership experience had no effect on the level of third-party funding. In contrast, we found evidence that leadership affects the patent output of departments. Presumably, heads of departments with leadership experience are more likely to take a possible route of commercializing research results by patents. Therefore, our results suggest that entrepreneurial universities can profit from a head of department with industry experience in those activities, which Etzkowitz (2016) summarizes as the initial phase of entrepreneurial universities (e.g. raising additional resources). However, if universities seek to enter in the second phase of Etzkowitz's (2016) classification, i.e. taking an active role in commercializing the intellectual property of its members, the leadership experience of heads gains in importance. Apparently, heads of departments with former leadership experience are more acquainted with this challenge or they are more likely to see and take the chance to apply for a patent and commercialize

the own scientific research. Thus, our results are in line with Kirby *et al.* (2011), who postulate that nowadays university leaders must be capable of identifying business opportunities.

Based on our research, we also derived several practical implications. When universities seek to focus on other, for example, entrepreneurial activities, then new competencies come into play. The entrepreneurial university requires scientists that can handle the demands of both universities and economy. In that regard, Etzkowitz and Viale (2010) refer to scientists with double and even triple lives in university, industry and government. Scientists with experiences outside the university will be capable of adapting quickly to changes introduced by the entrepreneurial university. Our results suggest that heads of departments with leadership experience are better equipped to commercialize research findings by patents.

Our results support the idea of encouraging scientists to acquire leadership skills and leadership experiences. Recent research suggests that the motivation to lead significantly influences how well a leader performs (Bergner *et al.*, 2018). This motivation is influenced by the individual's interests and previously gained leadership experience (Bergner *et al.*, 2018).

When interpreting the results of this study one has to bear in mind the limitations. We focused our research on natural sciences, technical sciences and engineering and the results can thus not be generalized to other disciplines. Moreover, we have excluded heads of departments who did not consistently carry out their position from 2013 to 2015, though this could have had an influence on our results. We have not dealt with dynamic effects. Such effects could occur, for instance, as more efficient researchers might more successfully acquire external funds, which further strengthen their capacity to publish and attract additional third-party funds. We have not considered experiences in the public sector or in non-profit organizations, as we assume that entrepreneurial universities increasingly align with requirements, tools and skills more commonly associated with the private sector. Finally, we measured only the number of patents as one form of commercializing scientific findings; however, it might also be of interest to investigate the impact of spin-off companies.

Abstract

Analysing the entrepreneurial role of universities discussed by scholars, this paper is directed to investigate diversification and multinationalisation strategy of universities through the proposition of a single case study. Thus, the purpose of this paper is to discover the reasons that led our university case study to develop its strategy and the role of its intellectual capital in supporting the chosen strategy. Our case is investigated through Secundo et al.'s (2016) collective intelligence framework for universities. Answering the research question, our findings include why our university case study chooses to pursue its business strategy to achieve teaching, research, and the third mission.

Keywords: entrepreneurial university, business strategy, intellectual capital, diversification, multinationalisation.

Academic Research Paper

1 Introduction

Universities changed their strategies during the time. They moved from being higher education centres to become entrepreneurial organizations to support the triple helix (Etzkowitz and Leydesdorff, 2000). Within the triple helix university-industry-government relations contribute to societal development through the knowledge promotion (Carayannis and Campbell, 2012; Lombardi et al., 2017; Trequattrini et al., 2018).

The changing university models allow for the understanding of entrepreneurial universities (Etzkowitz, 1983, Clark, 1998; Etzkowitz, 2016; Lombardi et al., 2017; Trequattrini et al., 2018). In this direction, we analyse the strategy construction of entrepreneurial universities (Buckland, 2009) and build on the intellectual capital (IC) of university (Secundo et al., 2018a). Thus, we investigate the university case study called “A” discovering its business strategy as entrepreneurial university, and how university IC supported its purpose aligned to its operating ecosystem (Secundo et al., 2018a; Secundo et al., 2018b).

Thus, we analyse the definition of a diversification and multinationalisation strategy adopted by university case study A as well as how its IC is composed referring to entrepreneurial university strategies (Dumay, 2013; Dumay and Garanina, 2013; Dumay and Guthrie, 2017) and contributing to fourth stage literature on IC (Secundo et al., 2018a). Our case is investigated through Secundo *et al.*'s (2016) collective intelligence framework for universities. Answering the research question, our findings include why our university case study chooses to pursue its business strategy to achieve teaching, research, and the third mission. Our results adds to the literature on University's strategies (Mintzberg and Rose, 2003) adopting a contingent approach (Etzkowitz and Leydesdorff, 2000).

The paper is organised as follows: Section 2 presents the literature review. Section 3 examines the methodology. Section 4 presents case study results. Section 5 proposes the discussion and conclusions.

2 Literature analysis

The advent of the fourth stage of IC research allows composing IC (Cuozzo et al., 2017) through resources supporting teaching, research and third mission activities (Lombardi et al., 2017; Secundo et al., 2018a). Universities use IC in developing strategies to obtain social and economic developments (Secundo *et al.*, 2018b). In this scenario, strategies of diversification and internationalization are investigated (Zanoni Beretta, Barzatta, 2011).

Universities can choose the diversification strategy adopting several activities (Neffke and Henning, 2013). Particularly, main activities supporting such strategy are based on the increasing number of courses and research activities (Mintzberg and Rose, 2003) or specialising in some courses and research activities (Agasisti, 2016; Donina *et al.*, 2015;

Seeber *et al.*, 2016). Diversification strategy of universities is aligned to their IC, analysing human capital, relational capital and structural capital.

Disclosing existing human capital, universities become more appealing to attract experts and researchers (Low *et al.*, 2015). Relational capital support universities in fortifying the brand (Nguyen *et al.*, 2016) and accessing new market sectors (Fernández-Olmos and Díez-Vial, 2012; Lombardi *et al.*, 2017). Structural capital helps universities in cutting production costs of new services (Camison and Villar-Lopez, 2010) and focusing research and curricula (Observatory of the European university, 2006).

Additionally, universities choose to adopt both a multinational strategy with international purposes and more abroad branches. Particularly, multinationalisation strategy (Guimon, 2016; Maslen, 2012; Pearce, 2016) allows to universities to have the local and international presence (Greenholz, 2000; Lombardi *et al.*, 2017). In this way, universities activates knowledge exchange (Lombardi, 2019; Powell, 2014) also in the relationships university-industry-government (Guan and Zhao, 2013; Lombardi *et al.*, 2017; Trequattrini *et al.*, 2018). Multinational strategy of universities is aligned to the IC, analysing human capital, relational capital and structural capital and allows for the recognition of universities as knowledge hubs.

In the light of previous literature, our research question is the following: *RQ1: Why does universities adopt diversification vs multinational strategy?*

3 Research Methodology

To develop our analysis, we used a qualitative method (Shah and Corley, 2006) through the application of a case study methodology (Yin, 2014). Thus, we adopted an exploratory case study with the purpose of extending IC theories in the University's contexts. Focusing on Italian University having a strategic plan oriented to third mission, we selected our case study A (or university A).

We fixed a specific research protocol to ensure reliability (Yin, 2014). After, we analysed university annual reports and the strategic plan and we conducted semi-structured interviews (Qu and Dumay, 2011) with university board members, analysing vision, mission, and objectives; the background and role of board members; the impact of chosen strategy on stakeholders, the role of IC in sustaining the strategy. Additionally, we used Secundo *et al.*'s (2016) collective intelligence framework based on four key questions to define the strategy: what, who, how, and why.

We used the open in-vivo coding in NVivo (Miles *et al.*, 2013) to analysed data. Our results were discussed among the authors and with the people interviewed (Yin, 2014). Lastly, we used a chain of evidence matrix to increase reliability (Yin, 2014).

4. Results

In this section, we show results defined through the application of the framework by Secundo *et al.* (2016), summarizing some main findings.

Adopting the what dimension by Secundo et al. (2016) framework, the university case study A performs teaching, research and third missions through an open model of governance with the involvement of stakeholder. The university A builds on the fourth stage of IC research (Dumay and Garanina, 2013; Secundo et al., 2018a) in the ecosystem in which it operates (Secundo et al., 2018b). The strategic plan of the university A' allows to recognize the diversification and the internationalisation strategy.

About the who dimension by Secundo et al. (2016) framework, main internal and external stakeholders are identified in relation to the strategy adopted. They are professors and researchers, strategic task force, employees and administrative offices, and national and international students, national and international students, professional institutions. Adopting the why dimension by Secundo et al. (2016) framework, the university A adopts international programme students and professors' exchange, the development of an international branch, multiple collaborations with institutions. Such strategy identifies the multinational strategy.

Adopting the how dimension by Secundo et al. (2016) framework, actions of the university A are explained in the light of the diversified international strategy. The university A increases diversified students programmes, invests in education directed to professors and employees, builds external collaborations with labour and territorial institutions, establishes several regulations and research indicators.

5. Discussion and conclusions

Our analysis provides both theoretical and practical contributions to the literature. First, the practical contribution supports the diversified strategy adopted by university A in pursuing teaching, research and third mission goals (Etzkowitz, and Leydesdorff, 2000). In this way, we found historical and economic reasons connected to decisions assumed during the time. The university A plays a role in the triple helix context (Etzkowitz and Leydesdorff, 2000; Trequattrini et al., 2018).

IC is being re-shaped in the entrepreneurial university strategies (Secundo et al., 2018a). The university A adopts a multinational strategy based for example on student and academic exchanges (Kosmützky and Putty, 2016); relationships and project opportunities; cross-cultural competence valuation. Additionally, the university A adopts the IC ecosystem and it has a role in the triple helix through intangibles (Secundo et al., 2018a; Secundo *et al.*, 2018b).

Confirming the relevance of contingency factors, the analysis shows the diversification and multinationalisation strategies by the university A. The future research is directed to continue this research through a multiple case study. Thus, the limitations of this paper originates from the analysis of one case study.

Abstract

An e-learning system, based on the Fee model (2009), consists of three components: technology, learning content and learning / e-learning design. In the literature on universities, there are not many contributions on the design of e-learning, understood as a process (Trentin, 2001).

This article intends to understand, through an empirical analysis, how European universities implement e-learning design. In particular, the goal is to study the e-learning and design system, within selected European universities, to understand the phases of the project and to understand how much the university takes into account the territory.

The study approach adopted to conduct the research was mixed: quantitative and qualitative.

First of all, the quantitative survey was carried out on the websites of the top 100 European universities in the Quacquarelli Symonds ranking.

Subsequently, the qualitative construction of some case studies and semi-structured interviews with managers of e-learning services of some European universities was carried out.

The quantitative survey shows that the 100 best European universities, present in the Quacquarelli Symonds ranking, adopt e-learning methods, allowing to identify, among them, the universities involved in case studies.

The qualitative construction of case studies and semi-structured interviews with managers of e-learning services of some of these European universities underlines a specific attention to the e-learning design of the courses, even if more focused on the professional figures working there and not entirely on the e-learning course project.

The article aims to provide a detailed study on the design of e-learning in the educational context. The analysis of multiple case studies allows us to identify how the selected universities carry out the activity of educational design through the use of technology.

The study has two main limitations. The first difficulty lies in the difficulty of having a complete view of the examined phenomenon. The second limit refers to the number of respondents and universities contacted.

The future objective will be to intensify these activities by involving other actors (teaching staff, governance) and new universities.

Keywords – E-Learning, Knowledge Management, European Universities, Knowledge, E-learning/Learning Design

Paper type – Academic Research Paper.

1 Introduction

E-learning is a teaching and learning system provided on a digital device such as a computer or mobile device (Brown and Voltz, 2005; Clark and Mayer, 2011); which allows the transfer of educational material (Carroll, 2013), which can cover part or all of the course (Dizionario Treccani, 2015), in blended mode. This system can be based on Cloud Computing (Masud and Huang, 2012), in which data storage takes place within the network, using hardware resources, in a secure manner (Ahmed, 2015); on request, paying based on their use (Riahi, 2015) and can be provided, free of charge, to a large number of students located in any geographical location (Sinclair, et al., 2015), provided you have an internet connection (Jansen, and Schuwer, 2015), through the so-called Massive Open Online Courses (MOOCs).

E-learning, in universities, can be considered as a tool to implement advanced technological learning (Almpanis 2015), to allow sustainable development in higher education (Azeiteiro et al., 2015), to allow improvement of the knowledge and skills based on technology (Bhuasiri, et al., 2012).

E-learning, according to Wild et al. (2002), has many of the same attributes of the basic knowledge management processes and, therefore, can be used as a tool for knowledge management to generate, encode and transfer knowledge, through the use of technology (Ruggles, 2009).

Liebowitz e Frank (2016) talk about a synergistic relationship between knowledge management and e-learning. According to Iqbal and Islam (2013), at least two factors are driving the fusion of knowledge management and e-learning: knowledge acquisition and information sharing (Chawhan, 2012; Shamizanjani et al., 2014), establishing knowledge-based learning within universities (Aurelie Bechina Arntzen, et al., 2009).

According to Chen, and Hsiang (2007) e-learning systems must be designed to emphasize knowledge development.

Fee (2009) states that e-learning systems consist of three components: technology, learning content and learning design.

Technology is a basic infrastructure that allows the implementation of e-learning (Urh et al, 2015) through the transfer of information during training or the acquisition of skills by users (Ghiringhelli and Quacquarelli, in Nacamulli, 2003).

The learning content refers to the associated learning material and activities (Al-Yahya, et al., 2015).

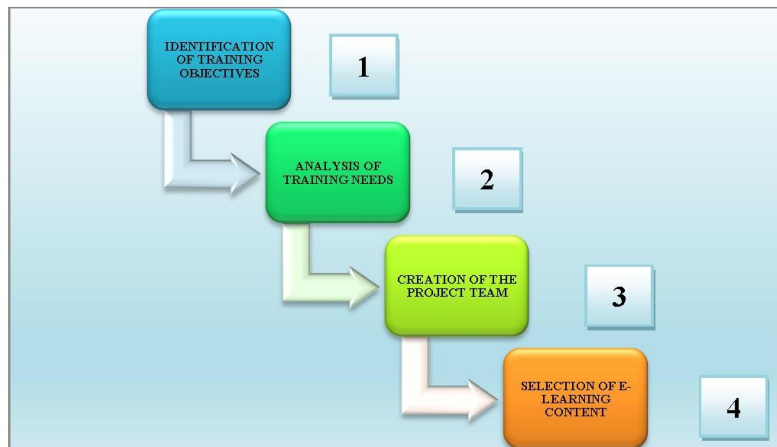

The project Learning/E-learning is the set of decisions (Horton, 2011) on how to plan activities and learning interventions (Conole, 2013, p.7), establishes objectives and teaching plans (Rienties, et al, 2015) based on educational information, an appropriate use of resources and technologies.

According to Trentin (2001) learning design is characterized by a complex educational process that includes four phases (see figure 1): (1) identification of the general objectives of the training course (Cocozza, 2004); (2) analysis of the current state of performance of the subjects to be trained and definition of the level of performance to be achieved (Esposito and Mantese, 2003) and (3) creation of a dedicated design team, in which various professional figures are involved. E.g.: Instructional Design; Curriculum Planner; Content Designer. (4) The selection of e-learning contents (Ghiringhelli and Quacquarelli, in Nacamulli, 2003) aims to transfer information within a training context; acquire skills from users; promote an educational model focused on cooperation and shared learning and finally promote the organizational and shared learning dynamics that take place in the communities of practice.

Following the Fee model (2009), within the literature on e-learning in universities, it emerges that it is particularly rich in aspects related to technology (Leidner, and Jarvenpaa, 1995; Arbaugh, 2000; Venkatesh, and Davis, 2000; Alavi and Leidner, 2001; Piccoli, et al., 2001; Martins, and Kellermanns, 2004; Bhuasiri et al., 2012; Hassanzadeh et al., 2012; Al-Adwan et al., 2013; Islam, 2013; Kurilovas et al., 2014; Songkram, 2015; Masud, 2016; Elkaseh et al., 2016) and educational content (Hwang, et al, 2006; Arbaugh, 2008; Franceschi, et al., 2009; Koutsabasis et al., 2011; Adeola et al., 2013; Carril et al., 2013; Parkes et al., 2013; Almpanis, 2015; Oproiu, 2015; Azeiteiro et al., 2015; Parkes et al., 2015), while the problem of e-learning design has not been studied in depth (Urh, 2015; Islam et al., 2015).

This article aims to understand, through an empirical investigation, the type of attention paid by universities to e-learning design. In particular, the objective is to verify how some selected European universities implement the design of courses, through e-

learning systems, following the process outlined by Trentin (2001) and therefore trying to bridge the gap in the literature.

Source: Adapted from Trentin (2001).

Figure 1: E-learning Design process.

The article is organized as follows: the theoretical background will be analyzed in the next session; the research method adopted will then be examined, then the main results obtained and the discussions; finally, the conclusions will be illustrated.

2 Theoretical background: the role of design in e-learning

"Good learning" in e-learning systems depends on a combination of work technology, meaningful content and effective e-learning design (Fee, 2009). These three components are complementary and must be carefully combined: the design must make the most of the content and the technology must allow both the content and the design. For professionals involved in the development of e-learning, not only access to content and technology is important, but also design.

The study by Al-Samarraie et al, (2017) analyzes the design of e-learning in order to understand how the organization and the structural aspects of the representation of e-learning, grouped according to their coherence, can facilitate the processes cognitive in reading and storing content. The authors, through an empirical investigation, have discovered that the incorporation of cognitively isolated elements into a system representation can influence the ability to read and remember the content, which in turn affects the user's preference for the use of e-learning system.

Benson and Samarawickrema (2009) consider the importance of addressing learning and the context of teaching in design e-learning through transactional distance theory. The authors suggested, through the analysis of some case studies, that it is necessary to design appropriate levels of dialogue and structure for students and the learning context in order

to reduce transactional distance, ie the separation between students and between teacher and learner.

Brown and Voltz (2005) analyze the e-learning resource design phase that combines activities such as design planning and teaching, creative writing and software specifications. The observations were based on the analysis of six areas – activity, scenario, feedback, delivery, context and impact – in order to cover the problems of all the disciplines involved in e-learning design, but in particular focus on learning as a motivation driving.

Anderson, et al. (2001) consider e-learning design as a process of exclusive prerogative of teachers who need to think about how to set up and build the course and which teaching materials to use. The authors examine the variable called "educational presence", within a computer conference environment, consisting of three categories: design and organization, facilitation of discourse and direct instruction.

The aim of Lister's research (2014) is to identify, through the similarities and differences of some models and research of common themes, the components that are important to include in the design of e-learning to improve learning.

Rientee and Toetenel (2016) have demonstrated the extent to which teacher-based learning design decisions involve the commitment, satisfaction and academic performance of virtual learning environments (VLEs), allowing them to build a shared vision.

Rienties, et al (2015), considering empirically Learning Management Systems (LMS) and learning performance, study learning design. This research combined three different data sources (i.e. learning design data, LMS and learning performance and showed that academics seem to design modules with an "invisible" design in their mind, capable of impacting the performance of learning.

The main objective of the research conducted by Rodríguez-Triana, et al. (2015) is to help teachers monitor their design decisions made or not in combined CSL (Computer Supported Collaborative Learning) scenarios. The results obtained show that the monitoring-sensitive design process and the underlying monitoring-sensitive scripting model were able to align scripting and monitoring, respectively two well-known approaches to Learning Design (LD) and Learning Analytics (LA).

The article by Lockyer et al. (2013) investigates how learning analysis can help assess whether a learning project improves understanding and assessment of the student's intent and teaching activity. This work found that the evaluation potential of the learning analysis would be significantly improved with reference to the learning project that documents the pedagogical intent.

The research reported by Bennett et al. (2015) was conducted to advance the understanding of university teacher design practices that could be aimed at identifying activities or influences that support such tools. The analysis considered design as a process through which teachers anticipate the characteristics of their students and respond to various forms of feedback, informed by their beliefs and their teaching competence, within the limits of their particular context.

According to Haya et al. (2015) Learning Analytics is a key tool to support Learning Design and the student social learning survey. The article through the adoption of the Analytics toolkit aims to explore the potential of computational methods that can support teachers and students who participate in collaborative scenarios and allow an effective learning process.

Teräs and Herrington (2014) describe the use of an educational design research process to find the right balance in an authentic e-learning project in a fully online postgraduate program implemented by the Tampere University of Applied Sciences (TAMK).

But according to an empirical survey conducted by Urh (2015), there is a lack of attention on the part of universities to design e-learning linked to the educational aspect (Islam et al., 2015). In fact, the correct training requires the teacher to understand how to design and distribute the course materials and how to guide the students appropriately, in order to transmit knowledge, skills and allow the learning and management of the related training process (Fee, 2009; Trentin, 2001).

This article, through empirical analysis, tries to fill this gap.

To do this we will try to define the concept of e-learning design with respect to four elements: Strategy; Organization; Users and context.

This sequel was adopted based on the three elements identified by Roberts (2004), strategy, organization and context, and "people" (users), by Daft (2010). This subdivision was made to have an e-learning vision according to different points of view.

The strategy identifies all the questions related to the hypothetical choices of the universities regarding the design of e-learning.

The organization is understood as the way in which they implement e-learning design strategies.

The user is intended as a possible user of the e-learning design service. This area includes all questions related to potential users of the service.

The context is linked to the general concept of technology and more precisely to the impact that technology has on the organization and the influence of the organization itself in reference to learning design.

3 Methodology

The research method adopted is mixed (Creswell, 2014): first the quantitative data were collected, through the examination of the websites of European universities and then the qualitative analysis, through the construction of a multiple case study and some interviews semi-structured.

The survey was implemented through two steps:

- (1) The collection of quantitative data on European universities.
- (2) Identification of universities and e-learning services managers to be interviewed and development of the four case studies, including the pilot case.

3.1 First Step.

In the first phase, the study focused on the acquisition of documentary information found on the Internet (Corbetta, 2014). The activities carried out by the various universities have been taken into consideration through the analysis of their websites. This method was adopted and compared with others, because it was considered more convenient in order to obtain quantitative data on European universities in a short time. The survey, in particular, was conducted by examining the websites of the top 100 European universities in a ranking, which allows for the collection of university data by region.

The international ranking used was Quacquarelli Symonds, known as the QS World University 2015/16, which includes the top 800 universities in the world divided into four sectors: research, teaching, employability and internationalization (ANVUR, 2014).

The ranking used focused exclusively on the 100 best universities, identified by region, which included the word "Europe" in the "drop down" list of "QS World University 2015/16". This ranking has been selected compared to others, because it allowed us to search for the best universities, by geographical area, noting only the European universities that are the subject of this research.

The method used to collect the data was characterized by the creation of a specific database in which different information was entered for each university based on the type of training offered.

The research, in particular, made it possible to verify the presence on the university's website of appropriate e-learning platforms. The survey was conducted by entering the "home page" of each university and searching through specific keywords such as "E-learning", "MOOCs", "Online Courses" and "Distance Learning" the system used.

3.2 Second Step.

Then we selected within the 100 European universities in an international ranking, three universities and were able to identify the university of the pilot case. The selection of case studies and pilot cases took place this way. Analysis of the data collected on the websites showed that the largest number of universities in the nationality ranking came from two European countries: the United Kingdom and Germany.

Within these two countries we selected: the University of Dresden (Germany) and Queen's University of Belfast - Northern Ireland (United Kingdom) because the learning / MOOC services provided were more consistent with the purposes of our investigations.

The third university was selected taking into account the presence in the ranking of an Italian university, with a long historical tradition in Europe and the adoption of teaching methods based on e-learning (University of Bologna (Italy)).

The three European universities identified were respectively: University of Dresden (Germany), Queen's University Belfast - Northern Ireland (United Kingdom) and University of Bologna (Italy).

The pilot case was built on data from a university not included in the 100 best universities in the QS rankings. The selection of this university took place on the basis of

the prestigious services offered by the University of Naples Federico II through the "Federica Platform".

We have identified, for each of these universities, the contacts of the managers of the respective e-learning services, always referring to the websites. The interviews were conducted with those responsible for e-learning services, because these professionals are mainly involved in the design and supply of these e-learning services.

The interviews were conducted in the period May-September of the year 2016.

We interviewed, within the four universities mentioned, five subjects who hold the role of manager, within adequate structures for the provision of the e-learning / MOOC service of appropriate IT centers.

In particular, the first interview was addressed to two managers of the Federico II University of Naples (pilot case), who played the role: one of Production Manager of Federica Web Learning and the other of Communication Manager Project "Virtual Campus" - web platforms: federica.unina.it; federica.eu.

The Federico II University has a Federica Web-learning service center (Center for innovation, experimentation and dissemination of multimedia teaching) active in the area of new multimedia technologies.

In this context, the Federica-Campus virtual project plays an essential role as an advanced web learning model for those who cannot attend university in the traditional way.

The second interview was directed to the manager of the MedienZentrum (multimedia center) of the University of Dresden (Case Study 1). The Media Center is a multimedia infrastructure that aims to digitize learning and teaching (Schoop et al, 2016). Nearly 100 people work at the Media Center. The team consists of scientists, designers, psychologists, educators and economists. MedienZentrum supports educators in the planning, implementation and evaluation of sustainable e-learning courses.

The third interview was directed to the manager of E-learning services and to the MOOCs of the University of Belfast (Case Study 2). This university has a Center for educational development that offers counseling and a series of professional development and support activities for the main study, learning, teaching and evaluation programs, as well as for the provision of e-learning services, mostly implemented through mixed learning.

The fourth interview was conducted at the head of the e-learning sector Center of Information Systems and Applications of the University of Bologna (Case Study 3). This infrastructure designs, implements and manages university IT services. Within this center, the e-learning sector, which aims to satisfy the demand for e-learning services at the University, plays an important role and provides the necessary support to those who provide training activities through the online teaching (blended learning).

The analysis of the case studies was carried out first of all by examining the data coming from the Internet, including, among others, the number of e-learning courses and MOOCs provided by the four universities identified.

Subsequently, we collected and processed the data that emerged from the interviews with the managers of the e-learning services of the four universities mentioned above.

Semi-structured interview questions were grouped into four parts, based on their content in: Strategy; Organization; Users and context and referring to the problems described in the previous section.

A final synoptic overview we prepared to test the similarities or differences (Yin, 2014) between the realities of the universities examined in relation to the design of e-learning.

4 Findings and discussion.

From the study of quantitative analysis it emerges that the 100 European universities identified provide training not only through classroom lessons, but also with a variety of web-based courses (E-learning) also in free mode (MOOC). Learning activities are provided at a distance (see Figure 2) in a different way: with limited access to members only (32%); with free access via MOOC (22%); the reserved and free mode (46%).

Source: Adapted from QS World University Rankings® 2015/16.

Figure 2: Access to e-learning services/MOOCs in the top 100 European universities.

From the analysis of the data coming from the websites of the four case studies relating to the Universities: (pilot case) of the Federico II University of Naples (Italy); University 1: University of Dresden (Germany), University 2: Queen's University Belfast (United Kingdom), and, University 3: University of Bologna (Italy), emerges as described in table 1.

An examination of the synoptic table (table 2), in which the questions posed and the relative answers provided by the managers of the four universities interviewed were divided into four parts (Strategy, Organization, Users and Context), the elements of homogeneity and diversity indicated below.

Table 1: A.Y. 2015/2016: Numerical data on the four selected European universities.

Description	Pilote-case: University of Naples Federico II – Italy	Case Study 1: University of Dresden – Germany	Case Study 2: Queen's University Belfast – UK	Case Study 3: University of Bologna – Italy

Within the "Strategy" framework, there is an element in common between the four universities: adoption of blended learning.

Specifically, in the area of strategy, with reference to the question of the existence of blended learning methods, all four respondents confirmed the existence of forms of blended learning in their universities.

In the other three boxes referring respectively to "Organization", "Users" and "Context" there are no similarities in the answers provided, but only non-conformities.

Table 2: Summary of parts of Interviews conducted a four European universities.

	Synthetic content question	Pilote-case: University of Naples Federico II – Italy	Case Study 1: University of Dresden – Germany	Case Study 2: Queen's University Belfast – UK	Case Study 3: University of Bologna – Italy
Strategy	1.Motivating the adoption of e-learning courses in universities.	Need to innovate their teaching methods	Need to innovate their teaching methods	Opportunities to offer students/users service at any time.	Opportunities to offer students/users service at any time.
	2.Presence of teaching forms in blended learning mode.	Adopting blended learning models.	Adopting blended learning models.	Adopting blended learning models.	Adopting blended learning models.
Organization	1.Choosing a course in e-learning and professional figures involved.	Assistance from course managers in carrying out educational activities in e-learning	The professionals involved in this project come from different fields.	The professionals involved in this project come from different fields.	The design is carried out independently by the teachers and there is only the coaching by a technician using the platform.
	2.Technologies adopted: Cloud Computing.	Using Cloud Computing on Federica.eu Platform	No-existence of Cloud Computing.	Using Cloud Computing	No-existence of Cloud Computing.
	3.Technologies adopted: Mobile-Learning.	Using Mobile Learning.	Using Mobile Learning.	Using Mobile Learning.	No-existence of Mobile Learning.
Users	1.The number of students likely to follow these courses in e-learning.	Existence of precise data.	Lack of reliable data.	Lack of reliable data.	Lack of reliable data.
	2.Types of services offered to users/students in a synchronous, asynchronous and collaborative way.	Provision of e-learning services in asynchronous form, without collaborative and synchronous forms.	Provision of e-learning services in asynchronous form, without collaborative and synchronous forms.	Adopting teaching methods both in synchronous, asynchronous form and also encouraging activities in a collaborative form.	The main use of the asynchronous system and only in specific cases is synchronous and collaborative forms, through forums and discussions.
Context	1.The main factors affecting the increase/decrease in the use of e-learning teaching methods in universities.	Increased use of such technologies due to institutional actors' policies, but also the tendency to use the different ways of delivering training.	Increased use of such technologies as a result of the ease with which students can use online digital devices anytime, and can share educational materials more easily with others.	Increased use of such technologies due to the development that the technological factor has gained in recent years in the university context.	Increased use of such technologies due to the development that the technological factor has gained in recent years in the university context.
	2.The use of such technologies: worsens or improves learners' learning.	Learning would depend on how learners use e-learning.	Inadequate statistical data to make a difference with traditional teaching methods.	Using technology could adversely affect learning.	Technology would improve students' learning

There are, therefore, situations in the different parts of the interview, in which not all four universities responded uniformly. The answers were divided in equal parts or only three respondents gave identical answers with respect to the fourth or two or are identical and the other two differ from the first and between them.

We must consider, in particular, what happened in the strategy section in which the answers of the interviewees to the question on the motivations related to the adoption of e-learning / MOOCs courses focused on two different aspects.

The managers of the University Federico II of Naples and the Technische Universität Dresden underlined the internal need of the organization to innovate teaching methods. The managers of the other two universities of Queen's University in Belfast and of the Alma Mater Studiorum-University of Bologna have focused on the opportunity to offer a service to students/users always, at any time, to facilitate the students who work and those outside headquarters.

The same situation is expressed in the part referring to the "Organization" in which there are two identical answers and the other two are different on the design of an e-learning course.

The manager of the University of Federico II, interviewed on the design of the e-learning course, stated that there is an intervention by the "course manager" which is divided into three phases: contact with the teacher; recording of lessons and publication of the event. In the first phase, the course director contacts the teacher to provide instructions on the preparation and publication of the slides. At the end of the production of the lessons, we pass to the second phase of the shooting. Recordings of lessons can be made at the center or at the teacher's office or in contexts relevant to the subject. The final phase is represented by communication and dissemination in order to publicize the presence of the course on the web platform. The manager of the University of Bologna emphasized that the teachers carry out the project independently, even if there is technical assistance from a technician on the use of the platform.

To this question, the manager of the Technische Universität Dresden has shown that the professionals involved in this project come from different fields.

The manager interviewed by Queen's University Belfast stressed that the project is subject to the approval of the faculty's executive committee and that the professionals involved are different. The educational designer and the graphic designers, the marketing team, the technical support and the academic module coordinator.

In the question that is connected to the existence or not of cloud computing, it emerges that in two universities this system is set up and the other two are not, while on the use of mobile-learning only one university is without one.

The following questions that refer to the use of cloud computing and mobile learning stand out in the use of these two systems, in the existing platforms at the University of Naples Federico II and in that of Queen's University in Belfast. On the contrary, the University of Bologna does not provide cloud computing or a mobile learning system. Finally, the Technische Universität Dresden does not use the cloud computing system, but instead has set up a mobile learning service.

Also in the "Users" area to the question regarding the number of students who are inclined to follow these courses through e-learning, three identical opinions emerge on the lack of such data and in the fourth, there are such extremes. It emerged that there are no reliable figures in the universities of Dresden, Bologna and Belfast. Only in the University of Naples it is possible to find the number of members for the federica.eu platform which corresponds to 10,000-12,000 students and on "Federica Web Learning (Federica.unina)" visited by over 500,000 users a month, since it is completely accessible by anyone.

The questions related to students interested in courses provided in synchronous, asynchronous and collaborative mode highlighted these three types in only two universities, on the contrary, in the other two there are different ways.

In the University of Dresden and in the University of Federico II, only the methods of supply are adopted in asynchronous form, while in the University of Bologna the asynchronous system is mainly used and only in specific cases the synchronous system.

Finally, the University of Belfast adopts teaching methods both in synchronous and asynchronous forms and encourages collaborative activities. The latter type is used, through forums and discussions within the University of Bologna, while it is completely

absent in the remaining two universities, namely, at the University of Dresden and the University of Naples Federico II.

In the "context" sector there are similar answers related to the increase in the use of learning technologies, although the reasons differ.

From the interview given to the managers of the four universities it emerges that there has been an increase in the use of these technologies in each of the universities in question. The motivation can be attributed to the policies of institutional actors in the University of Naples Federico II, but also to the tendency to use different technological methods to avoid attending university.

There is a total divergence in the answers given on the question of improving or worsening learning through the use of e-learning. At Federico II University, learning does not depend on the use of technology, but on the way in which students use e-learning. At the University of Bologna, on the contrary, it would seem that technology would improve students' learning. As deduced by the University of Belfast the use of technology could negatively influence learning, because it would imprison the user to the rules dictated by it and, finally, for the University of Dresden there is no statistical data to make difference with the traditional teaching methods.

The overall analysis makes it possible to affirm that, although the four universities adopt some of the strategies in common, they differ, as demonstrated by the analyzes relating to the "organizational aspect" and that connected to the "users". It should be noted that contextual issues have not been taken into consideration, as these are answers related to subjective issues.

It can also be stated that the empirical survey carried out to fill the gap established in the literature on course design (teaching activities) through e-learning in universities, highlighted the following problem.

It is clear, in fact, a certain attention on the part of the managers to situations linked to the phase relating to the composition of the "team" in the design of e-learning. Each university defines the professional figures that will be part of this specific team. All this means, therefore, that according to this analysis, there is a certain focus of the subjects questioned more on the activity linked to the construction of the course and therefore to the professional figures connected to them and not to the entire e-learning path as outlined by Trentin (2001).

5 Conclusions

This article explored issues related to learning methods adopted by European universities through the use of technologies.

According to Fee (2009), we can distinguish three components in the study of e-learning: technology, content and learning design.

The aim of the research was, in particular, to empirically verify how some selected European universities apply the planning of educational activities through e-learning.

Attention to the aforementioned topic arose from the discovery of a gap in managerial literature on the design of e-learning within universities. It has been discovered that there is not much research done in this area.

The survey was conducted using a mixed approach, characterized by the explanatory design in which the quantitative data were identified, identifying the universities that were the object of exploration and then the qualitative ones, through the construction of multiple case studies and semi-structured interviews. A pilot case was also used to better answer the questions to be included in the interview.

From the examination of the answers obtained from the qualitative interviews, we can deduce the attention of the four universities studied to the dynamics related to the design of e-learning courses, even if focused on the professionalism that operates and not on the entire e-learning design process. There is no specific attention by the four universities to the e-learning process (Fee, 2009; Trentin, 2001; Islam et al., 2015).

The universities interviewed concentrate their answers on the professionals who work in design, e.g. to the manager of the course at the University of Naples Federico II and Educational designer and Graphic designer, at Queen's University in Belfast.

In conclusion, it should be emphasized that, based on current data relating to the design of e-learning courses, there seems to be a certain affinity between the four experiences.

We are aware that the search is currently not complete, but that there are some limitations.

The first criticism is linked to the difficulty of having a complete view of the examined phenomenon and refers exclusively to the design of e-learning. The intention is therefore to ask new questions and make further inquiries, to have more certainties and to investigate more accurately.

The second limit refers to the number of respondents and universities contacted.

The future objective will be to intensify these activities by involving other actors (teaching staff, governance) and new universities.

Abstract

This paper explores the entrepreneurial activities and models of Science & Technology universities. Employing a mixed-method design with a questionnaire and semi-structured interviews we find three main entrepreneurial models based on different configuration of activities and different organizational and regional characteristics: (1) an “engage” model, which focuses on local economic development (2) a “formal” model, which focuses on the financial advantage of universities and their faculties and (3) a “comprehensive” model, which focuses on the local economic development and the financial advantage of universities and their faculties. This paper extends previous literature by encompassing the conventional distinction between formal and informal entrepreneurial activities. It also contributes to the emerging literature on entrepreneurial university models and the strategic approaches by identifying the different models of entrepreneurial universities in the European setting of S&T universities focusing on the role played by organizational and ecosystem factors in affecting the adoption of a specific model by universities.

Keywords – entrepreneurial university, entrepreneurial activities, entrepreneurial university models

Paper type – Academic Research Paper

1 Introduction

In the last 40 years, universities are increasingly using the knowledge from research and teaching to fulfil their so-called "Third Mission" in society and economy. Through knowledge generation and technology transfer activities, universities are indeed considered the engine of social, cultural and economic development (Etzkowitz et al., 2000). In this respect, the concept of entrepreneurial universities has recently been conceived (Etzkowitz et al., 2000) with reference to any entrepreneurial activity performed by universities *“with the objective of improving regional or national economic performance as well as the university’s financial advantage and that of its faculty (pp 313)’*. According to such a definition, universities perform a broad range of entrepreneurial activities, including patenting, licensing, research collaboration, consulting, networking, entrepreneurship education and support for the creation and growth of new ventures (either spin-offs or start-ups). Although several previous works have mapped the different entrepreneurial activities performed by universities (e.g. Philpott et al., 2011), the scope of these works was mainly limited to the distinction between formal and informal activities (e.g. Abreu and Grinevich, 2013). Moreover, although several studies have acknowledged entrepreneurial universities as a global phenomenon, only a few of them investigated the different entrepreneurial models that universities may adopt (e.g. Giuri et al., 2018; Baglieri et al., 2018). In fact, most of them considered, either explicitly (Etzkowitz et al., 2000) or implicitly, that universities undertake the same entrepreneurial activities to the same extent, and thus refer to a single model of entrepreneurial universities, ignoring the fact that universities could adopt different strategic approaches to the entrepreneurial paradigm. In this respect, there is a lack of studies aimed at identifying the interplay between the organisational and territorial factors that may induce a university to embrace a specific model.

In order to fill these gaps, this article aims at identifying: (1) a broader set of entrepreneurial activities; (2) different university entrepreneurial models analysing the role of organizational and ecosystem factors.

2 Theoretical background

2.1 Entrepreneurial activities

To embark on their new ‘mission’ of economic and social development, universities employed a range of entrepreneurial activities. They are involved in research and technology commercialization, incubation programs, more recently they also invest heavily in entrepreneurship education programmes (O’Connor, 2013) and provide funds for the technology development process (Markman et al., 2008), along with traditional research collaboration, networking, consulting and face-to-face communication with industry and society (Geuna and Muscio, 2009). Scholars have tried to categorize these activities by distinguishing between *“formal”* and *“informal”* activities. On the one side of the spectrum, scholars include patenting, licensing and spin-offs in the formal

entrepreneurial activities, which are also identified as *Research Commercialisation* (Perkmann et al., 2013); on the other side, training, networking, contract research, consulting and face-to-face communication in informal entrepreneurial activities have been identified as *Academic Engagement* (Perkmann et al., 2013).

2.2 Entrepreneurial universities models

Literature has provided a limited picture about the existence of different university entrepreneurial models with some notable exceptions (Giuri et al., 2018; Baglieri et al., 2018; Cesaroni and Piccaluga, 2016). Literature has acknowledged the importance of having a strategic orientation towards technology transfer and entrepreneurship in driving resource allocation decisions and setting priorities (Siegel et al. 2007; Giuri et al. 2018; Bozeman et al. 2015; Battaglia et al. 2017), and strategic positioning in the environment (Giuri et al. 2018), but it still lacks an analysis of the different strategic approaches reflected by different university entrepreneurial models.

This emerging literature has focused on the relationships and complementarities between research and technology transfer by looking at formal entrepreneurial activities and strategic university objectives (Cesaroni and Piccaluga, 2016; Baglieri et al., 2018; Giuri et al., 2018). These studies share the common view that entrepreneurial universities may be considered as a system of several entrepreneurial activities that the universities may perform differently. However, none of the existing studies has focused on a broad and empirically-based set of entrepreneurial activities or tried to identify the different models of entrepreneurial universities by adopting a combined ecosystem and organisational perspective.

3 Research methodology

The research methodology of this paper follows a mixed-method approach. This research benefits from the work of the CESAER¹ task force on innovation, which was formed to study the role of universities in innovation ecosystems. Specifically, we have adopted a sequential explanatory design composed of two sequential steps: a quantitative approach (based on a questionnaire) followed by a qualitative one (based on multiple case studies). We have also used information from the ETER² and RIS³ datasets to check for differences in organizational and regional factors. This research design enables the quantitative findings, related to entrepreneurial activities and models, to be further validated.

³ Regional Innovation Scoreboard

3.1 Data and sample

The data collection is based on a quantitative and a qualitative survey. The former investigates through a questionnaire the role of universities in innovation ecosystems, their activities, the degree of collaboration with other ecosystem actors, the existence of different funding mechanisms to foster entrepreneurial innovation and the main activities of TTOs. In this paper, we focus on the first section of the questionnaire which investigate the entrepreneurial activities performed by member universities. The questions used a four-point Likert scale. Universities were also asked to furnish the number of spin-offs, and the number of commercialized or pending patents for the year 2015.

The latter, though semi-structured interviews and written case study, corroborate the quantitative results, with the aim of investigating the strategy adopted by each university to foster entrepreneurship and innovation.

Overall, out of the 50 questionnaires that were sent, we received 20 answers, thus achieving a response rate of 40%. These sampled universities cover a population of approximately 502.000 students in S&T fields from 14 different European countries. Of these 20 universities, 6 agreed to participate in semi-structured interviews and written case studies. The descriptive statistics of the sampled S&T universities are reported in table 1.

3.2 Data analysis

The data analysis consisted of three stages. In the first stage, we used an exploratory factor analysis to group the different university entrepreneurial activities into macro-dimensions. In the second stage, in order to position each university along the spectrum of activities and to elaborate a taxonomy of the different models that universities adopt to foster innovation in their ecosystems, we employed a two-step cluster analysis: hierarchical clustering and k means. We performed a descriptive analysis to define and analyse each cluster using: organizational indicators retrieved from the ETER database (i.e. the involved academic staff out of the total number of staff; students enrolled on the

total number of academic staff and core budget); technology transfer indicators (i.e. spin-offs, patent applications and commercialised patents); ecosystem indicators retrieved from EuroStat and the Regional Innovation Scoreboard for 2017 (i.e. employment in the public and private sectors; R&D expenditure of the public and private sectors; co-publications of public and private and product/process innovations; lifelong education and population with tertiary education). The third stage comprised the confirmation of the quantitative results of the prior stages through a qualitative approach: the entrepreneurial activities and models, as well as the identification of the best practices for each cluster, were corroborated by means of semi-structured interviews with the rectors, vice-rectors and heads of TTO.

4 Results

4.1 A framework for classifying university entrepreneurial activities

The factor analysis revealed the presence of five factors. On the basis of a literature review on university technology transfer and entrepreneurial universities, and further confirmation through a qualitative approach, we denoted the five factors as follows: research commercialization, entrepreneurship education for students; the creation of an entrepreneurial climate; support for technology development, venture creation and growth; academic engagement (Table 2). After the first iteration, we noted that the first two factors (i.e. research commercialization, entrepreneurship education for students) presented high cross-loadings with the other factors. This implies that these variables represent factors *per se*, and they were therefore removed from the factor analysis, but reintroduced in the conceptual framework. The remaining ten items in the factor analysis explained 73% of the variation (Table 2).

Table 2. Rotated factor loadings. Method: Principal component analysis. Rotation: Varimax with Kaiser normalization

		Factor loadings			Cronbach's alpha	Reference

4.1.1 Research commercialization

Research commercialization has been also identified with *academic entrepreneurship* (Siegel and Wright, 2015), referring to either the founding a firm by faculty members with the objective to commercially exploit a patented or non-patented invention (Perkmann et al., 2013), or the licensing a patented or otherwise protected invention in return of royalties (Jensen and Thursby, 2001). Commercialization is regarded as a first measurable and tangible impact of UTT (Markman et al., 2008; Philpott et al., 2011). These activities are institutionalized (Geuna and Muscio, 2009) into a specific knowledge intermediary organization, the Technology Transfer Offices (TTOs), created to support researchers to consider commercializing their research results and to provide assistance along the process.

4.1.2 Entrepreneurship education

Entrepreneurship education has become an important activity for university managers, professors and researchers (Kuratko, 2005) because of the positive benefits associated of having students with entrepreneurial attitude, skills and intention which could foster entrepreneurship and innovation, and therefore, stimulate economic growth (Rauch and Hulsink, 2015). Several studies (e.g. Bae et al., 2014; Fayolle and Gailly, 2015; Nabi et al. 2017) have shown that entrepreneurship education can have an impact the entrepreneurial intention of academics and students. As a result, the number of entrepreneurship courses is increasing (Kuratko, 2005) as is the creation of entrepreneurship centres where these courses are offered (Siegel and Wright, 2015).

4.1.3 Creation of an entrepreneurial climate

An internally oriented entrepreneurial activity is the creation of an entrepreneurial climate within a university. Borrowing from the organizational climate construct defined in the context of innovation implementation (Klein and Sorra, 1996), we defined entrepreneurial climate as the extent to which entrepreneurship is rewarded, promoted and supported, and we included all the activities that foster such an entrepreneurial climate, including entrepreneurship training to the faculty, training staff (academics and non-academics) in the commercialisation of new technologies and assisting researchers in finding investors. The creation of an entrepreneurial climate is particularly important for universities to achieve the third mission. Philpott et al. (2011) argued that: “For universities embarking on the journey towards the entrepreneurial university ideal, they must first undertake education and training of their academic community”. The authors acknowledged that without such entrepreneurial training, a university risks having a “schizophrenic entrepreneurial divide within their institution”.

4.1.4 Support for technology development, venture creation and growth

Research commercialisation can be considered an old and consolidated form of academic entrepreneurship, which focuses solely on gaining direct financial returns while supporting a faculty along the process (Siegel and Wright, 2015; Corbett et al., 2014; Grimaldi et al., 2011). A new perspective on academic entrepreneurship that reflects wider social and economic benefits for a university ecosystem is materialising, with the support for technology development, venture creation and growth addressed to alumni, students and young researchers. The overall aim is to create an ecosystem that supports science-based entrepreneurship and innovation throughout the university (Fini et al., 2018; Corbet et al., 2014). The university ecosystem support includes a diversified range of activities: (1) incubators/accelerators, either as programmes or institutions (2) entrepreneurship courses (3) the provision of spaces where students, faculty members and external firms can connect and organise student business plan competitions (4) commercialisation funds for alumni and students (Siegel and Wright, 2015) to increase the level of technology development with a variety of programmes e.g. proof of concept, university seed findings, innovation grants etc. (Bradley et al., 2013; Hayter and Link, 2015).

4.1.5 Academic Engagement

Research commercialisation reflects a generative role of universities that is based on knowledge capitalisation and other capital formation projects (Gunasekara, 2006; Uyarra, 2010). In the last 30 years, universities have complemented this approach with a developmental role of innovation ecosystems, based on the concept of “engaged institutions” (Gunasekara, 2006; Uyarra, 2010). In this conceptualization, universities, through their resources, skills and knowledge - which determine a capacity to attract talent, innovative companies, university and other actors - play a significant role in regional and international networking and institutional capacity building (Gunasekara,

2006). As such, universities act as innovation ecosystem integrators by bringing together different actors (e.g. firms, governments, RTOs, banks, investment funds) and by indirectly governing the relationships between these actors. Universities become “regional animators” (Gunasekara, 2006; Uyarra, 2010) as they build regional and international networks while coordinating the activities of several actors in a synergic way and providing leadership and vision (Colombelli et al. 2017; Rissola et al., 2017).

Engaged universities perform different activities: collaborative and contract research, networking, consulting, training and other forms of knowledge exchange (Perkmann et al., 2013).

4.2 Entrepreneurial university models

The two-step clustering procedure revealed three clusters (Table 3). Through an ANOVA test we found statistically relevant differences between them. In order to characterise the clusters, we provided information on organisational technology transfer and regional indicators (Tables 4,5,6 and 7).

Table 3. Results of the two-step cluster analysis

	CLUSTER 1 n=6	CLUSTER 2 n=10	CLUSTER 3 n=4	ANOVA (F test)
Research commercialisation				
Mean	3,33	4,00	3,75	F = 6,80*

4.2.1 Cluster 1: the engaged entrepreneurial model

The first cluster contains six universities (30% of the sampled universities). Compared with the universities belonging to the other clusters, these universities perform all the entrepreneurial activities to a lesser extent. Among these activities, they give more importance to research commercialisation (3,33), academic engagement (2,54) and entrepreneurship education for students (2,50). However, despite a similar number of patent applications (44,8), this cluster is less effective in commercializing patents (5,5), as well as in spin-off creation (6,7). The organisational indicators reveal that this cluster has the highest number of students per academic (15,42) and a lower budget (157,9 M€). The analysis of some ecosystem indicators revealed the peripheral role that such universities play in these ecosystems, as demonstrated by the considerable share of employment in industry and construction (41,0 %) and the small number of people with tertiary education (0,461). The relatively high value of non-R&D innovation expenditures (0,384) revealed

that the firms in these ecosystems focus on incremental product or process innovation. In this respect, the role of universities seems to be secondary, with respect to the industries that are leaders in these ecosystems. Universities tend to support firms in solving specific technical problems and transferring mainly tacit knowledge. A case in point in this cluster is University A, which applies three major approaches to transform *knowledge generated into useful solutions for companies*: protection and commercialisation of research results in collaboration with companies (e.g. patent co-ownership), development of joint research projects with medium-large sized firms, and the creation of spin-offs within the university's ecosystem. Engagement through lifelong education is of great importance for these universities. University B, for example, collaborates with local industrial associations to offer master courses for managers, employees and graduate students. This master course is an example of work-study alternation and it is aimed at developing both technical and managerial skills.

In consideration of these factors, we called this cluster: *“engaged entrepreneurial model with focus on local economic development”*

4.2.2 Cluster 2: the formal entrepreneurial model

The second cluster is the largest and it contains ten universities (50% of the sampled universities). These institutions on average perform all the entrepreneurial activities. With respect to cluster 3, this group is more committed to commercialising research results (4,00) and to creating an entrepreneurial climate (3,32). This cluster is the one with the lowest students / academic ratio (9,29) and the highest core budget (324,4 M€). As far as research commercialisation concerned, this group of institutions is the best performing, with an average of 47 patent applications, 14,7 commercialized patents and 20,8 spin-offs. The great value of R&D expenditure of the public sector (0,695), lifelong learning (0,570), population with tertiary education (0,631) and the highest share of employment in the public sector (39,7%) has revealed the prominent role of universities in these ecosystems. The universities in this cluster build an entrepreneurial climate that stimulates bottom-up student initiatives (e.g. student-led entrepreneurial organisations, entrepreneurial projects run by students etc.) which are complemented with top-down management. An example is the initiative of University C through which entrepreneurial individuals (students, professors, researchers etc.) undertake entrepreneurial initiatives that support a university-wide innovative and entrepreneurial climate. In order to leverage on and manage such initiatives, the university has established a TTO core team that is actively engaged with these entrepreneurial individuals, thereby creating a university-wide entrepreneurial community and to ensure a synergic effect of the different entrepreneurial bottom-up initiatives. The effectiveness of research commercialisation resides in incentives for researchers (including non-monetary ones) and for TTO employees as well as in TTO budgetary and HR autonomy.

In consideration of these factors, we identified this cluster as *“formal entrepreneurial model based on the systemic exploitation of research results”*

4.2.3 Cluster 3: the comprehensive entrepreneurial model

The third cluster comprises four universities (20% of the sampled universities). These universities perform all the aforementioned entrepreneurial activities: academic engagement (4,00) supporting activities (3,95), research commercialisation (3,75) and entrepreneurship education for students (3,75). The entrepreneurial climate is more limited (2,56), but with a large variability within the cluster (standard deviation of 1,37). With respect to the organisational and technology transfer indicators, this cluster falls between clusters 1 and 3, while the ecosystem indicators are similar to the second cluster.

Research commercialisation is performed by means of the identification and capturing of innovation opportunities at an early stage. This is done, for example, at University D, through in situ short interviews not only with academic staff but also with MSc students. In doing so, the university TTO explores and maps the university innovation ecosystem and is very effective in signalling research collaboration opportunities with external actors. The university TTO then supports researchers in explaining their research through infographics, props, animations, prototypes and interactive objects. Finally, the selected ideas are exposed at a research exhibition, which is an annual event with external companies. The universities in this cluster have a holistic approach to entrepreneurial supporting activities. For instance, University D supports entrepreneurial individuals along the different stages of entrepreneurial journeys with different supporting tools. Through the incubator, the university offers different programmes that combine entrepreneurship education, support for early-stage start-ups to identify their market/product combinations in a pre-acceleration programme and support for late stage start-ups to help them accelerate. In this cluster, the universities adopt a student-based support system. The students with some entrepreneurial experience at university E coach other students that have new ideas. In addition to research commercialisation, supporting activities and entrepreneurship education, these institutions also engage with the ecosystems to create open innovation ecosystems where external parties can collaborate with researchers and benefit from their skills, knowledge and unique research facilities. These universities, in close collaboration with firms and governments, focus on fundamental and pre-competitive research areas with a high innovation potential. A case in point is University F. Its innovation strategy is closely linked to the research strategy, and in particular in those areas which show a high innovation potential. To achieve this, long-term innovation partnerships are undertaken and translational organisations, upon which new partnership can be build, are attracted. In doing so, the university creates and orchestrates the innovation ecosystem by providing leadership and vision for the future. Similarly, University E is committed to improving and expanding cooperation with the business community at an international, European and national level. Cooperation with regional knowledge institutions, companies and governmental bodies – by means of regional innovation clusters, for example – plays a significant role. Engagement and collaboration in this cluster is also performed with SMEs, which require special support, in consideration of their limited resources.

Given these factors, we identified this cluster as “*comprehensive entrepreneurial model with focus on local economic development and the university’s financial advantage*”

5 Discussion and conclusions

The findings of this paper contribute to university technology transfer and entrepreneurial university literature with respect to two main research streams.

First, we contribute to the literature that acknowledges different entrepreneurial activities. Our main contribution concerns the extension of the conventional distinction between formal and informal entrepreneurial activities (e.g. Perkmann et al., 2013; Philpott et al., 2011; Bradley et al., 2013b; D’Este and Patel, 2007; Link et al., 2007). We propose a framework that brings them together acknowledging other entrepreneurial activities.

Second, we contribute to the emerging literature on university entrepreneurial models (Baglieri et al., 2018; Giuri et al., 2018; Sánchez-Barrioluengo and Benneworth, 2018; Cesaroni and Piccaluga, 2016) by highlighting three different strategic approaches with different entrepreneurial activity configurations. In line with previous literature, we argue that entrepreneurial universities may not only focus on formal entrepreneurial activities with the objective of gaining financial returns but may also focus on other types of entrepreneurial activities with the objective of providing social and economic returns to the ecosystem (Cesaroni and Piccaluga, 2016). In addition, this study provides interesting insights about the relationship between a university’s organisational characteristics and characteristics of its ecosystem through the adoption of a specific model. In this vein, we contribute to the literature that acknowledges how different factors can influence university strategies (Grimaldi et al., 2011). In particular, organisational resources appear to be relevant in greatly influencing the ability of a university to implement the needed set of entrepreneurial activities in the medium term. In this vein, we acknowledge the importance of system-level factors (i.e. the institutional characteristics of regions) in shaping the university strategy (Grimaldi et al., 2011). We suggest the need for further research aimed at explaining which social, technological/industry, organisational and policy/institutional characteristics lead universities to embrace a specific entrepreneurial model.

Abstract

In the current knowledge-based economy, Higher Education Institutions (HEIs) are called to play different interconnected roles related to triple university missions. Alongside the two traditional missions of teaching and research, HEIs have experienced the emergence of the so-called “third mission”, which sees HEIs as knowledge-based agents part of ecosystems of public institutions, companies and citizens oriented to co-knowledge creation. Finding a balance between the traditional missions and the third mission can be a serious challenge. For this reason, HEIs need to revise their objectives, strategies and performance indicator systems to plan, monitor and assess their social, cultural, and economic impact. Actually, there is no shared approach (and related KPIs) to assess in an univocally and standardised manner the performance of HEIs, in order to effectively reflect the whole range of academic missions, by reducing the possible tensions between them created at various organizational levels. Thus, the authors decided to carry out a qualitative inductive study based on the institutional logics perspective to: i) analyse how HEIs performances are measured, ii) to improve university performance measurement systems and iii) to mitigate the tensions within and among the different missions and the logics behind them.

Keywords – Higher Education Institutions (HEIs), third mission, institutional logics, entrepreneurial university, key performance indicators (KPIs).

Paper type – Academic Research Paper

1 Introduction

Higher Education Institutions' (HEIs) role has been deeply evolving as a result of the two academic revolutions that have introduced, respectively, a second and a third mission besides the first one (Geuna & Muscio, 2009). First mission regards teaching activities that imply knowledge preservation and transmission. Second mission includes the research activity and, consequently, knowledge production. Indeed, third mission includes every activity that HEIs are asked to perform besides the teaching and research activities, including technology transfer (Battaglia et al., 2017; Chau et al., 2017) and the exploitation and dissemination of knowledge and other capabilities outside their boundaries (Etzkowitz, 1998). Recent studies have also started to theorize the existence of a fourth mission, which refers to the role of HEIs in contributing to the development of economies and societies, addressing real world issues, and co-developing the sustainability paradigm through multi-stakeholder partnerships (Bienkowska & Klofsten, 2012; Rinaldi et al., 2018; Trencher et al. 2014). In this regard, in modern knowledge-intensive societies and economies HEIs have increasingly started to engage a broader public than just students or the scientific community, being even more involved in complex ecosystems with institutions, industries and third parties (e.g. incubators, accelerators, competence centers, venture capitalists, etc.) (Clauss et al., 2018; Etzkowitz & Leydesdorff, 2000; Leydesdorff & Etzkowitz, 2001; Secundo et al., 2017).

The huge amount of internal and external interactions, the variety of partners involved in value co-creation processes, and the intangible nature of the most relevant resources generated by these processes make HEIs' performance assessment a difficult task (Hewitt-Dundas, 2012; Meissner & Shmatko, 2017; Öner, 2017; Secundo et al., 2017). Since the pursuit of all three missions requires the direct commitment of the academics, at all hierarchical levels, it follows that the three missions can "compete" among themselves. In general, tensions and contradictions between the different missions of the HEI, are mainly due to a structure of incentives that is not yet systematically organized (Secundo et al., 2017). To date, in effect, there is no shared framework of key performance indicators (KPIs) that effectively reflect the whole range of academic missions and the possible tensions that can exist among them at various organizational levels. This paper deals with this problem by adopting a well-defined management theoretical approach, i.e. the institutional logics perspective (Thornton et al., 2012; Wooten & Hoffman, 2008), in order to build a systemic framework. Thanks to an inductive analysis, based on semi-structured interviews and many secondary sources (Bryman & Bell, 2011; Zikmund et al., 2012), this paper identifies nine different institutional logics, which shape HEIs' activities and performances. Compared to the several existent sets of KPIs, the framework proposed by the authors can be intended as a metamodel, namely a high level conceptual representation that enables all the KPIs defined in the sets currently available in the practice to be reclassified and included under a specific category. Thus, our framework provides several insights: first of all, it offers a synoptic view as well as a comparison between different sets of KPIs; second, it identifies the performance areas that are not effectively covered (or overlooked) by the current indicators; third, it highlights the

tensions and the contradictions among either the three missions or within each one of the them; finally, it allows a comparison between generalist and vocational universities, especially with regards to their third mission and entrepreneurial role. The lack of homogeneity individuated in the different institutions (universities and national and international ranking agencies) provides insights on the potential causes and solutions to improve HEIs performance indicator systems and mitigate the tensions within and among the different missions and the logics behind them. The findings of this paper may contribute to the scientific debate and to the procedural practice (both to the policy and the single university institution level) with regard to HEI performance indicators and the organisational issues related to the role of such institutions in the society. To our knowledge, this is the first paper developing a framework of HEI performance indicators through the lens of the institutional logics. Our findings may thus contribute to the literature regarding the institutional theory.

2 Theoretical background

2.1 The three academic missions

Nowadays HEIs are called to play different interconnected roles that respond to three different missions. For a while, the teaching mission was the main activity in many HEIs. Then, institutional pressures (as a consequence of governmental initiatives and reforms) have led HEIs to draw a greater attention to research activities that have become increasingly important for either overall or individual assessments. Moreover, since late 1980s, pursuing just these two missions was considered not enough and the third mission started emerging (Etzkowitz & Leydesdorff, 2000).

The teaching activity is the older reputation key factor (Maassen, 2017). It consists of an education offering which mainly comprises courses at all levels (e.g. bachelor and master courses, postgraduate courses, doctoral courses, etc.). The educational activity should be fostered by the ongoing dialogue with the other economic actors of the territory (Sauder & Espeland, 2009), since a cutting-edge education is required to reflect the needs of the reference context (Barron, 2017; Brankovic, 2017; Marginson, 2007).

The research mission, usually characterised by a cross-disciplinary nature, can be fostered by both research centres and labs (Etzkowitz et al., 2000) and the participation in specific projects (Secundo et al., 2017). Research activities are in many cases related to the needs of the territory of which the universities are part (Trencher et al., 2017). However, the research evaluation, especially in terms of publications (Amsler & Bolsmann, 2012; Brankovic, 2017), is currently measured by its impact on the international community and it represents the key factor for both HEIs' reputation and academic career evaluation.

Finally, the third mission includes the relationships among HEIs and a broad variety of stakeholders at both local and/or national and international level (Etzkowitz & Leydesdorff, 2000; Etzkowitz et al., 2000), pointing out HEIs' role as knowledge-based agents for local value creation. It results in a series of multiple and integrated knowledge-

based activities that range from the traditional knowledge and technology development to innovation ecosystems development, as well as social innovation and community engagement (Geuna & Muscio, 2009; Hsu et al., 2015; Leydesdorff & Etzkowitz, 2001; Lockett & Wright, 2005; Secundo et al., 2017). Some concrete examples of third mission-related activities are: and continuing education and training courses (Marginson & van der Wende, 2007), consulting services (Jacob et al., 2003; Klofsten and Jones-Evans, 2000), patents creation and licensing (Jacob et al., 2003; Klofsten and Jones-Evans, 2000; Mazdeh et al., 2013), sponsored applied research (Clauss et al., 2018), startup creation and spin-offs (Clauss et al., 2018; Jacob et al., 2003), internal and external specific programmes to develop creativity and entrepreneurship mindsets (Clauss et al., 2018; Klofsten and Jones-Evans 2000).

2.2 The role of the institutional and organisational logics in measuring academic missions

The notion of institutional logic has been extensively developed by social sciences. It refers to the set of beliefs, rules, values and practices by which individuals produce and reproduce their material subsistence, organize time and space, and provide meaning to their social reality (Thornton et al., 2012). Oftentimes, organisations are called to deal with different logics shaping their identity. Rules and social expectations that legitimate an organisation behaviour are identified in the management literature as “organisational logics” (Spicer & Sewell, 2010). Organisational logics, thus, may be seen as a way of designing one or more different institutional logics within a specific organisational context (Dunn & Jones, 2010). Hence, according to institutional logics, the organisational context is composed by a range of forces including several (and often conflicting) sets of beliefs, rules, values, and practices that affect human behaviour (van Gestel & Hillebrand, 2011). In the institutional studies literature this field of forces is called organisational field (Wooten & Hoffman, 2008). Therefore, HEIs operate in a particularly complicated organisational field, in which different institutional logics operate, often conflicting each other. Having based this research on such a theoretical approach, that used both the institutional logics and the organisational field, a solid explanation of the variety of KPIs that are currently used for assessing HEIs’ performances could have been provided.

3 Methodology

The survey method adopted in this research is based on an inductive qualitative analysis (Eisenhardt, 1989; Yin, 2013), through which university KPIs could be mapped following the institutional logics perspective. The research was designed in two steps: i) a set of semi-structured interviews has been carried out by authors (Zikmund et al., 2012) and ii) secondary data sources have been analysed (Bryman & Bell, 2011). Then, the two steps have been combined through data triangulation in order to systematically classify KPIs and identify any rise of tensions among the three academic missions and even within each individual mission. In particular, in the first step, 9 in-depth interviews (Brinkmann & Kvale, 2015) have been carried out with the heads of the research activity,

the third mission, and technology transfer office from three important Italian HEIs. These semi-structured interviews have been carried out on the basis of a protocol open to new topics time after time, enabling to identify what organisational and institutional logics underlie the performances evaluation of HEIs in pursuing their three academic missions. Interviews lasted from 45 minutes to an hour and a half and they have all been conducted face-to-face by at least two out of the three authors. In order to ensure naturalness, the interviewees were only made aware of overall research purpose, without revealing specific questions and preventing them from coming up with the answers in advance (Easton, 2010). The interviews have been recorded and transcribed, and then triangulated with secondary data sources (Eisenhardt, 1989), whose analysis represented the second step of the research. Thus, the authors analysed the integrated and/or the performance plan of 4 Italian generalist universities (University of Milano-Bicocca, University of Bologna, University of Turin, Sapienza University of Rome) and 2 Italian vocational universities (Polytechnic University of Turin and Polytechnic University of Milan) to identify what KPIs underpin the assessment of both organisational and individual activities, goals, and objectives. This desk analysis of the practice has been accompanied by the analysis of the indicators employed by some of the main national and international agencies involved in HEIs evaluation and activities monitoring (Italian National Agency for the Evaluation of Universities and Research Institutes, U-Multirank, Quacquarelli Symonds World University ranking, European Indicators and Ranking Methodology for University Third Mission, Times Higher Education World University Rankings, Academic Ranking of World Universities). The indicators found in the integrated and/or performance plans were then compared with those employed by the rating agencies in order to check for matches or inconsistencies with regard to the institutional logics previously individuated. Finally, the authors carried out a coding process with the support of the software Atlas.ti in order to ensure relevance and comparability between theory and data, as well as reproducibility, accuracy, and rigour (Strauss & Corbin, 1990). Every source has been independently encoded by at least two of the authors of this paper. Through “open coding”, in a first stage, the issue under consideration has been discovered, labelled, and categorised. Consequently, the researchers discussed in order to achieve a shared interpretation of the findings. Using “axial coding” (Bryman & Bell, 2011), data have been reorganised with the aim of finding any link among both the categories and the subcategories established. More specifically, the number of codes attributed to the institutional logics was reduced to nine, respectively three for each mission, as further outlined in the next paragraph.

4 Results

The teaching mission is well established in the Italian HEIs. Indeed, for a long time, the career advancement has been based on the teaching ability of academics in many departments. The focal role attributed to the teaching mission has frequently been reflected in drafting handbooks and books as a main publication activity. Nowadays, the commitment in teaching activities by single academics is less incentivised and less

rewarded than in the past, while there is an increasing focus on research and international publications; however, teaching performance is still one of the main criteria for allocating funds to universities and departments. The data analysis has led the authors to identify three main institutional logics, with some overlaps and some conflicts among each other: the logic of inclusiveness, the vocational logic and the logic of excellence.

1- The logic of inclusiveness is focused on providing higher education to as many people as possible, assuming that HEIs should contribute to increase the cultural level of the territory. Some KPIs emerged from the analysis, for instance, are the total number of students, the percentage of incoming visiting students, the number of e-learning or blended learning courses.

2- The vocational logics is based on the idea that HEIs must provide students with the means required for a successful career, creating talented and skilled people for the reference territorial system. Some KPIs emerged from the analysis are, for example, the percentage of graduates with a curricular internship, the percentage of students employed 18 months after graduation in local companies, and the number of degree courses revised according to employment opportunities.

3- The logic of excellence is founded on the assumption that HEIs' mission is to provide students with the means required for a successful career and to contribute to the competitiveness of the territorial system through a meritocracy-based promotion. Some KPIs emerged by the analysis are the student degree of satisfaction, the percentage of outgoing visiting students, and the number of grants for deserving students.

The role of research as a key academic mission has rapidly and significantly evolved in recent years. Indeed, research has been historically seen as a domestic or local matter by a large number of HEIs, while, nowadays there are increasingly pressures toward internalisation and publishing in peer-reviewed journals recognised by the scientific communities even at a supranational level. According to the analysis of the primary and secondary sources, the authors have identified three main institutional logics, with some overlaps and some conflicts among each other: the logic of focalisation, the materiality logic and the logic of excellence.

1- The logic of focalisation is based on the assumption that the scientific research of HEIs must focus mainly on some specific issues, for which university itself wishes to become a reference point. The two KPIs emerged by the analysis are the participation in strategic partnerships with other leader HEIs in the same area and the participation in joint research centres.

2- The materiality logic is founded on the idea that the scientific research of HEIs must contribute to solve problems considered to be relevant beyond the academic contest. Some KPIs emerged by the analysis are, for instance, the percentage of private funding for research and dissemination activities out of the total, the per capita financing of national and international projects, and the percentage of publications cited in international patents.

3- The logic of excellence is focused on the assumption that the scientific research of HEIs should pursue the highest possible level, in terms of impact and recognition by the international academic communities. Some KPIs emerged by the analysis are the

percentage of papers published in highly-rated journals according to re-search evaluation criteria, the percentage of papers with foreign co-authors and the percentage of publications cited by other authors (impact factor).

The third mission tends to include just everything that is not teaching or research. For this reason, the various fields of study may have a very different perception of its content. For instance, the third mission is regarded by the tech departments in terms of patents and spin-offs, while the humanities departments consider it in terms of dissemination; by contrast, medical science thinks in terms of translational medicine, namely translating research findings into protocols and therapy options that ultimately benefit the patient instead of remaining just a publication. The social sciences tend to perceive the third mission mainly in terms of public engagement and cooperation with the civil society. Concerning this dimension of the third mission, recent studies have also started to recognize the existence of a “fourth mission”, which refers to the role of universities in contributing to the development of economies and societies and addressing real world issues, co-developing the sustainability paradigm through multi-stakeholder partnerships (Rinaldi et al., 2018; Trencher, Yarime, McCormick, Doll, & Kraines, 2014b). Despite the difficulty of identifying the third mission, the analysis of the sources has enabled the authors to identify three basic logics: the logic of dissemination, the translational logic and the entrepreneurial logic.

1. The logic of dissemination is founded on the assumption that HEIs must disseminate scientific knowledge and best practices to a broad audience and to the organisations which may benefit from that. Some KPIs emerged by the analysis are, for instance, the number of MOOCS, the number of public engagement initiatives, and the percentage of private funding for dissemination activities.

2. The translational logic is based on the idea that HEIs should contribute to translating the frontier research findings to new widespread solutions that may be then adopted by companies, institutions, and communities at an operational level. Some KPIs emerged by the analysis are the revenues from granted patents, the number of registered patents in the last 10 years, and the percentage of university patents registered.

3. The entrepreneurial logic is founded on the assumption that HEIs must directly contribute to creating new products, services and/or business models. Some KPIs emerged by the analysis are, for example, the total income of incubated companies, the revenues from technology transfer activities, and the number of active spin-offs and start-ups.

The results (tables from 1 to 9), followed by the explanation of the acronyms used (table 10), report show significant differences among the various logics. Starting from the teaching mission, the authors have pointed out a consistent coverage as to both the logic of inclusiveness and the vocational logic, and a broad and significant coverage as to the excellence logic.

With regards to the research mission, the logic of focalisation is almost ignored (only two indicators were found, both individuated only from the analysis of the integrated plans of the two polytechnics); the logic of materiality is only partially covered (missing

sources such as ANVUR and QS) whereas there is a broad and significant coverage as to the excellence logic.

Although the third mission is the more recent mission and it is not easy to measure the impact of HEI initiatives on the society, it seems to be well covered. The authors found a broad and significant coverage as to the dissemination logic, only a partial coverage as to the translational logic, and an almost full coverage as to the entrepreneurial logic (considerable attention from ANVUR and from the vocational universities in this case).

Tab. 1 – Teaching inclusiveness logic KPIs

Teaching inclusiveness logic	National and international evaluation agencies						Generalist universities				Vocational universities

5 Discussion and conclusions

This paper, based on the institutional logics perspective, classifies, through a framework, the KPIs in the HEI context. The ever changing role of the HEIs is in fact requiring a change also in their management. The emergence of recent logics related to the third mission, such as the entrepreneurial or the translational, has repercussions on the performance assessment system.

The purpose of this framework is not only to provide a valuable tool, firmly grounded in organisational theory, for analysing and comparing KPIs, but also to support HEIs in order to analyse and resolve tensions and contradictions as regards the goals that are specific to each institution. The nine institutional logics identified reflect nine different views of the role that HEIs are supposed to play in society, requiring strategic and organisational efforts required in order to harmonise them. The comparison among

the KPIs already part of the integrated/performance plans of the universities (both generalist and vocational) and the indicators considered by the most influential university ranking agencies provided insights for the development of a proper set of indicators which take into account all the missions of the universities.

According to the results, the teaching mission appears to be covered by a wide number of KPIs. Every logic presents a consistent or broad number of indicators. This is well explained by the fact that the teaching activity is the older reputation key factor (Maassen, 2017). The research mission, instead, shows a good coverage only with respect of the logic of excellence. The logic of focalisation and materiality are only partially covered from part of the two polytechnics. This result is not quite surprising since focalisation and relevance are the two research logics referring to a possible impact on the society, presenting some overlaps with the third mission as well. It would be interesting to analyse if a strong entrepreneurial attitude by universities (that is part of the third mission) also stems from a major focalisation and materiality in research. Concerning the third mission, both the dissemination and the entrepreneurial logics appear to be well covered. This means that universities are even more gaining understanding of the importance of create synergies with a huge variety of stakeholders, pointing out the role of universities as knowledge-based agents for local value creation (Geuna & Muscio, 2009; Hsu et al., 2015; Leydesdorff & Etzkowitz, 2001; Lockett & Wright, 2005; Secundo et al., 2017). Another interesting aspect is that, even if polytechnics are involved in a greater number of technologies transfer activities than generalist universities, they have not yet disclosed a systematic performance indicator system from what can be viewed by their integrated and performance plans.

The limitations of this paper can be all considered as further research opportunities. First, this research is mainly focus on the Italian context and it may be heavily influenced by country-specific characteristics; further research developments should be then focused on a comparative analysis in other Countries with different cultures and beliefs. Second, the role of HEIs is evolving very rapidly due to both internal and external factors. An analysis over time of the indicators could help to understand how the performance assessment systems are chancing, especially with regards to the more recent logics such as the entrepreneurial and the translational. Third, it is still not clear how to consider and represent the cross-sectional elements with respect to all the three missions (i.e., internationalisation). So, the framework still needs to be revised to give major importance to these cross-cutting elements.

Abstract

This paper aims to review and critique the Knowledge Management (KM) literature within Entrepreneurial universities, providing an overview of the results of a content analysis aimed to setup the emerging trends and suggest directions for future studies. The content analysis has been conceived into a larger and systematic literature review conducted on 1106 articles indexed at Scopus and initially submitted to a bibliometric analysis. Finally, 150 papers published in a variety of academic journals specializing in the field of Entrepreneurship, KM and Higher Education have been analyzed through a content and a bibliometric analysis to minimize mistakes in interpreting findings of collected studies. To undertake such analysis, we have used VOSviewer, a tool for constructing and visualizing bibliometric networks and clusters. KM within Entrepreneurial University is a research area of growing importance. Findings show that literature on KM models and tools in the Entrepreneurial University is fragmented and dominated by unrelated research. The content analysis here presented depicts the trends of a heterogeneous literature, but focused on some research streams such as: 1) Knowledge creation in Entrepreneurship Education; 2) Knowledge transfer in University-Industry collaboration; 3) Entrepreneurial University to support Knowledge based regional development; 4) KM processes for University's spin-offs. Implications for theory and practices are depicted.

Keywords – knowledge management, entrepreneurial universities, structured literature review, third mission, knowledge transfer

Paper type – Academic Research Paper

1 Introduction

Universities are historically identified as closely related to the growth of economy and society and the university's mission evolved during the centuries to respond to changing societal needs (Paleari et al. 2015). Lots of studies show that universities in developed countries have become increasingly entrepreneurial (Mowery et al., 2004; Siegel, 2006; Miller et al., 2018). Starting in the late '80s, academics and policy makers have coined the term "entrepreneurial university" (Etzkowitz, 1983, Clark, 1998; Röpke, 1998; O'Shea et al., 2005; Guerrero et al., 2018; Philpott et al., 2011; Etzkowitz, 2016), to describe universities that perform effectively their "third mission" contributing to the regional economic and cultural growth (Clark, 1998; Etzkowitz, 2000, Secundo et al., 2017).

In this context, the entrepreneurial university plays an important role as both a knowledge-producer and a disseminating institution (Guerrero and Urbano, 2012). The scope of the university activities involved in this "third mission" was defined by E3M (2010), which grouped them into three dimensions: technology transfer and innovation, continuing education, and social engagement. This raises Entrepreneurial universities as being knowledge hubs and strategic orchestrators of processes of knowledge creation, absorption, transfer and dissemination defined as KM processes in Entrepreneurial University. KM comes from strong and complex interactions of public-private stakeholders (Margherita and Secundo, 2011; Philpott et al., 2011; Etzkowitz, 2016; Maas and Jones, 2017) including faculty, staff, students, alumni, industries, and managers, but also citizens and entrepreneurs all involved in the knowledge creating and disseminating processes typical of the University's innovation mission (Etzkowitz, 2000; Vorley and Nelles, 2008). By presenting the results of a content analysis conducted into a larger and structured review of the literature (Secundo, et al., forthcoming), the article aims to identify lessons learned and research gaps, and by this to provide an agenda for future researches.

Next sections of the paper are structured as follows: after the introduction, in Section 2 the methodology is illustrated. Section 3 presents the review's findings in terms of content analysis. Conclusions and implications are detailed in the final sections.

2 Methodology

This paper is based on a structured literature review (SLR) as described by Massaro et al. (2016). A "SLR offers an empirical grounding that avoids missing seminal articles and reduces researcher bias" (Tranfield et al., 2003, p. 209). SLR approach lies in the

keyword and content analysis (McCulloh et al., 2013; Ribiere and Walter, 2013) and the inclusion of more detailed content-driven analysis to develop findings. Recently, SLR are evolving thanks to the wide availability of academic researches and go beyond purely synthesizing and deducing prior contributions (Massaro et al., 2016). To identify articles relevant to the literature review in this paper, the following steps have been followed: research questions definition; structuring of a research protocol; article selection from the Scopus database; definition of the coding framework; critical analysis and discussion of the results.

Firstly, the research questions that led the research done in this paper consisted in:

RQ1. What is the focus of the literature within KM for entrepreneurial universities?

RQ2. What are the implications for the research?

RQ3. What are the implications for the research?

For article selection we used Scopus database as it comprises over 20,000 peer-reviewed journals (Mishra et al., 2017) and is more ample than Web-of-Science (WoS) (Thelwall, 2018). Moreover, nearly 97% of papers indexed in Web of Science (WoS) are also enclosed in Scopus (Waltman, 2016). We queried the following KWs combination: “Knowledge management” OR “KM” and “Entrepreneurial University*” OR “Stakeholder University”. Data were collected in September 2018 - October 2018. One criterion was to consider only journal articles published up to 2018 (inclusive), excluding conferences, book chapters, research notes, editorials, and commentaries, (Keupp et al. 2012). We followed the exclusion criteria proposed by Vlaanderen et al. (2018). So from an initial set of 1106 items, we obtained 150 articles for analysis (excluding conference papers, book, book chapter, short survey and paper not sticking with our research questions).

The next step consisted in developing the coding framework based on similar research frameworks. In this article, we defined five categories for coding the articles, as follows:

- *Timing of the papers published*: Nr. of articles published over time;
- *Geographic distribution of articles*: Articles distribution among countries;
- *Types of Journals*: Distribution of papers among journals and citations received;
- *Analysis of Author and Citations*: Number of citations, citations per year, Citations and collaborations among authors;
- *Keywords and topics*: The type and frequency of keywords used and the emergent topic areas.

To undertake such analyses, we used VOSviewer, a tool for constructing and visualizing bibliometric networks and clusters (Van Eck & Waltman, 2014). While the results obtained on relation the first 4 categories have been detailed into a larger and systematic literature review that will appear in a forthcoming paper.

Finally, departing from the results obtained from descriptive analysis and in the aim of comprehending the emerging trends, research gaps as well as for identifying future directions a content analysis was conducted. In the next section the main findings of this analysis are presented and discussed.

3 Clustering and Content analysis

The bibliographic coupling was used for performing the content analysis (Kessler, 1963) for the 150 papers encompassed in the data sample. The results obtained from such analysis allows the identification of 7 clusters and 29 papers (as only papers with 20 citations at least are considered).

The clusters contain those articles that may spot a specific topic/approach. In addition, a clustering algorithm was adopted as proposed by (Van Eck & Waltman, 2014; 2017) to guide the content analysis of the articles.

Table 1 shows 7 clusters grouping 29 papers.

Table 1. Bibliographic coupling clusters

By reading clustered articles, four different researches areas emerged as follows:

- *Research area 1: Knowledge creation in Entrepreneurship education*
- *Research area 2: Knowledge transfer in University-Industry collaboration*
- *Research area 3: Entrepreneurial University to support Knowledge based Regional Development.*
- *Research area 4: KM processes for University's spin-offs*

Research area 1: Knowledge creation in Entrepreneurship education with a specific focus on the “Entrepreneurially equipped students: processes and strategies” in terms of new roles and configuration of business schools (Wright et al., 2009), co-learning processes and innovation in the supply of entrepreneurship education (Hannon et al., 2005), a more student-centered teaching practice (Jones and English, 2004). This is coherent with that done in recent years in Higher Education Institutions (HEIs) where dedicated Entrepreneurship Centers have been established with the aim to support a broad spectrum of learning and research initiatives, providing funding for various educational programs as well as supporting social community development (Maas and Jones, 2017).

Research area 2: Knowledge transfer in University-Industry collaboration - In such area, contributions have been identified in terms of “Models of Knowledge transfer from University to firms” and “Performance measurements in knowledge transfer.” Some of the most relevant contributions are: Acworth (2008) that illustrate the role of Knowledge Integration Community models to enhance University–Industry links by providing a comprehensive and effective approach to a multidirectional process of knowledge sharing, which goes beyond traditional, unidirectional ‘knowledge transfers’ from academia to industry; Siegel et al., (2004) that focus on identifying and analyzing the role of organizational practices in fostering and promoting successful university/industry technology transfers.

Research area 3: Entrepreneurial University to support Knowledge based regional development, with thematic perspectives on “Knowledge based models for regional development” and “Quadruple Helix collaboration,” About the first, there is evidence for the roots of regional development driven by knowledge based model in the study of Russo et al. (2007) that reflected on the role of universities as driving forces for urban development and as measurement of the Universities’ impact for economic development (Guerrero et al., 2015). Bramwell and Wolfe (2008) discuss the different mechanisms of knowledge transfer through which universities can contribute to growth and innovation of local and regional economies. Meanwhile, Lowe and Gonzalez-Brambila (2007) focus on analyzing the role of faculty entrepreneurs by assessing their productivity performance in terms of knowledge creation as expressed in publications, licenses etc.

Research area 4: A fourth area regards the KM processes for the Universities spin-offs, with two thematic perspectives related to the “Drivers for the development of spin-offs” and “Research commercialization.” About the first, different trends arise in the commercialization of tacit and explicit knowledge as well as incompatibility and non-complementarity of science and commerce (Duberley et al., 2007), effectiveness of knowledge transfers when a substantial part of the original research team joins the new venture as founders (Knockaert, et al., 2011). While Krabel and Mueller (2009) analyze the factors that influence scientists’ entrepreneurial activity, highlighting the relevance of patenting activity, entrepreneurial experience and personal opinions regarding the benefits of commercializing research.

4. Discussions and Implications

The aim of this section is to discuss and critique the main findings for answering RQ.3 “What are the implications for the research?” The answer to this question moves toward the implication of “*a future research agenda about KM in the Entrepreneurial University area*”.

A relevant aspect to consider is the rapid acceleration of digital technologies reshaping markets and society globally (Nambisan et al., 2017) on academic entrepreneurship (Rippa and Secundo, 2018). Among the actors involved in these disruptive changes, universities are challenged in the way they pursue and interpret their threefold missions; e.g., education, research and “third mission” (Lombardi et al., 2019; Dalmarco et al., 2018; Etzkowitz, 2016). As far as the latter is concerned, the impact of digital technologies needs to be investigated encompassing activities like research collaborations with industry, patent applications, transformation of innovative ideas in spin-offs, entrepreneurial education of highly skilled individuals, technology transfer or business incubators. A second research area requiring more research is related to the dissemination of entrepreneurship education outside the business school to cover all the University’s departments. Society requires people who are educated in the “Sense of initiative and entrepreneurship” (EC, 2006). Third, another neglected aspect of managing knowledge in universities is the ‘collective’ involvement of all the stakeholders contributing to achieving the third mission (Secundo et al., 2016) that moves from the assumption that considers a university as a collective intelligence system (Vargas et al., 2019) in which alternate processes of exploration and exploitation generate a twisting learning path (Centobelli et al., 2018). Finally, the comprehension of how knowledge flows from Industry to University remains underdeveloped since the prominent studies in the field analyzed how the knowledge moves from academia to industry (Chedid and Teixeira, 2019). Given the vibrant nature of research on entrepreneurial universities from one side and KM from the other side, future studies that address the dynamic and multifaceted aspects of the above-mentioned future research areas should be welcome in additions to this literature. This may also be another entry point for micro researches trained in psychology and Information technology, a group currently conspicuously absent from this research stream. This provides useful implications for the definition of future research

contributions by scholars that could offer additional perspectives of investigations, also thanks to the involvement of a larger number of practitioners.

5 Conclusions and future research

In the conclusions of this study, it is important to recall its initial motivation, based on the argument that the Entrepreneurial University represents a particular research context because of a different level of representativeness, accountability and responsiveness of different stakeholders, requiring focused studies about KM studies. Universities are now viewed as key economic actors within regions and are central actors in shaping and influencing entrepreneurial ecosystems. This has meant that universities now have to become more entrepreneurial in offerings, outlook and culture (Miller et al., 2018). Content analysis performed in the paper allowed identifying four main thematic clusters as main areas of specialization of the scientific debate, with related sub areas. We categorize the main areas as: 1) Knowledge creation in Entrepreneurship education (focus on the “Entrepreneurially equipped students: processes and strategies”), 2) Knowledge transfer in University-Industry collaboration (focus on “Models of Knowledge transfer from University to firms” and “Performance measurements in knowledge transfer), 3) Entrepreneurial University to support Knowledge based regional development (focus on “Knowledge based models for regional development” and “Quadruple Helix collaboration”) and 4) KM processes for the University spin-offs (Focus on “Drivers for the development of spin-offs” and “Research commercialization”). The analysis of papers included in these areas allowed deriving a more robust awareness on the state of art for the debate on KM and Entrepreneurial University in terms of conceptual and organizational models, causal mechanisms of functioning, tools and performance metrics, and impact on regional development.

Some limitations can be identified in the nature of journals analyzed as well as the database selected. As authors, we are aware that this could represent a limitation since we cannot assume that valuable research related to our topics could have been published on different venues not listed in our database. Second, the validity of the evidence collected is limited to the timeframe considered. Third, as every beginning of a new journey (Massaro et al., 2016), a SLR is relevant for the contribution of inspiration more than for the state of the art it is able to provide. Accordingly, we hope this work contributes to identifying lacks in the debate on KM and entrepreneurial university and providing inspiration for the future works of scholars and practitioners interested in the advancement of such promising future research areas.

Abstract

*The overall aim of this paper is to provide knowledge on the importance of **systems thinking as strategic in understanding organisational community systems**. If “systems” literature can be complex and inaccessible since there are many different approaches to and ways of understanding systems thinking, the article explores the theory and practice behind the use of systems approaches in tackling public challenges as they represents a different way of looking at the world. The latter is understood as an open, complex set of systems that are social ecosystems themselves but are interconnected to external environments. The starting point is the recognition that all individuals consist of and are part of multiple interconnecting systems – biological, social, organisational.*

The systems thinking approach takes this recognition and makes use of it as the basis for understanding and changing the world. It also sees the relationships within and between systems as crucially important by recognising that there is huge complexity in these relationships. These open systems need to keep evolving and learning, as if they are micro organizations, in relation to changes and needs of multiple stakeholders. Systems become, then, learning organizations.

In essence, systems thinking is a worldview; merely, an attitude of inquiry and reflection. Thinking and working, in ways that recognise the interconnectedness of the community, is the first step to being able to make the systemic changes that community residents expect to see.

*The proposed approach is firstly based on the review of the literature available on **systems change following systems thinking** as its precursor, and collaborative community governance. In order to testify the suggested research question, this paper is based on a case-study approach (Yin R.K. 2005, 2006, 2009, 2013) whose value resides in allowing an in-depth investigation of complex issues in their natural real-life settings. It provides not only phenomena’s insights but practical challenges in understanding the case as an integrated whole. In particular, starting from the relevant scientific literature, this paper aims at creating a relationship between evidence from the scientific literature review and facts provided by the case-study so to highlight the levers and main featuring*

aspects that make a specific organisational model. This will help acknowledging the underlying elements for a first possible theoretical framework to explain how sustainable development of communities and territories can be achieved through the perspective of systems change.

Starting from the consideration that the underlying values of PORTA FUTURO BARI are transparency, reliability, ethics, solidarity, cooperation, talent and creativity's enhancement, the originality of this paper is related to the value of the experiment itself, which has an impact on the community and the metropolitan territory as a whole.

Originality is also given by the approach used to explain the unfolding dynamics of community organisation aimed at delivering development through the perspective of systems change that leverages on some variables present within that system such as power/authority, communication, relationships (social capital) and modelling capacity.

The paper will tell if, first of all, such an experiment at the local level is successful in creating an urban hub that is a community platform where people are empowered to make change of the systems where they are embedded in. Hence, to understand if the local community is able to design and promote the building of sustainable actions, practices and organisations that offer new opportunities for participation and engagement of peoples, for sharing and integrating spaces, resources and values for knowledge creation, for co-creating value through co-producing people for a collaborative-driven urban development.

Keywords – organisation, systems thinking, systems change, collaborative governance

Nature of the proposed paper: Academic Research Paper

1 Introduction

The crucial point of this paper is how to produce change into systems starting from the perspective of systems thinking as applied to the study of community organizations. The case-study presented in this work tells about a service delivery-based local experiment conducted by the Municipality of Bari, named PORTA FUTURO.

PORTA FUTURO BARI is an employment service hub, funded by the Regional Government (Apulia Region) under the National Operative Plan “GOVERNANCE and SYSTEM ACTIONS 2007-2013, ACTION 3, also supported by the project named “Networked young community: the Public Sector at the service of a new policy of employment”

This local social experiment aims to adequately orient metropolitan users to the job market, with particular attention to youth, and to promote the matching with the current supply system. The goal of this employment centre is to consolidate what can be defined as a Territorial Community, made of public institutions, public and private agencies, representatives of trade unions and professions, enterprises and cooperative systems, universities, research centres and schools, gathered together in a fruitful and systematic debate on issues regarding the social issues and its related dynamics.

Conceived and planned as an aggregator that mobilises resource, information, competences, skills and opportunities, PORTA FUTURO is aimed to become a driver for

social innovation and local development. However, it is important to point out that PORTA FUTURO is an umbrella project which develops in two steps and time lines. The first step, which is already finalised, refers to PORTA FUTURO 1, a generation Job Centre committed and specialized in welcoming, supporting and guiding young people to access training and job market. While PORTA FUTURO 2 stands as an incubator/accelerator that will welcome a series of start-ups and, at the same time, advanced services to support, consult and launch of innovative start-up on the territory. Having said that, the paper will respond to the following research question:

RQ1: can systems thinking be useful for community groups? And if yes, which elements could be most useful to lead to systems change?

The paper attempts to explain the connections between literature review on systems thinking and the empirical evidence collected through the case-study by addressing the need for systems thinking in the public sector as it encourages practitioners to understand and analyse the contexts within which they operate, and to design programmes that can adapt as conditions on the ground change. Hence, the theoretical underpinnings of systems thinking are useful and functional to the achievement of territorial development. It increases the possibility of transformational change since it helps practitioners to bring together many different stakeholders, especially those with radically different backgrounds and perspectives, to identify problems and solutions to challenges.

Moreover, systems thinking is, today, pivotal and functional to deal with the achievement of Sustainable Development Goals whose debate within the international community is overwhelming. Mapping the activities around the individual goals will certainly accelerate progress. But looking across the goals at possible synergies and trade-off takes us to the next level. Clearly the SDGs do not work in isolation, for example health (SDG 3) is impacted by food and nutrition, sanitation, education and increasingly climate change; the sustainability of cities (SDG 11) is an amalgamation of a number of the other goals such as food, energy, education, infrastructure. A strong system approach is required to successfully deliver SDGs, which enables organisations to operate jointly, on an inter-relationship based level and sustainably.

2 Literature review

2.1 Systems thinking as a theory and an approach

Traditional thinking encouraged scholars to focus on individual parts of a problem occurring within a system. But what it is meant by systems? They are social, environmental, economic and political systems. These interact to form bigger market, governance and ecological systems. Each of these systems is made up of multiple inter-linked parts and actors that influence each other (e.g. formal and informal institutions, natural processes, people and behaviours). For instance, a market system is made up of companies, government agencies, rules and regulations and physical assets (such as infrastructure) as well as environmental, social and political factors that will influence how the market operates and who participates in it. It is not possible to understand what is

happening in any of these systems by looking at their individual parts, understanding the broader context, appreciating interactions among levels and taking an interdisciplinary approach (Leischow and Milstein, 2006).

However, this approach was weak in approaching issues of organizational change since it lacked of systems understanding in order to quick-fix problem solution.

To understand what is happening in each system it is strongly important to grasp how the different parts of the system interact and affect each other, which actors are affecting the system and what motivates them. In other words, it is important to understand not only the tangible side of the system (its infrastructure, to put it bluntly), but the intangible factors of a system, such as the different human activities that are having an impact on the system as a whole.

Today, new challenges are making the future increasingly unpredictable and are forcing scholars to think in different ways. The reality is that any combination of factors and conditions could occur. Together, factors would combine to create challenges that communities would have to deal with or opportunities they would have to respond to and, of course the exact combination of opportunities and challenges affecting the individuals of a community could change, each and in every moment. What systems thinking implies is that it is necessary to be informed by a deep understanding of the bigger picture of what is happening, of all the different components that they need to respond to. In other words, each system exists within and interacts with a hierarchy of nested systems (Midgley, 2000).

Systems thinking is that missing piece which also represents that missing glue that holds it all together. By identifying interactions between different parts of a system, being a city, a sector, an organisation, it makes sure that each part delivers more than the sum of the parts going deeper to address the underlying causes. A systems approach highlights the importance of the circumstances, or context, in which an action is taken in order to understand its implementation and potential impact. Arguably, the work of systems thinking is never done and efforts to bring this body of thought and practice into an organization are always challenging. Hence, it is important to argue that to develop systems thinking as an organizational habit of mind means learning and practicing in order to arrive at the managing change within a system. The systems approach offers a further advantage with respect to the well-recognized gap between research and practice, which limits the extent to which advances in research translate to advances in improving public policies in general. Most efforts to link research to practice and policy have merely highlighted the challenges of transferring knowledge from single-discipline, highly controlled research to practice settings. Interdisciplinary investigation using a systems approach can potentially help close this gap (Mabry et al., 2008).

A systems approach to solving collective problems requires new tools, including data, methods, theories, and statistical analysis different from those traditionally used in linear approaches. No single discipline can provide these tools. Therefore, it is necessary to approach research on public issues with a collaborative team of scholars and researches who bring knowledge and expertise from a variety of disciplines and sectors (Leischow et al., 2008). The theoretical frameworks and methodologies that result from such

collaboration can generate new conceptual syntheses, new measurement techniques (e.g., social network analysis), and interdisciplinary fields of inquiry (e.g., behavioural genetics) with the capacity to tackle complex population problems (Fowler et al., 2009).

In essence, systems thinking is a worldview, and an attitude – of inquiry and reflection. Thinking and working in ways that recognise the interconnectedness of the world is the first step – it seems to me – to being able to make the systemic changes that we need to see.

The purpose of this short introduction is to clarify what systems thinking means to lead, then, to the significance of systems change.

2.2 System change as an approach to manage complexity

System thinking enables to see complexity and unpredictable “emergent change” everywhere. Much systems thinking seems to assume that to change a system, it is important to have some power or authority within that system. Community organisations, though, rarely have formal power over the thing they are trying to change, especially groups of people who have come together to try and take control of a neighbourhood or parts of its asset. But what is systemic change?

A greater understanding of systems and how they behave enables to design interventions that bring long-term change to how systems operate, or systemic change. A key part of systemic change for organisations is a change in the relationships between stakeholders so that poor women and men hold more of the power (including the power to influence the system) and benefits within the system.

From this stage point, it is important to note that a small shift in one element of a complex system can produce larger changes in other elements (Meadows, 1999) so to produce a far-reaching impact on the community as a whole as they are designed to maximize benefit and minimize negative consequences. To explain change and accurately envision future changes, let alone achieve them, it is very much helpful to emphasise on the term “*complexity*”. In complex systems, change results from the interplay of many diverse and apparently unrelated factors. Those of us engaged in seeking change need to identify which elements are important and understand how they interact. Systems are in a state of constant change and as Boulton argued, one of the authors of the book *Embracing Complexity: Strategic Perspectives for an Age of Turbulence*” (Boulton, 2015) the use of the metaphor of the forest is adequate to explain complexity as it typically goes through cycles of growth, collapse, regeneration, and new growth. This metaphor also encourages organisation scholars to adapt their analysis and strategy according to the stage that their political surroundings most closely resemble: growth, maturity, locked-in but fragile, or collapsing. In the early part of the cycle’s growth phase, the number of species and of individual plants and animals increases quickly, as organisms arrive to exploit all available ecological niches. The forest’s components become more linked to one another, enhancing the connectedness of the ecosystem while multiplying the ways the forest regulates itself and maintains its stability. Nevertheless, the forest’s internal connectedness and efficiency eventually reduce its capacity to cope with exogenous shocks paving the way for a collapse and eventual regeneration.

Change in complex systems occurs in slow, steady processes such as demographic shifts and in sudden, unforeseeable jumps. Nothing seems to change until suddenly it does, a stop–start rhythm made by events that disrupt social, political, or economic relations and which can open the door to previously unthinkable reforms. Events alike have also been defined as critical junctures (Acemoglu, Robinson et al, 2009) often force political leaders to take up sound policies and make them more willing to take the risks associated with innovation, as the status quo suddenly appears less worth defending.

The literature review on systems change delivers some important key points to be considered. In the effort of promoting systems change it is important to:

- **Foster community and cultivate networks**, this means that most of the qualities of a living system are aspects of a single fundamental network pattern: nature sustains life by creating and nurturing communities. Therefore, lasting change would require a density of interrelationships within a community. To achieve systems change, leaders must cross department boundaries and bring people addressing parts of the problem around the same table.
- **Work at multiple levels of scale**, referring to the core ecological system of “nested systems”. Like Russian "matryoshka" dolls that fit one into the other, most systems contain other systems and are contained within larger systems: cells within organs within individuals within communities. Having considered that, changing a system affects both the systems within it and the systems in which it is nested. The challenge for change agents is choosing the right level, or levels, of scale for the changes they seek. The answer is often working at multiple levels: top down, bottom up, outside in, and inside out.
- **Make space for self-organisation**, meaning that the central concept is that a network pattern is capable of self-organization. Networks that can effect systems change do self-organise when the right conditions are established.
- **Seize breakthrough opportunities when they arise**. Since systems change can be so difficult as a system encounters a point of instability where it is confronted by new circumstances, instability itself can either precipitate either offer a breakthrough of new possibilities due to systems' capacities for self-organization.
- **Facilitate change**, it means that it is opportune to create conditions that take advantage of the system's capacity for generating creative solutions through the nurturing of networks of connection and communication, creating climates of trust and mutual support, rewarding innovation. Effective leaders recognize emergent novelty, articulate it, and incorporate it into organizations' designs.

3 Porta Futuro Bari as a case-study

This case-study provides an overview of an experimental local government project which explains how people, within a community, commonly go about creating a social and environmental value to develop the necessary skills to run sustainable businesses. Access to suitable training, and clear pathways to land-based careers, are crucial to common good land use. Unfortunately, in many cases these are not forthcoming whereas,

at the moment, it is difficult for people to develop secure livelihoods and careers due to the labour market crisis. This is both because of a lack of structured training and work pathways, and because of wider structural issues. The experience of PORTA FUTURO aims to shed light to the systemic change that has occurred in the premises of the Metropolitan area of Bari where institutions and communities have identified space for improvements by introducing and justifying a strategy for improving a critical situation as regards to employment issues.

The history of PORTA FUTURO BARI comes from a past experience conducted in the City of Rome. On July 5, 2011, the Province of Rome, on the basis of other similar national and international experiences, inaugurated in Rome PORTA FUTURO, a new generation Job Centre hosted at the premises of the new “Mercato del Testaccio”. It was intended as a pilot experience on work placement and fully integrated with the functioning of the Employment Centres existing on the territory. It later gained positive results at both national and EU level. Porta Futuro Rome currently provides youth with reception, orientation, training and networking services on work and skills development issues.

Following the numerous contacts between the Puglia Region and the Province of Rome since the very start of the experimentation of Porta Futuro, the Puglia Region has signed a Memorandum of Understanding with the Province of Rome in September 2012 with the aim of transferring part of the gained know-how from the Rome’s experiment to the Apulian regional territory. On the basis of the results obtained in the three-year period of operation, the Ministry of Public Administration subsequently supported the idea of making PORTA FUTURO as replicable experiment also in all Convergence Objective Regions so to fund the “Young People on the Net: the Public Sector at the service of a new employability” Project leveraging on grants connected to PON GOVERNANCE 2007-2013, ACTION E.

3.1 Why Porta Futuro in Bari?

The motivations behind the creation of PORTA FUTURO in Bari are of two types: one is related to the need of cope with the current economic and social crisis of the area; the second refers to the political programme of the Mayor elected in 2014 and actually in power which included the adoption of strategic employment policies.

According to the first motivation, the historical moment that the local context is going through is characterized by a strong economic and employment crisis that has generated a strong social fragmentation and widened the range of exclusions, especially of the youngest, which today affects more than 46% of the young population resident in the Metropolitan Area of Bari. A condition of social emergency that forces the system of local authorities to question themselves on their role as active promoter of active development and protection policies, more inspired by the principles of collaboration and horizontal subsidiarity, to be shared with the main economic and social actors engaged in the territory.

On top of attempting to find a solution to a wider collective problem through stringent public policies, there is also the issue of revitalising and regenerating the fragile

neighbourhood where PORTA FUTURO is going to be located, that is “Quartiere Libertà”. This neighbourhood, born from the first expansion to the west of the city as a territorial sign of a need to establish productive and infrastructural functions and further subjected to aggressive urban sprawl phenomena and consequent housing and social degradation, is currently characterised by a strong level of gentrification, initiated during the 1980s and 1990s, also due to the immigration waves of the last twenty years. In the middle of all this, there is the Tobacco Factory that will host PORTA FUTURO BARI, as it stands as the icon of decades of abandonment and structural inertia, a mere representation of a structural incapacity of dialogue between institutions (constituency, municipality, university, ministry) and programmatic myopia on the vision of rebirth of this neighbourhood. Taking into account these premises, PORTA FUTURO stands as an extraordinary opportunity for a neighbourhood regeneration programme and social re-composition upon which creating a renewed identity and rebuilding a stronger motivation.

As far as the second motivation is concerned, the Municipality of Bari, as declared in the political program of the current Mayor, in collaboration with the main representatives of the territorial economic-social partnership and in line with the measures adopted by the new Apulia Region Extraordinary Work Plan on employability, has planning integrated interventions to address the issues of work and the protection of the weakest social groups exposed to the crisis, including PORTA FUTURO, will have a strong strategic centrality. Also, the Apulia Region welcomed this project and immediately deployed all the necessary means to promote the experimentation through the setup a specific and local model for its own territory. By sharing the powers with the Municipality of Bari, the first pilot project started off in the City of Bari in the prestigious Tobacco Factory building where the Institutional Pact between the Region and the Municipality could be finally welded by virtue of delivering youth policies for urban transformation. On these premises, it is important to note that this has been the start of a closer relationship between public investments on employment policies addressed to job placement and training through modern guidance services able to provide effective responses to the job demand of young people in the Metropolitan area of Bari.

3.2 The vision of porta futuro

PORTA FUTURO BARI complies with a series of national and territorial goals policies regarding the activation employment policies to support young people's access to the labour market, which are as follows:

- objectives of the European Commission on NEETs
- objectives of the Apulia Region regarding either the strengthening of human capital either urban regeneration
- the programming and objectives of the Puglia Region regarding Smart Competences (Smart Puglia2020)
- the schedules and objectives contained in the Pact for Bari between the Region and the Municipality
- the programmatic guidelines of the Mayor 2014-2019.

Applying a systems thinking approach starting the premises above, the vision of PORTA FUTURO BARI is to create an urban hub with a metropolitan dimension, which can foster the full integration of young people in the labour market on the territory, guaranteeing reception, support, training and placement both at the level of demand (under 35) and supply (companies, districts, representations).

The main objectives of PORTA FUTURO BARI are four:

1. categorize the needs of young people by qualifying the social demand for work through a system of reception and skills balance;
2. strengthen the skills of young people through training and job placement;
3. support individual and collective experiences of self-employment, youth entrepreneurship and/or social innovation practices also through the forms of incubators;
4. foster a more efficient and effective dialogue between the school system, professional training, public educational and training agencies, employers and union representatives and districts aimed at producing value.

PORTA FUTURO BARI consists of two phases in an evolutionary logic and, in line with the main national and international experiences, the two phases/sections will be complementary but specialized in functions:

- *Phase 1 (2015-2016)*: recovery, restructuring and redevelopment of the Tobacco Factory, ground floor for the provision of the following services: reception, skills assessment, job placement through basic training policies and company recruitment;
- *Phase 2 (2017-2020)*: extension of the space on the first floor as well as functions focusing on social innovation and business start-up experiences, including a residential portion to incubate new business initiatives according to a logic of turnover. This space will host an innovation atelier and a FAB LAB (from the Italian “fabrication” laboratory) that is a small workshop that offers personalized digital fabrication services, equipped with a series of computerized tool, capable of creating, in a flexible and semi-automatic way, a wide range of objects.

3.3 How does Porta Futuro work?

Considered the above premises, it is important to take into account that PORTA FUTURO as a whole is an ambitious, innovative and challenging project also from the Governance point of view. This mainly for three reasons:

- i. it is the setting where various territorial actors cooperate to create a management framework, putting their own commitment into a system as well as their competences, for the achievement of common goals;
- ii. it is the result of a strong commitment, by the multi-tier local governments, to solve contingent economic and social issues and to consequently equip themselves with tools for planning, management and monitoring beyond the due observance of rules, laws, guidelines and principles of good governance;

- iii. it is supposed to solve the strong fragmentation in the provision of employment services that, so far, have involved different actors (Universities and schools from one side, and institutions from the other one) acting individually without any coherent and synergic effort. In this scenario, PORTA FUTURO's effort in designing and offering a coherently designed policy for employment means to seriously think in terms of effectiveness by identifying new indicators that measure experience and punctually verify user satisfaction, thus resolutely going beyond the simple detection of system efficiency data. This latter attitude requires an approach strongly oriented towards citizens as a user and, in terms of governance, it means formulating specific performance metrics, preparing new reporting systems to be punctually assessed in addition to the usual administrative and financial statements.

At this point, it is important to argue that the governance of a complex organizational actor such as PORTA FUTURO, equipped with a set of resources and skills of its own and many others borrowed from a network of actors and external collaborators (who are also bearers of different and distinctive knowledge, resources, cultures and skills), cannot be resolved in merely prescriptive terms. It is not possible to prefigure a system of rules, standards and procedures capable of pre-ordering all the possible operational interactions between the actors. The ability to manage the relationships between the actors involved and engaged in the project all contributing at creating value for all, is fundamental for the success of PORTA FUTURO.

4 Conclusions

The overall goal of this work has been oriented towards the need to give sense of the importance of systems thinking, while facing with an overly complex view, particularly in dealing with some of today's challenging organizational, social and economic issues. Starting from systems thinking, this paper seeks a subversive approach to bring systems change to the conversation.

Firstly, this paper has explained how systems thinking expands upon the multilevel, multi-sector strategies to support policies supporting employment in a developing area. It provides a primer on the concepts of such thinking and examines how the systems approach can be applied to identify the determinants, strategies, and actions that must be considered to address the economic and social crisis. The case-study provides a practical example of how systems thinking can be used to advance effective change as regards to public policies in the realm of employment issues.

The research question was: can systems thinking be useful for community groups? And if it can, which elements could be most useful? By the case-study described, it could be argued that PORTA FUTURO delivers insights from systems thinking that can be useful for community groups of people trying to change a system.

Born in the wake of the Roman experience PORTA FUTURO BARI and compared to other similar examples at the national and international scale (Barcellona, Bologna, Turin), has distinguished itself for effectiveness and innovation. It allows the integration

of two types of innovation, tangible (within the infrastructural recovery of the site and of the urban neighbourhood) and intangible (with the immaterial benefits of the multiple services delivered to young people, businesses and citizens) both oriented towards the creation of favourable conditions and spaces for socialization and social inclusion in the neighbourhood area with important effects of urban regeneration and local development.

A pivotal role has been played by the Community of the City of Bari, more particularly, its awareness of being a Community that recognizes itself in a model of growth being sensitive to inequalities and rights; a Community enabled to design policies adequately oriented towards integration, inclusion and cohesion; a Community that manages to bring together not only institutions but also economic and financial actors, category representatives, civil society, associations and the third sector on the objectives of social cohesion, development and equity.

The actions conducted by the Community and at the level of the Community are nurtured by a systems thinking approach that provides a way to understand adaptive challenges, as well.

Abstract

Alumni are one of the most important assets of the universities and their role and place in the university is more often becoming matter of scientific discussion. Author suggests universities to apply systems thinking and look at the wider environment and interactions of various subsystems, alumni community being one of them.

Many authors discuss Higher Education and Research Institution (further HERI) customers and their segmenting (Weaver, 1976; Juran, 1988; Conway, Mackay and Yorke, 1994; Kotler and Fox, 1995; Pereira and Silva, 2003; del Barrio-García and Luque-Martínez, 2009; Taiwo, 2010). The research approves that alumni are HERI customers not only at the particular moment when they purchase HERI services but also continuously (Kotler and Fox, 1995; Heckman and Guskey, 1998; Taiwo, 2010).

Alumni as customer lifecycle is adapted to classical customer lifecycle and merged with Alumni Triple Helix Segmentation. The alumni lifetime engagement is cyclic and with each cycle, it aims for deeper engagement and closer ties, more personal relationship and higher investment in the university. Alumni knowledge management exploits the concept of alumni being customer – that changes attitudes and perspectives towards the strategic activities and knowledge that HERI intends to manage in alumni matters.

Keywords – alumni, knowledge management, systems thinking

Paper type – Academic Research Paper

1 Introduction

Higher education has a history of hundreds of years. Right now, because of rapid technology development and the globalization, the higher education market is radically changing. It is not only privilege of elite circles, higher education nowadays is widely available. Universities are not only centres of knowledge, they are becoming generators

of innovative companies and cornerstones of countries' future prosperity. The higher education market is quite uneven – university competition is moving to the government level where all self-respecting countries take part by generous funding of excellence initiatives. USA and western Europe dominate the rankings and continue to invest strategically in the higher institutions. Worldwide the new life-cycle of a student is transformed to a life-long relationship with the university. After graduation starts new phase of mutually beneficial relationship of alumni and universities. Alumni relations and fundraising is a large industry in USA and Western Europe – it provides significant share of higher education financing and provides means for industry cooperation with universities supporting common research, valorisation, career development. Alumni play a vital role in university support and development. In business it is common and convenient to apply monetary measures for success. Rather in alumni–university relationship intellectual capital, knowledge, information and connection to the labour market are difficult to measure and thus underestimated and insufficiently applied as success metrics. Most commonly knowledge management is associated with organizational efforts to manage its' inner knowledge for better and sustainable business development. Customer knowledge management goes over organizational borders and involves three types of knowledge – to, from and about the customer. That precisely fits with alumni role in the university because the university cannot exist nowadays without the knowledge and experience of the industry because it is preparing the resources that will be the future driver of the labor market. At the same time it is important for the university to tell to alumni and industry what is going on in the campus of the university – what skills students are learning, what are recent inventions, what equipment is in the campus and how these all can be applied in the industry for mutual benefit. Implementation of alumni knowledge management model and systematic use of metrics will timely indicate strategic and knowledge gaps between the universities and the industry. Cooperation with alumni has a multiplier effect because it increases the quality of higher education, it provides technology and knowledge transfer, development of intellectual capital and increase of university brand value.

2 Systems thinking in HERI

The organizations are designed in functions. Each function has its own target and budget. But, as we all know, we work across the functions. So we shouldn't be surprised that we see tensions between meeting functional goals and serving customers. The system governs the way we behave together and the way we behave to our customers. Systems thinking is management approach that looks at the overall system and main processes and integral part of the system rather than separate entities. The key to improvement is looking at the processes as interrelated. Same with key stakeholders of the organization. Understanding them as subsystems and their various interrelated roles and relationships is critical to achieve desired targets, improvements and continuous positive impact on community. Same concept applies to universities – it is important to apply systems perspective (Banathy, 1999; Ison, 1999; Furst-bowe, 2009; Dunnion, 2012). However the

challenges arise due to traditions, organizational structures, academic autonomy and financing issues (Furst-bowe, 2009). There are several frameworks used by HERI that help organizations to implement systems thinking – e.g. Baldrige Education Criteria for Performance Excellence (Furst-bowe, 2009), the Vanguard Method (Dunnion, 2012), etc.

(Muraškovskis, 2015) describes three principles of systemic thinking – hierarchy, evolutionism and emergentism:

- Hierarchy – arrangement of items in different levels, branching and interconnecting links among these items;
- Evolutionism – development of a system within time. We can look at it from two viewpoints – as system itself (ontogenesis) or part of a whole (phylogenesis).
- Emergentism – interconnectedness, interaction and evolution of subsystems.

In other sources emergentism is described as concept “when the whole is greater than the sum of the parts” (Morowitz, 2004; Hitchins, 2007).

By applying these principles when we think about higher education, we can look at the forces that affect it on a wider scope. If we analyze the place of alumni, particularly their knowledge in whole system, we have to look for all intersections of alumni/university knowledge and processes by applying hierarchy and emergentism principles. Until now alumni have not been considered as integral part of the system but they are important subsystem with great influence on the HERI processes (Furst-bowe, 2009; Pham and Jaaron, 2017). Universities must look for most effective ways to engage alumni for increased impact on the study process, research, employability, innovations and resulting impact on community as a whole. In next chapters author discusses the role of alumni within the HERI system and particularly the knowledge management as a way of engagement for sustainable development.

3 Knowledge management in universities

Universities shift from their traditional academic to a new entrepreneurial role as promoters of innovation to significantly contribute to their local economics. Moving away from universities’ traditional two roles of creating knowledge (research) and disseminating knowledge (teaching), (Draghici *et al.*, 2015) describe three main roles for the universities: “education (smart people), research (new knowledge) and knowledge transfer to society (entrepreneurship, technology, expertise)”. (Oosterlinck, 2001) discusses that universities are expected not only to be active in science and technology development but also to turn these developments into innovations and even further implement creation of new ventures. Thus universities are required to maintain bilateral knowledge flow to keep up with innovative learning and teaching (Metaxiotis and Psarras, 2003). Knowledge management in universities:

- Creates link between work and education;
- Helps to create talents matching to workplace demands;
- Contributes to convergence of new knowledge with existing one;

- Incorporates real problems in the learning and knowledge creation process.

Universities are players of the knowledge industry (Rowley, 2010). Universities must foster creation and sharing of knowledge among most important stakeholders – teaching, non-teaching staff, students, alumni, sponsors and other (Hoq and Akter, 2012). Hoq and Akter in their research propose in university context to adapt three layers of knowledge management (Hoq and Akter, 2012) that are described also by (Pan L. and Scarbrough, 1998). Researchers Trivella and Dimitrios propose three basic elements for knowledge management in universities: people, processes and technology (Trivella and Dimitrios, 2015). Academic and nonacademic staff must collaborate, share and access the knowledge, be aware of existing processes (policies and procedures) and it all must be supported by appropriate technological solutions. (Oosterlinck, 2001) adds another factor context (or environment as in the model of (Davenport, De Long and Beers, 1998)) relating to the culture and history of the institution, that are influencing norms, values and attitudes.

Traditional higher education institutions, where significant part of funding is public, are encumbered with excessive control by government institutions. The requirements of accountability dictate quality and governance practices and often negatively impact efficiency and ability to follow the pace of other players of knowledge intensive industries. Now universities must balance between curiosity or mission driven academic research and strategy driven corporate R&D research. At the same time, lifecycle of students' relationship with universities has shifted from traditional view of termination at the graduation point to a life-long relationship. Nowadays needs of students and alumni are continuous growth in knowledge and skills demanded by rapidly developing market. Continuous learning availability is growing with expanding support of technologies. Universities are large, specific and complex organizations with many organizational branches and diverse functions and activities. Thus, the most important first step is to apply systems approach to know which is strategic knowledge and sources of such knowledge.

4. Alumni knowledge management for sustainable development of HERI and communities

4.1 Alumni as *HERI* subsystem

All alumni (alumnus, alumna) definitions are very similar – “A former member of a group, company, or organization” (Cambridge University Press, 2017). However, interpretations can vary. Universities sometimes redefine a wider or narrower scope of alumni. Wider definition comes by including in the concept all persons who have ever entered the organization, even if not formally graduated (e.g. students who are excluded because of academic debts). Narrower concept, on the contrary, deals only with those graduates who after graduation meaningfully reconnect to their alma mater and participate in university activities. (Medeisiene *et al.*, 2017).

Some universities involve students in alumni definition calling them “alumni in training” – according to this concept, universities engage students in alumni activities as if they were alumni (Pumerantz, 2005)(Cohen, 2016)(Feudo, 2010). This concept helps to demonstrate alumni relations to the students from the very beginning of their life in the university thus making them loyal alumni after the graduation.

Alumni are one of the most important assets of the universities (Chi, Jones and Grandham, 2012) but what is their role and place in the university?

Many authors have researched HERI customers and their segmenting according to the impact, roles, as primary, secondary, tertiary or as internal and external. Defining HERI customers is not a trivial task and there is a lot of scientific discussion about it (Weaver, 1976; Juran, 1988; Conway, Mackay and Yorke, 1994; Kotler and Fox, 1995; Pereira and Silva, 2003; del Barrio-García and Luque-Martínez, 2009; Taiwo, 2010).

Customer definitions describes individuals or organizations that purchase the goods or services at a particular time period or intend to do so (Britannica, 2011; Oxford university press, 2017). Alumnus (alumna – female, alumni - plural) is “a person who has attended or has graduated from a particular school, college, or university” (Cambridge University Press, 2017). At first customer and alumni definitions are controversial since customer definition describes present or future transaction but the alumni definition regards the transactions and relationship that have ended. This has been a common perception in European HERI for a long time. Recently most of universities implement alumni relations management as a common practice and an important part of HERI strategic management. Alumni are HERI customers not only in when they actually purchase HERI services but also continuously because the value of their diploma always depends on the HERI performance at that particular moment (Kotler and Fox, 1995; Heckman and Guskey, 1998; Taiwo, 2010).

Author offers new Alumni Triple Helix Segmentation principle that adds to typical segmentation of finances and knowledge the binding element – co-creation capacity. In each segmentation component four subgroups emerge – streamline, status, star and strategic. Such segmentation divides alumni in three strategically most important segments and additionally in each of these segments allows engaging alumni according to their level of activity. This segmentation will set up basis for alumni knowledge management according to their engagement segment and level of activity. The concept is adapted from key account management. There the customers are segmented according to their attractiveness and organization’s relative business strength as seen by the customer. (Homburg, Workman and Jensen, 2000) define KAM “as the designation of special personnel and/or performance of special activities directed at an organization’s most important customers”. Currently industry applies KAM also in B2C and it is supported with university programs (University of Pretoria, 2016).

4.2 Alumni knowledge management

Alumni knowledge management model (Figure 2) exploits the concept of alumni being customer – that changes attitudes and perspectives towards the strategic activities and knowledge that HERI intends to manage in alumni matters. The model also discovers

all possible combinations of HERI-alumni intersections by combining university strategic functions with typical alumni relations processes and implementing knowledge management cycle in each of these intersections.

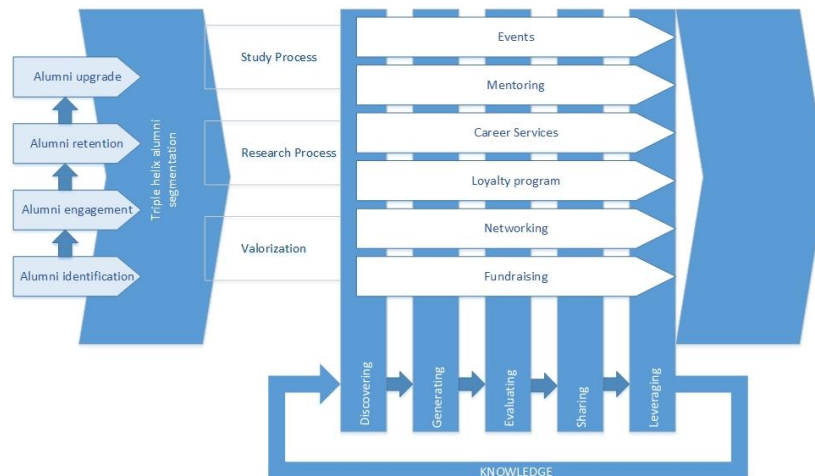

Figure 2 Alumni Knowledge Management model inspired by model of (Gebert et al., 2003)

Model is based on Alumni Triple Helix Segmentation and Key Account Management principles of customer upgrade from least active place in segmentation to the most engaged position. The approach involves customer (this case alumni) identification, engagement, retention and upgrade to the next segmentation (involvement) level. Alumni engagement and knowledge management takes place in all intersections of university and alumni activities. Typical HERI processes are study, research and valorization processes (Draghici et al., 2015). Typical alumni relations processes are event management, mentoring, career services, loyalty program development, networking and fundraising activities. Knowledge management cycle (Jashapara, 2004) involves knowledge discovering, generating, evaluating, sharing and leveraging in each of the intersections of university and alumni relations processes. However full implementation of such a model requires significant organizational and IT support as well as intrinsic interest and understanding in all HERI organizational structures to engage alumni.

5 Conclusions

Universities in their lifetime always have engaged in cooperation with their alumni. The underlying reasons for organized alumni gatherings and university deliberate relationship building with alumni have been the same in 18th century as well as nowadays - networking among alumni, alumni lobbying and knowledge support for improvements in the universities and financial support by alumni to the university. Nowadays, because of rapid technology development and the globalization, higher education market is radically changing thus it is important to research which activities exactly support alumni

long-term engagement in universities. Literature review reveals that alumni are HERI customers not only in direct meaning when they purchase HERI services but also continuously because the value of their diploma always depends on the HERI performance at that particular moment. By applying systems approach we see the wider role of alumni – they are a bridge between HERI and the society at large. The real success of the HERI is often measured by the success of its alumni and how they represent its values in everyday lives and work. Strengthening this bridge involves two way cooperation, including alumni in all possible life stages of HERI in a participatory way. Research proves that universities must invest in alumni relations to improve alumni engagement and views about continuous collaboration with HERI. University must acknowledge alumni as customer role and treat them respectively at the same time demonstrating them challenges and possibilities in this role. Alumni knowledge management is until recently underestimated resource of HERI and community development as a whole. Author has developed a model that describes alumni knowledge management in all university and alumni process intersections.

Abstract

The aim of this paper is to describe and analyse a best practice event organized and managed by the Italian Public Administration concerning the achievement of UN's Sustainable Development Goals (SDGs). Specifically, we are going to answer the following research questions: RQ1, Which approach is the most appropriate for the management of highly complex events and inter-institutional projects?; RQ2, Which is the connection between 2030 Agenda and great events?

Large-scale events, which are characterized by a dynamic complexity involving different national public administrations and institutional levels, require a special attention in selecting an adequate event management systems. For this reason, after a detailed literature review on network management, this chapter aims to define the basics of a theoretical framework useful to understand collaboration among several actors, considering that participative approaches should help achieve outcomes in a more effective way. Furthermore, this paper explores the concept of sustainable development and focuses on the traditional elements of social, environmental and economic pillars within context of planned events.

Given the objective of this work, the analysis of a best practice event will be useful to identify the main variables, in terms of sustainable strategic planning, execution and control, required to achieve the greatest level of efficiency in terms of cost optimisation and quality of service delivery, also exhorting the Italian public sector to look for a structural renewal, to better use its available resources, as well as to foster a global sustainable growth. From this point of view, a relevant experience is the case of the Extraordinary Jubilee of Mercy, coordinated by the Prefect of Rome, explored in the last section of the paper. Indeed, the latter, decided to adopt actions consistent with sustainability standards, thanks to the design of an inter-institutional network and the engagement of institutions at different levels. The Prefect of Rome achieved, in a very short term, three main results: coordination of the activities of the working groups (SDG 17, “Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development”); integration of internal and external surveillance and

communication systems (SDG 9, “Build resilient infrastructure, promote inclusive and sustainable and foster innovation”); collaboration with higher education institutions to acquire and disseminate knowledge (SDG 4, “Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all”). To systemise and combine the outcomes of these processes, as well as to analyse their consistency with sustainable development, the System Thinking technique was used.

Keywords – Network management; 2030 Agenda; Sustainable Development Goals; Sustainable events; Italian Public Administration

Paper type – Practical Paper

1 Introduction

Events, especially the large-scale ones, produce several impacts on the territory, which cannot be exclusively related to an economic nature. The evaluation of the environmental and social effects (according to a triple bottom line approach) of an event is very complex, not only because the effects are often indirect and intangible, and therefore difficult to be perceived and measured in time, but also because the variables which affect the outcomes are actually manifold. Moreover, because of the wide range of the goals pursued and of the heterogeneity of the subjects involved both directly and indirectly (stakeholders), it appears very difficult to single out the parameters according to which measure the success of an event. Several scholars, indeed, state that “the performances measures are different according to the subjects involved in the valuation (promoters, organizers, communities, sponsors, public...) and to the goals pursued” (Gartner & Lime, 2000; Bowdin et al., 2011; Richards & Palmer, 2010).

Consequently, the organizational efficiency needs to pivot on the specific competencies of the civil and ecclesiastical authorities. The visitors’ hospitality will result attentive, inclusive and relished inasmuch as the institutions will be able to work in synergy and harmony.

Interesting theoretical inputs can also be obtained from the analysis of the case study of the Extraordinary Jubilee of Mercy, co-designed and co-organized by two national governments (Italy and the Vatican State) and involving the Catholic Church “as a recognized universal international institution” (Meneguzzo et al., 2017).

According to what has just been written, in the last Jubilee, a sort of “responsible cooperation” among the several stakeholders has been enacted, with the activation of bidirectional relations between all the involved subjects and of concrete steps in a long-term vision, keeping in mind what the event will leave to the territory, the so-called legacy (Allen et al., 2011).

This paper highlights some initiatives and operations carried out during the 2016 Jubilee of Mercy which might steer the sustainable growth of the City of Rome if implemented on the long run. To this aim, this analysis focuses on some of the

Sustainable Development Goals which constitute the most ambitious challenge for the international community until 2030.

Our contribution starts from the analysis of this event, in which the authors have been directly involved as participants to the inter-institutional task force in charge of managing the event (led by the Technical Secretariat for the Jubilee). The paper is divided into three sections: the first one is dedicated to a thorough analysis of the existing literature on event management, with a focus on the sustainable theories of the planning, implementation and evaluation of large-scale events. In the second section, the case of the Extraordinary Jubilee of Mercy is examined, with reference to the management and organizational decisions taken by the Italian institutions. In the end, section three presents a conclusive evaluation of the issue.

2 Theoretical network management framework

Participative approaches could be useful for analyzing the design and the implementation of the event ‘Extraordinary Jubilee of Mercy’, so, theoretical framework includes studies related to the organizational and network management sciences, in particular to the coordination mechanisms in order to understand the effectiveness of the network in terms of guidance and building stakeholder commitment (Mandell, 1999; Klijn, 2010).

Prominent international scholars have suggested that, in complex and changing times, in fragmented societies, participative approaches (Agranoff and McGuire, 2001; Milward and Provan, 2003) should help accomplish outcomes in a more effective way. In their researches, complexity is referred to as the increased connectivity among organizations (public, private and nonprofit actors) at different levels (local, national and supranational), interacting in an external and multi-dimensional environment (economic, social and cultural).

There is a growing need for contemporary governments to look at innovative methods to deal with complex and social problems, the so-called ‘wicked issues’ (Clarke and Stewart, 1997), and networks seem to be at the forefront of this change (Mandell, 1999); thus the engagement of public actors is considered the rule rather than the exception (Ferlie et al., 2005).

As a consequence, in the last stage of public governance, the shift to network management (Kickert et al., 1997) happened naturally according to the societal requirement going beyond the traditional models, which were inadequate to understand the features of the external environment, considered complex, dynamic and diverse (Eljassen and Kooiman, 1993). As stated by Isett et al., the study of networks in public administration literature has rapidly evolved, identifying three mainstreams that emphasize exactly how networks in the public sector are nowadays used as a mechanism to encourage collaborations (Isett et al. 2011). Shortly, these are: (i) policy networks, as a set of public agencies, private sector and nonprofit organizations with a common interest, looking for decisions and pursuing political agendas in a specific area of policy; (ii) collaborative networks, as pools of government agencies, nonprofit and for profit

organizations, working to ensure citizens' satisfaction in providing public services and goods; and (iii) governance networks, where collective actions of several actors are required to find solutions to public issues which cannot be solved by one individual.

As stated by Pollitt and Hupe, "networks are envisaged as the more adequate way to make sense of contemporary complexity", and problems are identified in the lack of knowledge, the involvement of many interdependent players and various decision-making arenas (Pollitt and Hupe, 2011). Thus, networks are considered multi-organizational arrangements in managing problems; they overturn traditional governing structures through formal and informal ties, characterized by reciprocity, mutual interdependencies and various individuals and organizational actors involved in the formulation, implementation and delivery of public services.

In this sense, public networks are recognized by scholars (e.g. Milward and Provan, 2003), as well as by practitioners and even policy-makers, as a model of governance characterized by quality, flexibility and innovativeness in improving coordination in order to increase efficiency and effectiveness (e.g. in the arenas of health and social care, local development, education, security and culture). Network management investigates the way networks are governed and managed and, in particular, which are the mechanisms to promote and build stakeholders' commitment to the final achievement (Provan and Kenis, 2008).

3 Theoretical sustainable event management framework

In recent times, the attention for sustainability, also in events, has increased. By sustainable is defined "a development that satisfies the needs of the present without compromising the ability of future generations to satisfy their own needs" (World Commission on Environment and Development, 1987).

By approaching the event evaluation in terms of sustainability, it is necessary to examine different points of view: it is the case of the environmental, cultural, economic, political and social sustainability. Thus, "for an event to be sustainable, it should be part of a larger strategic project of cultural, social and economic development" (Richards & Palmer, 2010).

The capacity to organize and manage events based on the principle of sustainable development implies the existence of strong and cooperative institutions able to initiate inclusive, representative and reactive decision-making processes (target 16.7), involving all the stakeholders according to the "quintuple helix scheme" theorised by Carayannis and Campbell (2010). In this model, the government, businesses, universities and civil society cooperate toward the sustainable development, sharing resources, instruments and especially, know how. The virtuous circles initiated by the cooperative approach stimulate, indeed, the crossed fertilisation of sustainable ideas and projects (innovation) able to overcome the limitations of the "mental models" (knowledge mix, expertise, capacity) of the single subjects and of the limited resources available. In this way, large-scale events cannot be clustered within the boundaries of a single public administration or agency, but are characterised by a dynamic complexity that involves several offices and

institutional levels (central/federal; regional; metropolitan/local). Moreover, in times of economic crisis and expenditure cuts, institutions arise as solid only when they manage to operate soundly in terms effectiveness, responsibility and transparency (target 16.6 “Develop effective, accountable and transparent institutions at all levels”) but also with economy and efficiency.

For these reasons, it is important to examine, in the upcoming section, the Extraordinary Jubilee of Mercy, an example of best practice of the Italian public administration. The need for achieving extraordinary objectives with ordinary resources led the Prefect of Rome, through the Technical Secretariat for the Jubilee to single out modern, innovative, shared and long-lasting solutions for the management of the event, based on the synergies between all the subjects involved and in line with the SDGs (Fiorani & Di Gerio, 2016).

4 Case Study: The Extraordinary Jubilee of Mercy

In the Catholic tradition, the Jubilee is a major religious event which dates back to the XIV century with Pope Boniface VII. The 2016 Holy Year was defined “extraordinary” not only because it does not fall within the traditional 25-year timeframe, but also because it was the first “thematic” – dedicated to the Mercy – and “decentralised” Jubilee in the history of Christianity. With an unprecedented decision made by Pope Francis, the Holy Doors were opened also in the cathedrals and sanctuaries in all the Dioceses of the world, including 91 States and 560 Doors of Mercy. In line with this “globalist spirit”, the first Holy Door was opened in Bangui, Central African Republic, on the 29th November 2015. The Extraordinary Jubilee of Mercy, announced by Pope Francis on the 11th April 2015 and formally inaugurated on the 8th December 2015, ended on the 20th November. More than 21 million people arrived to Rome during 2016 from 36 different countries. Such an exceptional inflow of visitors and notable personalities determined important implications for the hospitality system in general, and for the mobility services, infrastructures and national security.

As Morcellini said (2016), “the Jubilee of Mercy set a milestone in Rome’s capacity to organize large-scale events, offering a very different image of the Capital from the one pictured by the medias”.

In this way, the strategic management of the event was assigned by the Italian and the Vatican State governments to the Prefect of Rome. The Prefect was in charge of defining the planning framework for managing the event and of ensuring that the whole information and communication systems worked. In view of these objectives, the Italian government (DPCM, the 4th September 2015) resorted to an innovative instrument: the Prefect of Rome was supported by the Technical Secretariat for the Jubilee (TSJ)¹, a task force aimed at fostering the cooperation among the several local administrations and the integration of their operations. Under the management of the TSJ, the Prefect created

¹ The ‘Technical Secretariat for the Jubilee’ included 10 experts representing public administrations and territorial institutions (Ministry of the Interior, Lazio Region, Municipality of Rome), as well as delegates from Civil Protection, Carabinieri Corps and Fire Corps.

eight thematic working groups, with the task of linking the different areas, and invited all interested institutions to participate (Figure 1).

All parties involved were proactive and accepted to share their resources, their information and competencies: this led to the creation of a new concept of large-scale event, which capitalizes on the synergies between all institutions involved, both at the intra-institutional and at the inter-institutional and inter-governmental levels, and between the eight working groups.

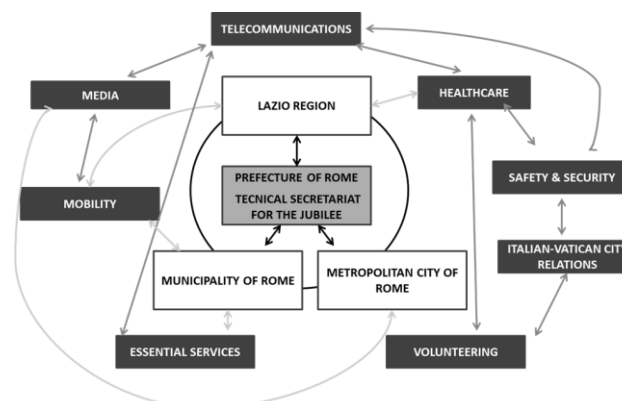

Figure 1. Inter-institutional synergies
(Di Gerio C., Fiorani G.)

A thorough evaluation of the direct and indirect effects, both on the short and medium-long term, is an essential part in the reviewing phase of the event management. Similarly, the social and environmental impact needs to be assessed, in line with the UN Sustainable Development Goals.

The System Thinking map (Figure 2) shows some of the effects related to the Jubilee.

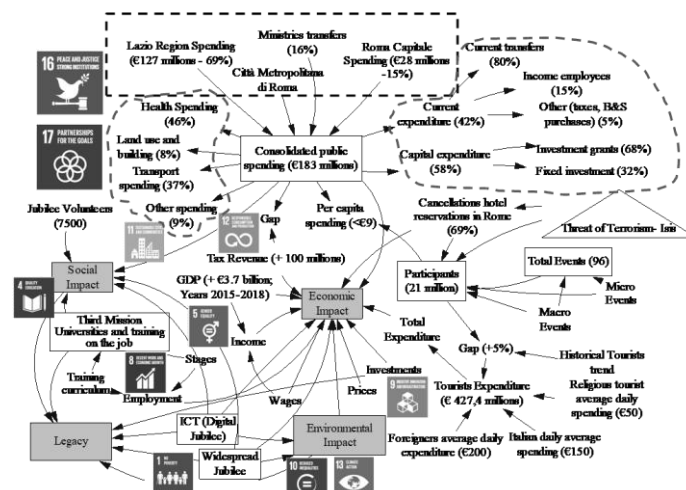

Figure 2. Multi-dimensional impacts: a sustainable Jubilee
(Di Gerio C., Fiorani G.)

As Figure 2 shows, the partnerships (SDG 17, “Partnership for the goals”), i.e. the inter-institutional collaborations between public administrations, nonprofits institutions and enterprises, through the eight thematic working groups coordinated by the Technical Secretariat, together with the presence of strong institutions (SDG 16, “Peace, Justice and Strong Institutions”), are the key success factors of the last Jubilee.

The cooperation with university proved to be paramount (SDG 4, “Quality Education”). This goal, which underlines the link between primary education and professional training, was achieved through a memorandum of understanding between the Prefecture and the three State universities of Rome (La Sapienza, Tor Vergata, Roma Tre) which ensured a scientific and organisational support to the planning, management, communication and post-event evaluation activities. In the “Third Mission” field, the three public universities contributed significantly to the success of the event, sharing their know-how and resources (teachers, recent graduates, spaces and equipment) and offering to students the opportunity to serve an internship, with the aim to let them put into practice what they learned.

Many technological (product and process) innovations (SDG 9, “Industry, innovation and infrastructure”) realised during the Jubilee had a relevant positive impact on the responsible production and consumption models (SDG 12, “Responsible Consumption and Production”). A bright example is the inter-institutional centralised Jubilee Management Room (JMR), hosted by the System Room of the Rome Local Police forces, which played a major role in coordinating the Jubilee-related operations on the field, in monitoring the unfolding of events and assessing the different scenarios in real time. The JMR took advantage of an innovative shared cartographic system so to support the operations of all the Authorities watching the Jubilee events and flank the operation rooms of the single national and local police corps. Within the JMR, the creation of an integrated communication system based on TETRA radio allowed the numerous security forces on the field to share information through a single radio frequency. The JMR also had control on a comprehensive video-surveillance system based on the feed of the single local administrations with the aim to ensure a high degree of security for both the pilgrims and the local community. Thanks to the software and hardware sharing, the numerous entities involved through inter-institutional and public-private partnerships managed to rationalise their projects and intervention policies.

The JMR and the coordination activity of the Prefecture allowed to create public value and to initiate an “intelligent” management process, through a sound use of the resources available on the territory, and constituting a best practice model to be applied to future complex events. It is noteworthy that the planning carried out by the TSJ during the Holy Year was characterized by a particular attention to maximising savings and making the spending more efficient (SDG 12). The short timing (with an advanced notification coming just eight before the inauguration of the event) and the scarcity of financial resources demanded to resort to innovative solutions, including zero cost measures, considerable private capitals contributions, and the exploitation of the equipment already in possess of the national and local administrations.

This Jubilee was also modern, digital and built on a network basis. The 2016 Holy Year was, in fact, the first in the age of social networks, tablets and smartphones, in the era of the continuous connection to the Internet. The Jubilee website and App provided information on monuments and churches, jubilee on foot itineraries, and mobility services. Communication was coordinated by the Italian institutions through the creation of a single website dedicated to the Jubilee called “Roma per il Giubileo” and a physical single Press Point from which all relevant information was conveyed.

The JMR and the single Press Point constituted the brightest examples of the integration of the several entities and administrations which, going beyond their identities and traditions, were called upon to joining their forces within a single operations room, under the same supervision and with a shared “Roma per il Giubileo” logo.

In order to explain more exhaustively the success of this large-scale religious event and the efforts made by the governmental institutions, it is noteworthy to address the link between the Jubilee and the other SDGs.

The interventions to make the City of Rome more inclusive, safe, flexible and sustainable during the event were manifold (SDG 11 “Sustainable Cities and Communities”). Concerning the mobility aspect, the public transport service was strengthened so to meet the high demand peaks in the celebration days and to guarantee the social and environmental sustainability of the event. Moreover, thanks to a single direction of the mobility information¹, it was possible to harmonize the messages about eventual service disruptions or delays, and to convey urban and extra-urban mobility updates in case of necessity. The development of public transport made the City of Rome more sustainable in terms of road system, emissions reduction and livability. The positive environmental impact (SDG 13 “Climate Action”) of the Jubilee is also related to its global and widespread character, which minimized the movement of pilgrims allowing them to obtain the indulgence even in their own countries.

In order to crack down on illegal and unfair treatments to tourists and to raise the security perception of the Italian capital, Codacons, a network of associations for the consumers protection, realized a project called “Sportello del Pellegrino” aimed to provide legal assistance to pilgrims in more than 100 languages and fully managed by volunteers. Furthermore, several initiatives were achieved in favor of disabled pilgrims (SDG 10 “Reduced Inequalities”), in order to guarantee the righteous services. In this way, the App for urban mobility (Mapful) provided information on accessible routes for disabled.

The Jubilee was the driver for the economic and employment growth in the City of Rome and its Province, in particular in the tertiary sector (SDG 8, “Decent Work and Economic Growth”). Nevertheless, the tourist inflow forecasted in 2015 was considerably reduced by the threat of ISIS terrorist attacks, the characterization of this event as a “widespread” Jubilee and the resort to unconventional staying options such as flat-sharing platforms and ecclesiastic structures.

¹ Using ICT to support pilgrims and tourists’ mobility and transfer.

5 Conclusions

The case study here analyzed shows that no one of the 17 2030 Agenda SDGs is feasible without the contribution of strong institutions. In this framework, the so-called quintuple helix cooperation, made up by governments, businesses, non-profit organizations, the civil society and the universities, emerged as paramount in order to ensure the success of the Jubilee.

Moreover, the issues of sustainable development are deeply rooted in an innovative, efficient, digital open and cooperative in public administrations. Based on this recent experience, the extraordinary spirit of sharing and cooperation which inspired the activity of all those involved in the success of the Jubilee of Mercy might constitute a valid example for all the future large-scale events in Italy and abroad. In fact, the challenge for great events is to think over development model in terms of sustainability and efficiency in favor of integration, cooperation, social innovation and able to create inclusive networks; thus the engagement of several public actors is considered the rule rather than the exception.

In conclusion, the case of the Extraordinary Jubilee of Mercy, in our opinion, provides useful theoretical and empirical indications in the field of public management and governance and represents an important conceptual and operational challenge for the Italian public administration system. The integrated system for the management of the event, based on quintuple helix approach and integrated networks, could provide important indications for the future management of large events (sports, culture, promotion of the economy and the image of the country) and for the management of intervention policies facing environmental emergencies (such as recent earthquakes in Central Italy). This change of mind could be useful to turn a best practice into ordinary reality.

The other relevant aspect emerged from the paper concerns to the introduction of a multidimensional assessment of the impact of the event. Short and medium-long term aspects should be taken into consideration, such as social and environmental impacts and legacy, in line with United Nations' Sustainable Development Goals (SDGs). Goal 16 ("Peace, Justice and Strong Institutions") is definitely the one closer to a religious event like this and is the one which better meets the aims of the Jubilee: to promote pacific and inclusive communities and societies for the sustainable development. The extension of the event in the several countries (widespread Jubilee), the legal support provided by the Sportello del Pellegrino, the operations countering corruption and criminality, the public access to information, the promotion of initiatives to reduce inequalities, and the role played by the institutions for a representative, inclusive and reactive decision-making process are all examples of effectiveness, responsibility and transparency.

To conclude, we can answer the research questions stated in the Abstract section.

For what concerns RQ1 (*Which approach is the most appropriate for the management of highly complex events and inter-institutional projects?*), the case of the Extraordinary Jubilee of Mercy highlights the need to adopt a syncretic public policy implementation approach. Indeed, the syncretic approach adopted by the Technical Secretariat for the

Jubilee achieved important results in terms of continuously rebuilding the network of interested actors and developing a collaborative network. Several issues were solved, such as those linked to the traditional institutional fragmentation at local level, the complexity of the network of actors involved, the strong cultural resistance of several stakeholders, both public and private, the implementation of systemic actions, and the lack of financial resources. Despite the high complexity of the event, the TSG was able to avoid a governance process that could be influenced by too many crowded working groups and meetings. Other methodologies, such as the implementation scenarios and the evaluability assessment, largely adopted in the US administration since the '80s (Poister, 1981), could provide useful indications for the management of large inter-institutional events. Ready-to-use technologies, the employment of available equipment and the interaction among public and private administrations were the key factors for delivering a high degree of efficiency and quality.

Concerning RQ2 (*Which is the connection between 2030 Agenda and great events?*), the integration of economic, environmental and social measures allows us to obtain a holistic view of the impacts generated by an event and, at least, its real level of sustainability. Such, material and immaterial legacy is added, considered as the starting point for the creation of a sustainable and smart city attentive to improving the quality of life of its citizens, businesses and institutions and the general well-being of the community.

As many studies show (A GlobeScan, 2016; www.asvis.it; AIESEC, 2017) additional governmental efforts are required over the next 12 years in order to lead the world countries to the full implementation of the 2030 Agenda, also with respect to event management. The Italian government committed itself to this aim with resoluteness and resilience, as in the case of the Joint Italian-German-French Declaration on the US withdrawal from the Paris climate agreement, bearing in mind the outstanding results achieved in the organization of the Jubilee.

Abstract

In recent years, positive correlations between some factors of collaborative group task processes and the increasing of collective intelligence (CI) have been presented. This work introduces a hypothesis that argues the existence of a new factor of positive influence for the increasing of collective intelligence in collaborative group tasks operating in cooperative environments: self-determination. Therefore, we present an argumentation based on Cooperative Multiagent Systems that spotlights the significance of self-determination in these particular environments. Furthermore, we also introduce a preliminary design of an experimental setup and a methodological framework for validating the hypothesis empirically in human organizations. Our propose consists on measuring, on the one hand, the level of self-determination from the individuals that participate on the decision-making processes, and on the other hand, on measuring the level of collective intelligence achieved by performing collaborative group task. Finally, we propose to use statistical analysis to explore if there are positive correlations between self-determination and collective intelligence in cooperative environments, such as collaborative organizations.

Keywords – Collective Intelligence, Self-determination, Collaborative Organizations, Cooperative Multiagent Systems, Self-determinant Governance

Paper type – Academic Research Paper

1 Introduction

This work argues that individual *self-determination* empowers organizations to collectively take more intelligent decisions, under the assumption that the problems they are solving are collaborative, and the individuals that shape the organization can be considered minimally rational, i.e., the actions they decide to execute guarantee an increase of their performance in the environment (Russell & Norvig, 2004). According to (Romme, 1999), *self-determination* in an organizational or decision-making process is the ability of an individual to block collective decisions that he or she considers may negatively affect their expected utility. In turn, *collective intelligence* is understood as the collective ability to decide joint actions that allow improving the value captured from the environment, i.e., increase their utility.

This argument is based on the theory of Cooperative Multiagent Systems (Wooldridge, 2009, Ferber & Weiss, 1999), and arises from some considerations on how, in cooperative environments, there is an alignment between the level of individual expected utility, and the level of expected utility of the organization; in such a way that the organization only maximizes its utility when all its agents also maximize their individual utility (through the same joint action), and vice versa. In this context, rational agents having the ability to block actions that are considered to be detrimental to their expected utility, ensure that no not-intelligent joint actions are executed.

We also present an experimental setup for complementing the theoretical validation with an empirical one, by reporting the correlation between individual self-determination and collective intelligence. We introduce a methodological framework for measuring, for each decision made collectively, the level of self-determination self-perceived by individuals, based on tools for developing measurement models provided by the Self-Determination Theory (Ryan & Deci, 2000); together with a method for measuring the level of Collective Intelligence (*CI metric*) in collaborative group tasks based on tools introduced by (Woolley et al., 2010, Engel et al., 2014, 2015).

The interest to delve into factors of positive influence for increasing collective intelligence in these contexts is fundamented in its potential impact on new organizational typologies such as Collaborative Networked Organizations (CNO) that emerge in the context of research in Human-Computer Interaction and Collaborative Crowdsourcing (Engel et al., 2015, Bingham et al., 2015), focused on studying the potential for *the many to outperform the few* based on new collaboration opportunities resulting from novel means for people to access information, services and other resources (Camarinha-Matos et al., 2009; Dutton, 2008).

Furthermore, the demonstration of an existing positive correlation between individual self-determination and collective intelligence presents a two-fold motivation for designing human-centric governance systems that respect individual self-determination, such as the existing Sociocracy (Endenburg & Bowden, 1988), Holacracy (Robertson, 2007) or Sociocracy 3.0 (Priest & Bockelbrink, 2017), as well socio-technological artifacts for facilitating its adoption. On one hand they are rendered indispensable for increasing the collective intelligence of the organization adopting the governance system, while

resulting in an increase in satisfaction of the needs of the individual humans that compose the organization.

In recent years, positive correlations between some factors of collaborative group task processes and the increasing of collective intelligence have been presented, both in groups collaborating face-to-face and on groups collaborating through socio-technological systems. Woolley et al., (Woolley et al., 2010) highlighted three factors that show strong correlations with the increase of collective intelligence in groups, and consequently can be considered as factors of positive influence: (1) the average of social sensitivity, i.e., the (average) ability to correctly detect the feelings and viewpoints of people by observing their facial features, (2) the number and distribution of speaking turns, and (3) higher proportion of women in groups. However, as far as we could investigate, there is no systematic research by these authors, or others, that focuses on exploring the level of self-determination from individuals who participate in a decision-making process as a factor of positive influence for the increasing of collective intelligence. Hence, we understand that this positive correlation is an unexplored factor that is worth investigating.

This paper is organized as follows. Section (2) presents and develops the main argument, providing definitions of the necessary concepts and explaining the causality of the proposed correlation, i.e., that the increase of individual self-determination leads to the increase of collective intelligence in particular environments. Next, Section (3) introduces the proposed experimental setup for validating the hypothesis empirically. On the one hand, in (3.1) a particular adaptation of the Self Determination Theory (Ryan & Deci, 2000) questionnaires for scale-building is proposed, in order to measure the level of self-determination from each individual participating in a decision-making process. On the other hand, in (3.2) the framework used by (Woolley et al., 2010, Engel et al., 2014, 2015) is introduced, used for measuring the level of collective intelligence of a group through the resolution of collaborative tasks. Finally, the main conclusions are presented in Section (4) and the references used in Section (5).

2 Self-Determination as an heuristic for *Optimal Joint Policy* search

In agent theory (Russell & Norvig, 2004; Wooldridge, 2009), *intelligence* is defined as the ability of an agent to choose those actions that maximize its utility in a work environment. The difficulty for finding these intelligent actions depends on some characteristics of the agent's working environment, namely, whether it is: *static* or *dynamic* (i.e., the environment behaviour can change over time or not); *deterministic* or *stochastic* (at any given state, the same action always produces the same outcome, that is, for the same action, the environment always transitions to the same successor state); *episodic* or *sequential* (either the optimality of future actions depends or not on the present action); totally or partially observable (agents can determine or not what is the current state of the environment), and *single agent* or *multiagent* (there are other rational agents operating in the environment or not). The latter can be further characterized as *cooperative* versus *competitive* environment (explained below). Each of these

characterization results in an increasingly complex formalization of what is considered a solution to the artificial intelligence problem.

The simplest, yet realistic characterization of the problem in which our argument is framed considers a cooperative multiagent problem. A *multiagent system* can be understood as a system made up of more than one rational agents that has to be coordinated for learning those joint actions that allow them to maximize their utility in a given environment. Differently from the single agent case; in multiagent problems agents present interdependencies, that is, agents not only have to reason about which of their own actions are best for maximizing their individual utility, but they also have to reason about the effects produced by the other agents actions. In other words, agents has to learn the *joint* actions that maximize their utility, and their individual intelligence is measured in terms of these joint actions.

In the simplest workspace, i.e, the static, deterministic, episodic, totally observable, and single agent, a solution is a single action that guarantees a maximum return from the environment. When the workspace turns to be sequential, solutions becomes sequences of actions. This is the case for the well-known search and planning problems (Russell & Norvig, 2004), that help the agent to find objective states (i.e., they model the utility as zero for every state and some arbitrary non-zero positive value for the objective state). If the workspace is now stochastic (as well as sequential), sequence of actions are not appropriate, as the stochasticity of the workspace results in the same sequence reaching a whole set of possible states, with the objective state being only one of them, without certainty that it will be reached. What is required here is to maximize the probability of reaching that objective state. For that, solutions are expressed in terms of *policies*: functions from states to actions, that indicate what action should the agent execute in each state. A solution in these cases is therefore the *optimal* policy, the policy that maximizes the probability of reaching the objective state. For more general problems with a general utility function over the state space, the solution is the policy that results in the maximum *expected* utility extracted from the environment, computed from the expected utility that could be obtained starting from the initial state, and the expectation computed over all possible state trajectories the agent could traverse when acting on its policy, with bifurcations arising from the stochasticity of the actions.

Finally, in a *multiagent system*, agents present interdependencies, that is, agents not only have to reason about which of their own actions are best for to maximizing their individual utility, but they also have to reason about the effects produced by the other agents actions. In other words they have to learn which are the *joint* actions that maximize their individual utility. When the multiagent system is embedded in a sequential and stochastic workspace (and regardless of the dynamicity and observability of the environment), the solution for some agent is a joint policy that produces a maximum expected utility for that agent, that is, a function that indicates for each state (or observation in the more general case of partial observability), what is the joint action that when the agent starts at some initial state, guarantees to produce the long-run maximum expected utility for the agent. Interdependencies between the agents' actions may result in the impossibility to optimize the policy for each individual agents. In the particular case

of *cooperative* multiagent problems, agents are motivated to coordinate themselves because there is a solution that benefits all of them (win-win), as opposed to the *competitive* problems where the solution implies that if one agent maximizes its utility, another may be harmed (win-lose). So in cooperative problems, there is a policy that guarantees, not only to maximize the expected utility of the collective, but also the expected utility of each agent.

In this context, self-determination can be understood as a sensory and cognitive heuristic for finding optimal joint policies, based on the fact that in cooperative environments, any joint action that is harmful to at least one of the agents, is harmful to the organization. Therefore, providing individual agents with the self-determinant ability to block joint actions that from her own perspective could be harmful to her own individual utility, results in the blockage of joint actions that most probably are not those recommended by an optimal joint policy for the collective. In this regard, individual self-determination works as a heuristic for reducing the search space for the optimal joint policy.

3 Design of the experimental setup

In order to empirically validate the correlation between self-determination and collective intelligence, we present a preliminary design of an experimental setup and a methodological framework for data gathering and data analysis that combines both, qualitative and quantitative methods based on (Zhou, 2019). Definitive questionnaires for measuring self-determination are not included.

The main purpose is to measure the level of self-determination from each individual participating in the decision-making of a collaborative joint action, together with the level of collective intelligence (*CI metric*) reached after executing the actions produced by these decisions. According to this, a particular adaptation of the scales offered by the Self-Determination Theory is proposed for measuring self-determination (Ryan & Deci, 2000), and the framework presented by (Woolley et al., 2010, Engel et al., 2014, 2015) for measuring the collective intelligence of groups, the IC metric, is introduced.

By obtaining these measures, it would be possible to study and validate if there are positive correlations between the level of self-determination from each individual participating in the decision-making and the level of collective intelligence (CI) arising by performing the group task. The measurement methods are explained in detail in the following sections.

3.1 Measuring self-determination

In order to measure the level of self-determination, Self-Determination Theory (Deci & Ryan, 2000) offers tools for designing different scales based on *self-regulation*, which assess domain-specific individual differences regarding the types of motivation or regulation. Since, according to Self-Determination Theory, motivation can vary in the

degree of being *autonomous* versus being *controlled*, or in other words can vary depending on the level of self-determination (Deci & Ryan, 2015).

The basis for designing our particular measurement tool are the questionnaires for measuring self-determination in work environments such as the Work Extrinsic Intrinsic Motivation Scale (WEIMS) (Tremblay et al., 2009). These questionnaires have been adapted for measuring self-determination in particular work contexts, also for virtual context such as crowdsourcing micro-tasks platforms (Naderi, 2014). However, to the best of these authors' knowledge, there are no questionnaires designed for properly analyzing the level of self-determination in collaborative decision-making processes. Instead, this aspect has been only partially covered in more general questionnaires related to the level of satisfaction at work (Deci et al., 2017). Thus, a questionnaire to carry out this concrete measurement would be designed following the proposal of (Zhou, 2019): a mixed methods model of scale development and validation analysis. This method introduces 5 different steps.

Step 1: Qualitatively investigating the scale construct. In this stage the phenomenon that is going to be studied is defined as the construct of the scale: self-determination. To this end, we will propose an ethnographic approach to carry out fieldwork (participant observation, semi-structured interviews) over different organizations operating with self-determinant governance structures in order to look into which issues may affect the levels of self-determination of individuals' decision-making, such as the decision-making mechanism; the invisible power structures (Freeman, 1970), i.e, informal networks that exercise dominance in the form of social pressure, or the overload associated with the inclusion of all individuals in decision-making processes.

Step 2: Converting qualitative findings to scale items. Transforming qualitative data to measurable items is a mixing strategy that indicates how qualitative and quantitative data are integrated. In this work, the main goal objective is to spotlight undercovered variables that can affect the levels of individual self-determination discovered in the field work, and classify them in the dimensions or levels of self-determination proposed by Ryan & Deci (Ryan & Deci, 2000). This work differentiates between *autonomous motivation* and *controlled motivation* and suggests that behaviors can be classified based on the degree to which they are autonomous or controlled. Therefore, they introduce a self-determination continuum showing types of motivation with their regulatory styles, loci of causality, and corresponding processes. From more self-determinant to nonself-determinant they distinguish between: (1) intrinsic regulation, (2) integrated regulation, (3) identified regulation, (4) introjected regulation, (5) external regulation, (6) amotivation. In order to explore and test the variables discovered in the fieldwork, a Lickert scale questionnaire would be designed for relating sets of questions with the different dimensions of self-determination proposed by Ryan&Deci (Ryan&Deci, 2000).

Step 3: Conducting mixing validation to review items' content-based validity. Mixing validation indicates that both qualitative approaches (reflection, debriefing, panel review) and quantitative methods (sorting and calculation) are used to validate that the selected items or constructs from the field work tackle exhaustively the construction of the scale to be measured.

Step 4: Administering the scale on the target population. The quantitative survey is a primary method to administer the new instrument (May, 2001). Accordingly, the questionnaire would be sent to a representative sample of the scale we want to measure. Issues related to the size and sample distribution requirements will be considered, specially that advanced statistical analysis, such as factor analysis, require hundreds of responses for each item.

Step 5: Conducting quantitative validation to examine item's construct-based validity. The responses of the items will be analyzed statistically and validated using factor analysis methods (Stevens, 2012).

3.2 Measuring Collective Intelligence (CI)

As it have been shown in (Woolley et al., 2010; Engel et al., 2014; 2015), groups can be characterized by a collective intelligence factor that measures their ability to collectively perform in a wide range of different tasks, which allows the prediction of the groups' performance on other tasks in the future. That is, like individuals, groups have characteristic levels of intelligence, which can be measured systematically through the Collective Intelligence metric (CI metric) based on the statistical approach that psychologists used to measure individual intelligence (Woolley et al., 2015).

In all these experiments, three factors were significantly correlated with the collective intelligence of a group: (1) the average of social sensibility from group members, (2) the number of speaking turns, i.e., the groups where the conversation was dominated by some people express less intelligence than those where conversation is more distributed, (3) higher proportion of women in groups, since women show a better average on social sensibility. However, to the best of these authors' knowledge, there are no systematic research by these authors, or others, that focuses on exploring the level of self-determination of individuals who participate in a decision-making process as a factor of positive influence for increasing of intelligence collective. Consequently, we propose to use the CI metric tests used by (Woolley et al., 2010; Engel et al., 2014; 2015) for measuring Collective Intelligence. These tests are based on a selection of tasks from all quadrants of the McGrath Task Circumplex, a well established taxonomy of group tasks based on the coordination processes they require. These tasks include solving visual puzzles, brainstorming, making collective moral judgments, and negotiating over limited resources. Furthermore, these IC metric tests have been evaluated both, in face-to-face experiments and also in online experiments, i.e., technology-mediated, through a testing platform. Thus, we propose to adapt the online testing platform presented in (Engel et al., 2014;2015) to facilitate participation.

Finally, for exploring if there is a positive correlation between the level of individual self-determination and the increasing of collective intelligence in a group, we propose to embed the questionnaires designed to measure the level of self-determination to the online testing platform used by (Woolley et al., 2010; Engel et al., 2014; 2015) for measuring the CI metric from a group that solves collective task collaboratively. Accordingly, for each completed task we will obtain, on the one hand, the CI metric score associated with the task; and on the other hand, the level of self-determination expressed

by each of the participating individuals. With this pairing, we will be able to explore if there are positive correlations through different statistical analyzes, i.e., we would be able to check if the tasks with a higher CI metric score are also those in which the participants express a higher level of self-determination.

4 Conclusions

In this work, we introduce the hypothesis that individual self-determination is a factor of positive influence for increasing collective intelligence in cooperative multiagent problems in sequential stochastic environments. To validate it, a theoretical argument has been presented as well as an experimental design to perform an empirical validation.

In section (2) an argument framed in agent theory (Russell & Norvig, 2004) is presented. As it have been shown, theoretically there is an existing positive correlation between *self-determination* and the increase of collective intelligence in cooperative multiagent systems because in this particular contexts, any joint action that is harmful to the organization is harmful to at least one of the agents, and vice versa. Consequently, as it has been shown, *self-determination*, i.e., the individual capacity of an agent to block collaborative joint actions when she thinks that it may affect her individual expected utility, serves as a heuristic to collectively compute the search for the optimal joint policy of the organization.

This heuristic is based on reducing the search space of the optimal joint policy by discarding those joint actions that sure are not in the optimal joint policy, i.e., that have been objected by at least one of the individuals, and therefore, are not collaborative. Consequently, it is assumed that when discarding non-collaborative actions, the remaining joint actions, those that are part of a joint collaborative policy, have a greater chance of being in or close to the optimal joint policy.

In section (3) an experimental setup has been presented, describing the tools for measuring both, the level of self-determination from individuals; and the level of collective intelligence in collaborative task solving (CI metric). Accordingly, these tools have been described and evidences from its validity have been presented, concluding that they are able for measuring the level of self-determination of different individuals participating in a joint activity (Deci & Ryan, 2015), and for measuring the level of collective intelligence of a group (CI metric) (Woolley et al., 2010; Engel et al., 2014; 2015). Furthermore, we showed how these tools have been adapted to particular situations previously (Tremblay et al., 2009; Naderi, 2014) and we introduced a methodological framework (Zhou, 2019) to properly validate an adaptation to the particular problem posed in this work .

Finally, we have offered an explanation of how the gathered data will be computed in order to test the correlations, demonstrating that the proposed experimental setup would be able for validating the main hypothesis presented in this work: individual self-determination is a factor of positive influence for the increase of collective intelligence in cooperative certain cooperative contexts.

Abstract

OECD's countries in the last 15 years are changing their public management systems (Keating, 2001). The diffusion of the New Public Management philosophy (Gruening, 2001; OECD, 2010; Pollitt & Bouckaert, 2000) determine an increasing innovation in the public field.

Innovation management is relevant to improving and increasing performance in healthcare organizations (Dey, Hariharan, & Ho, 2009; Fleuren, Paulussen, Van Dommelen, & Van Buuren, 2014). Moreover, this is strictly connected with an efficient accounting and information system able to process, store and share data (H. Xu, 2011).

In Italy, each Local Health Authority (ASL) adopts a different innovation program defined by the Region of reference. In Piedmont from 2016, the HTH system is used which presents various possibilities for analyzing and managing patient data with pathological addictions (Regione Piemonte, 2015).

In the management of clinical pathways, the management of data and the use of shared platforms among healthcare professionals brings about a better concentration on the need expressed in terms of care and improving its efficiency (Leape et al., 2009).

The management of high volumes of users requires the appropriateness of the care and definition of those useful and functional data to increase performance; in this sense, observations are made more and more necessary concerning the granularity of the data (Biancone, Secinaro, & Brescia, 2018).

In the diagnostic and therapeutic path knowledge acquires a determining role for the well-being of the community of reference. The knowledge we refer to assets comprised, traditionally, human capital, structural or organizational capital, and relational or social, and often they are summarized in the holistic notion of intellectual capital (IC) (Marr et al., 2004; Schiuma et al., 2008).

The theoretical GAP detected relates to the granularity and the type of information contained in the electronic health record whose influence and impact on the different aspects of the IC are unknown (H. Xu, 2011).

This paper contributes on the cycle of innovation and join the theory of rational administration based on the budget.

Our analysis will focus on the case study of the department of dependencies of the Local Health Authority "City of Turin".

The data management system matches the needs of national information through the annual report to the Italian and international Parliament through the comparison in Europe of data dependencies.

Keywords: Technology; ICT; Innovation; Health Sector; Accounting

Nature of the proposed paper: Practical Paper

1 Literature Review

OECD's countries in the last 15 years are changing their public management systems (OECD, 2010; Pollitt and Bouckaert, 2000). The diffusion of the New Public Management philosophy determines an increasing innovation in the public field (Gruening, 2001; OECD, 2010; Pollitt & Bouckaert, 2000).

According to Rogers (2003), innovation stems from the adoption of new guidelines and subsequently from implementation and adoption actions both at the individual level and by multiple adoption units.

Innovation management is relevant to improving and increasing performance in healthcare organizations (Dey et al., 2009; Fleuren et al., 2014). Moreover, this is strictly connected with an efficient accounting and information system able to process, store and share data (H. Xu, 2011).

The change and the novelty effect can be implemented through the provision of a new service, a new way of working or a new technology that is dedicated to the service of the patient .

According to Iyawa et al. (2016), innovation applied to the digital health sector has different applications. These include changes to internal information systems and data management, but also the use of Electronic Health Records (EHR's) as a combination of past and present data of patients who are in charge of a health service and are instrumental in making health decisions (Iyawa et al., 2016).

In this sense, what is created is a structured process that involves, first of all, the generation of the idea of innovation to be brought to the health system (Omachonu & Einspruch, 2010) and, afterward, an initial evaluation of what has been thought of by the reference management.

Innovation management is related to the experiential novelty element that is linked to factors such as physical and virtual structures, as well as the set of relationships with stakeholders and human capital (Marr et al., 2013).

Digital transformation and the use of information systems represents an element of innovation within the healthcare system (Iyawa et al., 2016). The impact it can create is threefold.

First, digital transformation allows improving the quality of care by reducing errors (Leape et al., 2009) and promoting patient safety.

Second, a coordinated data management system increases productivity and improves efficiency throughout the medical process (Agarwal et al., 2010).

Information is now an essential point of innovation (Pollitt and Bouckaert, 2000).

Third, the use of electronic medical records can lead to a positive economic return for the healthcare organization (Wang et al., 2003).

One of the main features of data management systems reflects the direction and priorities that health managers intend to give both in clinical and administrative area (Williams et al., 2019).

The management of high volumes of users requires the appropriateness of the care and definition of those useful and functional data to increase performance; in this sense, observations are made more and more necessary concerning the granularity of the data (Biancone et al., 2018).

The inclusion of structured data within electronic health records allows, ultimately, to increase its granularity, provided that it is accompanied by the structuring of a method capable of verifying its continuous quality (Tange et al., 1998).

For this reason, in recent years there has been more significant interest in the correct management of qualitative and quantitative data, considered vital to improving service and health outcomes (Frost & Sullivan, 2012); this requires a structured process of data quality analysis (Biancone et al., 2019; Neda Firouraghi et al., 2018; World Health Organisation, 2017a).

The metrics used to determine the quality of the data refer to the completeness of the data and their inclusion according to the time criteria established by the health units (Leape et al., 2009; World Health Organisation, 2017a).

Besides, each dimension refers to the consistency of the data internally and externally. In the first case, this means the information capacity of the same data over time in line with what is established by documents and databases, in the second case, instead, the external coherence aims to compare two measures on the basis of the same indicators within the same structure (World Health Organisation, 2017b).

In the diagnostic and therapeutic path knowledge acquires a determining role for the well-being of the community of reference. The knowledge we refer to assets comprised, traditionally, human capital, structural or organizational capital, and relational or social,

and often they are summarized in the holistic notion of intellectual capital (IC) (Marr et al., 2013; Schiuma et al., 2008).

The theoretical GAP detected relates to the granularity and the type of information contained in the electronic health record whose influence and impact on the different aspects of the IC on the accounting and analytical process are unknown (Xu, 2011).

2 Research question(s) or purpose of inquiry

The research aims to explore the methods and dynamics with which healthcare professionals use information tools, with particular reference to the case study of HTH regional software.

Additionally, we will analyze the variables that are effective in improving cost control.

3 Methodology

The clinical record of the ASL "Città di Torino" case study is analyzed to identify the information that most affects the organization to confirm the research hypotheses. In order to carry out our analysis, the case study method was adopted (Yin, 1994). The validity of the collected data is confirmed by the triangulation of different sources of data, interview, archival sources, and direct observation (Gibbert & Ruigrok, 2010). Direct observation is allowed thanks to the assistance provided in 2019 by the Department of Management of the University of Turin thanks to a convention that includes both advice on the ICT system and on the mapping of the data collection processes useful for the construction of the Data Quality Framework (Bai et al., 2018; Biancone et al., 2019; Zozus et al., 2014). The case study was based on the concept of Internal validity too confirmed through interviews of the public managers (Cock & Campbell, 1979; Yin, 1994) and external validity or generalization of the results that can be obtained through an analytical process of mapping the results obtained and therefore reproducible (Lee & Baskerville, 2003; Numagami, 1998; Yin, 1994).

Please consider Figure 1 as a tool of analysis for the initial structure of the Innovation Cycle (Lerro, 2012; Guertler, Wiedemann and Lindemann, 2015).

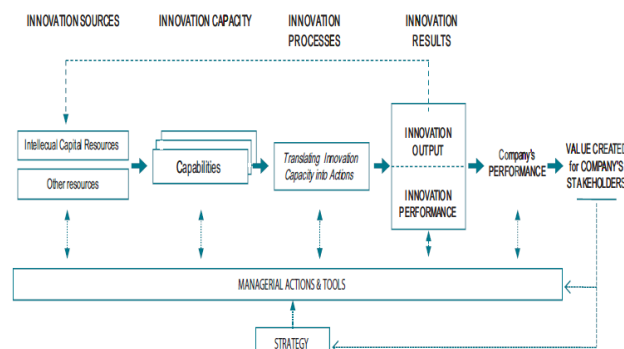

Figure 1: The innovation cycle

Additionally, the article considers the methodology of rational administration based on the balance sheet as a useful tool for corporate decision-making and based on information flows distinguished in the three available phases (Figure 2) (Brescia, 2019; Buchi et al., 2011).

Source: adapted from (Brescia, 2019; Buchi et al., 2011)

Figure 2: Administration process based on the balance sheet

1.1. Case study and sample

The Asl "Città di Torino" has been dealing with the phenomenon of Addictions for years. This function is carried out through the diffusion of outpatient clinics and administration services on the territory.

The broad nature of the treatment intervention is ensured by 29 operating sites, which include health clinics (8), drug administration centers (6), detained assistance centers (1) and specific locations such as the alcology treatment center (4), the pathological gambling center (4), the anti-smoking centers (4), the Drop-In¹ (1) and, finally, centers for new addictions (1).

The territorial competence of the Local Health Authority extends over the entire city of Turin and includes 882,523 residents. Of these, only 0.62% is currently in charge of the services of the dependencies.

There are 1.10 structures per 100,000 inhabitants in line with the national average between 0.7 and 2.5 structures (Dipartimento per le politiche antidroga, 2018).

In terms of estimating direct costs, the most significant impact is given by the forecast budget for employees (42,96% of total direct costs) (Doetter & Neri, 2018; Tradori, De Bernardi, & Brescia, 2019), residential assistance (35,48%), purchase of health services (9,68%), semi-residential assistance (7,89%), consumption of drugs and health goods (3,99%).

The staff involved in the treatment of addiction is made up of 351 professional figures. The subdivision includes: administrative staff (20; 5.70%), health care workers (7; 1.99%), caseworkers (38; 10.83%), professional educators (43; 12.25%), professional

¹ A structure suitable for low-threshold adult patients.

nurses (62; 17,66), doctors (77; 21,94%), psychologists (92; 26,21) or collaborators (12; 3,42%).

In 2018, there were 5497 patients. Of these, 4336 (78,88%) were already in charge of addiction services, 1161 (21,12%) returned following a previous interruption of treatment. The sample includes 1186 women (21,58%) and 4311 men (78,42%).

The primary substance of abuse is heroin for 2481 people (47,21%), alcohol for 1206 (22,95%), cocaine for 482 (9,17%), cannabis for 408 (7,76%), gambling for 270 (5,14%). Finally, 123 patients (2,34%) are in charge of tobacco addiction, 187 (3,56%) for crack and 340 (6,19%) for other addictions; for 242 patients is difficult to understand analysis. The diagnostic groups that have been created to better respond to clinical reporting needs are related to:

- substance dependence (2863 patients);
- alcohol dependence (799 patients);
- substance abuse (404 patients);
- pathological gambling (229 patients);
- alcohol abuse (113 patients).

The granularity of the data requires particular attention to the type of user and the standardization of care, identifying, however, thanks to the computerized system integrated care projects aimed at a higher output. Better standardization and personalization skills can avoid dispersions and allow greater planning capacity with a greater possibility of performance analysis.

4 Results and findings

The analysis of the cycle of innovation and the structure of the virtual medical record shows that some information is not collected completely.

The HTH electronic health record system has used since 2016. The transition to a new system corresponds to the definition of innovation source which, according to Lerro (2013) coincides with human capital. According to Suhonen and Paasivaara (2011), each project innovation in the health field should be accompanied by educational processes, promote workplace spirituality and management of enthusiastic.

The capacity of innovation, in the case study, has not been investigated because the health management decided to implement a data management system electronically as an element of uniformity for all regional clinics.

The innovation output is linked to the possibility for operators (doctors, nurses, psychologists, and educators) to have a virtual space with different types of health information and data that are reported in Figure 3.

	Innovation Source	Innovation Capacity	Innovation Processes	Innovation Results
Personal data Social data sheet Medical data sheet Psychological data sheet Educational data sheet Anamnesis Diagnosis Treatments Delivered Scheduling Monitoring Treatments received Vaccines Hospitalizations Relations Competences	It coincides with the knowledge of the patient, which is linked to the experience of health professionals. Each of them is part of organizational innovation.	Within the case under study is represented by the organizational capacity to integrate all health information and data. That involves the subsequent compilation of the electronic file.	The process is represented by the desire to use the electronic file as a tool that can improve the efficiency and effectiveness of clinical pathways.	The result of the process is based on the value created for the patients. The knowledge-based approach allows for better identification and, subsequently, a justification for improving the effectiveness of care.

Figure 3: The Innovation Cycle in the care path

Moreover, some sections do not specify information concerning the social, medical, psychological, nursing and educational cards, the planning of the treatments and drugs to be submitted, the vaccines carried out, allergies, hospitalizations carried out within the health system; such failures could affect the appropriateness of care within the data retention process.

The use of data and virtual medical records does not in itself lead to economic savings in health care but affects a higher quality of care and results related to the service (Biancone, Secinaro, & Brescia, 2018a).

5 Critical discussion of findings

The most treated cases concern users with problems of unhealthy addictions (drug addiction, alcoholism, gambling) that require special attention to psychological aspects (Miller & Brown, 1997) and data related to previous hospitalizations, useful elements to better direct the activities of health workers in the various health offices. The lack of a complete analysis of this information can lead to a reduced capacity for process and organization of care, besides, it shows a decrease in the granularity of the data useful for the activities of reading the digital medical record (Tange et al., 1998).

Moreover, as reported by figure 4, the missing information concerns the exploratory health area in part of the social, medical, psychological and educational data sheet. Besides, at the same time vaccines, allergies, relations, and competencies are not reported in the electronic part but only in the paper medical record. The main reason for this is the lack of an information flow management policy due to the relatively growing adoption of the electronic file.

In general, this also reflects a lack of attention in terms of the exploitation of the data present today.

The compilation of the EHR's is foreseen for the operational-health area with specific importance to the anamnesis and the diagnosis as well as a qualitative description of the treatments that are provided.

The last hybrid area between the health and economic-managerial area is currently not compiled. Furthermore, the missing information concerns the treatments received and provided, the area of the planning of therapeutic activities, as well as hospital admissions. However, the lack of such information denotes the lack of cost planning (Migliavacca et al., 2016).

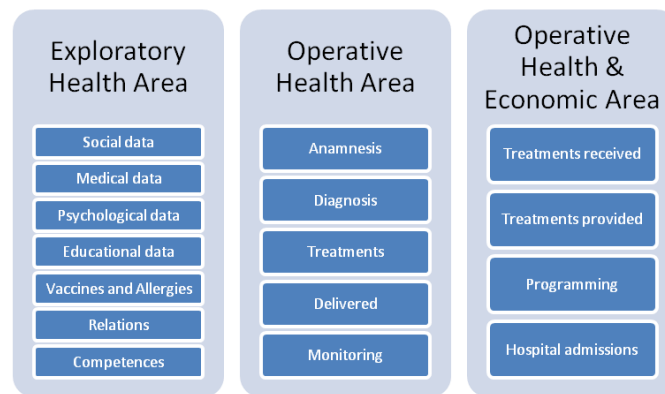

Figure 4: HTH medical areas

Diagnostic groups and services are linked to specific projects such as work and social rehabilitation, home rehabilitation or health promotion and prevention. Each of them has direct costs that engage multidisciplinary teams of professionals and person-hours by type of project. Therefore, that costs should be allocated by the treated dependence. However, this is not the case today because it is not linked to the electronic patient record and therefore not visible. To date, the information tool does not contain the precise data of the performances worked functionally to the integrative care projects.

Furthermore, the capacity of innovation through the use of EHR's shows a lack of programming and control analysis. The lack of data generates difficulties in the precise calculation of direct costs in healthcare structure, which according to Long et al., (1998) represent the higher cost derives for the care of patients with addictions.

In this case, the process of innovation requires the adoption of a data quality framework (Bai et al., 2018) aimed at increasing the granularity and completeness of the data in the treatments received and provided, by programming and hospital admissions (Figure 5).

In particular, according to Xu et al., (2014), the economic data functional to the final evaluation of performance, and to managerial decisions concern personnel costs, the costs of health materials and expenses for health services.

Within the innovation cycle, there is a lack of enhancement of the services provided and the value of human capital and individual skills, as they are not necessary for budget purposes. Therefore, the main limitation consists in not taking into account the reporting

systems; if they are not adequate, they can affect the ultimate effectiveness of the output and the results of the innovation.

Figure 5: innovation process in the medical record HTH

Therefore, it is useful to combine the methodology of the innovation cycle with that of the rational administration based on the budget that deals with outlining the information flow at the base of company decisions, and therefore also those related to innovation. The three stages of programming, execution, and control are shown with the respective accounting documents in the original graph in figure 6.

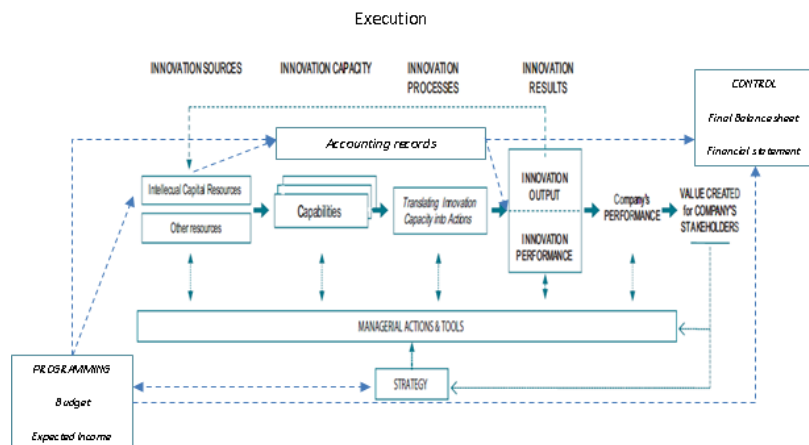

Figure 6: innovation and balance sheet cycle

6 Analysis of possible research impacts in terms of theory development

The confirmation of the Innovation Cycle theory is a valuable tool for managing the organization and appropriateness of care, especially considering the precise parameters (Admissions, Allergies, Vaccines). The selection of a precise innovation process makes it possible to enhance the data entered into databases and virtual clinical records; it is also true that the lack of data produces a lower incidence on the Innovation Cycle.

According to Agarwal et al. (2010), the digital transformation within health care can increase care effectiveness and management efficiency as well as a higher rate of productivity.

According to Buchi et al., (2011), any process presupposes the three critical moments of rational administration based on the balance sheet; for this reason, it will be useful to enhance the missing parameters both on the side of process innovation, aimed at the analysis of micro-costing.

The analysis is qualitative and lays the groundwork for future quantitative studies of the Innovation Cycle fallout on data health organization.

We firmly believe that the valorization of the output deriving from human capital cannot be separated from a better and effective information system at the service of the operators themselves. That also has a direct benefit in the final innovation output through the precise estimation of direct costs.

7 Analysis of possible research impacts for public managers and policy-makers

The redefinition of priorities, company policy and strategies can increase the training of professionals, in particular, the use and compilation of the electronic folder and the information contained therein.

The change of the strategy goes through a process of structuring corporate governance, which takes into account the specific tasks and objectives of compiling software as in the case of HTH. Moreover, it tends to create a personalized care path with the addition of educational projects, reduction of second analysis and further investigations with a doubling of previous diagnoses related to hospitalizations, effective vaccines, allergies with possible influences on the therapies administered.

The four diagnostic areas including substance dependence, alcohol dependence, substance abuse, pathological gambling, and alcohol abuse represent the main service behind which human capital provides its services. The higher completion of the electronic file tool can create a positive impact in terms of economic/financial planning of individual health departments (Wang et al., 2003), as well as providing greater power of decision towards patients (Lin B. & Chan H.G., 2000). Additionally, it would be possible to reduce the costs for duplication of diagnostic tests already carried out.

A further element of reflection may derive from the historical analysis of the indicators of economic needs connected to the individual therapeutic pathways aimed at the epidemiological evaluation. The analysis of the process and the approach implemented in the case study could, through the completeness of the data, allow the transition from financing based on historical costs to financing based on a micro-costing approach (Xu et al., 2014).

The focus, from prior planning, can quickly return the data of the service provided, making it unnecessary to link the cost and the computer systems currently in use.

In conclusion, the theory of the innovation cycle is a good representation of how innovation can spread across the enterprise. If the sources and capacity for change can be easily matched, the innovation process within the reality analyzed is more complicated. This also has an impact on the results.

The observation in the field has allowed denoting four elements:

- the difficulty of managing highly innovative elements;
- the lack of training about the possibilities given, in this case, by the care path electronic record;
- the lack of a data quality framework and, subsequently, the possibility to have precise direct costs;
- the need to link the innovation cycle to the phases of rational administration based on the balance sheet in order to have a better management of innovation in this field.

The information GAP can be solved, through the solution of the four points mentioned above, with strong leadership to pursue a complete and useful information system in all phases, from the path of diagnosis to the treatment of the patient.

Nowadays, the use of the methods in the application can also allow better internal programming of human resources and health expenditure; especially, through the compilation of information such as treatment provided and received, programming and hospital admissions.

Due to the problems of compilation and an information system with several databases and currently still in transition, it is not possible to define the performance arising from the cycle of innovation, to this end, it is difficult to collect the effectiveness of each therapeutic project.

Abstract

The Health Technology Information (HTI) is an important driver for change for the health sector. The evolution of HIT impacts directly on the health system. Health Information Technology is defined as “the application of information processing involving both computer hardware and software that deals with the storage, retrieval, sharing, and use of health care information, data, and knowledge for communication and decision making” (Thompson and Brailer, 2004; Payton et.al, 2011). The main electronic software of HIT is health records (EHR longitudinal), health medical records (EMR) and electronic prescribing. It can be expected that the utilization of HIT could lead to care coordination and improved outcomes. In this article the purpose is to make in evidence the creation processes di new knowledge thought the HIT tools. Also, we make a review of the scientific studies on the implementation of the different health information technologies. Consequently, this study may fill the gaps that previous studies may have encountered due to the timing of the studies prior to EHR - EMR implementation. The involved sample is the Scientific Institutes (IRCCS) located in Italy and specifically in the Sicily Region.

Keywords – Health Technology Information, Health Sector, Italy, IRCCS, Knowledge;

1 Introduction

The Health Information Technology (HIT) will radically transform the healthcare sector by increasing efficiencies, decreasing expenditures and increasing quality of health care delivery. Prevalence of chronic diseases and the need for improved quality of care and patient outcomes necessitates the application of HIT to streamline patient care, eliminate waste, and improve care coordination, with the goal of ultimately improving patient health outcomes. Health Information Technology is defined as the “application of information processing involving both computer hardware and software that deals with the storage, retrieval, sharing, and use of health care information, data, and knowledge for communication and decision making” (Brailer, 2004; Payton et.al, 2011). This could include software applications such as electronic health records (EHR longitudinal), health medical records (EMR) and electronic prescribing. The Italian government’s Decree Law 179/2012—otherwise known as the ‘Decreto Crescita 2.0’ (‘Growth 2.0 Decree’)—calls for the computerisation of the PA and, in particular, the setting up of electronic healthcare records and the development of a single electronic database accessible by all healthcare providers. The electronic health record (EHR) is the main electronic record-keeping tool, used to collect, store and display citizens’ health and socio-health data. The EHR is expected to generate not only economic benefits—that is, direct cost savings on the production, conservation and reproduction of healthcare documents—but also temporal advantages—that is, it will significantly reduce the time required to locate patients’ previous medical records. This has led the Scientific Institute (IRCCS) —to lead the way in implementing an electronic medical record (EMR) system, primary building block of the future electronic health records (EHR).

This paper aims to respond to the following research questions: to make in evidence the creation processes of new knowledge thought the HIT tools; and the factors that can influence the implementation process. In order to seek these responses, the paper first reviews the relevant literature and illustrates the research methodology and approach. Then it analyses the introduction of EMRs in an observed case study.

2 Theoretical framework

During the past 20 years, with huge advances in information technology and particularly in the areas of health, various forms of electronic records have been studied, analyzed, designed or implemented for improving many aspects of health care (Ajami and Bagheri, 2013). HIT is the application of information technology to health and healthcare (such as bed side terminals, assistive technologies, handhelds, electronics and electronic medical records, etc.) brings together the management and computerization of health information with a wide range of stakeholders; it means that has far-reaching effects on the delivery and consumption of healthcare and health-related services (Payton et.al, 2011). In this paper, HIT is defined as the use of ICT by formal (i.e., professional) and informal caregivers to deliver healthcare services in complex and non-traditional settings. ICT includes the multiplicity of tools that allow the convergence and integration of all

technologies that process information, tools for data management, communication technologies, automation and the whole series of services that organizations adopt to improve their productivity (Castellini et. al, 2006). The digitalization of health processes represents a fundamental step to improve the cost-quality ratio of health services, limit waste and inefficiencies, reduce the differences between territories, as well as to innovate front-end relationships and improve the quality perceived by the citizen. Basically, the HIT professional would combine the use of social media, collaborative platforms, online portals, bedside terminals, assistive technologies, handhelds, electronics, and electronic medical records into “effective means of accessing, communicating and storing information to improve patient care and population health, and reduce healthcare expenditures” (Burns et. al., 2012, Lehoux, 2004, Sheikn et.al., 2015). The benefits of using HIT have been widely studied (Devaraj and Kohli, 2000, Melville et al., 2004), and they show how to significantly change the way with which hospitals interact with patients and other healthcare stakeholders (Kohli and Tan, 2016). HIT can contribute to hospital profitability by reducing paper chart pulling and document transportation (Wang and Biedermann, 2010), reducing medical errors, potentially lowering medical liability costs (Mello et al., 2010) as well as decreasing back office expense (McLeod et al., 2008). In fact, with the growing emphasis on providing the right information to the right person anywhere at any time in today’s globally interconnected world, the healthcare system has been moving toward the EMR and EHRs use (see table N° 1).

Table N°1: Definition EMR and HER (Longitudinal)

Electronic Medical Record	EMR defined as digitally stored healthcare information throughout an individual’s lifetime with the purpose of supporting continuity of care. The flow of clinical information - divided into phases - can be performed in different places, at different times and with different clinical and care staff, through a strong process integration. May include such things as observations, laboratory tests, medical images, treatments, therapies; drugs administered, patient identifying information, legal permissions, and so on. A digital version of the paper charts are in the clinician’s office. An EMR contains the medical and treatment history of the patients in one practice.
Electronic Health Record (Longitudinal)	EHRs focus on the total health of the patient, going beyond standard clinical data collected in the provider’s office and inclusive of a broader view on a patient’s care. EHRs are designed to reach out beyond the health organization that originally collects and compiles the information. EHRs are designed to be accessed by all people involved in the patients care, including the patients themselves. EHR can be defined as a longitudinal record of the health information of a patient, able to be shared among different healthcare environments and also accessible to the patient himself. With fully functional EHRs, all members of the team have ready access to the latest information allowing for more coordinated, patient-centered care.

Source: our elaboration

It is obvious that the paper record system is incapable of supplying with all the patient information they need in a way that they can utilize it. In accord to ICT Healthcare Observatory (2015), EMR represents the main area where healthcare organizations focused their economic resources. The level of use of the functionalities, however, is still

partial, as well as their diffusion at the level of the whole structure; in fact, only 6% of the EMR are dematerialized and the degree of maturity and interoperability among the available electronic records is still too low.

3 Research methods

This paper is part of a larger study on the adoption and implementation of HIT in health care organizations. It uses a sequential design of mixed methods, starting with a quantitative survey followed by a qualitative phase in two parts:

- On-desk analysis: reviewing the literature using the online database (PubMed and Scopus) through specific keywords (such as Information Systems, HIT, EMR and HER) in order to assume the current state of research; and the mapping of the spread of the main HIT applications (EHR - EMR) within the Italian health context. For this reason, we proceeded to develop a survey on IRCCS (Scientific Institute), present in the Italian context; it was possible to identify through the portal of the Ministry of Health (2018), which includes in this typology n°49 Institutes.

- On the empirical analysis: with semi-structured interviews focusing on the understanding and the implementing that the different people (DG- DS- DA- Office ICT Referent) attribute to the EHR and EMR tool.

The study offers a comprehensive framework that captures knowledge and importance of information technology for the improvement of health care system. The finding of the research is a first step toward to ensure a more consistent and comprehensive understanding of HIT implementation. Despite of the potential benefits of electronic health records, the implementation of this technology faced with barriers and restrictions, such as cost constraints, technical limitations, standardization limits, attitudinal constraints-behavior of individuals, and organizational constraints. We chose to analyze the IRCCS for their distinctive characteristics. They represent the excellence in the organization and management of health services and in the medical and biomedical research field. Moreover, the number of IRCCS present in Italy is not extremely high, resulting in an easily identifiable unit of analysis and allowing a faster and higher rate of feedback for the purposes of our research.

4 Case study Analysis

4.1 Mapping – web site- ICT tool

The first Step was the mapping (website) of the spread of the main HIT applications (EHR - EMR) within the Italian health context. For this reason, we proceeded to develop a survey on IRCCS (Scientific Institute), present in the Italian context; it was identified through the portal of the Ministry of Health (2018), which includes in this typology n°49 Institutes.

Source: our elaboration

Fig. a): ICT Presence: Sitographic Analysis

Private-sector companies deploy ICT solutions to optimise organisational performance precisely because of its potential to reduce transaction and agency costs (principal-agent issues), but also to rationalise their business processes. The introduction of ICT to the public sector is expected to produce similar results (Bekkers, 2003). Cordella and Bonina (2012) highlight how ‘the success of private sector adoptions to streamline organisational procedures and support electronic mediated exchanges (e-commerce) can act as a stimulus to radicate the engagement of ICTs as a in the public sector.

Source: our elaboration

Fig. b) & c): Presence ICT and ICT Tool: Public sector

Source: our elaboration

Source: our elaboration

Fig. d) & e): Presence ICT and ICT Tool: Private sector

The literature cites the factors that need to be taken into account and managed appropriately during the implementation process: the adequacy of the project leadership; the type and influence of the organisational culture (participatory and cooperative or authoritarian and hierarchical); the adequacy of the system implemented; the training provided (Scott et al., 2005; Heeks, 2006; Pagliari, 2007). These factors are critical and can lead to the total failure of a project, causing the healthcare provider to suffer economic and structural damage (Heek, 2006).

4.2 The observed case study

Electronic Health Records (EHRs) are today seen as tools that allow the storing of a patient's history and retrieval of information. Their potential in improving the care process is widely recognized. The case study dealing with the implementation of a project of the EMR at IRCCS, a Scientific Italian institute. The EMR is split into different information fields, the most significant and numerous of which is laboratory tests. The study uses a qualitative approach, based on the observation of a case study to respond to the research question. In particular, the case study method (Cavaye, 1996; Creswell, 2007) enables the object of analysis to be investigated in its natural state by taking into account multiple dimensions that are difficult to analyse using a quantitative approach (Yin, 1994). According to Darke et al. (1998, p. 274) '*case study in research is useful in newer less well-developed research areas particularly where examination of the context and the dynamics of a situation are important*'. In this first phase, the observation of the case study was based on a documentary analysis (social documents, company website and regulations). In the second phase of the observation of the case study, the main sources are the semi-structured interviews, which primarily concerned the introduction of the EMR. Semi-structured interviews were defined based on the objective of the study and the literature on the subject. The semi-structured interviews consisted of 16 questions.

5 Conclusion

Firstly, the research - on the web site - showed that ICT is spreading on health care. This study of research has highlighted - between the literature and the web site - the implementing the ICT tool (as to EHR and EMR) and the potential benefits of the electronic health records which can give for the health care system. In fact, EMR and EHRs meet the goals of integrating patient medical history with facilitating improved quality of higher productivity, but are expensive for organizations, potentially impacting on financial performance and productivity (Kohli and Tan, 2016; Devaraj and Kohli, 2000; Li and Collier, 2000). Since the enactment of "Digital healthcare", the adoption rate of EHR (longitudinal) and EMR systems has increased (Agency for digital Italy, 2018). But, because the case study is different, it would like to have highlighted the main organizational impacts and critical factors in implementing IRCCS, which represents a particularly healthcare organization. The research conducted on observed case study has the aim to identify the organizational impacts and the critical factors of computerization and digitization of medical records. More generally, it would like underscored the

strategic role played by ICT (Zardini et al., 2010) and the efficiency in the healthcare system. But the semi-structured interviews are still being systematized.

6 Limits and future step

The use of Health Information Technology would like the improvement of quality, safety, and efficiency; the reduction of health disparities; the engagement of patients and families in care decisions; the improvement of public health; the ascension of privacy and security of patient health information. Ultimately, it is hoped that meaningful use compliance will result in improved outcomes, increase transparency and efficiency, empower individuals. We do not know how to best design, implement, and use health information technology (HIT). A comprehensive framework that captures knowledge on implementation, use and optimization of health IT will help guide more effective approaches in the future. The proposed research is an essential first step towards ensuring a comprehensive understanding of health, implementation and use. Despite of the potential benefits of electronic health records, such as constraints, technical limitations, standardization limits, attitudinal constraints of individuals, and organizational constraints. A lot of studies indicate that the other factors limit to implement the EHR are resistance to change.

Multi-dimensional Open Innovation Platform Ecosystem Framework

Sergey Yablonsky

Graduate School of Management
St.-Petersburg State University
Russia, 199004, Saint-Petersburg, Volkhovsky per., 3

Abstract

Ecosystems are of growing significance in research and industry business practice. Definitely, they will change the way how managers perceive central aspects such as strategy, business models, innovation, organization, and competition. There is still a lack of research on the question of how firms can design and integrate different types of ecosystems based on predominant possibilities and purposes. This paper depicts framework of main types of ecosystems and shows how and why these distinct types are being used. These insights lead to propositions for researchers as well as implications for practitioners. Finally, it intends to produce several pathways for future research on open innovation platform ecosystem orchestrators, development and governance.

Keywords – Open Innovation Platform, Ecosystem, Business Model, Framework

Paper type – Academic Research Paper

1. Introduction

Enterprises that leverage the power of platform business models have grown dramatically in size and scale over the past decade. The rise of platforms as new organizational form is now active in North America, Europe, Asia, Africa and Latin America (Evans, Gawer, 2016). No longer the sole domain of social media, travel, books or music, platform business models have made inroads into transportation, banking and even healthcare and energy (Evans, Gawer, 2016). The research above shows that there are differences in how platforms relate to the firm and the firm to the platforms they manage.

Digital business is a creation of new business designs by blurring the boundaries between the digital world and the physical one due to the convergence of people, businesses and things. It promises an unprecedented convergence of a) people, b) businesses and c) things that changes existing business models and creates new revenue opportunities and platform designs (Yablonsky, 2018 a,b). In digital business, business and technology are inextricable. To model a business, managers must understand what is needed for a business to achieve its goals, and how these goals translate into actionable strategy. For example, turning products into digitalized services that generate a steady

revenue stream implies significant changes within all the other components. A digital business requires much more than technology (for example, leadership, talent, skills and new business models).

To architect a digital business platform, organizations must lead their business to take a business driven, outside-in approach. Digital business platforms empower flexible and dynamic digital business. Unlike a traditional business, with a clear inside and outside, a platform provides business with a foundation where resources can come together in different combinations - to create value. Some resources may be inside, permanently owned by the company; some may be shared; and some can come from an outside ecosystem. The value comes largely from dynamic connection of those resources and the actors, and the network effects between them. Platform design facilitates matches among providers and consumers (“users”) or, in other words, a creation or exchange of goods, services and social currency, so that all participants can capture value.

2. Research design and methodology approach

This research seeks to answer the following research questions:

Which dimensions and characteristics distinguish platform ecosystems through their types?

What frameworks could be adopted and used to facilitate understanding, analysis and structure of platform ecosystems and their relationship?

To answer the research questions, we first follow Reuver et al.’s (2017) recommendations to provide clear definitions for key concepts in the digital platform context. Subsequently, we follow Nickerson et al. (2013) step-by-step and well-structured method for taxonomy development. In this process, we code digital platform articles to identify a sample of main digital platform ecosystems’ instances. The resultant taxonomy postulates digital platform ecosystems’ dimensions and characteristics. We investigate an opportunity for cross-fertilization between digital platforms and different types of platform ecosystems.

We initiated our process through a conceptual-to-empirical approach by defining the primary 5 components/dimensions of an established data-driven business model pattern conceptualization (Yablonsky, 2018 a).

We develop taxonomy’s frameworks by analyzing different dimensions and layers of platform business ecosystem, open innovation ecosystem and knowledge ecosystem concepts. In our main research we aimed for a platform value chain, platform ecosystems, and data-driven platform business models to develop taxonomy in order to facilitate understanding, analysis and structure of platform ecosystems and their relationship. The purpose of the paper is also to analyze and clarify the place of ecosystem layer in the platform business model and digital platform stack (Yablonsky, 2018). Based on theoretical conceptualization, combined with empirical evidence, we propose a taxonomy framework for business ecosystems related with multi-level taxonomy containing more than 100 entities. This framework provides new dimensions of platform ecosystem research for ecosystem typology and analysis, and illustrates how the platform innovative

ecosystems can be complemented by the real instances in the global and emerging markets.

3. Defining platforms and ecosystems

We should distinguish a technology platform from a business platform, which includes technology platform as a main block.

Definition 1. (Gawer, 2009)

A *technology platform* is defined as building blocks that act as a foundation upon which an array of firms (a business ecosystem) develop complementary products, technologies or services, proposing such requirements for a platform:

- It should perform a critical function of the overall system or should solve a crucial technological issue of an industry,
- It should be easy to connect to, “build upon” and provide space for new and unplanned usage.

Definition 2. (Parker and Van Alstyne 2015)

A *network technological platform* or *network platform* is usually based on digital network(s) building blocks. Network platforms differ from product platforms because of stronger network effects, switching costs and multihoming costs.

Definition 3. (Eisenmann et al., 2011)

A business platform is a nexus of rules and infrastructure that facilitates interactions among network users.

Definition 4. (Parker and Van Alstyne, 2015)

A *business platform* is a published standard, together with a governance model, that facilitates third-party participation.

Platforms have unique characteristics, with one of the central features being the presence of network effects (Parker, Van Alstyne, Choudary, 2016)). The value of platform affiliation for a user depends on the number of other users.

Most of today’s platforms are principally digital. They capture, transmit and monetize data, including personal data, over the Internet and other networks (Evans and Gawer, 2016). They may not be purely digital, but most successful digital platforms currently take advantage of the digital innovations and power of pervasive Internet connectivity in the hand of billions of users. A platform provides common standards, interfaces and tools to power core technologies in order to increase the productivity and profitability of a company, a set of companies, or users (Teece, 2017a,b). Platform technologies are essential for coordinating suppliers and buyers to deliver consumer value.

Starting from Moore (1996) and Kauffman (1993), the ecosystem concept has been actively discussed in management studies. The primary motivation for utilizing ecosystem concepts has been the desire to exploit self-organizing properties of natural ecosystems (Briscoe & Sadedin, 2007).

Valkokari (2015) distinguished three different economic ecosystem types:

- *Business ecosystems* as well as *service or industrial ecosystems*, where the economic outcomes and business relationships between actors are highlighted.

- *Innovation ecosystems* and *regional clusters* focus on mechanism and policies fostering the creation of innovative startups around so-called regional hubs or clusters.
- *Knowledge ecosystems* have their main outcome in creation of new knowledge through joint research work, collaboration, or the development of knowledge base.

Definition 5. (Teece, 2012)

A *business platform ecosystem* contains a number of firms and other institutions that work together to create and sustain new markets and new products. An ecosystem may be anchored by a platform. The co-evolution of the ecosystem is typically reliant on the technological leadership of one or two firms that provide a platform around, which other system members that provide inputs and complementary goods align their investments and strategies with.

A *business ecosystem* contains a number of firms and other institutions that work together to create and sustain new markets and new products. Business ecosystems continue to advance, becoming the basis of innovative business models. In a digital business ecosystem main digital economic agents (humans, business and smart things/smart machines) can play any combination of roles, such as customer, partner, supplier, employee or competitor.

A platform-based business ecosystem consists of

- Platform,
- Target Group of Customers,
- Target Ecosystem partners,
- Complementary products and services,
- Rival platform ecosystems, and competitive environment in which they exist, upstream and downstream parts of a platform value chain (Tiwana, 2014).

The co-evolution of the business ecosystem is typically reliant on the technological leadership of one or two firms that provide a platform around, which other system members that provide inputs and complementary goods align their investments and strategies with. Usually platform organizations exist in a "business ecosystem" — the network of other organizations that interacts to create shared value (Tiwana, 2014). Teece (2017) mentions that today the concept of "industry" as a group of firms performing similar activities and competing or cooperating with each other is less and less aligned with the way firms think about themselves. In the digital economy firms see their role less in industries and more in business ecosystems.

Platform by enterprise typology indicates (Evans, Gawer, 2016)

- *asset heavy enterprises* with heavy physical assets and *light platform business ecosystem* (example: Samsung with Tizen platform),
- *asset mixed enterprises* with heavy physical assets and platform business ecosystem (example: Apple with App store platform), and
- *asset light enterprises* with light physical assets and *heavy platform business ecosystem* (example: Uber with Uber app platform).

The main outcome of a *knowledge ecosystem* is a new knowledge, and it could be shaped by pointing out the network nodes where the knowledge is created and retained

(Valkokari, 2015). Open source communities are a well-known example of this ecosystem type based on knowledge exchange (Koenig, 2012) and therefore recent research highlights how colocation can also mean virtual proximity, like emotional closeness, between the actors (Coughlan, 2014).

The *innovation platform and ecosystem* approach emphasizes fostering the creation of growth, interaction, and innovative startups around so-called knowledge hubs (Engel & del Palacio, 2011). Within the innovation ecosystem, the financial network that supports the actors (both companies and research institutes and other technology developers) has recently been identified as one of the key platform investment type (Evans, Gawer, 2016). Several concepts about value co-creation within open innovation, such as “collaborative”, “democratized”, “open”, “networked” or “co-“ innovation have been introduced (Lee et al., 2012; Abbate et al., 2015). The technology-intensive business organizations, from specialized startups to diversified multinational enterprises, increasingly participate within innovation ecosystems in different roles such as adopters and patrons of open platforms, and stewards and promoters of innovation communities (Muegge, 2011).

An open innovation process (Chesbrough and Rosenbloom, 2002; Chesbrough and Bogers, 2014) comprises a number of activities that involve resources within and beyond organizational boundaries, mostly human participants (Chesbrough et. all, 2018). The characteristics of the activities and resources within this process depend on the specific purpose of an open innovation platform (Abbate et al., 2015). Open innovation is a multi-dimensional phenomenon that should be described from different perspectives – cultural, organizational and technological spheres – have transformed significantly under the development of innovative network technologies.

This paper investigates business ecosystems and the open innovation platform (OIP) ecosystem in particular. It contributes to research in the strategic management domain by presenting a set of multi-dimensional frameworks that identify how OIP business ecosystems improve management within organizations. Strategy has to guide platform business models portfolios and related business ecosystems trajectories.

4. Ecosystem frameworks

As shown by Parker, Van Alstyne, Choudary (2016), platforms all have an ecosystem with the same basic structure, comprising four types of actors/player/roles:

1. *Owners* of platforms or platform *sponsors* control their intellectual property and governance. The owner sets the direction, controls the underlying platform technology and provides the overall organizing structure for the platform via rules, governance, and ecosystem support. It can assist the ecosystem work by helping participants see how they are better off by being part of the system rather than outside of it. This role can be performed by one or many firms.

2. *Platform providers* operate as a platforms’ interface with users. Platform provider is the point of contact for common components, rules and architecture for the users of the platform. This role can be done by one or many firms.

3. *Users (supply side) or the producers* create their offerings. These are content and application developers. Producers provide specific items that attract users to the platform – music, games, information, services etc.

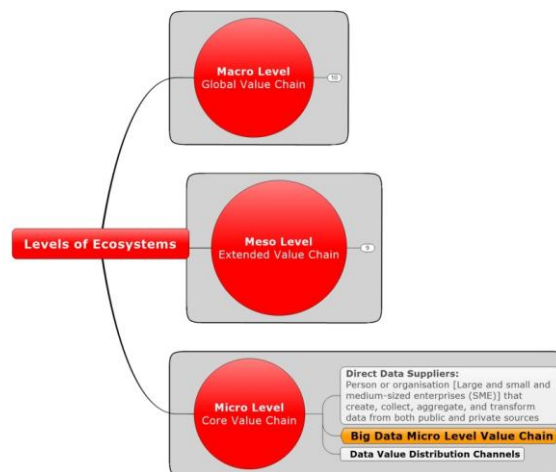

4. *Users (demand side) or the target consumers* of the platform solutions and services use producers’ offerings. They can be individuals, businesses, organizations.

Figure 1 illustrates the main set of ecosystem dimensions.

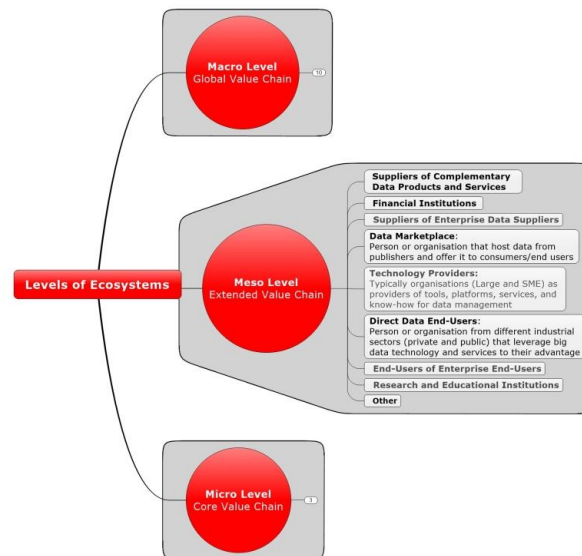

Figure 1. Ecosystem dimensions.

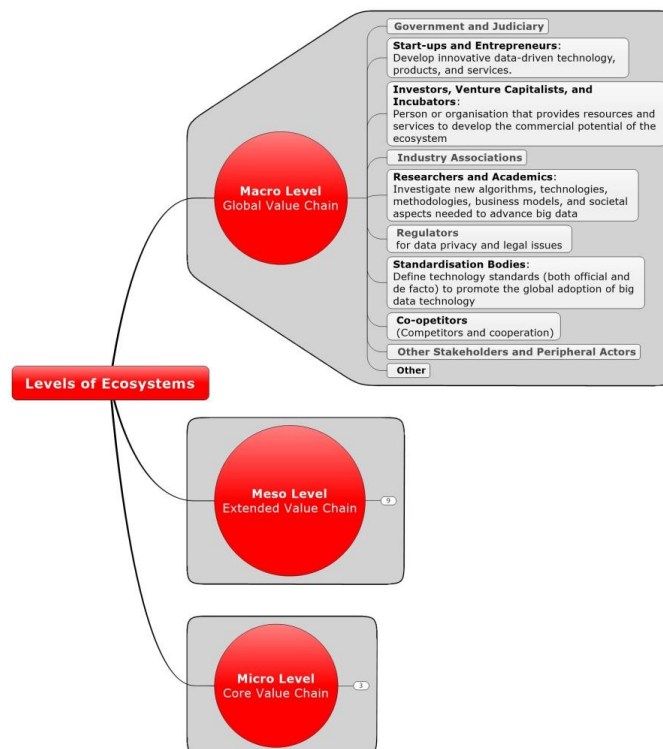

Figures 2, 3, 4 summarize three main levels of platform ecosystems.

Figures 2. Ecosystem micro level

Figures 3. Ecosystem meso level

Figures 4. Ecosystem macro level

Figure 5 summarize the differences and relationship between the three ecosystem types.

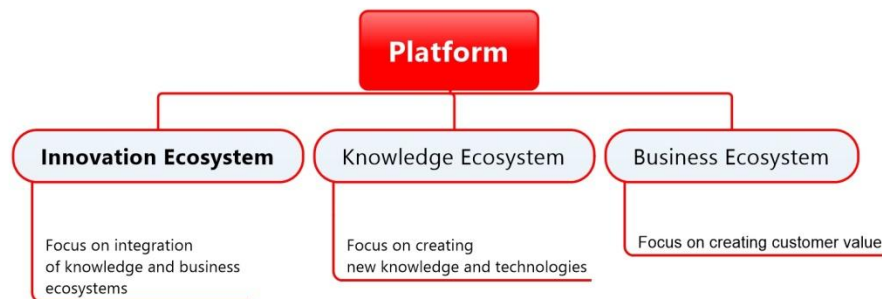

Figure 5. Three platform ecosystem types

It is shown on the Figure 5 that there is different logic of action in the different ecosystem types (Clarysse et al., 2014; Valkokari, 2015) and the same actor can be involved and play different roles in each ecosystem. From the viewpoint of each individual actor, the interaction area between the ecosystem types and their relationships are different. Thus, highly mobile actors, platform owners, or keystone companies are examples of actors boosting the interaction between the ecosystem types. On the other hand, a platform – an organization of things such as technologies or complementary assets (Muegge, 2013) – also may be the interconnecting factor between the ecosystems (Valkokari, 2015). Because of these interconnectivity actors and platforms, ecosystems do interact with each other and therefore are evolving and emerging next to each other. Furthermore, there are both dyadic and triadic interactions between the different types of ecosystem, as indicated in Figure 5.

To meet the needs of potential target consumers, the platform can adopt four major types of innovation ecosystem governance models (Kaganer et al, 2013):

- *Facilitator*: connects suppliers and buyers directly through a bidding process; *case examples*: Freelancer, Elance, oDesk,
- *Arbitrator*: engages multiple suppliers through competitions; *case examples*: crowdSPRING, 99designs, MediaPiston, InnoCentive, Witmart,
- *Aggregator*: aggregates hundreds or thousands of microtasks performed by multiple suppliers; *case examples*: Mechanical Turk, MobileWorks, CrowdFlower, CloudFactory,
- *Governor*: provides project governance and certifies supplier quality; *case examples*: TopCoder, Trada, uTest.

A platform ecosystem usually goes through periods of competitive strength and weakness as external circumstances change, and these dynamics also need to be managed by the platform owner. Teece (2017a,b) described a platform ecosystem lifecycle as consisting of four phases: Birth, Expansion, Leadership, and Self-Renewal. This model provides a useful framework for thinking about how platforms and dynamic capabilities interact.

There are such broad categories of ecosystem value chain types:

- *Linear value chain ecosystem* orchestrates and optimizes the organization's value chain. It is a particular favorite type when multiple partners are involved in a complex value chain.
- *Platform-led ecosystem* mediates the ecosystem using a platform.
- *Decentralized ecosystem* is the business ecosystem itself, which defines and mediates the transactions among partners. Cryptocurrencies, such as Bitcoin, are well-known case of decentralized ecosystem.

These ecosystem types have resulted in different types of business models. In the value chain, the business ecosystem opened up the reach and range of value. Today the platform ecosystems provide access to a wider range of partners with complementary capabilities, and the ability to create and coordinate these highly complex, demand-driven supply networks. Each of mentioned ecosystem types has created its own business model opportunities. These opportunities require a change in perspective, away from a traditional, input/output process to a dynamic ecosystem perspective.

The digital value of platform ecosystem is represented on Figure 6.

Figure 6. Digital value of platform ecosystem

The following key stakeholders are seen as the main actors along the platform value chain:

- *User Enterprises* in all sectors, who want to improve/transform their services and products using innovative technology, data products and services;
- *Data Generators and Providers*, who create, collect, aggregate, transform and model raw data from various public and non-public sources and offer them to customers.
- *Technology Providers*, who provide tools and platforms that offer BD management and analytics tools to extract knowledge from ecosystem data, curate and visualise it;
- *Service Providers*, who develop applications on top of the tools and platforms to provide services to User Enterprises.
- *Entrepreneurs*, who build innovative businesses and services based on the demand and supply side;
- *Researchers and academics*, who provide access to state-of-the-art research in innovative technologies;
- *Policy makers*, responsible for establishing policy framework conditions that foster the adoption of innovative technology in various sectors.

5. Conclusion

This paper puts in evidence a broad overview of platform ecosystem concept modelling using taxonomies and knowledge management tasks. We have investigated the knowledge areas of platform ecosystem governance and created business ecosystem taxonomy framework. This framework was used to find answers on the basic Why-What-Who-How *business ecosystems* relationship questions. For that the Micro-Meso-Macro levels of business ecosystem were developed. Taken together, we introduce a *multi-dimensional platform ecosystem framework* dealing with open innovation ecosystem agenda.

The outcomes of the application could be used for planning, oversight, and control over ecosystem management and the use of ecosystem's knowledge-related resources for research purposes.

Abstract

This paper aims to explore the role of knowledge developed within Open Innovation Platforms (OIPs) – i.e. internal knowledge – in supporting the initiatives launched online. The paper uses a quantitative methodology based on two regression analyses and data collection was done through four well-known OIPs. The final sample consists of 212 projects.

In this study we adopt a knowledge-based perspective and consider OIPs as knowledge platforms. We coded internal knowledge based on two levels of analysis: backers (prior OI experiences) and OIPs (community size).

The findings demonstrate the influence of internal knowledge on the success of projects launched on OIPs. Both our explanatory variables – i.e. internal knowledge at the backers level and at the OIPs level – have a positive impact on the outcomes of the initiatives. We measured the success of initiatives through two dependent variables, i.e. the number of ideas submitted and the number of backers involved.

This study provides insights on successful drivers of OI mechanism and it could be able to provide valid information for different actors. The paper also contributes to the current debate on the role of knowledge in the OI context and sheds some light on the nascent research field related to OIPs.

1 Introduction

In recent years, Open Innovation (OI) has emerged as a new relevant mechanism of knowledge-sharing. The concept of OI is now widespread and an increasing number of Open Innovation Platforms (OIPs) are spreading all over the world.

Through online OIPs, companies use the crowd as a source of innovation thanks to its knowledge (Jeppesen and Lakhani, 2010; Sawhney et al., 2003). Over the years, more and more companies have resorted to outsourcing the generation of ideas to external and unknown backers, i.e. crowdsourcing (Howe, 2008; Kozinets et al., 2008; Surowiecki, 2005).

Since its origin, the OI paradigm (Chesbrough, 2003a) has caught the attention of many scholars and practitioners. The research stream based on OI is currently characterized by a multitude of contributions that analyze different aspects related to this new phenomenon. The literature in this field is mainly focused on the impact of OI practices on company performance (Spithoven et al., 2013; Ahn et al., 2015; Rauter et al., 2018).

In recent years, however, a growing number of scholars have begun to analyze OIPs and to investigate the role of the Open Innovation Intermediaries (OIIs) (Sieg et al., 2010; Tran et al., 2011; Randhawa et al., 2017; De Silva et al., 2018).

Despite the growth in popularity of OI, scholarly understanding of the underlying dynamics of success among OIPs is currently limited. While the number of studies focussing on OI is constantly increasing, there is a scarcity of empirical studies that investigate the determinants of success of OI initiatives launched through online portals. In particular, there is a lack of contributions that explore the impact of knowledge on the outcomes of the projects on OIPs. The present study aims at contributing to fill these gaps. To the best of our knowledge, there are no prior studies that investigate the successful drivers of projects launched on OIPs, and even more studies focused on the role of knowledge – as will be explained in the following paragraphs – deriving both from the platform (communities) and from the innovators that solve problems/challenges (backers).

Starting from the current literature that consider OIPs as knowledge platforms (De Falco et al., 2017) and previous works that use a knowledge-based perspective for studying OIIs (Randhawa et al., 2017; De Silva et al., 2018), we try to adopt this perspective to explore the OIPs.

The paper is organized as follows. The next section provides a description of OIPs and the related actors' goals. Section 2 presents the literature review and provides the research hypotheses, followed by presentation of the data and methods in section 3. Results are reported in section 4, while the final section provides conclusions and discusses implications.

1.1 OIPs

Companies recur to OIPs in order to open their innovation process and acquire knowledge from external actors (West and Bogers, 2014). As Chesbrough (2003b: 5)

reported: “platforms provide an architecture to combine internal and external innovations”.

A growing number of actors, mainly companies, recur to external ideas from undefined innovators (Howe, 2008; Kozinets et al., 2008; Surowiecki, 2005). OIPs are virtual places where users are invited by innovation seekers – i.e. the proponents of online projects – to support initiatives through their ideas. Backers – also known as innovators or problem solver – contribute to solve the challenges proposed through the submission of one or more ideas. They respond to the call in order to provide their ideas and get a reward.

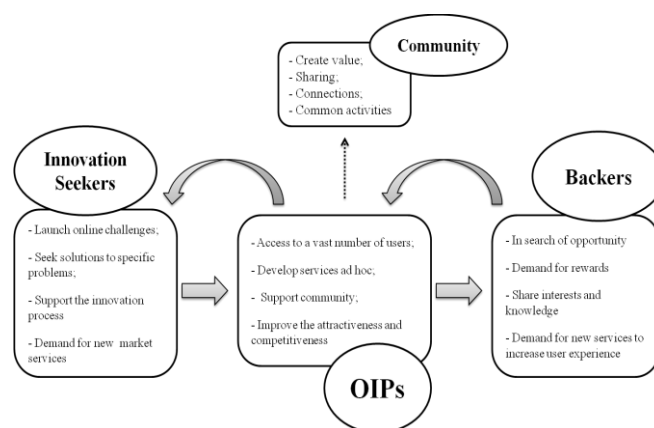

OIPs play a key role in the OI process ensuring access to a multitude of users, both on the demand and the supply side. In fact, they allow the interaction between innovation seekers that launch the challenge and backers that respond to the call. OIPs are also actors that facilitate and regulate activities. Platforms generate network effects and create value by facilitating relationships between different groups of individuals. The value of the service offered to the user derives from the number of people using it.

The more users are present within the OIP, the more successful it will be. In fact, if there are many backers registered as members of the community, this will lead potential promoters of initiatives to launch challenges on the platform; at the same time, if there are many initiatives to be backed on the platform, this will attract the innovators, who will be able to choose among numerous alternatives.

The main goals of the actors can be summarized as follows:

- Innovation seekers open the online call in order to get external ideas;
- Backers submit ideas in order to participate to the innovation process and obtain a reward;
- OIPs favor the development of the community and support the interaction between the parties in order to have a high number of successful projects.

Figure 1 provides a graphical representation of the network effects of the OI mechanism and summarizes the actions of the involved actors.

Source: elaboration by the authors.

2 Literature review and hypotheses development

The current OI literature is rich in studies that – starting from the contribution of Chesbrough (2003a) – highlighted the relevance for companies to resort to external sources (Herzog and Leker, 2010; West and Bogers, 2014).

Recently many scholars started to focus on OIIs that act as facilitators in connecting resources and knowledge between different external actors (Winch and Courtney, 2007; Sieg et al., 2010; Howells, 2006).

In this vein, the studies of Aquilani et al. (2016a,b) analyzed the services provided by OIIs. The first contribution (2016a) provided insights on the underlying dynamics of innovation seekers' choices and on the strategic relevance of OIIs activities, while the second work (2016b) presented new evidences on OIIs services.

In the last few years, some scholars adopted a promising knowledge-based approach to examine OIIs. Randhawa et al. (2017) have resorted to a knowledge-based perspective in order to investigate the influence of OIIs in facilitating collaborations between companies and online user communities. Also De Silva et al. (2018) used this perspective and explored how knowledge-based practices by OIIs affect value creation.

In addition to the literature on OIIs, also a literature on OIPs is developing in recent years, even if it is still at an early stage. In this research field, De Falco et al. (2017) suggested that OIPs are knowledge platforms that create value for the parties. The scholars found that the combination of digital platform and collaborative innovation play a key role for the creative process.

This new research stream is also characterized by the greater importance that communities are assuming. Several studies, in fact, provide evidences of the important role of the community in OIPs (West and Lakhani, 2008; Kathan et al., 2014; Di Pietro et al., 2018), especially in supporting the sharing and integration of knowledge.

The understanding of the dynamic of OIPs is a new challenge for scholars and the few studies that tried to face this topic started to analyze the form of motivations on collaboration and the knowledge of participants to the OI mechanism (Frey et al., 2011; Battistella and Nonino, 2012, 2013).

Frey et al. (2011), investigated the impact of motivation and knowledge of individuals participating in innovation projects. The scholars analyzed how these two type of factors are able to explain the performance of contributors to OIPs.

The studies of Battistella and Nonino (2012; 2013) focused specifically on motivational aspects: the first paper (2012) identified – through 116 OIPs – potential motivations for participating and collaborating in OIPs, taking into consideration the different stages of the innovation process; the second study (2013) explored 26 OIPs and examined how motivational systems and platform models affected the attraction of the individuals with different innovation roles.

Starting from the nascent research stream that analyzes the role of OIPs as knowledge portals and following previous studies that have given significant importance to the knowledge in the OI system (Randhawa et al., 2017; De Silva et al., 2018; De Falco et al., 2017), we adopt a knowledge-based perspective to explore OIPs. In the present study we

focus on the knowledge deriving from participation in the OI mechanism and we suggest that OIPs generate internal knowledge for the actors involved. More precisely, we argue that OIPs are virtual place where it is possible to develop a stock of knowledge.

In the current literature there is a lack of studies that consider this point of view and that in particular use the knowledge-based perspective for OIPs. Prior studies, in fact suggest that online platforms are a virtual loci where OIIs support interactions and exchanges of ideas and knowledge between the two parties involved (Howells, 2006; Gassmann *et al.*, 2011), i.e. the innovation seekers and the innovation solvers. However there are no prior works that specifically adopt a vision of an OIP as a locus of knowledge sharing where participants can increase their experience. We suggest that OIPs enables participants to build an additional stock of knowledge within the community.

Many scholars worldwide shared the idea that communities create new knowledge and implement the knowledge derived from the experience (Kozinets *et al.*, 2008; Erickson and Kellogg, 2003; Liedtka, 1999; Boland and Tenkasi, 1995; Brown and Duguid, 1991).

Communities are online groups of people who share knowledge and enthusiasm as well (Komito, 1998; Kozinets, 1999). They are often considered as voluntary associations of backers who share a common interest, such as the development of innovations – in the OI context – in a given product or service category (West and Lakhani, 2008). The interaction between the members of a community and thus the network established within communities, represent a process of collective invention (Von Hippel, 2005; Osterloh and Rota, 2007; Von Krogh and Von Hippel, 2006).

In line with these studies we embrace the importance of knowledge deriving from communities and we apply this concept also to OIPs. In particular, we argue that an active and vibrant community, characterized by a high number of members is able to build greater knowledge for OIPs and has more probabilities to influence the success of projects/challenges launched on online portals. This is more evident especially if compared to static, less populated communities. In fact a low number of members have limited capabilities to interact and share common activities, thus consequently to create knowledge.

In addition to the knowledge deriving from belonging to the community, we also recognize the importance of knowledge deriving from previous experiences on OIPs by the participants. Backers who have supported other projects before, acquired experience and obtained useful information on the logic of OI mechanism and on the needs of innovation seekers.

Backers rely on their own existing knowledge bases and – as suggested by Frey *et al.* (2011) – their diversity of knowledge and experience affects the quality of their contribution. The scholars (2011: 404) reported that “*innovators blend previously unconnected pieces of existing knowledge to achieve their creative leaps*”.

In the present paper we share the concept that backers firstly leverage their prior knowledge, in fact we consider the knowledge deriving from previous OI experiences. Moreover, we also support the idea that these “creative leaps” could come from the connections and exchanges between the community’s participants. Thus we posit that

OIPs presents a further stock of knowledge created by these actors within communities. Regarding this aspect, a number of scholars highlighted that reuse and transfer of knowledge contribute to the generation of substantial innovations (Hargadon, 2003; Majchrzak et al., 2004).

Prior studies provided evidences that knowledge reuse or transfer is a significant factor in facing new problems or innovative challenges (Jeppesen and Lakhani, 2010; Lovett and Anderson, 1996; Lüthje et al., 2005). Even if backers have a different expertise with respect to the field of the problem and are therefore unable to use their pre-existing knowledge (Jeppesen and Lakhani, 2010), they can leverage the existing body of knowledge embedded in the community. In the OI virtual context, the lack of knowledge stimulates backers to identify connections – useful to develop solutions (Novick, 1988) and so to solve the challenges – and to assimilate external information from the community in a logic that recalls that of absorptive capacity (Cohen and Levinthal, 1990).

In this vein, Frey et al. (2011) proposed that backers with diverse knowledge: a) should identify more connections in order to increase the number of possible combinations of knowledge elements they can create; b) should have flexibility regarding their original idea and explore alternative solution paths in order to develop alternative ideas or increase their ability to help others with the development of their solutions. The scholars suggested that these elements are facilitators of the creation of more ideas of higher quality. They reported (2011: 404) that: *“overall, individuals with a broader stock of existing knowledge are more able to blend disparate knowledge elements and should find more connection points between their knowledge base and a given innovation challenge”*.

In the present paper, both the types of internal knowledge that we considered could represent an added-value for the OI process. In more detail they could affect the success of initiatives in the virtual environment, where projects are characterized by uncertainty. The internal knowledge developed within OIPs could be a strategic element in pushing projects to attract more ideas and more backers. At the same time, the prior knowledge of backers could affect the success of online initiatives.

2.1Hypotheses

As already stated, the purpose of this study is to examine the impact of knowledge on the success of projects launched on OIPs.

Knowledge is a strategic asset for OIPs and in this study, we suggest that it could represent a strategic lever for successful OI initiatives to achieve superior performances in terms of ideas and backers involved.

In this paper we focus on the important role of OIPs as knowledge platforms and we explore the influence of the internal knowledge created through OIPs on project's outcomes.

In sum, we consider both the knowledge that OIP develops thanks to the relationships established between backers of the community, and the knowledge that backers acquired thanks to the support of previous projects.

We argue that communities are a significant source of knowledge for OIPs, and backers that belong to a community acquire an additional stock of knowledge. Furthermore, we assume that backers who have already supported other projects are more experienced than others and – thanks to their acquired experience – they are able to better support other projects as well as a greater number of them.

Put simply, we analyze knowledge on two levels – i.e. backers level and OIPs level – and we assume that both the stock of knowledge held by backers (derived from prior OI experiences) and by OIPs (derived from their communities), could represent successful drivers for the OI mechanism.

According to the above analysis, we propose two research hypotheses linking internal knowledge to projects' success.

Hypothesis 1: higher internal knowledge at the backers level positively affects the success of online initiatives in the OI context, expressed in terms of number of ideas presented and number of backers involved.

Hypothesis 2: higher internal knowledge at the OIPs level positively affects the success of online initiatives in the OI context, expressed in terms of number of ideas presented and number of backers involved.

3 Data and methods

For this study, we collected data from four OIPs: Opeindeo, Openinnovation-suedtirol, Crowdspring, Guerra-creativa. Data collection was done through these OIPs because they are well known platforms and do not belong to private companies (portals created by these firms – e.g. Unilever, PhilipMorris, Tim – are used for themselves).

These platforms cover a variety of initiatives and include the challenges of all the categories. Our final sample consists of 212 projects: 61 from Opeindeo; 19 from Openinnovation-suedtirol; 60 from Guerra-creativa; 72 from Crowdspring. We consider all the challenges posted on the first two platforms (i.e. Opeindeo and Openinnovation-suedtirol), while for the other two platforms (i.e. Crowdspring and Guerra-creativa) we include the initiatives posted between August 2018 and March 2019. As regards the challenges on these last two OIPs, the sample of their projects is not necessarily representative of the overall population of Crowdspring and Guerra-creativa projects. In fact data-collection of these initiatives was performed as a random choice.

In order to examine how internal knowledge can influence the outcomes of initiatives, we carried out an empirical work based on two regression analyses.

3.1 Variables

The success of initiatives launched on OIPs is measured through two dependent variables: the number of ideas and the number of backers. The first variable includes the total number of ideas submitted at the end of the online call. A high number of ideas posted allows call proponents (innovation seekers) to have more choice and to increase the quality level of the projects. Contrariwise, a challenges that receives no ideas is a

failed project. For a project, even receiving a few ideas could be a negative thing, in fact the proponents of the call could be faced with low quality ideas or innovations. Thus, we consider the number of ideas as a proxy of success of the initiatives. A high number of ideas generate competition between a multitude of innovators and elevate the level of competition.

The second dependent variable includes the total number of backers at the end of the online call that submitted their ideas. The number of backers assumes an important role because the success of the projects cannot disregard a large number of innovators. Also in this case, a higher number of backers that respond to the call influence both the quality of the ideas and the level of the challenge.

We consider these two variables because the logic of OI implies an active participation of the crowd/backers, so the goal of proponents is to receive a high number of ideas and involve a high number of innovators. Innovation seekers – when launching the call – aim to accumulate a large number of ideas as well as a large number of backers. The latter will continue to follow the project, as well as the proponent, and in the future they could become supporters also for future initiatives or in the case of the launch of new products/services.

The two explanatory variables used in this study consider the internal knowledge on two levels: backers and OIPs. At the backers level, we considered the knowledge which derived from the participation in other previous projects launched online in the OI context. This prior experience represents a significant factor in the virtual environment of platforms. More experienced backers are more accustomed to OI process – and thus to innovation – and so they can better respond to the challenges. As for the internal knowledge at the backer level we used the sum of the number of projects that backers had supported before. This variable represents the degree to which the backer has been supportive of OI projects, thus establishing contacts and a relationship with the community. This measure included only projects backed before the challenge considered, thus avoiding problems of overlapping projects.

At the OIPs level, instead, we considered the size of community at the time of the launch of the projects. Communities are dynamic, so their members vary over time. It is very common indeed that the number of registered backers changes over the months: many sign up only to support a specific project that interests them, after which they unsubscribe from the platform; others instead participate in numerous projects, following the example of some friends or crowd orientation. For a platform it is important to have an active and populated community. Communities, in fact share knowledge and facilitate the process of generating new ideas. In this vein, new projects launched on OIPs benefit from larger communities. For both our explanatory variables we used the logarithmic transformation (natural logarithm, \ln).

We included several control variables in our analyses: comments (no.), updates (no.), photos (no.), duration (days), sector, awards and the category of the innovation seekers. The last three variables are expressed as dummy variables. Variable definitions are reported in Table I.

4 Results

4.1 Descriptive Statistics

Table I provides descriptive statistics of the variables. The two dependent variables, i.e. number of ideas and number of backers, respectively report maximum value of 1,088 and 687. Both the minimum number of ideas and of backers is zero. The average number of ideas submitted online is about 172, while the average number of backers that supported the initiatives is about 89.

Regarding the explanatory variables, internal knowledge at OIPs level – that is, the community size of the platforms - ranges from 5 to 28,931, while at the backers level internal knowledge – that is, the number of project backers have supported in the past - it ranges from 0 to 3,987. The averages values of the two variables are respectively 4,335 and 443.

Challenges are mostly launched by companies (62%) belonging to production industry (61%) and that offer material rewards (69%). Initiatives are open online for about 34 days and present on average 182 comments, 8 photos and about 3 updates.

Table I. Descriptive Statistics and Variable Description

	Obs	Mean	Std. Dev.	Min	Max	Variable description
<i>Dependent variables</i>						
No. Ideas	212	172.34	167.81	0	1,088	Number of ideas submitted at the end of the online call
No. Backers	212	89.41	131.91	0	687	Number of bakers at the end of the online call
<i>Explanatory variables</i>						
Backers Internal Knowledge	212	443.25	747.17	0	3,987	Number of projects that backers had supported before
OIPs Internal Knowledge	212	4,335.11	6,964.93	5	28,931	Community size of the platforms
<i>Control variables</i>						
Comments	212	182.68	294.26	0	1,376	Number of comments posted during the online call
Duration (days)	212	34.77	20.14	4	135	Duration of call in days
Updates	212	2.77	3.51	0	18	Number of updates posted during the online call
Photos	212	7.90	4.51	0	25	Number of photos posted during the online call
Sector	212	0.61	0.49	0	1	Dummy = 1 if the innovation seeker belongs to production industry; 0 otherwise
Innovation seeker category	212	0.62	0.48	0	1	Dummy = 1 if the innovation seeker is a firm; 0 otherwise
Awards	212	0.69	0.46	0	1	Dummy = 1 for material rewards; 0 otherwise

4. Regression Results

We performed two different regression analysis. In both Model 1 and Model 2, a negative binomial regression is employed, in fact the two dependent variables are a count, respectively the number of ideas presented (Model 1) and the number of backers involved (Model 2).

Both in the first model and in the second model, robust standard errors are used and control variables are included. Furthermore, in the analyses we checked for multicollinearity and heteroskedasticity, and there were no points of concern.

The evidence supports our two hypotheses. First, a higher internal knowledge at backers level has a positive influence on both the number of ideas (coefficient = 0.370, significant at 1%) and the number of backers (coefficient = 0.305, significant at 1%). Second, a higher internal knowledge at OIPs level positively influences the number of ideas (coefficient = 0.157, significant at 5%) and the number of backers (coefficient = 0.279, significant at 1%).

Among the control variables, three have significant coefficients (sector, awards and the category of proponents), while the rest of them have little or no impacts.

Table II. Regression Results

	Model 1:			Model 2:		
	No. Ideas			No. Backers		
Explanatory variables

5 Conclusions

This paper seeks to make a first few steps towards an analytical understanding of OIPs and their underlying mechanism.

The success of initiatives launched online through OIPs is determined by several factors. What effectively leads to the success of projects is unexplored and the successful drivers are factors not yet investigated.

This study advances the extant knowledge in the OI research context. Firstly, it contributes to the current literature that recently started to explore the importance of platforms in the OI process. Second, this study shed some lights in the nascent stream of research that consider the knowledge-based perspective for OIPs.

The results of this study highlight the key role of the internal knowledge developed within the platforms in the success of initiatives. The internal knowledge at both the considered levels – i.e. backers and OIPs – has a positive impact on the initiatives' outcomes, thus supporting projects in obtaining superior results in term of ideas and backers.

This work offers some exploratory insights that hopefully could be useful for different actors. In particular, the study could be able to provide valid information for OIPs managers, innovation seekers, innovators (backers) and policy makers.

Platform manager should consider the importance of both backers and communities in explaining the success of projects. OIPs manager should improve the size and the quality of their communities, as well as favor the share of knowledge between backers and develop common activities. These managers should also support the members of the community to acquire more experiences through an active participation to different initiatives. These actions could be useful to have backers with more knowledge and larger – and also vibrant – OIPs.

Innovation seekers, whether companies or not (e.g. government or non-profit associations, etc.), should pay more attention to the characteristics of OIPs, especially to the communities and the experiences or skills of the backers. The choice of the platforms could be a significant element to consider when they launch the challenges.

Backers should acknowledge the importance of communities as loci where it is possible to collect an additional stock of knowledge. Furthermore, backers should acquire more experience in the OI mechanism with a more proactive participation.

Finally, policy makers could reflect on the important results in term of numbers of OIPs and in general of the OI tool. They should encourage the use of OIPs and they could favour the participation of public operators and government agencies in the OI system. Policy makers could foster interaction between the actors of the innovation ecosystem and support the OI mechanism through incentives.

Abstract

Innovative concepts and technologies for citizen participation have become key components of Smart Cities concepts. Smartness of cities cannot be reduced anymore to IT infrastructures and communication networks, but needs to comprehend smart interaction between citizens too. Based on the new U_CODE approach for citizen participation in urban development, this paper presents User Engagement Protocols (UEP) that are able to concert the a broad variety of activities and contributors to urban co-design projects. In analogy to music scores where “protocols” for individual players are derived from a Master Score, specific UEP can be deduced for all stakeholders and user groups from a comprehensive choreography of the entire participation process. The paper presents the methodical steps that lead to the establishment of this master protocol, as well as to specific UEP for Citizens, Expert Planners, Authorities, or Faciliators. It demonstrates how U_CODE manages to coordinate co-creative activities of a multiplicity of participants with its new methodology and digital tools.

Keywords – Co-Design, Smart City, Public Participation, urban development, user engagement

Paper type – Academic Research Paper

1 Background

Smart Citizen Interaction Over the past years, innovative methods and technologies for citizen participation have become mandatory components of Smart Cities concepts (Piskorek et al 2015). With the, the smartness of cities cannot be reduced to IT infrastructures and communication networks, but needs to comprehend smart interaction

between citizens as well as smart governance mechanisms too (Kustra et al 2017). Instead of a technology-driven, technocratic view on Smart Cities, sociotechnical notions of smart citizenship and cities as based on democratic participation via digital media has come to the fore.

Demand of Citizen Participation Over the past decades, citizen engagement has turned out a major demand in many fields and disciplines, ranging from science, administration to urban planning and development (Selle 2014). As a specific field, Urban Planning and Design i.e. the creation of urban districts, compounds and neighbourhood has emerged as a field with high applicability of citizen engagement and participation (Münster et al 2017). Research and practice have established a variety of approaches to support the involvement of various stakeholders and user groups in the process of city-making, e.g. Planning Cell ors Design Charettes (Stelzle & Noennig 2017, 2019). Some cities have strongly pushed their activities in the field and started to implement solutions to enable broad participation as a key aspect of smart city development in areas such as economy, governance, environment, mobility, or housing (Griffinger 2007). While especially the interface between policy-makers and citizenship raises the demand for effective means of citizen participation, areas like mobility or living are touched similarly by the question: Who is involved in processes of urban development, what impacts do far-reaching decisions have on society and the individual?

Existing Shortcomings The existing approaches for citizen participation, however, face serious shortcomings. They suffer from *a) low reach* – as they are hardly capable of addressing audiences that are larger than 200...300 persons in a single event or campaign; *b) high costs* – as they impose relatively high costs due to need of facilitation by highly-skilled moderators as well as extensive preparation and post-editing by the process owners; *c) buerocratic spirit* – as they incline to raise administrative issues in spite of attractive creative tasks which are usually left for professional designers (Münster et al. 2017).

At the moment most cities run offline procedures for participation in urban development issues such as German zoning plan law (Bebauungsplanverfahren). As paper-based procedures, they require citizens to visit the city hall during office hours and leave written comments, which in turn need to be processed manually. By law, respective administrative information needs to be published via city bulletins which, however, few citizens read. Therefore, existing participation formats only have minimal impact – they do not provide for sufficient interaction with, and feedback from citizens.

U_CODE solution Most smart city publications assume that new digital communication and interaction technologies can help to create more liveable and participatory cities (Gorynski & Mikolajczyk 2019; McKinsey Global Institute 2018), including e.g. the German Federal Government's Smart City Charta (BBSR/BBR 2017). Still, there are only few solutions that address the above mentioned deficits (Münster et al 2017, Stelzle et al 2017).

In order to establish an entire new approach and quality in citizen participation in urban development, a consortium of European researchers and developers has created within a H2020 project (2016-2019) the Urban Collective Design Environment,

U_CODE. Complementing established formats like Planning Cells, Design Charettes, or World Cafés etc. we propose with U_CODE Urban Collective Design Environment a new way of citizen engagement in urban development, based on advanced tools and processes of digital co-creation. U_CODE systematically exploits the opportunities of digital means in order to achieve *a) wide outreach* up to a scale of massive participation due to web-based interaction processes and data platform, *b) low cost deployment* due to provision of easily replicable software and hardware solution, and *c) rich co-creation experiences* with innovative co-design tools based on Virtual Reality, Serious Gaming, and interactive design technologies (Stelzle et al 2018).

Key Challenge As key challenge U_CODE addresses the question: How to engage a large number of highly diverse participants in a coordinated creative activity? Its conceptual core therefore is a process methodology for massive urban co-creation, which is to ensure goal-oriented, coordinated collective activities in cooperation with mandated planners and decision-makers, that eventually leads to feasible and creative urban design propositions (Hofmann et al 2018). U_CODE supplies this process methodology with an entire suite of new tools that enable, among others:

- crowdsourcing of relevant information and background data,
- collective co-creation of design propositions,
- sentiment and discourse analysis of the ongoing project debates,
- public presentation, voting and feedback.

Level of Development / Output The output of the U_CODE project is a comprehensive toolset whose individual tools are conceptually and technically developed to prototype level. The method and process design has been tested and validated in lab environment with a so-called Dummy Test Bed (12/2017-03/2018), as well as specific co-design tools (VR, Multitouchtable, Online Co-Design Game) (2018-2019). Pilot applications of the entire process and toolset in real-world projects are planned for the final months of the project (Spring-Summer 2019).

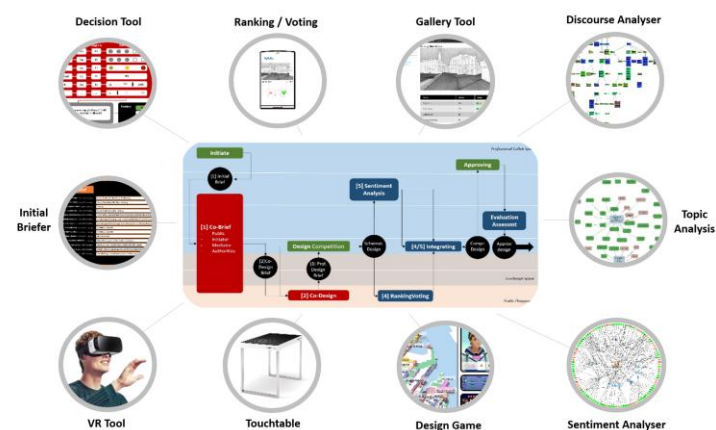

Fig. 3 U_CODE Process Methodology (centre) and accompanying tools (margins)

Engaging User Groups To devise a feasible and successful co-creation process, it is necessary 1) to specify the different users and stakeholders, and b) to precisely line out how they are supposed to contribute to the process. During the mid-term review of the U_CODE project (10/2018) it was recommended to establish a comprehensive User Engagement Protocol (UEP) as a key supplement for the technical tools and methodology. This paper is to address this demand.

Definition of User Group In the U_CODE context, following user groups were defined and described in detail elsewhere (Stelzle et al 2017): *Citizens* – the non-professional audience interested in, or related to, the planning, design, and development of their immediate or larger urban environment; *Planners* – professional planners and design experts mandated and responsible for urban design and planning work; *Authorities* – public institutions administering urban planning and development projects; *Project Initiator / Owner (PIO)* – persons or institutions with intrinsic interest in driving a project campaign, originators of a project idea; *SuperModerator (SuMo)* – Facilitator and Process Owner of a U_CODE campaign; expert consultant for U_CODE based projects.

User Engagement Protocol (UEP) The specific focus of this paper is to provide an outline for a UEP that is capable to concert the activities and contributions of a multiplicity of different stakeholders and user groups within U_CODE-based urban co-design campaigns. The project team recognised during the so-called Dummy Test Bed (12/2017-03/2018) that a precise operations manual is indispensable for conducting a smooth and successful co-design process. For each contributing user or participant an explicit and specific choreography needs to be issued that indicates what kind of activity, contribution, or input is to be delivered at what time with what means for what kind of output.

Analogy to Music Score A suitable analogy for the conceptualisation of such UEP are symphonic music scores which form the common basis for musicians as well as for conductors, allowing the successful performance (co-creation) of a complex piece of music. In concert practice, there usually exists a comprehensive Master Score outlined by the composer and annotated by the conductor, which the conductor monitors during live performance. From this master score, individual scores are derived for each single player or instrument, only showing this specific voice or role.

Similar to such scores, coordination documents need to be established a) to configure the overall process in accordance to project setup and context (Master Score), and b) to guide the individual contributions and activities of each user group and participant (specific UEP). These choreographic scores are to direct how Citizens, Expert Planners, Authorities, Facilitators etc. interact within a U_CODE process, how the various tools will be applied, and how the multiple activities and contributions will merge into meaningful co-creation.

2. Outline of User Engagement Protocol Process

Conceptual Steps The following paragraphs present the conceptual steps that lead to applicable UEPs. Whereas the first steps form a general synthesizer that – in accordance to project-specific context and requirements – defines a comprehensive co-design procedure to which concrete tools and activities are associated, the last step derives specific engagement protocols for each stakeholder or user group. The conceptual steps (a) ... (f) – which are explained in detail below – are linked by a backward logic.

In order to derive individual UEPs (f), it is necessary to determine the overall Master Score (e) beforehand. Such a comprehensive score can be composed from selected and configured tools (d) as well as from the overall process configuration, i.e. sequence of activities (c). The selection and configuration of tools and processes in turn are implied by the project setup and context (b). To explicate the implications and inferences of the project as clearly as possible, the project needs to be patterned in a structured format (a). A clear definition of the project setup and context is conditional for the stringent and quick definition of the necessary processes and tools.

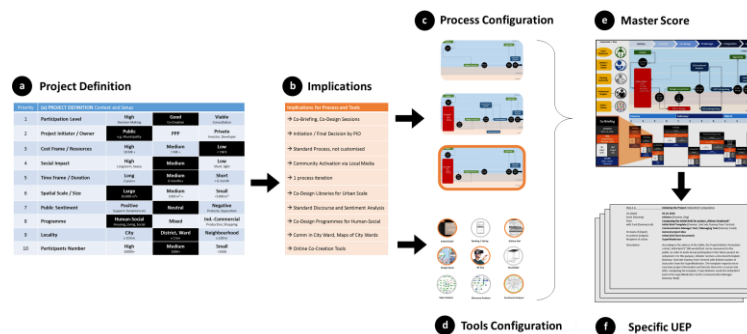

Fig. 2 Overview Conceptual Steps toward User Engagement Protocol

(a) *Project Definition*

In a first step, the project will be defined by a list of key parameters e.g. Targeted Participation Level, Cost Range, Expected Participants Number etc. With a structured questionnaire, the SuperModerator (SuMo) collects these information from the Project Initiator / Owner (PIO) or other sources. A prioritisation of the parameters helps to determine the influential decision making criteria for defining appropriate processes and tools in the succeeding steps.

Priority	(a) PROJECT DEFINITION Context and Setup			
1	Participation Level	High Decision Making	Good Co-Creation	Viable Consultation
2	Project Initiator / Owner	Public e.g. Municipality	PPP	Private Investor, Developer
3	Cost Frame / Resources	High 10 M€ +	Medium 1 M€ +	Low < 1M €
4	Social Impact	High Long term, heavy	Medium	Low Short, light
5	Time Frame / Duration	Long 2 years+	Medium 6 months+	Short < 6 month
6	Spatial Scale / Size	Large 10.000 m ² +	Medium 1000 m ² +	Small <1000 m ²
7	Public Sentiment	Positive Support, Donations etc	Neutral	Negative Protests, Opposition
8	Programme	Human-Social Housing, Living, Social	Mixed	Ind.-Commercial Production, Shopping
9	Locality	City x 10 km	District, Ward x 1 km	Neighbourhood x 100 m
10	Participants Number	High 10000+	Medium 1000+	Small <1000

Fig. 3 Overview Conceptual Steps toward User Engagement Protocol

(b) Implications

In a second step, essential implications for the upcoming definition of process and tool configuration will be drawn from the project description. To do so, IF-THEN schemes deduce inferences from the key parameters surveyed in step (a). An example: IF Participants Number is 1000+ THEN Online Co-Creation Tools need to be selected for the co-creation process.

Priority	(a) PROJECT DEFINITION Context and Setup				Implications for Process and Tools
1	Participation Level	High Decision Making	Good Co-Creation	Viable Consultation	→ Co-Briefing, Co-Design Sessions
2	Project Initiator / Owner	Public e.g. Municipality	PPP	Private Investor, Developer	→ Initiation / Final Decision by PID
3	Cost Frame / Resources	High 10 M€ +	Medium 1 M€ +	Low < 1M €	→ Standard Process, not customised
4	Social Impact	High Long term, heavy	Medium	Low Short, light	→ Community Activation via Local Media
5	Time Frame / Duration	Long 2 years+	Medium 6 months+	Short < 6 month	→ 1 process iteration
6	Spatial Scale / Size	Large 10.000 m ² +	Medium 1000 m ² +	Small <1000 m ²	→ Co-Design Libraries for Urban Scale
7	Public Sentiment	Positive Support, Donations etc	Neutral	Negative Protests, Opposition	→ Standard Discourse and Sentiment Analysis
8	Programme	Human-Social Housing, Living, Social	Mixed	Ind.-Commercial Production, Shopping	→ Co-Design Programmes for Human-Social
9	Locality	City x 10 km	District, Ward x 1 km	Neighbourhood x 100 m	→ Comm in City Ward, Maps of City Wards
10	Participants Number	High 10000+	Medium 1000+	Small <1000	→ Online Co-Creation Tools

Fig. 4 Implications for Tools and Processes

(c) Process Configuration

In this step, the overall process will be determined in accordance to the implications of (b) and (a). At the current state of development in the U_CODE project, this activity is carried out without a specific tool. In later stages of development, however, a specific software tool “Process Configurator” is envisioned to support this task. There are two options to establish the configuration:

Customising Processes With an appropriate Configurator Tool, it will be possible to design highly project-specific, customised processes. This, however, demands high skills

on the side of the SuperModerator (SuMo) as well as sufficient resources. Based on the so-called Minimal Viable Process (the base line process for good participation established by the U_CODE project, Stelzle et al 2018), suitable sequences and process structures can be configured e.g by providing feedback loops or multiple iteration of specific activities. Especially by process configuration, the key qualities of high-level participation processes can be controlled, such as: process transparency, divergence/convergence shifts, user-oriented communication, context adaptation.

Selecting Standard Processes In order to provide for a more quick and efficient form of process definition at the current state of development, and to sidestep complicate deliberation, U_CODE provides a menu of pre-set standard processes from which the most appropriate option can be selected by way of a questionnaire re. project context and setup pattern. Based on the Minimal Viable Process, a number of “easy select” standard process configurations are predefined for regular projects. However, in the middle run it is the aim for U_CODE to provide project-specific process designs instead of merely selecting predefined standard processes, in order to ensure higher quality and context-fit of the process configuration.

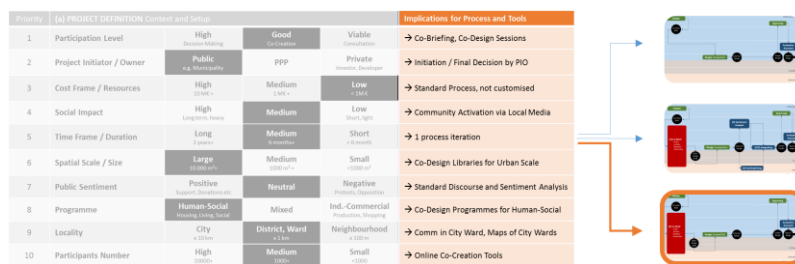

Fig. 5 Selecting a Standard Process according to project implications

(d) Tool Configuration

Similar to the step of Process Configuration (c), the Tool Configuration is based on implications drawn from step (b) and (a) too. There are two forms of tool configuration. *Tool Selection*: For regular projects, a standard selection of tools are prepared. In addition to these so-called Minimal Viable Tools (i.e. the toolset necessary to supply the Minimal Viable Process, Stelzle et al 2018), optional tools can be selected from an extended tool menu for inclusion in the overall process. *Tool Setting*: The tools themselves can be set up in accordance with project context and setup. Example: In terms of building typology or programme it would cause confusion if participants were able to select supermarkets in a project that aims for housing solutions. Here, a precise definition of component libraries, functional programs and design features is necessary to enable feasible and meaningful propositions. For regular projects, standard pre-sets of components and functionalities are prepared.

Fig. 6 Tool Selection according to project implications

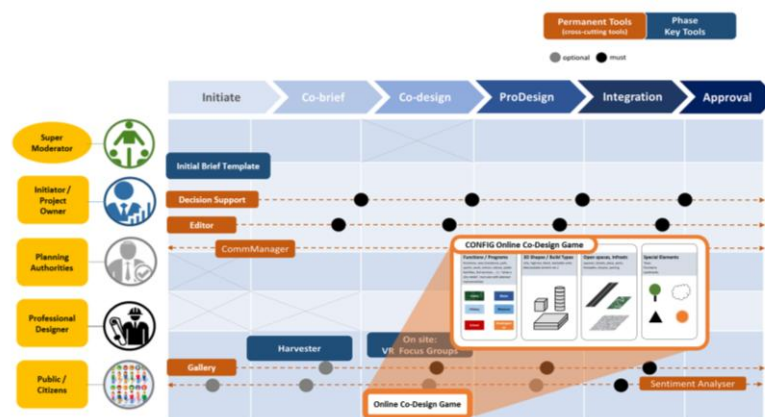

Fig. 7 Setting tools and components (highlighted: Online Co-Design Game)

(e) Compiling the Master Score

Integrating the outcomes of steps (c) and (d) and arranging all activities and processes along a feasible timeline, this step generates the overall choreography or “Protocol” for the entire process. Establishing this Master Score as well as monitoring the actually running process with view of this document is a key task of the SuperModerator (SuMo). This Master Score comprises all tools and timelines, as well as the roles and activities for all stakeholders and user groups: When they need to be involved, how long with which tools, and how the output of one activity forms a necessary input for another. At the current stage of development, there exists no specific digital tool for the creation of the Master Score within U_CODE. For further phases of development, however, the development of specific software application is envisioned to support this highly complex process step.

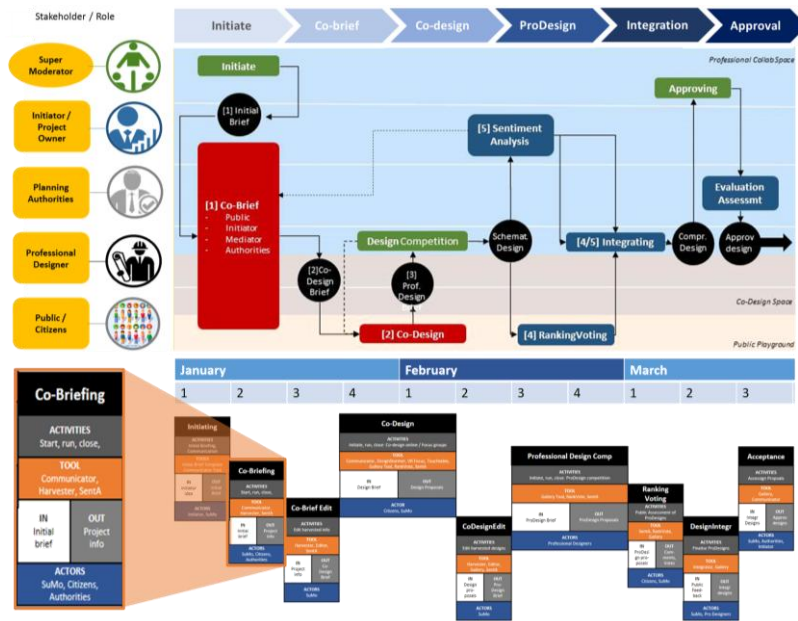

Fig. 8 Master Score: Process View (up), Operations Plan (down), highlighted: Co-Briefing Phase

(f) Specific User Engagement Protocols

From the comprehensive Master Score (e), specific User Engagement Protocols can be derived. These UEPs precisely determine for each participant or stakeholder group the individual activities, contributions and timelines. Presented in the form of Operation Manuals, they indicate who to work with at what stage of the process, and what the expected input and output are. Example: “As PIO, I need to search and contact a SuMo in month 1, inform him about size / program / scope of my project, and determine with him level of participation. The result we consolidate in an Initial Brief Document”. From the specific UEPs the SuMo in turn infers the necessary forms of communication and contacting for each stakeholder or user group (which, technically speaking, turn into UEP activities for the SuMo himself). For the creation of the UEPs, existing “Smart Flow” functionalities of the project management and platform solutions can be used that technical partners bring into the U_CODE project consortium. This allows for the automated generation of a large number of individual UEPs from an appropriately set up Master Score.

Step 1.4.	Initiating the Project: Initial Brief Composition
On (date)	05.01.2018
Actor (Dummy)	Initiator (Dummy: Jörg)
Does with Tool (Dummy tool)	Composing the Initial Brief for project „Kleiner Grasbrook“ Initial Brief Template (Dummy: LiveCode Dummy from Torsten) Communication Manager Tool / Messaging Tool (Dummy: Email)
On basis of (input)	General project idea
to achieve (output)	Initial brief (text document)
Recipient of action:	SuperModerator
Description:	According to the advices of the SuMo, the ProjectInitiator formulates a short, initial brief (~100 words) that can be announced to the public, in order to invite broad participation in the future project development. For this purpose, Initiator receives a structured template (Dummy: LiveCode Dummy from Torsten) with limited number of characters from the SuperModerator. The template requests necessary basic project information and formats them into a concise text. After completing the template, ProjectInitiator sends the Initial Brief back to the SuperModerator via the Communication Manager (Dummy: Mail).

Fig. 9 Specific UEP for Phase “Project Initiation” / Stakeholder “Initiator”

3. Conclusions

The UEP process presented in this paper allows for precisely scheduled interactions of multiple stakeholders and user groups in urban co-design projects based on the U_CODE approach. It results in comprehensive choreographies for an entire co-design campaign, as well as in user-specific operation manuals, clearly defining for each individual participant his / her role and form of contribution. The presented conceptual process was practically tested and validated in a so-called Dummy Test Bed (12/2017-03/2018). At that time, all tasks and steps were carried out manually. Currently (4/2019), a number of tools and processes can be processed via software and platform applications already. However, the complex tasks of configuring tools and processes, and deriving comprehensive operations manual for a large number of actors suggests to automate the entire process to the largest possible extent. For supporting especially the Super Moderator (SuMo) with appropriately automated routines, the project management functionalities of platform solutions brought into the project by U_CODE’s industrial partners (conject, aconex, Oracle) provide a promising outlook.

Abstract

Since technology, institutions and markets continuously change, business models are also dynamic configurations that evolve through micro- adaptations and/or disruptive changes. This dynamism enables economic resilience, that is, the (re)generation of system-level economic sustainability, mainly through the mechanism that in the entrepreneurship literature is called “creative destruction”. But what about social and environmental resilience? How, and under what conditions, can business model dynamics contribute to the (re)generation of environmental and social sustainability, as well? Even if business model (re)generation is today recognized as a key force to the resilience (and fragility) of social-ecological systems, we have scant understanding of how its actual contribution to sustainability could be assessed and maximized (Schaltegger & Wagner, 2011). This study contributes to addressing this challenge by developing the Common-Good DPM approach. This approach results from the cross-fertilization between Dynamic Performance Management (DPM), which is a system-thinking based method, the theory of the commons, and institutional theories. The Common-Good DPM approach is a sustainability-oriented tool for sense-making, monitoring, testing and designing around the dynamic link between business models and sustainable development models, thus leveraging business model evolution for sustainability transformations. The Common-Good DPM approach is conceived to concretely enable participatory and adaptive modelling, in which sustainability-relevant knowledge is collectively co-created through feedback based learning. In addition, the Common-Good DPM approach is data-driven, and may both enable and leverage effective big data management.

Keywords – Business model, Sustainability, Commons, Dynamic Performance Management, System Dynamics

Papert Type - Academic Research Paper (ongoing research)

1 Introduction

The concept of business model is a broad one, that allows for several possible definitions (Baden-Fuller & Mangematin, 2013; DaSilva & Trkman, 2014; Morris, Schindehutte, & Allen, 2005). In this study, we build upon Zott & Amit (2007) and Ricciardi, Zardini, & Rossignoli (2016), and we define the business model as the system of the key value-creation, value-distribution and value-capture interactions that enable an undertaking's economic sustainability (Furnari, 2015). For example, people use Google's free services, which in turn allow Google to collect users' data, which in turn are delivered to interested customers, thus enabling Google's economic sustainability: this is a synthesis of Google's business model.

This definition of business model is applicable not only to enterprises, firms and one-person undertakings, but also to public administration bodies (whose economic sustainability typically derives from public money, after specific political decisions and agreements) and non-profit organizations (whose economic sustainability may derive, for example, from donations). In this light, a business model is viable in that it sufficiently fits the undertaking's technological, institutional and market environments (e.g., the local labour market), and particularly the needs of its customers/payers and users/beneficiaries: two categories that in several business models do not overlap, like in the Google case.

Since technology, institutions and markets continuously change, business models are also dynamic configurations that evolve through micro- adaptations and/or disruptive changes (Ricciardi et al., 2016; Zott, Amit, & Massa, 2011). This dynamism enables economic resilience, that is, the (re)generation of system-level *economic* sustainability, mainly through the mechanism that in the entrepreneurship literature is called "creative destruction" (Chiles, Bluedorn, & Gupta, 2007).

But what about social and environmental resilience? How, and under what conditions, can business model dynamics contribute to the (re)generation of *environmental and social* sustainability, as well (Boons & Lüdeke-Freund, 2013)? Even if business model (re)generation is today recognized as a key force to the resilience (and fragility) of social-ecological systems (Berkes, Colding, & Folke, 2003; Cantino, Devalle, Cortese, Ricciardi, & Longo, 2017), we have scant understanding of how its actual contribution to sustainability could be assessed and maximized (Schaltegger & Wagner, 2011).

Merely measuring the extent to which a (new) business model is compatible and compliant with extant sustainability norms and expectations (Bocken, Short, Rana, & Evans, 2014) is not sufficient. Sustainability-related beliefs, norms and expectations often become obsolete and are soon replaced by new beliefs, norms and expectations, hopefully based on more advanced knowledge (like, for example, in the case of biofuels). Therefore, the assessment of business models' contribution to sustainability should be a process that adds to the extant body of knowledge, rather than merely conforming to it (Schaltegger, Hansen, & Lüdeke-Freund, 2016).

This study contributes to addressing this challenge by developing the *Common-Good DPM approach*.

2 Dynamic Performance Management

Dynamic Performance Management (DPM) is a method for adaptive and recursive system modelling (Bianchi, 2016) that allows the researcher to map a system's key resources (in terms of stocks), results (in terms of flows), performance drivers (in terms of ratios, usually expressing capabilities) and input variables (in terms of behavioural drivers and institutional/operational constraints) (see Figure 1).

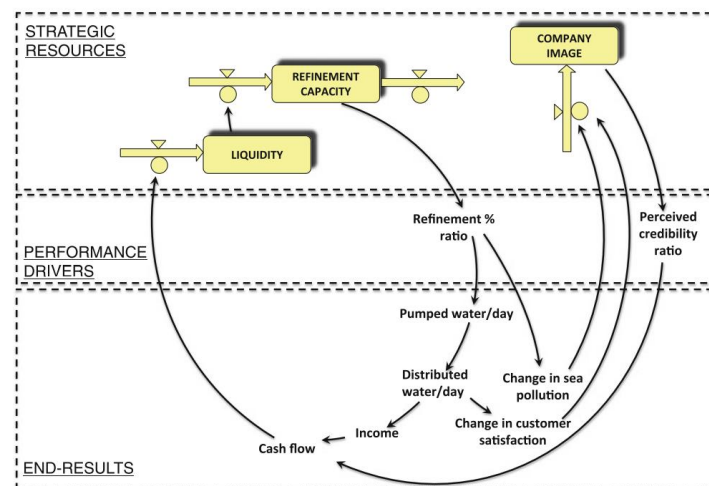

Figure 1- An instance of DPM modelling: a layer & arrow model of a water utility company.
Source: Bianchi (2016).

DPM is considered particularly interesting in that it allows to model not only linear cause-effect relationships, but also feedback effects, including virtuous cycles, vicious cycles and homeostatic loops (Sterman, 2000). That far, DPM has mainly taken the individual organization as the level of analysis: in this case, DPM modelling can provide an effective translation of a business model into a system of correlated resources, results, performance drivers and input variables (Cosenz, 2017). However, DPM can also be used to conduct system-level modelling. In this case, a DPM model can represent how a specific business model is embedded in, and interacts with, its social-ecological system. Therefore, DPM could be used for the assessment, simulation and design of a business model's system-level impact under specific inputs (Borgonovi, Bianchi, & Rivenbark, 2017). The possibility of including common resources and capabilities into the model, along with the resources and capabilities controlled by the individual firm, transforms DPM into a powerful tool to map the (re)generation (or destruction) of public value that results from the implementation of a certain business model.

Despite its potential, however, DPM has been quite overlooked by management scholars interested in sustainability issues that far. Indeed, DPM has been much more used to model dynamics at the single organization's level than at the system level. The reason for this underutilization is twofold, in our opinion.

The first reason is that studies leveraging DPM tend to (implicitly) adopt the resource-based view (RBV) as a theoretical lens (Peteraf, 1993); therefore, these studies typically assume that rent maximization is the key goal of the analysis, and the key resources to be included in the model are those resources that allow the organization to develop competitive advantage, such as internal competencies, customer base, or liquidity. It is not surprising then, in our opinion, that this approach is perceived as hardly adaptable to sustainability-focussing studies.

The second reason that has that far discouraged scholars from adopting DPM for sustainability-relating research has to do with the difficulties of participatory modelling when different and conflicting views and interests are at stake (Rossignoli, Ricciardi, & Bonomi, 2018). Defining DPM variables (key resources, results, performance drivers and inputs) and the relationships between variables is not a neutral process. DPM scholars claim that, due to the high levels of complexity addressed, DPM can be effective in supporting the (re)generation of public value only if all key stakeholders contribute to DPM modelling through participatory processes (Bianchi, Bovaird, & Loeffler, 2017), so that collective learning and progressive model fine-tuning are enabled (Ferraro, Etzion, & Gehman, 2015). However, governing these participatory processes is a challenging task that would require specific attention and solutions. In the absence of a DPM modelling protocol that successfully addresses these issues, it is not surprising that overwhelming pluralism, intractable conflicts and irreconcilable disagreements end up hindering an effective modelling process.

3 Complementing system dynamics with institutional theories and the theory of the commons

This study complements the DPM approach with two further conceptual tools that, in our opinion, allow scholars to overcome the two limitations of DPM modelling listed above: the theory of the commons, and institutional theories. The complementarity between system dynamics, the theory of the commons, and institutional theories is attracting increasing scholarly attention (Etzion, Gehman, Ferraro, & Avidan, 2017; Luna-Reyes & Gil-Garcia, 2011) and is a promising solution to address the role of business models (as systems of interactions) in sustainability transformations.

The theory of the commons proposes the common good as a key goal to governance and management action, and defines the common good as the social-ecological system's capability to (re)generate the critical resources that could be available for collective use on the part of a certain community, such as, for example, clean air or a tourist destination's reputation (Cantino et al., 2017). In addition, the theory of the commons investigates the governance and organizational factors that enable (or destroy) such common good. Therefore, the theory of the commons effectively complements the RBV lens in drawing the interplay between a business model and its social-ecological system's fragility, and provides DPM modelling with a sound and sustainability-oriented toolbox.

Institutional theories (Wooten & Hoffman, 2008), on the other hand, have a strong explanatory power for the dynamics of the relational space where a business model is

embedded in, particularly as for social expectations, legitimacy needs, façade behaviours, technological standards, mimetic imitation of reputed best practices, compliance, values and beliefs. Institutional theories provide sound conceptual tools for identifying BPM variables (especially inputs) that are key to behavioural architectures (Bianchi & Williams, 2015), and for modelling the relationships between BPM variables. In addition, institutional theories (and particularly the literature on institutional logics and organizational fields) can provide effective tools to manage the tensions between and across different sustainability logics (such as the charity logic and the environmentalist logic), thus enabling an effective protocol for DPM participatory modelling (Rossignoli et al., 2018).

4 Towards the Common-Good DPM approach

The Common-Good DPM approach that results from the cross-fertilization between DPM, the theory of the commons, and institutional theories, is therefore a sustainability-oriented tool for sense-making, monitoring, testing and designing around the dynamic link between business models and sustainable development models, thus leveraging business model evolution for sustainability transformations (Zollo, Cennamo, & Neumann, 2013).

In the Common-Good DPM approach, the typical framework including resources, performance drivers and results/flows is replicated at the level of the individual organization (thus representing its business model) and at the level of the commons, that is, the social-ecological system that (re)generates resources for collective use (see Figure 2). This allows scholars to map the interrelated cause-effect relationships between the business model and the system's (sustainable) development model.

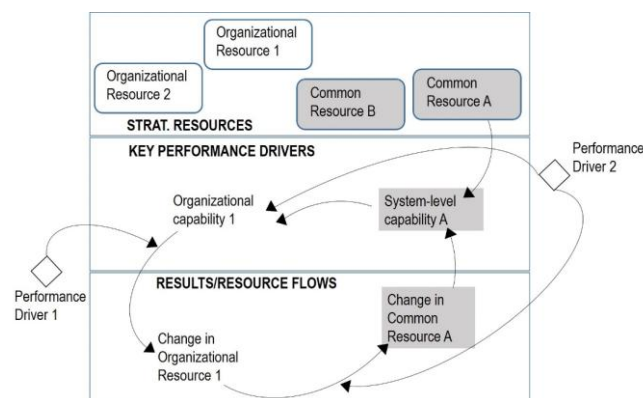

Figure 2- The typical structure of the proposed Common-Good DPM modelling, including both organizational-level and commons-level strategic resources, performance drivers/capabilities, and results/resource flows.

The Common-Good DPM approach is conceived to concretely enable participatory and adaptive modelling, in which sustainability-relevant knowledge is collectively co-

created through feedback based learning. In addition, the Common-Good DPM approach is data-driven, and may both enable and leverage effective big data management.

Abstract

Despite their heterogeneity, Industry 4.0 enabling technologies have been recognized as a unique multi-faceted set of innovation that is able to provide disruptive innovation and define a new industrial paradigm, whose pervasiveness is experienced irrespective of sector, company size, or adopted business model. In this paper, we present the preliminary results of an analysis, based on case studies retrieved in extant literature on this topic, aimed at investigating whether and in which way Industry 4.0 enabling technologies impact on companies' sustainability, especially with respect to the environmental and social dimensions. The goal is to contribute to provide an overall view wherein the different Industry 4.0 technologies are analyzed in terms of their implications on the social and environmental dimensions of sustainability.

Keywords – Industry 4.0, sustainability, Global Reporting Initiative disclosure, case studies.

Paper type – Academic Research Paper

1 Introduction

The rapid improvement, in terms of cost, easiness of use, and performance, of sensors, actuators, information and communication apparatuses as well as the standardization of manufacturing systems (Weyer *et al.*, 2015) and interoperability (Liao *et al.*, 2017) allow

production processes to gain both flexibility and responsiveness. Such innovative technologies, which connect digital and physical systems, enable companies to carry on complex analyses and make real-time decisions so as to address market pressure and the fickleness of the environment wherein they operate (Gabriel and Pess, 2016).

These technologies have different fields of adoption and may be implemented independently of each other, however they have been recognized as a unique multifaceted set of innovation that act as a breakthrough for industrial ecosystems, irrespective of sector, size, or adopted business model. To stress their pervasiveness, the ability to carry on disruptive innovation and define a new industrial paradigm, they are often referred to as a whole by using the expressions “digital transformation” (Ustundang and Cevikcan, 2017), “fourth industrial revolution” (Schwab, 2017) or, more frequently, “Industry 4.0” enabling technologies.

Since the first adoption of the expression Industry 4.0 (Kagermann *et al.*, 2013), the attention devoted by scholars to this new industrial paradigm has rapidly grown, in both the technological and the business field (Kamble *et al.*, 2018). Nonetheless, even though sustainability is an inescapable topic of current debate among practitioners, scholars, and the wider public opinion, to our knowledge, the literature that investigates whether and to what extent Industry 4.0 is able to impact on sustainability is surprisingly scant, and does not depict a clear role of Industry 4.0 with respect to the three dimensions that define sustainability, i.e. economic, environmental, and social (Bonilla *et al.*, 2018; Kamble *et al.*, 2018; Stock *et al.*, 2018; Savastano *et al.*, 2019). For instance, the increased responsiveness of production systems might play a role in improving efficiency in terms of materials and energy required, as well as waste and emissions generated. On the other hand, the common opinion about the social impact of Industry 4.0 is often less optimistic. Innovative technologies will increase the demand of skilled workers in specific fields (such as robotics, or data analysis and integration), but might represent a challenge for the job market, by destroying jobs or at least requiring major conversion of medium- and poor-skilled workers (Lorenz *et al.*, 2015; Roblek *et al.*, 2016). Finally, the impact of Industry 4.0 might result problematic with respect to the economic dimension. The improved capability of large companies to offer very customized services will augment the power of such companies and favor the creation of few big multinational players, so causing an unfair distribution of profits among companies and, within each company, among stakeholders.

To our knowledge the only empirical study concerning the assessment of the influence of Industry 4.0 on the three pillars of sustainability is the one by Varela *et al.* (2019). Based on a literature review, they first identified the main contributions regarding the relation or influence of Industry 4.0 on the economic, environmental, and social dimension of sustainability. Then, based on the review results, Varela *et al.* formulated some hypotheses and tested them on a sample of Iberic companies. The result of the test showed a strong relation between Industry 4.0 and the three pillars of sustainability, with a strongest factorial weight for environmental sustainability (expressed in terms of energy consumption, circular economy and environmental practices with partners), followed by social sustainability (expressed in terms of salary remuneration, work conditions and

surrounding society), and economic sustainability (expressed in terms of profits, turnover and market share).

From the analysis of the literature, it emerges that the research has mostly considered the impact of specific technologies on sustainability rather than considering the new industrial paradigm as a whole, and has focused on single dimensions of sustainability rather than assuming a comprehensive perspective. The goal of this paper is then to contribute to develop an overall view of the implications due to the diverse Industry 4.0 technologies on the social and environmental dimensions of sustainability.

To this aim, we have investigated the literature on Industry 4.0 enabling technologies and their implications on sustainability, specifically focusing on case studies concerning Industry 4.0 technologies, which have been identified according to the methodology described in the next Section. Selected cases have been scrutinized against the topic specific standards and disclosures provided by Global Reporting Initiative (Section 3).

The analysis is in progress. Preliminary results, illustrated in Section 4, show that although Industry 4.0 enabling technologies have implication on both social and environmental dimensions, they mostly relate to the latter, in particular, to the topic Energy (GRI 302).

2 Methodology

The goal of the paper is to assess the implications deriving from the adoption of Industry 4.0 enabling technologies on the environmental and social dimensions of sustainability. To achieve such a goal we examined all the case studies dealing with the adoption of Industry 4.0 enabling technologies reported in Scopus in the period 2011-2018. We searched for papers that reported in the title, abstract or keywords, the expressions ‘Industry 4.0’ & ‘case stud*’ and also ‘Industry 4.0’ & ‘sustainability’. The search returned 352 (of which 345 into English) and 115 papers, respectively. As reported in Table 1, an analysis of the retrieved papers in both cases (‘Industry 4.0’ & ‘case stud*’ and ‘Industry 4.0’ & ‘Sustainability’) shows an exponential augment of papers, which tests the increasing interest towards the topics.

Table 1. Occurrence of retrieved paper per year, based on search key.

Year	‘Industry 4.0’ & ‘Sustainability’	‘Industry 4.0’ & ‘case stud*’
2018	72	206
2017	33	94
2016	5	35
2015	2	8
2014	3	2
Total	115	345

As reported in Table 2, the novelty of the topics is clearly stressed by the large number of papers related to conferences (conference papers or conference reviews are about half of the total number of papers). The topics are of interest of almost all

disciplines, engineering and computer science being those with larger occurrences (Table 3).

Only the papers written into English were considered. Duplications as well as studies different from case studies on Industry 4.0 enabling technologies were successively eliminated. Finally, among case studies, only those which discussed the implications of technology adoption on environmental and social sustainability consistently with what reported in the Sustainability Reporting Guidelines published by the Global Reporting Initiative (GRI), were further analyzed. GRI Sustainability Reporting Guidelines (GRI, 2016), a de facto standard in the field of sustainability reporting, include three universal standards applicable for every organization preparing a sustainability report as well as topic-specific standards used to report information on an organization's material impacts on economic topics (200 series), environmental topics (300 series) and social topics (400 series). For example, in the 300 series, GRI 301 deals with Materials, and includes the following specific disclosures, namely: Material used by weight and volume (301-1); Recycled input materials used (301-2); Reclaimed products and their packaging materials (301-3). The disclosures are associated with qualitative or quantitative indicators. We only considered the papers in which, even though not explicitly, disclosures associated to 300 and 400 series (environmental and social dimension of sustainability) were mentioned.

The analysis is in progress, so far we analyzed in details 15 cases.

Two (out of three) authors separately read the 15 papers to identify the technologies adopted as well the sustainability implications associated to their adoption. The technologies were classified according to the scheme provided by the Italian Ministry of Economic Development (<https://www.mise.gov.it/index.php/it/industria40>). Such a scheme identifies nine main categories of Industry 4.0 enabling technologies, namely collaborative robots, additive manufacturing, augmented reality, simulation, digital integration, industrial internet, cloud, cybersecurity and big data & analytics.

The sustainability implications were associated with each case where mentioned either in a textual form or by using indicators. Both qualitative (textual descriptions) and quantitative (indicators) information was collected by the two authors. Successively, the two authors read the papers again to verify the completeness of their lists. The lists so obtained were then compared. No consistency index was used to compare the lists, as considerations were almost always consistent.

Once the technologies and the implications were identified, the list were analyzed and discussed, to identify the most frequently studied technologies, the most frequently cited sustainability implications as well as possible correlations among technologies and sustainability implications.

3 Analysis and discussion

A description of the cases so far analysed is reported in Table 4.

Table 4. Cases description.

Case study	Description
SMALL Factory (Bedolla <i>et al.</i> , 2017)	Reproduction of a smart factory for educational purposes in a laboratory environment, in terms of both hardware and software, so as to integrate traditional manufacturing processes and new technologies according to the Industry 4.0 paradigm
Intelligent bandsaw monitoring system (Bagheri <i>et al.</i> , 2015)	Three bandsaw machines have been setup at different geographical locations and connected, configured and controlled by a 5-level Cyber-Physical System architecture
Augmented reality for virtual user manual (De Amicis <i>et al.</i> , 2018)	Assembly of a simple scale model of a car assisted by an augmented reality animation device
Technology for Ambient-Assisted Living Manufacturing (Gregori <i>et al.</i> , 2017)	Development of an assistive working environment that favors human-machine interaction and social sustainability, considering human needs within the design phase
Device Data Ingestion for Industrial Big Data Platforms (Ji <i>et al.</i> , 2016)	Heterogeneous device data ingestion model (synchronization, slicing, splitting and indexing) for an industrial big data platform of two Chinese companies

Case study	Description
Blockchain-enabled emission trading scheme (Khaqqi <i>et al.</i> , 2018)	Use of an open blockchain platform, Multichain, as the platform to publish bids and offers of a reputation-based emission trading system
Topology optimization for an automotive dashboard (Mantovani <i>et al.</i> , 2017)	Topology Optimization (TO) methods applied to design an aluminum sport car dashboard in view of weight reduction with torsional and bending stiffness targets
From mechatronic to Cyber-Physical Systems (Penas <i>et al.</i> , 2017)	Implementation of the extension of mechatronic systems to cyber-physical systems in a manufacturing industrial case study (tablets production)
Smart grids and urban drainage systems (Poonpakdee and Koivaniit, 2018)	Effect of systems architectures, centralized systems, and decentralized systems, to the accuracy of global aggregation
EOS P700 selective laser syntering machine (Qin <i>et al.</i> , 2017)	Service orientated Internet of Things framework focusing on the energy consumption modelling in the additive manufacturing process for reducing the power usage during production
Deep Digital Maintenance (Rødseth <i>et al.</i> , 2017)	Development of a new maintenance model called deep digital maintenance (DDM) that enables integrated planning where maintenance and production planning can be more integrated
Intelligent Mining Engineering Systems (Rylnikova <i>et al.</i> , 2017)	Robotized technologies, machinery and mechanisms rooted on artificial intelligence, and mining and transport system automatic controls applied to underground mine production areas
Digital Twin Data Modeling of an industrial component (Schroeder <i>et al.</i> , 2016)	Modeling and simulation of a digital twin for an industrial valve embedding information related to the whole life-cycle of that product
Virtual Engineering Factory (Shafiq <i>et al.</i> , 2016)	Assimilation of virtual engineering objects (VEO), virtual engineering processes (VEP), and virtual engineering factories (VEF) to provide a real-time, intelligent, monitoring scheme and for support decision making
Prefabricated components for eco-solidarity architecture (Sferra, 2017)	Process innovation for construction material sector, based on Industry 4.0, in view of adopting pre-fabricated components for environmentally and socially sustainable emergency architecture

As to the Industry 4.0 enabling technology, the analysis shows (Figure 1) a predominance of cases on Internet of Things (10 cases) and Big Data & Analytics (5 cases). No case deals with cybersecurity. Internet of Things is usually adopted with other technologies, in particular Simulation and Big Data & Analytics. The Cloud is always mentioned with other technologies. Virtual Reality is the sole technology never discussed (in the analysed cases) with other technologies.

From the set of cases included in the analysis, it emerges that the adoption of Industry 4.0 enabling technologies most frequently is mentioned in association with environmental implications. Specifically, as shown by Figure 2, the most mentioned topic of the environmental dimension is Energy (GRI 302), followed by Materials (GRI 301), Emissions (GRI 305), and Water (GRI 302), and Effluents and Waste (GRI 306). Only three social implications are mentioned: the one having most occurrences is Occupational Health and Safety (GRI 403), whereas less common are the implications cited with respect to Training and Education (GRI 404) and Customer Health and Safety (GRI 416).

Figure 1. Occurrences of Industry 4.0 enabling technologies within the selected cases.

Figure 2. Occurrences of social and environmental impacts within the selected cases.

We also tried to find out possible associations among technologies and environmental and social implications (Table 5).

Based on the small set of cases that have been included in this preliminary analysis, we observe that the implications of technology adoption on environmental and social technologies are distributed. Internet of Things seems to have most implications on Occupational health and safety (GRI 403) and Energy (GRI 302), whereas less frequent are the implication on the other sustainability topics; Big Data & Analytics is in the half of cases associated with the Materials topic (GRI 301). Implications of Simulation are equally distributed between environmental and social dimensions, whereas Robotics & advanced automation is mostly related to the environmental dimension.

Table 5. Associations between Industry 4.0 enabling technologies and environmental and social implications, according to Global Reporting Initiative standards.

	Internet of Things	Big Data & Analytics	Virtual and Augmented Reality	Simulation	Horizontal & Vertical integration	Additive manufacturing	Robotics & advanced automation	Cloud	Cyber-security
GRI 301 – Materials	1	3					1		
GRI 302 – Energy	3	1		1		1	1		
GRI 303 – Water	1			1			1		
GRI 305 – Emissions	1	1			1		1		
GRI 306 – Effluents and waste	1			1					
GRI 403 – Occupational health and safety	4	1		2			1	2	
GRI 404 – Training and education	1		1	1					
GRI 416 – Customer Health and Safety	1								

4 Conclusions

The paper illustrates some preliminary results of an analysis aimed at exploring the adoption of Industry 4.0 enabling technologies and its implication on the social and environmental dimensions of sustainability. The analysis of extant literature shows that the attention devoted to Industry 4.0 has rapidly flourished. However, to our knowledge most research focused on specific technologies whereas an analysis of all Industry 4.0 enabling technologies and their impact on the environmental and social dimensions of sustainability have been so far overlooked.

In the attempt to contribute to fill such a gap, we examined case studies on Industry 4.0 enabling technologies, as presented in the literature, and tried to assess the implications of their adoption on the environmental and social dimensions of sustainability. The analysis is still in progress, as only 15 of the selected cases were analysed in details. Preliminary results shows the predominant technologies (*i.e.* Internet of Things and Big Data & Analytics), the technologies most frequently adopted in combination with others, and the occurrences of the implications on sustainability expressed consistently with GRI disclosures. Once the analysis will be completed, the resulting framework will illustrate possible associations among technologies and their sustainability implications.

Abstract

Our investigation proposes a preliminary analysis on the diffusion of digital technologies in Entrepreneurship centers as emerging mechanisms to deliver entrepreneurial activities. Our research question is: how entrepreneurship research centres (Italian Contamination Labs) are adopting digital technologies to support the variety of entrepreneurial activities they deliver? An explorative study of 12 Entrepreneurship centers named “Contamination Labs (CLabs)” is conducted. Empirical evidence will provide evidence about the role that Digital technologies could play in supporting and enhancing the processes that the Italian Contamination Labs could play (e.g. presenting their own programmes and activities) and their indirect role (e.g. undertake joint programmes/activities with other faculties) in promoting enterprise and entrepreneurship activities of the academic entrepreneurs.

Keywords – Digital technologies, Entrepreneurship center, Contamination lab, Entrepreneurship education, Academic entrepreneurship.

Peper Type - Academic Research Paper

1. Introduction and Research aim

Extant research suggests that entrepreneurship centres (Cassia et al., 2013; Maas and Jones, 2017) can play an important role in stimulating entrepreneurship activities within Higher Education Institutions (Finkle et al. 2006, 2013, Nelles and Vorley, 2011), and in increasing the visibility of entrepreneurship as a profession and as a field of study (Fisher et al., 2011; Cassia et al., 2013). According to Siegel and Wright (2015) the establishment and growth of entrepreneurship centres is an emerging perspective of academic entrepreneurship, that includes a wider social and economic benefit to the University ecosystem overcoming the traditional goal of economic revenue from research commercialization. The goals of entrepreneurship centres vary significantly between new firm creation, researching market opportunities, developing enterprising and entrepreneurship skills among students and staff, and contributing to the capitalization of knowledge (Del-Palacio et al. 2008). In Italian Universities, in 2012 the MIUR Italian Ministry of University and Research financed the Contamination Lab, a places where University's students will be involved entrepreneurship education activities such as idea generation, business games and in business plan competitions (for example E-capital business plan competition) and idea challenge proposed by companies. Huffman and Quigley (2002) and Russell et al. (2008) note that business plan competitions provide a mechanism for new business start-up and for encouraging entrepreneurial ideas, talents and potential. Der Foo et al. (2005) noted their role in team building and utilising new technologies. Activities such as business skills development, team-building, mentoring, judges' feedback and networking represent core activities of an effective business planning competition (Russell et al., 2008). Streeter et al. (2002) and Atchison and Gotlieb (2004) identify that such competitions offer the opportunity to develop both generic skills and entrepreneurial mindset and business knowledge competencies.

In parallel to this evolution, another interesting phenomenon is the rapid acceleration of digital technologies (such as social media, internet of things, MOOCs, 3D printing, Big Data, etc..) that are reshaping society globally (Nambisan et al., 2017). Across various studies, the notion of "digital platform" has gained considerable traction when addressing such managerial challenges of digitisation (Gawer & Cusumano, 2014). Digital technologies are opening up fascinating innovation opportunities for entrepreneurs (Yoo et al., 2010; Cohen et al, 2017, Urbinati et al., 2017) and can become the dominant source for innovation also in entrepreneurship centre. Despite the relevance of both fields, to our best knowledge surprisingly few studies have focused on the analysis of digital and smart technologies in the whole spectrums of entrepreneurship centres activities and processes and this justify the paper's aim. This research gap is more evident in Italy where the launching of the entrepreneurship center for student's education are still in infancy. The MIUR Italian Ministry of University and Research launched in 2012 a first competitive call for asking the Italian Universities to propose some projects to activate the so called "Contamination Lab" as Virtual and Physical environment where students with different background could be involved into entrepreneurial learning activities to promote their entrepreneurial awareness and innovative ability.

With the aim to cover this gap, our investigation proposes a preliminary analysis on the diffusion of digital technologies in the Italian Contamination Lab (CLab) launched as Entrepreneurship centers within the Universities to deliver entrepreneurial activities for Universities' students. Our research question is: *how entrepreneurship research centres (Italian Contamination Labs) are adopting digital platforms to support the variety of entrepreneurial activities they deliver?*

In the attempt to provide and answer to this question an explorative study of 12 Entrepreneurship centers named "*Contamination Labs (CLabs)*" is conducted taking in consideration the active CLabs located in North, Centre and South of Italy Universities. Findings will provide some preliminary insights about the strategic role of CLab in terms of creating the so called "entrepreneurship and sense of initiative "competence among all the students. Moreover, the analysis will focus on the adoption of the digital technologies inside the CLab to sustain and foster the processes and activities toward the achievement of the University's third mission aim.

The remaining of the paper is organised as follows. Section 2 briefly introduce the background around the key concept of Entrepreneurship research centres and Digital Technologies. Section 3 introduces the research methodology. Section 4 presents the preliminary findings. Section 5 discusses and concludes the paper.

2. Research Methodology

Fifteen case studies of the Contamination Labs financed by the Italian Ministry of University and Research in the 2017 – 2020 were firstly identified and analysed. Among this in the period of observation, just 12 were active. The collection of data was obtained between October 2018 and December 2018 and the active targeted sample was chosen from the comprehensive list of the Contamination lab (CLab) belonging to the Italian network of Contamination lab managed by the University of Cagliari (Italy).

2.1 Research context

A CLab is a physical environment where students are involved in the development of an entrepreneurial mindset, creativity and innovation through the adoption of learning strategies typical of the Entrepreneurship education. The laboratory involves all the University's students with different backgrounds (Business, Humanities, Social science, Science, Engineering, Biology, arts etc..) through innovative extra-curricular activities within a learning program having a duration of six months. The founding values of the CLabs are interdisciplinarity and contamination among different experiences, background and competences through new learning models and the development of innovation projects with an entrepreneurial and social vocation, in close collaboration with the territory. The National Program for Research foresees a strengthening of the investment in the Contamination Labs (CLab), intended as places of contamination between university students and graduate students of different disciplines. CLab entrepreneurial learning activities are part of the students' curriculum as an optional course, specifically, attendance to structured courses and seminars can worth as ECTS (European Credit

Transfer and Accumulation System). The scientific committee of each CLab decide the criteria for evaluating students' performance, considering not only the knowledge acquired but also the objective reached, the student's attitude in the group and the respect of the timeline for the project works development. The Italian CLab Network is the network connecting all the CLabs managed by the University of Cagliari contamination Lab (<http://clabitalia.it/>).

2.2 Data collection and analysis

12 Italian CLabs have been analysed. All the CLab chief (Coordinator) in the list were firstly contacted by e-mail and with positive respondents a skype call was agreed to collect further details about their mission, process, and activities. Moreover, a web survey has been prepared to address the main questions related to the types and intensity of adoption of digital technologies. The survey is divided in three sections. The first is a general section, where question about the governance structure of the CLabs are formulated (university of affiliation, number of employees, types of managerial structure, typologies of activities performed. In the second section respondents are required to indicate the types of digital technologies adopted and the related impact, and also which technologies will be strategically adopted in the future. Digital technologies had been listed based on authors' elaboration of digital artefact, platform and infrastructure concepts by Nambisan (2017). A final section asks respondents to indicate barriers and constraints to the adoption of digital technologies in their daily activities. A phone or face to face interview was agreed in January 2019 to finalise the data analysis.

3. Findings

In 2016, 17 Contamination labs has been launched by 16 Italian Universities starting from a competitive call at national level involving all the Universities. Among those CLabs, at the time of the survey, 12 were operative and they had already started the educational activities. So far, our analysis will comprise the whole set of the active contamination labs in Italy. The main idea behind the CLab is to create a place where: 1) it is possible to foster cooperation among students, entrepreneurs and academics; 2) students, entrepreneurs and academics share knowledge and create new understandings and work together to form plans of action (co-learning); 3) students set their own agendas and then act to carry out the action with the help of entrepreneurs and academics; 4) students are embedded into entrepreneurial culture; 5) teachers and mentor show the best practice in entrepreneurship and innovation in the creation of new businesses; and 6) students learn to manage all stages of the knowledge transfer process to support organic growth within the high technology sector for set up a start-up.

The whole CLab sample provided answer to the online survey. The table 1 presents the description of the CLabs' sample. The list of CLab shows an equal distribution among north (4), center (2) and south (5) Italy. The total funded amount is 4.1MI Euros. The entrepreneurial program of each CLabs is strictly guided by the MIUR (Italian Ministry of University and Research) according to the general recommendation off the

European Union in terms of Entrepreneurial Competences development at all levels of education. In some cases, every year two educational programs are launched in parallel with the 2 semesters within the CLabs, in other cases one program is managed. For this reason, big differences in term of number of trained students as reported in Table 1.

Table 1 - Contamination Labs

CLAB Code	Location	Year of launching	Number editions activated	N. of the students Participating to the CLab
Clab 1	South	2017	2	120
Clab 2	North	2017	2	130
Clab 3	South	2014	5	500
Clab 4	South	2017	2	90
Clab 5	Center	2013	6	536
Clab 6	South	2014	16	640
Clab 7	Center	2013	5	60
Clab 8	South	2017	3	120
Clab 9	North	2017	2	200
Clab 10	North	2013	6	580
Clab 11	North	2018	2	60
Clab 12	North	2017	2	80

Academic entrepreneurship implies specific activities to make the university more entrepreneurial. Among these, the entrepreneurship centres can play the role of intermediary between researchers and industries, providing opportunities to enhance the social and economic impact on the territory. Then, we can also count activities such as the creation of spinoffs and startups, the engagement of local communities through events and workshops, entrepreneurial education activities, the organizations of business plan competitions and, finally, contracts with industries and public administrations.

We asked each CLab which of those activities are considered as the most strategic in the present and which they supposed to be strategic in the immediate future. Right now, the most strategic activity expressed by Clabs is entrepreneurial education with an average score of 4.50 followed by intermediation activities (with 4.33). On the contrary, the less strategic initiatives promoted by the CLabs are the management of intellectual property right and hackathon. This is in line with the general aim and mission of the CLab.

When we look into the prospective strategic activities CLabs aim to plan, the most relevant one still remains entrepreneurial education (with 4.67). This is reasonable as literature demonstrated how education is the most powerful tool to train young people and to guide them in the achievement at first of an entrepreneurial mindset and awareness. If we move to the deltas between present and future strategic activities, research contracts with external actors and startup/spinoff creation are the two activities that count the largest difference. This means that CLabs are considering strengthening those two areas of activities. This result is coherent with the fact that the CLabs are financed just for three year by the MIUR and that they are looking for becoming sustainable in the long period to become permanent research centers for entrepreneurship to accomplish the third mission aim.

Table 2 - Strategic activities importance in the present (now) and in the future (in 3 years)

	Intermediation activities			Hackathon			Intellectual property			Spinoff/Startup			Local community			Entrepreneurial Education			Business plan competition			Research contract

Average	4,33	4,42	0,08	3,25	3,42	0,17	2,83	3,08	0,25	3,83	4,42	0,58	3,92	4,33	0,42	4,50	4,67	0,17	3,67	3,83	0,17	3,67	4,17	0,50

Digital technologies are mainly used for promotional purpose (see table 3). Social media is the most adopted technologies, with an average score of 4.33. Digital platform, with 3.17, is the second most used digital technologies. In general, CLabs make little use of digital technologies for their daily activities. If we analyse future strategies, there is a general consensus about the intention to adopt e-learning technologies to improve students' participation in the general course related to knowledge about the global future trends, basic knowledge on business management and Business planning. MOOC, indeed, is the technologies with the highest delta when comparing actual and future declaration of digital technologies adoption.

This evidence could be explained by the fact that in this first phase of activities CLabs are more focused on the development and management of the entrepreneurial learning activities to facilitate the generation of students' business ideas.

DI: digital infrastructure (e.g.: social media, MOOC)

DP: digital platform (e.g.: IoT, 3D, Big Data)

DA: digital artifact (e.g.: AR, VR, blockchain)

Furthermore, we surveyed the level of impact of each digital technology families on the activities CLabs organize and manage (table 4). We categorized three digital technology families to make the survey easier to be filled by the interviewed CLab Chief and /or CLab project managers. We grouped technologies such as social media and MOOC in DI (digital infrastructure); technologies like IoT, 3D printer, Big Data, Intelligent app in DP (digital platform); and finally, technologies as augmented and virtual reality, blockchain in DA (digital artefact). In the questionnaire, it was asked to indicate the impact of the digital technology families on the activities based on a 4 – point scale: no impact at all (0), low impact (1), medium impact (2), high impact (3). In general, the impact appears to be low or with no impact at all. Few CLabs adopt strategically some digital technologies while some CLabs do not use at all any digital technologies or they do not rely any impact on their activities. Digital infrastructures present the highest rate of impact, especially on intermediation activities, spinoff and startup activities, local community engagement activities, entrepreneurial education activities and business plan competition activities. This is probably due to the fact that social media is a technology included in this family, and as previously showed, social media is the most used technologies bay CLabs.

What are the strategic activities carried on by the CLabs, and are the digital technologies adopted to facilitate such activities? The picture that emerged from this section reports a medium capacity of CLabs to strategically involve external actors in their activities, and a medium ability to promote new venture creations among their students. Moreover, as a sort of validation of the previous analysis, managers of CLabs declare a medium use of digital technologies to engage and inspire new entrepreneurs as a result of their activities.

The last section of the questionnaire asks CLabs to report barriers and constraints in relation to the ability of a CLab to operate and the easy of adoption of digital technologies. The most cited criticalities to solve their missions and scopes are difficulties when involving internal professors and technicians in the CLabs activities and the great heterogeneity of the class appears to be a limit when evaluating the general involvement of the students.

Table 5 - Strategic activities of CLabs

	The Clab has strategic collaboration contracts with firms	The Clab collaborates with firms and institution	The Clab is able to engage citizens and external actors in its activities	The Clab is able to retain ex students	The Clab is able to promote new venture creation by the Clab's students	The Clab is able to involve researchers and technicians in new venture creation activities	The educational activities are performed thanks to the most powerful available technologies	The Clab is able to offer digital technologies facilities to startupper and entrepreneurs	The Clab is able to create knowledge sharing mechanisms thanks to the adoption of digital technologies
Clab 1	4	4	3	4	3	2	5	4	4
Clab 2	4	4	3	3	2	1	3	3	3
Clab 3	4	4	3	2	4	1	4	3	3
Clab 4	3	3	4	4	4	3	4	4	4
Clab 5	4	4	4	5	5	3	3	4	4
Clab 6	2	2	2	3	3	3	3	3	3
Clab 7	3	4	3	4	2	2	2	2	2
Clab 8	3	3	4	4	3	2	3	3	3
Clab 9	4	4	3	4	4	2	4	3	3
Clab 10	4	4	4	2	2	3	4	2	2
Clab 11	2	4	4	5	4	3	4	3	4
Clab 12	5	4	3	1	2	1	3	2	2
Average	3,50	3,67	3,33	3,42	3,17	2,17	3,50	3,00	3,08

What about the adoption of digital technologies? CLabs declare that the most critical barriers is the cultural one. Digital technologies are not so much diffused regularly in the daily activities of the university they belong to. And this aspect creates high constraints for the adoption of technologies to support students in their activities.

4. Discussions and Conclusions

Empirical evidence will provide evidence about the possibilities and constraints of digital technologies for the entrepreneurship centre's goals, governance and processes to better understand the challenges posed by the digital revolution to the activities of the centre. CLabs surveyed declare a low level of adoption of digital technologies. If social media such as facebook are widely adopted, such social media serve just as promotion tools of the CLab activities. Technologies like blockchains, big data, 3D printers are poorly adopted. Surprisingly, MOOC are totally not adopted neither considered as strategic. The strategic vision for the future changes a little bit, since such technologies are view as important for the sustainability of the centre, but cultural and time constraints are evidenced as the more important barriers to the adoption of the digital technologies.

There is the need to know more about what entrepreneurship or enterprise education actually "is" when implemented in practice and the real challenge could be to embed this type of course in the Universities' curriculum. This is problematic because the entrepreneurial approach to teaching entrepreneurship is the antithesis of traditional approaches to teaching. Academic assessment processes evaluate and test knowledge and skill rather than behaviour, therefore widening the assessment process to accommodate behaviour is the real challenge for academic institutions, although it is a challenge that is beginning to be undertaken.

Academic policy and decision makers need to be convinced of the value in offering such courses before they can be inserted into mainstream programmes. Arguably course developers will need to employ their own entrepreneurship behaviours to establish such programmes in mainstream academia.

CLabs sought to introduce entrepreneurship education into the science, medicine and engineering faculties, adopting the approach of encouraging the development of enterprise attributes and competencies rather than focussing on business start-up but also to other dimensions such as employability, social entrepreneurship, academic entrepreneurship and intrapreneurship. By adopting this “enterprise for life” approach C Lab formula emphasised the value of an entrepreneurial attitude and enterprising behaviour to enrich people’s lives and to contribute to social change.

The assumptions of CLab formula were built starting from the main issues, objectives, methods and evaluation analysed in other context, with the aim to cover the gap existing in Italian University system in this field. The guidelines of CLab are:

- Entrepreneurs and academicians have a great deal of knowledge and experience to share with others (theoretical and practical), some of which will be of value to students who wish to start an entrepreneurial career;
- Students of different disciplines have a knowledge and experience to share in a common space;
- The collaborative and co-learning environment is necessary for encouraging this exchange of information;
- Involving students, entrepreneurs and academicians in the process of education should be a solution leading to effective learning of entrepreneurial knowledge, skills and behaviours;
- The safe environment of c Lab is supportive and allows collaboration among students, entrepreneurs and academicians with the aim to encourage the acquiring of entrepreneurial behaviours;
- teaching and training programmes for entrepreneurship in all schools are provided;
- the use of business plans as a pedagogical tool for preparing future entrepreneurs;
- “innovative methods” that include game simulations; video and filming; role models or guest speakers; business plan creation; and project works, games and competitions, setting of real small business ventures, workshops, presentations and study visits public symposia and awareness campaigns, dissemination of research results to the community; students’ consulting projects with local entrepreneurs, technology transfer activities, incubation services;
- the students’ self-assessment of the business idea and its feasibility, creativity and the written presentation are used as evaluation tools.

Research implications regard the potential role that Digital technologies could play in supporting and enhancing the processes that the Italian Contamination Labs could play (e.g. presenting their own programmes and activities) and their indirect role (e.g. undertake joint programmes/activities with other faculties) in promoting enterprise and entrepreneurship activities of the academic entrepreneurs.

Practical implications will concern insights for the entrepreneurship centre governance body involved into the guidance of processes such as entrepreneurial competence development, knowledge transfer and innovation in the university ecosystem and social engagement through the utilization of the digital technologies.

Limitations of the study and future research. The main limitation regards the fact that the study has been realised just at the beginning of the first edition for each CLabs. A new survey will be launched at the end of June 2019 when each CLab will close the current on-going edition. This will allow to compare the results.

Abstract

Our paper consist of a literature review about business model research in academia, which represents a premise to identify the main topics, as well as the evolution of the studies.

As for the methodology, we used EBSCO database, searching for academic papers having “business model” in the title and in the abstract published from 1975 until now.

This paper contributes to the literature in two ways. First, it provides a wide analysis of the extant literature on business models. Besides the classification by main topics, we aim to outline the trend of these studies over time.

Moreover, by this review we propose to understand how much literature has already investigated, and to identify new roots for future research on empirical and practical application of business model in business studies.

Our work is the first step of a project. In order to contribute to previous literature, we propose to view corporate business models as the crossroads of different disciplines, as management and accounting and finance are. Further developments of our research, actually, could concern the study of the characteristics of sustainable business models applied by firms, in order to select which key factors of firms’ business model positively affect their performance and their value.

Keywords – Business model, Sustainability, literature review.

Paper type – Academic Research Paper

1 Introduction

Business Model (BM) has been widely investigated by academic literature. This is a well-known event, especially in recent years.

According to Wirtz et al. (2016), a BM is an aggregated representation of the relevant activities of a company. It describes how marketable information, products and/or services are generated by means of a company's value-added component. In addition to the architecture of value creation, strategic as well as customer and market components are taken into consideration, in order to achieve the superordinate goal of generating, or rather, securing the competitive advantage. To fulfill this latter purpose, a current business model should always be critically regarded from a dynamic perspective, thus within the consciousness that there may be the need for business model evolution or business model innovation, due to internal or external changes over time. In line with Baden-Fuller and Morgan's (2010) suggestion to interpret business models in a systematic way, we suggest that all the existing conceptualization made by literature, especially strategic management literature can co-exist, as they supplement each other and can open their boundaries to other stream of research, such the accounting literature and financial literature. This can be a contribution that is voted to fill the gap in literature about the effectiveness of a BM, the profitability of a BM, the sustainability of a BM, the capability of a BM to produce dynamic capabilities. In few word, to answer the question about what BM is beneficial to firms.

The business model approach can be viewed as activity systems that cover internal and external activities in which firms are (Zott and Amit, 2010). As regards BM, several accruals emerge from extant literature, about the definition, the topic, the perspective of analysis (field of research), its taxonomy, and its effect on competitive advantage of firms, giving the fact that the comprehension of BM is still lacking (what a BM is, what it is not, its boundaries, how to create a good BM, its description, its characteristic and its effective reflections on firm performance).

These are the main questions still unanswered by literature (Teece, 2010). In order to better understand how much literature has already unveiled and how much it is still far to be found out, we provide a structured literature review on business model, to clarify the research topic on BM and its future roots and to reply our research questions:

RQ1: Which are the focus of the literature on business model?

RQ2: How has the research on business model evolved over the time?

RQ3: what are the future developments of the research?

The contribution of this paper is not only to provide a literature review, as a simple portrait of the current state of the art about BM research, but also to focus on its theoretical perspectives and lacks, so to be able to understand what we have actually learned about it and which are the existing gaps in literature, also empirical one. So this work to our intention is a dynamic recognition of existing literature on this theme, wondering the BM utility as a tool to use BM in practice and the future developments from an academic perspective.

The paper is organized as follows. In the next section, we describe the evolution of the researches on business model. In paragraph 3 we will describe the research methodology that we have applied. In paragraph 4 we will provide the results obtained in our research. We last present the discussion and the conclusions.

2 The academic history of business model

The BM term has been receiving growing attention from managerial academic researchers, as a management tool to gain performance and capture value. The wide use researchers made of its application lead to non-unique and heterogeneous comprehension of the effective and concrete meaning of the term BM.

At the beginning (early Sixteens') of the scientific research, the term BM was associated to information technology, that is the way firms built up business processes and made information and functional/operative processes, from an engineering perspective (operative system modelling). Only in Seventies' literature have been started to associate the term BM to managerial and strategic issues within the behaviour of firms, in order to address the research to put BM in a holistic and organic managerial framework. So, BM has been intended as a managerial tool to obtain performance (Konczal, 1975). Meaning that BM started to be viewed as the architecture of firms to behave and to capture value, and from a theoretical perspective to be examined into several and different components.

Until the end of 1990's, in literature, scholars put their attention to single and static aspect of BM (structure, activities, and purposes). In the meanwhile, from the earlier 2000s', literature has devoted progressively more attention to a dynamic picture of a BM (business model dynamics), concluding that firm can obtain competitive advantage through business model innovation or reinvention (Voelpel et al., 2004), rather than a simple change or incremental improvement in a stated BM (Demil and Lecocq, 2010).

Starting from the 2000s', literature has been progressively focusing on the strategic aspect of business models, since it was clear that BM are the ways to build an organization. As technological development over time and the creation of electronic business were established, the same BM received more and more attention from a managerial and strategic perspective. As BM differentiation was introduced, it was possible to understand the strategic orientation of firms to gain competitive advantage on the market. At the same time, the association of BM to technological development makes easier to analyse the innovation processes undertaken by firms. In this way, the differentiation of BM made possible to establish different components relevant at a strategic level, and to theorize about the strategic perspective of BM (Chesbrough and Rosenbloom, 2002).

Amit and Zott, actually, in 2001, in their seminal work on e-commerce, tried to define the business model concept, in order to generate an integrated model of value creation on the firms by combining strategic management literature with other theoretical perspective about firms' theory and innovation theory. The same Hedman and Kalling who in 2002

explain the theoretical foundations of business model in different organizational theories combined with strategic process perspective.

Over time, BM has been progressively associated to the development of e-commerce and renewal technology (Cavalcante et al., 2011) and became an abstraction which identifies the representation of the company and its strategy. So, in this period the BM was linked to the strategy of a company up to starting that BM is an important phase of the behaviour of a company between its strategic planning and the action (Casaneus-Masanell and Ricart, 2010).

In very recent years, BM have becoming a depiction of the way firms do formulate their value proposition in order to implement their financial performance, so to represent the enhancing of the strategy about customers and the general environment. The value proposition, according to Haslam et al., 2015, has three components: the value creation, the value capturing and the value manipulating, which affect the three phases of the firms' behaviour (planning, action and control) by the leading functions (planning, organization, control and feed-back). Starting from the seminal work of Chesbrough (2007) and of Zott e Amit (2008), academic researchers have started to view BM as a factor affecting the value proposition of firms.

Along with the development of technology, authors focused their attention on the market domain of technology, so that firms can understand the viable ways of gaining rents belonging to technological change (Amit and Zott, 2001). In such approach, several elements become relevant to define the value creation and capturing process of firms, so that firm may pay attention to different components/functions of a BM to pursue the going concern principle. For instance, external institutional and environmental and several internal factors can affect BM creation towards the stakeholder *plethora* (customers, financial lenders, suppliers, competitors, markets). It is necessary to move from the concept of BM, to its components and functions. Several authors have faced this issue in different high technology sectors. As for the elements of a BM, Wirtz et al. (2016) depict several internal and external elements that put together lead a firm to gain competitive advantage. Among internal resources, the most important is the strategy through which management and corporate governance define the long term objective to maintain competitive advantage (competitive strategy). Another internal resource is represented by human resource (knowledge, capabilities, competencies of human resource within organization). Above these the "leadership capabilities" are the most important organizational competencies. Leadership and culture have been determined by Chesbrough (2010) for playing important role in embracing new business model and leading the change to the new model. Among internal resources, Authors also include the revenue model and financial structure of firms as an important component to define a BM.

The external component are mainly the market structure, the firms' stakeholders policy (management), the networking capabilities of firms, industry. It should be the case to add institutional and regulator factors which can affect the structure of BM.

3 Research Methodology

This article applies a structured literature review methodology, which allows to analyze a great number of articles and to identify relevant characteristics in a specific research field, in order to understand the main topics and the future developments on it (Paoloni and Demartini, 2016).

3.1 Selection of articles

We retrieve data from EBSCO database on December 2018, for the period starting 1975. We chose EBSCO because it is widely used in the literature and allows us to be confident to the quality of the publications. We selected articles having “business model” both in the title and in the abstract. We obtained 1212 articles. Then we introduces some filters, selecting only papers published on academic journals and only publications available in pdf. At the end of the selecting process, we obtained 429 articles.

3.2 Defining the analytical framework

We read the title, the abstract and the keywords of the selected articles to be sure that they are relevant. After this analysis we removed 16 articles that are off topic. After reading the titles, the abstract and the keywords of all the relevant articles (413 manuscripts), the authors defined the analytical framework that is composed by these two classifications:

- A. Article focus
 - 1. framework;
 - 2. BM innovation;
 - 3. BM and sustainability;
 - 4. BM and value;
 - 5. BM and disclosure;
 - 6. Other.
- B. Research method
 - 1. narrative;
 - 2. literature review;
 - 3. qualitative;
 - 4. quantitative;
 - 5. mixed.

In order to classify papers and to understand their focus, we did not use a software, but a manual approach by reading the abstracts.

An advantage of this approach over a computer-aided analysis is that humans can better judge the meaning of words and phrases within a context. A disadvantage is that a manual approach is less cost-effective and flexible. Furthermore, the classification entails the use of a personal judgment that could affect the results. To reduce the risk of the bias, authors worked together to identify the main classes and to classify abstracts.

Another problem is that, by reading only titles, keywords and abstracts, the team of researchers may have neglected some relevant information required to carry out a complete classification according to the analytical framework. For instance, in some cases, abstracts do not always provide details on the methodology applied by authors but only give some generic information.

As regards the article focus, the purpose of this classification is to identify the specific topic of articles to gain insights the topics of existing literature in order to reply to research questions.

As we said, the different topics identified by the authors are the following.

Framework: includes those articles that analyze the characteristics and the components of BM, in order to define a framework of it. Some of these studies propose a classification about different BM (Kortmann et al., 2016; Yao et al., 2018).

Sometimes, the articles refer to particular sectors, the most recent studies have often focused on innovative high-tech sector (Muñoz and Cohen, 2018; Remane et al., 2017; Spieth et al., 2018), the internet industry (Guo et al., 2017; Spiegel et al., 2016), the circular economy (Manninen et al., 2018; Ranta et al., 2018; Urbinati et al., 2017), and the energy sector (Bidmon and Knab, 2018; Poudineh et al., 2017).

BM innovation: includes those articles that analyze the changes and the evolutions of the BM to keep innovative, to ensure business growth and to create and capture value.

Some of these studies propose tools and procedures to guarantee innovative and growing BM (Futterer et al., 2018; García-Gutiérrez et al., 2016; Prendeville et al., 2017; Winterhalter et al., 2017); others investigate the motivations and effects of innovation (Comberg et al., 2017; Rayna et al., 2016) and others the choices that must be made to innovate a BM (Broekhuizen et al., 2018; Johnson et al., 2008).

BM and sustainability: includes those studies that examine the characteristics that BM must have to be sustainable and reduce negative impacts on the environment.

Some studies propose a classification of sustainable BM (Yip and Bocken, 2018); others analyze the critical factors for the transition from traditional BM to sustainable BM (Long et al., 2018; Pal et al., 2018); others, finally, suggest some strategies to implement sustainable BM (Ribeiro et al., 2018; Rauter et al., 2017).

In this category, we classified also all the articles that study the innovation finalized to improve the sustainability of the firm. Recent studies, in fact, recognize that business contributions to sustainable development are founded in new business models (Roome et al., 2016) and in transformation of previous traditional models (Stubbs and Cocklin, 2008).

BM and value: includes few researches which analyze the effects of BM on company performance (Haggège et al., 2017; Wei et al., 2017), on its reputation (Ma and Osiyevskyy, 2017) and its value (Guo et al., 2017).

BM and disclosure: includes few researches examining the disclosure made by companies on their BM (Bagnoli and Redigolo, 2016), the different reports that can be used to disseminate information on BM (Lassini et al., 2016; Mellone et al., 2016; Michalak et al., 2017) or the effects of the BM disclosure (Haslam et al., 2015).

Other: it is a residual category that includes all those articles that do not belong, to our opinion, to the previous categories. In “Other”, we also include articles related to BM research, namely the literature reviews that address all the previously outlined topics and the special issue editorials specifically dedicated to BM.

From the above classification, it can be deduced that topics n. 1) and 2) (framework and innovation) can be inserted in the field of management. The topics n. 3, especially with reference to CSR aspects, n.4 and n.5 (value and disclosure) can be included in the field of accounting and performance.

As about the research method, it is possible to distinguish the following:

narrative: theoretical articles without quantitative analysis;

literature review: narrative articles dedicated to the review of extant literature;

qualitative: articles with qualitative analysis through case study, experiments, survey or interview;

quantitative: manuscripts with empirical analysis based on information obtained from databases, financial statements or other reports;

mixed: articles that applied multiple methods (for instance literature review and case study).

4. Results

This section provides the descriptive results of our research.

The analysis of the abstracts allowed us to examine the different articles, identifying for each of them the prevailing topic. The results of this survey are shown in the following table and graph.

Table 1: articles focus

Topic	N.	%
framework	182	44,07%
innovation	110	26,63%
sustainability	60	14,53%
value	26	6,30%
disclosure	6	1,45%
other	29	7,02%
Total	413	100,00%

Graph 1: articles focus

Table and graph 1 highlight that most researches have focused their attention on the development of a framework for BM, sometimes investigating their characteristics for specific business industries (D'Souza, 2016; Riehle, 2012; Stal, 2018), sometimes their components (Da Silva, 2013; Ranta, 2018; Sachsenhofer, 2016) and proposing different classification for BM (Chjatterjee, 2013; Hahn, 2018; Krech, 2015).

Articles on innovation examine the changes of the BM needed to guarantee the competitiveness and the business growth (Comberg, 2017; Ebel, 2016; Gebauer, 2017), sometimes analyzing the effects on the market (Rayna, 2016) or on the innovation of the same company (Iivari, 2015).

Previous researches that investigated the theme of sustainability among BM focused their attention on sustainability-oriented BM, with better social and environmental impacts. Among this category, some studies combine innovation and sustainability, testing the possibility of replacing the traditional BM pollutants with sustainable BM, in order to identify of successful BM also analyzing social impacts (Carayannis et al., 2015; Gauthier, 2016; Richter, 2013; Roome, 2016; Zhao, 2018).

Just few researches focused their attention on accounting field and in particular on the topics value and disclosure. Articles on value examined, generally through empirical analysis, the correlation between BM and firm value and performance (Anwar, 2018; Brenes, 2016; Gerasymenko, 2015). Papers on disclosure analyze the information that companies voluntary provide on their BM (Melloni, 2016; Michalak, 2017).

Table and graph 2 show the different methodology adopted by the articles of our research.

Table 2: articles methodology

Method	N.	%
narrative	156	37,77%
qualitative	171	41,40%
quantitative	43	10,41%
literature review	21	5,08%
mixed	22	5,33%
Total	413	100,00%

Graph 2: articles methodology

The previous table and graph show that more than 40% of our sample adopt a qualitative research approach. Among this group, we can distinguish the following methods:

Table 3: qualitative methodology

Qualitative	N.	%
case study	119	69,59%
interviews	33	19,30%
survey	10	5,85%
experiment	7	4,09%
other qualitative	2	1,17%
Total	171	100,00%

Graph 3: qualitative methodology

As regards exclusively the empirical research and the case studies, we examined the geographical area of the research (regardless of the author's nationality), distinguishing between:

1. North America (Canada, USA);
2. South America (Brazil, Patagonia);
3. UK;
4. North Europe (Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Netherlands, Scandinavian countries, Switzerland);
5. South and East Europe (Italy, Spain, Portugal, Estonia);
6. Asia (China, Hong Kong, Korea, India, Indonesia, Japan, Pakistan, Philippines, Singapore, Taiwan);
7. Oceania (Australia, New Zealand);
8. Mixed.

No study was found for Africa. It is important to note that in some abstract (n. 34) there was no information on the country of the research.

The country of research allow us to identify the places more investigated and the new areas that could be subject to investigation.

The following table and graph shows the results of the analysis.

Table 4: geographical area of the research

Country	N.	%
North Europe	45	35,16%
South Europe	14	10,94%
UK	9	7,03%
North America	15	11,72%
South America	4	3,13%
Asia	22	17,19%
Oceania	2	1,56%
Mixed	17	13,28%
Total	128	100,00%

Graph 4: geographical area of the research

As we can see from the above table and diagram, only few researches have been carried out in developing countries (Bittencourt, 2016; Brenes, 2016; Dembek, 2018; Gabriel, 2016; Jamasb, 2018; Mason, 2017; Matos, 2013), in most cases, papers analyzed developed countries, and in particular Europe (53,13%). Some studies propose a comparative analysis between developing and developed countries (Bolis, 2017; Havemo, 2018; Maniora, 2017).

5 Discussion and conclusions

Our research shows that business model has been widely investigated by literature especially in recent years with a growth of the number of articles concerning this issue.

Our paper is focused on a structured review of the main literature extant on this topic, assessing which are gaps and limits and potential development of the research on BM. We addressed our work through three research question arising from the research methodology.

As for RQ1 and RQ2, we note that at the beginning of the period, most of researches is settled on management field, with a high percentage of articles on framework (40,07%, n.182 see table 1) and innovation of BM (26,63%, n.110 see table 1). Most of the literature indeed took a look of BM from a management perspective to understand how BM were influenced by strategy. Among this mainstream scholars, they took care to investigate different business models for different sectors, especially high-tech ones.

In recent years, scholars have also addressed their study following different theoretical settings, also combining CSR, value and corporate disclosure issues.

From the qualitative approach we adopted, it emerges that great part of literature is devoted to a mere depiction of BM (structure, management, design).

Other scholars have focused on the internal and external characteristics of a BM considering that the BM originates from the internal components of the company, especially the organization, but at least theoretically it involves the whole environment and it affects the market, too. Other researchers gave us an interesting insight on barriers and inertia due to the change in the BM.

The most used by scholars is the qualitative approach to case studies, which also to our opinion is the most useful to investigate by an inductive approach the phenomena related to BM.

More than 50% of papers analyze Euro-zone; the reason why it could represent an interesting question to answer to for future.

So, the overall conclusion of the previous two questions is for a general persisting gap also from an empirical and managerial perspective.

About RQ3, very poor and rare literature has faced factors affecting the evolution and the change of BM research in specific sectors and, above all, in the most innovative companies that continuously change and adapt their BM, to capture growth and value. Another emerging issue for future research is the identification of the variables which affect the BM evolution and adaptation to become over time, sustainable BM. We refer, both internal, as human resources, knowledge storage and management, firm size and

business industry, and external, as institutions, composition of market and so on. In this way, by the help of case studies, it could be possible to learn inductively the variables which affect the behavior of firms.

To do this, literature should examine if cultural and institutional factors (stakeholder pressures, environmental uncertainty, national culture, world bank indicators etc.), and internal organizational value (sustainable activities, ESG score, organizational culture and values, management style, organizational structure, etc.) are associated to sustainable business model.

The empirical literature gaps concern also the effects on financial performance of BM in accounting perspective. BM and accounting is still representing a glass ceiling in the literature. Few scholars in fact have intended the BM as a tool that can affect the financial performance of companies, mainly through its disclosure. No one has ever considered the BM as an aspect of corporate disclosure, while at the political level several organizations have tried to intend BM as a tool to give disclosure to stakeholders.

Since Rasmussen (2007) gave us a framework of BM within the theories of firms, scholars should undertake the study of BM as a determinant of corporate financial performance.

Starting from the intuition of Pedersen et al. (2018), who analyzed the relationship between Business model evolution and innovation, corporate sustainability and organizational value, we smell profitable avenues to understand if sustainable business model are effectively perceived as value creator.

Finally, we must conclude for some limitation of the paper. First, we used only a source (EBSCO); for future, we will employ other database to enlarge our article sample. Moreover, we structured the literature as a personal judgment. Furthermore, reading only the titles, keywords and abstracts is not sufficient to provide all the detailed required to complete the analytical framework and the classification.

Abstract

The dynamic environment that firms face forces them to respond quickly and flexibly to market changes in order to survive the competition. Proof of this is the call from different political, economic, social and academic institutions to companies to increase their efforts in the social and environmental fields, through the development of three essential pillars: economic, social and environmental (Triple Bottom Line).

Based on these ideas and with the purpose of linking the management of sustainable intangible assets with the performance of the firm, in this research we define sustainable intangible capital as the set of knowledge that a company can take advantage of to carry out an economic, social and environmental management that allows it to achieve competitive advantages.

Although in recent times intangible assets are considered the basic factor of production, it is necessary to show that the mere possession of them will not guarantee a superior performance. For that reason, the objective of this work is to analyse the dynamic role that the corporate social responsibility and the strategic knowledge management exert in the relationship between sustainable intellectual capital and firm performance.

To analyse the objective proposed, three hypotheses were proposed, which were tested using a quantitative methodology based on PLS on 120 Spanish hotels with three or more stars.

Findings do not support H1, which indicates that sustainable intangible capital does not influence hotel's performance in a significant way. On the contrary, the mediating hypotheses H2 and H3 have been supported, showing that corporate social responsibility and strategic knowledge management exert as mediator dynamic capabilities and a multiple mediation effect exists. This means that those capabilities create the values, the philosophy and the necessary foundations for sustainable intangible capital to influence on performance from a significant point of view.

With this research theoretical and practical contributions are made.

Keywords – Sustainable Intangible Capital, Strategic Knowledge Management, Corporate Social Responsibility, Performance.

Paper type – Academic Research Paper

1 Introduction

In the literature, we find more and more works in which the fields related to intangible assets, corporate social responsibility (CSR) and performance (PFM) are linked (Chang & Chen, 2012; Huang & Kung, 2011). However, in this research we intend to go a step further. Although in recent times intangible assets are considered the basic factor of production, it is necessary to show that the mere possession of them will not guarantee a superior performance. For that reason, based on the *resource-based view* of the firm (Collis & Montgomery, 1995; Peteraf, 1993; Rumelt, 1984) and the *theory of stakeholders* (Waddock & Graves, 1997a, 1997b), in this paper we highlight the role of CSR and the strategic knowledge management (SKM) as the dynamic capabilities which are necessary for a SIC to lead a greater firm PFM. So far, we have not found works in the literature that, in a holistic way, incorporate these variables as well as the relationships proposed.

Consequently, the objective of this work is to analyse the dynamic role that the CSR and the SKM exert as a mediator variables in the relationship between SIC and PFM.

To achieve the proposed objective, we analyse the tourism sector and, more specifically, the hotel sector. The fact that (1) Spain is the second most visited destination in the world behind France (OMT, 2018); (2) the literature of social responsibility in the hotel sector is characterized by its scarcity (Peña et al., 2019; Bohdanowicz & Zientara, 2009; Holcomb, Upchurch & Okumus, 2007); (3) and the strong impact that this sector causes in both, natural and social environment, justify the choice of hotel industry.

This work makes several theoretical and managerial contributions which will be exposed in the last section of the paper.

2 Literature review

2.1 Sustainable intangible capital and performance

Sustainability issues have been increasingly incorporated into the specialized literature on the management of intangibles, mainly from the environmental field. Proof of this is the proliferation of works such as Delgado-Verde et al. (2014), Chang & Chen (2012), Huang & Kung (2011), López-Gamero, et al. (2011) or Claver-Cortés, et al. (2007), which focus on the green intellectual capital, and try to identify and classify the 'green' or environmental intangibles that companies have, analysing the positive links between them and competitive advantages, as well as green innovations and CSR. However, considering only the environmental aspects within the company's set of intangible assets, takes us

away from the sustainability approach proposed by the Triple Bottom Line (TBL): economic, social and environmental issues.

In order to cover this existing gap in the literature, in this paper we make an effort to define SIC under the TBL approach. To this end, based on the work of López-Gamero et al. (2011) and considering the philosophy of the TBL, we define SIC as the set of knowledge that a company can take advantage of to carry out an economic, social and environmental management that allows it to achieve competitive advantages. From this definition, we can break down SIC into three main dimensions: (1) Environmental intangible capital: constituted by those intangibles from human, structural and relational capital linked to the conservation and management of natural resources. In the case of hotels, this dimension plays a very important role because it is highly linked to the quality of the tourism product (Benavides-Velasco, Quintana-García & Marchante-Lara, 2014); (2) Economic intangible capital: constituted by those intangibles from human, structural and relational capital linked to the generation of prosperity at different levels of society and the profitability of economic activity (GRI, 2011). From the hotels point of view, this dimension is also very important because it positively influences the organizational confidence and the perception of the consumers, being critical to differentiate the products and services of the competitors (Benavides-Velasco, Quintana-García & Marchante-Lara, 2014); (3) Social intangible capital: constituted by those intangibles from human, structural and relational capital linked to the impact that the company has on the social system in which it operates and in which employees, customers and society in general are included (GRI, 2011). In the hotel sector, the consideration of this dimension is essential, due to the strong impact that this sector causes in its social environment.

The strategic nature of SIC, coming from its heterogeneity, specificity, difficulty to be imitated and transferred, will lead companies that possess it to have a higher performance or competitive advantages (Peteraf, 1993; Barney, 1991). In the same way, Bontis, Janošević & Dženopoljac (2015) and Kim et al. (2012), point out the degree to which intangible assets affect the financial results of hotel companies. Nemec Rudez & Mihalic (2007) highlight the new opportunities that knowledge assets offer to the hotel sector, while Engström, Westnes & Westnes (2003) consider intangible assets as the key resources and drivers of organizational performance and the creation of value in the hotel sector.

For all the above, we formulate the first hypothesis.

H1: Hotel's SIC positively influences its PFM.

2.2 The mediator role of CSR in the SIC-PFM link

Surroca, Tribó & Waddock (2010) highlight the potential of the *resource-based view* as an analytical tool to study the relationship between CSR and the financial result through mutual connection with the resources of the company. Within these resources, intangibles such as innovation capacity, human capital, reputation and culture, can contribute highly to improve the results obtained with CSR actions, through: (1) the incorporation of more responsible attributes within products and services (redesign, packaging, inputs, etc.); (2) the introduction of commitment-based human resource

practices (advanced training, participation in teams and empowerment); (3) the development of a good reputation for social responsibility (improves relationships with stakeholders) (Castelo Branco & Lima Rodrigues, 2006); (4) the rise of a humanistic culture (promotes employees seeking solutions to reduce the impact of the company on the natural environment).

Moreover, Garay & Font (2012) consider that hosting SMEs have important competitive reasons to act responsibly and, precisely, the study by Holcomb, Upchurch & Odumus (2007) supports this idea, as their results showed that leading hotels such as Hilton, Accor or Marriott adopt the integration of social and environmental objectives in their operations and use them as a basis for the development of unique competitive advantages.

These arguments, together with the fact that several empirical studies highlight the existence of a positive interaction between the dimensions of intellectual capital and CSR activities (Castelo Branco & Lima Rodrigues, 2006; Renneboog, Horst & Zhang, 2008), leads us to formulate the following hypothesis:

H2: Hotel's CSR acts as a mediating capability between its SIC and PFM.

2.3 The mediator role of SKM in the SIC-PFM link

A SKM plan should contain a set of major initiatives that must be undertaken to achieve economic, social and environmental goals. In this task, following Dayan et al. (2017), who consider that knowledge management is a factor for the formulation and implementation of organization strategy, we consider that a SKM process would include the existence of a knowledge vision and diagnosis, together with the formulation of knowledge strategies and the existence of an infrastructure to support their implementation.

Regarding the vision and diagnosis phase, it is necessary to instil a vision of knowledge that emphasise knowledge creation as an activity and build an appropriate context for the creation and transfer of sustainable knowledge flows between all members of the firm. A diagnosis will reveal the strengths and weaknesses of the hotel's sustainable intangibles. The strategic diagnosis must be followed by the formulation of a knowledge strategy which should focus, on the one hand, on the creation of sustainable intangibles and, on the other hand, on making these intangibles visible to the internal and external stakeholders of the hotel. This will increase the credibility of the hotel in terms of sustainability and strengthen the relationship between SIC and PFM. Once the knowledge strategy has been formulated, it will be necessary to provide the company with mechanisms that enable its efficient application. Among them: a humanistic culture, human resource practices, organisational design and technological platform. These ideas lead us to formulate the third hypothesis:

H3: Hotel's SKM acts as a mediating capability between its SIC and PFM.

Figure 1 shows the developed model and the hypotheses proposed.

3 Methodology

The population under study comprised 1000 Spanish hotels with three or more stars included in two databases: SABI (Iberian Balance Sheet Analysis System) and Turespaña. A questionnaire addressed both, to the CEO and the Human Resources Manager of the hotel sent through post and e-mail was used to collect information. A total number of 120 questionnaires considered valid were collected, which means covering 12% of the population. To check non-response bias a Student's t-test was used, indicating no significant differences for means comparison based on the control variable 'category' between the hotels which did not answer the questionnaire and those which did.

The relationships proposed in the hypotheses were tested using a variance-based structural equation modelling based on Partial Least Squares (PLS).

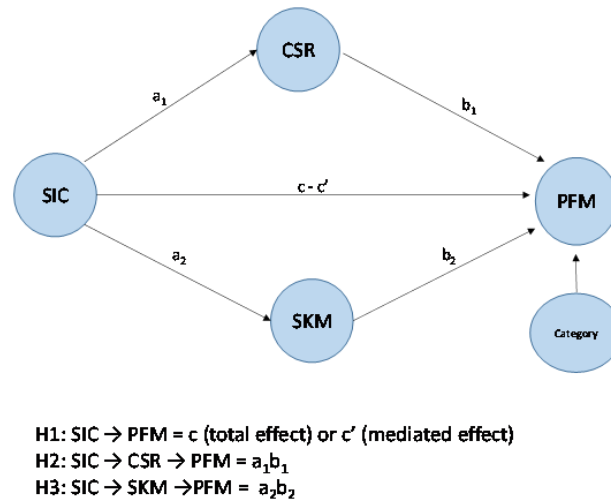

Figure 1: Model proposed

Measures

Sustainable intangible capital. This variable was considered as a second-order construct made up of two first-order formative constructs: Green Intangible Capital (GIC) and Social and Economic Intangible Capital (SEIC). On the one hand, GIC was measured by means of a seven-point Likert scale with seven items, taking as a reference and adapting the measures provided in the studies carried out by Chang & Chen (2012) and Huang & Kung (2011). On the other hand, SEIC was measured through a seven-point Likert scale with 14 items, taking as a reference and adapting the measures coming from the study of Subramaniam & Youndt (2005).

Performance. This variable was treated as a second-order construct shaped by two first-order reflective constructs: Environmental Performance (EP) and Hotel Performance (HP). EP was measured by means of a seven-point Likert scale with five items, using the

measures included in the studies of Paillé et al. (2014) and Chow & Chen (2012). To measure HP, perception measures were used based on Gibson & Birkinshaw (2004).

Corporate social responsibility. This variable was considered a second-order construct made up of two first-order reflective constructs: Employee and Customer Social Responsibility (ECSR) and Environment and Society Social Responsibility (ESSR). Both of them were measured through a seven-point Likert scale using the measures obtained from the studies of Bai & Chang (2015), Chang & Chen (2012) and Turker (2009). ECSR was measured by seven items, while ESSR was measured by four items.

Strategic knowledge management. This variable was treated as a first-order construct which comprised seven formative indicators. These indicators derive from the insights developed within a multiple-case study undertaken previously (Hill & Birkinshaw, 2014) and adapted from the paper of Claver et al. (2018). All of them were measured by means of a seven-point Likert scale.

Control variable. Category of the hotel (three, four or five stars hotel) was used as control variable in order to monitor possible alternative explanations for the relationships proposed.

4 Findings

The PLS methodology does not allow calculations directly on the second-order constructs. For that reason, for the treatment of multidimensional constructs we use the *two-stage approach*, using the '*latent variable scores*' or aggregated scores (Wright et al., 2012). Once the final model was designed (figures 2 and 3), we proceeded to evaluate it following the three main stages for the evaluation of the models in PLS. We have used the Smart PLS3 software.

Figure 2. Model with total effect

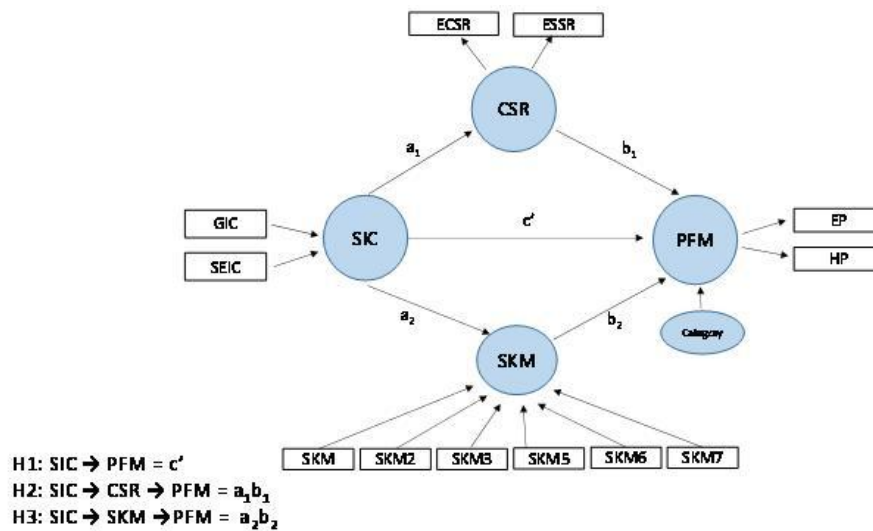

Figure 3. Model with a two-path mediated effect

4.1 Global model assessment

The most commonly used measure to evaluate the global fit of the model is the SRMR (standardized root mean square residual) index. According to Hu and Bentler (1998), for a good fit of the model, the SRMR index should be less than 0.08. In our model, the SRMR index is 0.073, which indicates a good global fit of the proposed model.

4.2 Measurement model assessment

The proposed model is constituted by both reflective (Mode A) and formative constructs (Mode B) and, in the context of PLS, the evaluation of each of them is done differently.

Reflective constructs assessment (Mode A): PFM and CSR

The individual reliability of indicators was evaluated through the value of their loadings (λ). According to the literature, these loadings should exceed the value of 0,7 ($\lambda > 0,7$). As we can observe in table 1, all loads exceeded the value of 0,7.

Construct's reliability is evaluated by means of Cronbach's α index and the composite reliability index. Both of them should exceed the critical value of 0,7 in every variable. The existence of convergent validity is verified through the examination of the extracted mean variance (AVE), which should be situated above 0,5 (Fornell & Lacker, 1981). Table 1 shows all these values and all of them are above the critical values of 0,7 and 0,5 respectively.

Finally, discriminant validity is evaluated through the Heterotrait-Monotrait Ratio (HTMT), which has a threshold of 0,85 (Kline, 2011). From table 1, we can observe that the data confirm the existence of discriminant validity.

Table 1. Measurement model assessment (Mode A)

Loadings (λ)		
	PFM	CSR
ESSR		0,778
ECSR		0,887
HP	0,869	
EP	0,831	

Construct reliability and convergent validity coefficients			
	Cronbach α	Composite reliability	AVE
PFM	0,817	0,839	0,722
CSR	0,773	0,821	0,697

Discriminant validity coefficients (HTMT)		
	Category	PFM
PFM	0,295	
CSR	0,262	0,737

Formative constructs assessment (Mode B): SIC and SKM

Firstly, it is necessary to analyze the potential multicollinearity between the indicators, which was analyzed from the Variance Inflation Factor (VIF), which should be < 3.3 . It was observed that one of them (SKM4) had a value of $VIF > 3.3$. For that reason, this indicator was eliminated and the SKM construct was made up of six indicators instead of the seven that initially formed it. After the elimination of SMK4, the remaining indicators showed VIF values < 3.3 , thus fulfilling all of them with the established requirement and confirming that there is no multicollinearity between them (see table 2).

Secondly, weights and their significance are analyzed. In order to assess the significance of the coefficients, the non-parametric bootstrapping technique of 5.000 samples was used to obtain the t statistics and the confidence intervals. According to the theory, all weights should be positive and have a p value < 0.05 to be significant. Table 2 shows that all weights are positive and, except for the one corresponding to the SKM2 indicator, they are all significant. However, according to Chin (1998), eliminating an indicator could decrease the information to explain a construct, so we do not eliminate this indicator in order not to leave the SKM construct with only five indicators.

Table 2. Measurement model assessment (Mode B)

Multicollineality analysis

	VIF
SEIC	1,110
GIC	1,110
SKM1	2,007
SKM2	1,848
SKM3	2,781

p**<0,01 (significant at 99,99%), p***<0,001 (significant at 99,999%)

4.3 Structural model assessment

We firstly evaluated the possible co-linearity problems. According to Hair et al. (2014), there will be signs of co-linearity when the VIF > 5. Because in our model all the values do not exceed the value of 5, we can confirm that co-linearity problems do not exist. Table 3 shows the VIF, f^2 and Q^2 values.

Table 3. VIF, f^2 and Q^2 values

VIF values

	SKM	CSR	PFM
SIC	1,000	1,000	1,472
SKM			2,611
CSR			2,842
Category			1,104

f^2 values

	SKM	PFM	CSR
SIC	0,246	0,029	0,386
SKM		0,153	
CSR		0,133	
Category		0,014	

Q^2 values

	Q^2
SKM	0,099
PFM	0,233
CSR	0,178

A second analysis focused on the algebraic sign, magnitude, and significance of the path coefficients which show the estimates of structural model relationships (see table 4).

Table 4. Path coefficients and significance

			Confidence intervals		
	Weight	p-value	5.0%	95.0%	Significance
Model with total effect					
SIC→ PFM (c)	0,198	0,062	-0,011	0,153	NO
Category→PFM	0,095	0,086	-0,014	0,213	NO
Model with a two-path mediated effect					
SIC→ PFM (c')	-0,129	0,094	-0,293	0,030	NO
SIC→ CSR (a ₁)	0,528***	0,000	0,422	0,633	YES
SIC→ SKM (a ₂)	0,444***	0,000	0,291	0,608	YES
CSR→PFM (b ₁)	0,236***	0,004	0,017	0,457	YES
SKM→PFM (b ₂)	0,456***	0,000	0,217	0,658	YES
Category→PFM	0,095	0,086	-0,014	0,213	NO

p**<0,01 (significant at 99,99%), p***<0,001 (significant at 99,999%)

As we can observe from table 4, in the model with total effect (figure 2), the direct effects corresponding to the relationships Category→ PFM and SIC→ PFM (c) are not significant. These results show that, on the one hand, the hotel category, although the path coefficient is positive, does not exert a significant influence on the PFM of the hotels. On the other hand, H1 proposed a positive relationship between SIC and PFM and, although the path coefficient (c) is positive, the relationship is not significant. Therefore, H1 cannot be confirmed.

From the same table 4, in the model with a two-path mediated effect (figure 3), we can observe that four of the six direct effects turned out to be significant. However, it has been found that, when introducing the mediating variables CSR and SKM, the path coefficient (c') is negative, contrary to that stipulated in our H1.

The third analysis had to do with the assessment of the value of R^2 . According to the theory, R^2 value should be between 0 and 1. In our work, the values of R^2 for SKM, PFM and CSR were of 0,197, 0,400 and 0,278 respectively, which indicates that almost 20% of the variance of SKM was explained by SIC, 40% of the variance of PFM was explained by SIC, SKM and CSR, and 27.8% of the variance of CSR was explained by SIC.

The fourth analysis consisted in the assessment of the sizes of the effects f^2 . Table 3 shows the values of f^2 obtained for our study and, as observed, the exogenous variable that contributes most to explain the endogenous variable PFM, is the variable SKM. The greatest effect of f^2 is found in the relationship between SIC and CSR.

Finally, the structural model was also evaluated using the Stone-Geisser test Q^2 through a blindfolding procedure (Chin, 1998). A Q^2 greater than zero implies that the model has predictive relevance. The findings in table 3 confirm that the proposed model has predictive relevance for all dependent variables.

4.4 Mediation analysis

According to the proposed model (figure 3), H2 and H3 represent mediation hypotheses. Table 5 shows that the indirect effects are highly significant. It means that, on the one hand, CSR is a mediating variable between SIC and PFM, so H2 is accepted (a_1b_1). On the other hand, H3 (a_2b_2) –which reflects the mediating effect that SKM has in the relationship between SIC and PFM– was accepted.

Variance Accounted For (VAF)¹ was calculated to know whether mediation is partial or total. VAF < 0,8 indicates that the mediation is partial and VAF > 0,8 means that there is a full mediation. In our study, because VAF value is 1,65, we can say that the mediation is full.

Table 5. Mediating effect test

Total effect of SIC on PFM (c)		Direct effect of SIC on PFM (c')		Indirect effect of SIC on PFM	Confidence intervals	
Path coefficient	p-value	Path coefficient	p-value		5%	95%
0,198 (ns)	0,062	-0,129 (ns)	0,094	H2= $a_1b_1 = 0,125^{***}$	0,006	0,252
				H3= $a_2b_2 = 0,202^{***}$	0,083	0,342

***p<0.001

5 Discussion and conclusions

The need for hotels to behave as intelligent organizations to face the continuous challenges imposed by their environment, has led us to analyse whether the CSR and SKM behave as dynamic mediating capabilities in the relationship between SIC and PFM, constituting this as the main objective of our investigation. To reach it, three hypotheses were formulated, which were contrasted using the quantitative methodology of PLS. Findings shed light on the following aspects:

H1 proposed that hotel's SIC positively influenced its PFM. According to the results and contrary to what is expected, H1 cannot be supported, because the direct effect of SIC on PFM (c) is not significant. However, these results are in line with the approaches of Bontis, Janošević & Dženopoljac (2015), which point out that, although conceptually the impact of intangible assets on PFM is obvious and logical, in practice this relationship cannot be fully confirmed in all sectors. Their research shows that investment in intellectual capital is not always adequately capitalized. Under this premise, findings show that we cannot expect the effects of the exploitation of the SIC to automatically appear on hotel's PFM.

H2 and H3 proposed that CSR and SKM acted as a mediating capabilities between hotel's SIC and hotel's PFM. Findings show that, as we proposed in the model, the mediating hypotheses H2 and H3 have been supported, showing that a multiple mediation effect exists. On the one hand, hotels with a good reputation for social responsibility can improve relations with external stakeholders. For that reason, we think that this attracting the best employees, increasing their motivation, loyalty and commitment to the company (Castelo Branco & Lima Rodrigues, 2006). On the other hand, the start-up of activities to manage the intangible assets and the formulation of knowledge strategies emerge as a set of major initiatives that must be undertaken to achieve economic, social and environmental goals. This means that the dynamic capabilities CSR and SKM create the values, the philosophy and the necessary foundations for SIC to influence on PFM from a significant point of view.

¹ VAF= (Indirect effect)/(Total effect)

Contributions

This research has theoretical and practical contributions. From a theoretical point of view, firstly, it offers a definition of SIC from the TBL perspective, breaking down SIC into three dimensions (environmental, economic and social intangible capital). This way of defining SIC is novel, because it does not integrate only the green or environmental aspects. Secondly, with this paper we have gone a step further in the relationship between intangibles and performance. Until now, most of the works showed a direct and positive relationship between both variables. However, findings show that the simple possession of intangibles does not guarantee a superior performance. Thus, CSR and SKM capabilities have proven to be especially useful in setting the necessary values and offering the right climate for the company's sustainable intangibles to adequately capitalize its performance. Thirdly, with this work we shed light on a sector in which the literature linking SIC-CSR-SKM-PFM can be described today as scarce.

From a practical point of view, managers should know the three components of SIC, as well as the best way to exploit them, in order that this translates into a greater performance of the hotel or the establishment of competitive advantages from sustainable aspects. For that reason, managers should pay special attention to the creation of a SIC supported by a set of values from CSR and SKM, which provide these intangibles with the necessary infrastructure to positively influence the PFM of the hotels.

Limitations and further research

This research presents a main limitation, which derives from the fact of offering only a vision of the relationship between SIC and PFM from the hotel sector, making the results obtained cannot be generalized to the rest of the sectors of the economy. Therefore, it is our contention that extending our study to firms outside hotel industry could result in new and complementary insights.

Abstract

Integration of advanced 5G technologies in future business models will enable businesses to offer new disruptive, virtual and persuasive business models (BM's) that business community and society have never seen before. With this comes new and disruptive ways to download, see, sense, generate, capture, deliver, receive and share knowledge between BM's, humans and machines. Advanced, changed and new approaches to knowledge sharing in multi Business Model Innovation (MBMI) will hereby be a reality. These approaches to knowledge and knowledge sharing will play important role in future business model ecosystems (BMES) "life" and "sustainability". Future Knowledge based Business Model Ecosystem (KBMES) will enable creation of BM's operating within real time, anywhere, with anybody and with anything. They will be operating proactive and not just reactive – and they will be formed persuasive to knowledge creation, capturing, delivery, receiving and consumption.

The paper investigates some of our first investigations on these 5G knowledge based business models and systems. The paper examine how advanced 5G MBMI technologies will impact knowledge sharing and knowledge generation in multi business model innovation (MBMI) in the future. The paper present a conceptual framework on how to facilitate knowledge sharing in MBMI with advanced 5G technologies for the purpose of "creating, capturing and delivering BM's to KBMES with high quality, effectiveness and efficiency in a time where the "life" of BM's continuously diminishes and demands change in realtime.

Paper type – Academic Research Paper

1 Introduction

One main challenge of 5G and the related digitization of MBMI is modeling BM's related to humans, machines and business partners real time behavior and cognitive processes. Related to MBMI processes - How can humans, machines and BM's behavior and "cognitive processes" be transformed into logical expressions? Logical expressions that can be digitized and automated. There seems hardly any research in this field related to MBMI – but the technology – now 5G, AI, Robotics, Machine learning, Virtual Reality are all offering their capabilities to the Business Model Community.

5G is by many experts claim to be a different technology based business platform and business operating and intending to operate in the future 5G technology based BMES seems to be very optimistic as they invest heavily in 5G. 5G technology is however today still under early testing and businesses are preparing with a mixture of resignation and anticipation – but they seem to be convinced that this revolutionary 5G technology will open new great BM opportunities. The new 5G based BM's are expected to capture value from a widespread adoption of the Internet of Things (IoT).

Future 5G and related technologies will bring a wave of new BM service due to massive digitalization of services in an integrated physical, digital and virtual world. This will require novel Knowledge based BMs (KBM) and new KBMES based on a different Business mindset – pushing Businesses to really think, act and do on behalf of knowledge exchange and sharing in integrated physical, digital and virtual KBMES. Massive numbers of connected devices as seen in figure 1 will provide and demand data that will be transformed to knowledge that humans, machines and businesses can value from.

Figure 1. Estimated connected devices in Billion 2015 – 2025 [Tanwer 2018]

5G Digitalization of Multi Business Model Innovation (MBMI) is the enhancement associated with the application of digital technology in all aspects of MBMI, the MBMI Process and the single Business Model's (BM) requirement along its lifetime circle. This

together with big data analytics will affect all areas of a BM's life and lead to new ways of working, communicating, operating, cooperating, collecting and sharing knowledge between BM's, in MBMI processes and Business Model Ecosystem (BMES) (Lindgren 2018).

For the business, it is about gaining business knowledge advantage on behalf of information delivered by digitized BM's, MBMI and BM's operations in the aim of achieving greater efficiency, higher MBMI intelligence, better profit, harvesting other values, gaining agility and not least developing its competences – either it is technologies, Human Resources, Organizational Systems or Culture.

Businesses have always adapted and changed their BM's with the changing times, but with the influx of 5G technologies combined with mobile-, cloud based- and social big data analytics the speed of change will be able to accelerate with a pace at which today's businesses will be highly challenge. They need to evolve their BM's to KBM and they need to change their clockspeed (Fine 1998) to which they innovate, transform, operate, and strategically manage their BM's on behalf of knowledge. So, each business can if they “KNOW HOW” - build its own co-operational and financial arrangements of its BM's to achieve its strategic visions, missions, goals and strategic plans. The aim is to find a way or a model

How to handle MBMI knowledge to value the MBMI process and support the MBMI process in a more advanced way than previously supported by the new 5G advanced sensor technologies and related AI, Machine Learning, libraries of MBM and BM archetypes and Multi Business Model pattern analysis.

2 Design/research methodology.

This paper report on our first findings and preliminary experiment carried out in a cross-interdisciplinary CGC research group. The research is inspired and related to the investigation of a “MBMI knowledge home” [Prasad 2016] and “MBMI brain framework” [Valter 2018] concept that is expected to be able to facilitate advanced MBMI processes, sensing and persuasive business models in a near future.

The research center MBIT/CTIF Global Capsule began in 2007 to explore “knowing” on how a Business Model (BM) look like and is constructed [Amit 2010] [Zott 2011] [Foss 2015][Lindgren 2018]. In 2013 CGC Research center's researcher got th generic BM construction – The Business Model Cube [Lindgren 2018) accepted as a standard under the umbrella of the OMG standardization system and this framework is used to carry out the experiments within 30 established B-labs worldwide.

In 2016 MBIT/CGC began to experiment in the first B-labs with MBMI's technology to support “downloading”, “seeing” and “sensing” capabilities in Technological Business Model Innovation teams. With support of these technologies, MBIT/CGC wanted to come closer to finding out

How a BM really is constructed?

How a BM really look like? Feel? Sound? Smell? and taste? through the “lenses” of Cognitive Automation, intelligence to information and knowledge intensive processes of MBMI.

Further CGC Research group wanted to find out

How would BM’s look like if advanced technologies and related advanced knowledge sharing could support human and machines to “see” and “sense” BM’s and BM’s knowledge?

The prime endeavor of CGC research intended to have a profound MBMI infrastructure and MBMI knowledge home, which uses concurrent and futuristic technologies and concepts to on board and to enhance the seeding, nurturing, flourishing, and reaping stages of MBMIs in businesses and research. The conceptual model as shown in figure 1 consist of four parts, the Human Intermediary; the Machine Intermediary; Business Models Patterns Analysis and the Knowledge based Business Model Ecosystem. Each of the four parts describes separately the proposed MBM archetypes for each part and gives when possible case examples from our case research and database. The intent with this increased conceptual model is to add parts we found important in our further research and provide an overview in combination with knowledge and insight in the possibilities with digitalization of the business model concept. The term BM is used as a digital representative of the BM’s and the conceptual model’s intent in our first experiments to limited to a digital representative version of the BM’s and further businesses that has a Multi Business Model Approach [Lindgren 2018].

3 The Conceptual Model Design of a MBMI Knowledge Home and Brain.

The conceptual model consists of the human intermediary part, which represents all the interaction between the business reality and the BM with any human being. The arrows mark with red in figure 2 shows the possible interactions in the human intermediary BM interaction section.

Human Intermediary Business Model Interaction

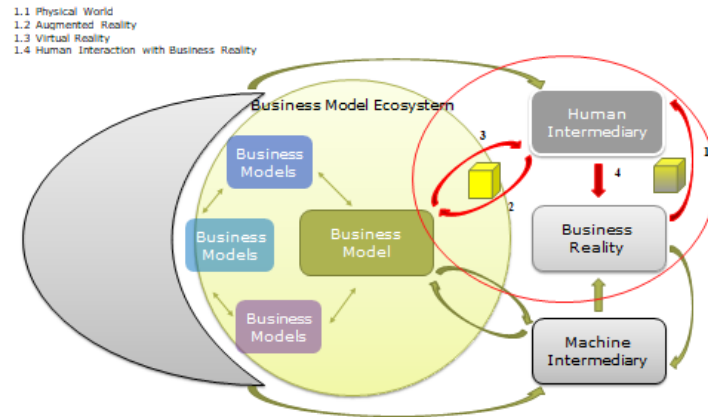

Figure 2.: Human Intermediary Business Model Interaction inspired from [Valter 2018].

Regarding the types of Archetype two and three in the human intermediary business model section, we have shown the interaction archetypes patterns and described these within in an earlier articles [Lindgren 2018]. The human intermediary BM's archetypes are concentrated on the human, as intermediary between the business reality and the BM. The interaction archetypes patterns within the human intermediary business model section displayed are solely concentrated on the interaction archetypes patterns between the human and the BM.

Secondly, the conceptual model consists of the machine intermediary section, which represents the interactions between the business reality and the BM through any machine. The arrows marked with red in figure 3 show the possible interactions

Machine Intermediary Business Model Interaction

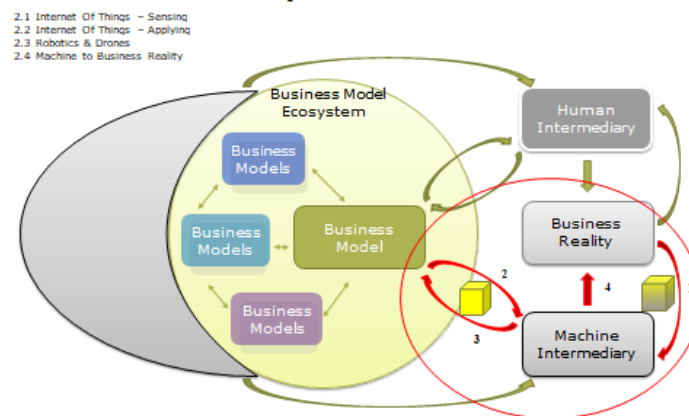

Figure 3.: Machine Intermediary Business Model Interaction inspired from [Valter 2018]

Archetype one and four in the machine intermediary BM's interaction section in figure 3 have the Interaction archetypes patterns described in common in (Valter 2018), while the machine intermediary BM's interaction archetypes are concentrated on the machine as intermediary between the business reality and the business model, the interaction archetypes in the machine intermediary BM interaction section solely concentrated on the interaction archetypes patterns between the machine and the business reality.

Thirdly, the conceptual model consists of the artificial intelligence and deep learning section, which represents the interaction between deep learning patterns analysis, the business model, the human and the machine. Figure 4 show the possible interactions.

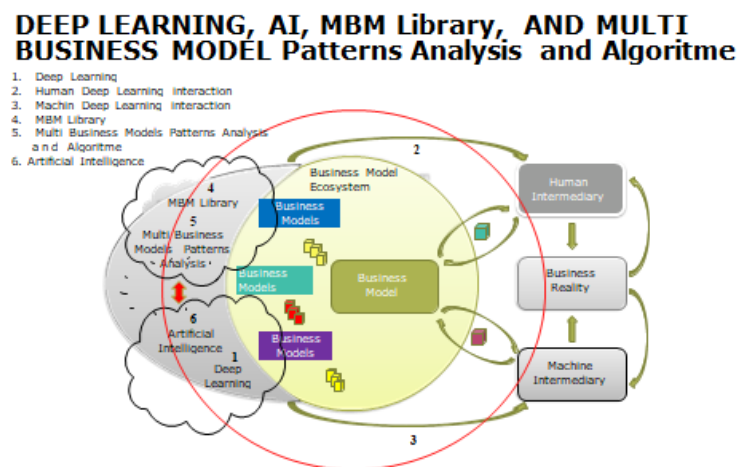

Figure 4.: Business Models Patterns Analysis with Artificial Intelligence and Deep Learning combined with a Multi Business Model Library inspired from [Valter 2018].

Interaction Archetype patterns one, two and three are described in more details in (Valter 2018). In this paper we decide to split up AI and Deep learning and add one more part to the model – a Multi Business Model Library. The Multi Business Model Library consist of all existing known Business model Arche Types and combination of BM's in the business. The Multi Business Model library continuously adapts new types or even archetypes of BM's and combination of BM's – "BM archetype stored in the Knowledge Home or what we call the Business "Multi Business Model Innovation Brain" as we show in figure 5.

Multi Business Model Innovation Brain interaction supported by AI, Deep Learning, Multi Business Model Patterns Analysis and Multi Business Model Library

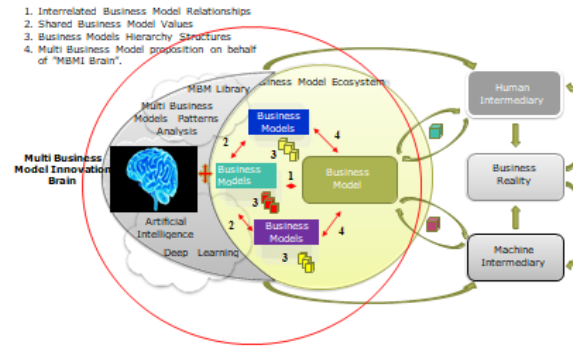

Figure 5. Multi Business Model Innovation Brain Interaction with Human and Machines Lindgren 2019

The BMES interrelated BM interaction with the business Multi Business Model Innovation Brain represents the relationships between the BM's and BMES. BMES Interrelated Archetypes one, two and three are described in table 1.

Table 1.: BMES Interrelated BM Interaction Archetypes inspired from (Valter 2018)

Business Model Ecosystem Interrelated Business Model Interaction Archetypes	Description
<p>Archetype one: Interrelated Business Model Relationships</p>	<p>This is where the relationships between the business models are defined. As a simplified case example, a movie theater's BM and the BM of the parking lot in front of the movie theater are connected since the same customer uses both services and a big change in one of the BM's would affect the other BM, like if the parking fee is raised considerably, the customers would be more likely to find another movie theater.</p>
<p>Archetype two: Shared Business Model Values</p>	<p>This is where the shared BM values are defined. As a simplified case example, if a Business measures the customer satisfactions at one sales locations by having two buttons, one happy smiley and one angry smiley, then this aggregated knowledge over time would potentially be a shared knowledge between multiple BM's, since several BM's could potentially have effect on that value, which would make it a shared value and shared knowledge.</p>
<p>Archetype three: Business Models Hierarchy Structures</p>	<p>This is where the BM's hierarchy structures are defined, where the lowest level is all the businesses and their relationships to fulfill a BM, higher levels consist purely logical grouping of lower levels.</p>

4 Cases on Collaborative knowledge sharing and generation in MBMI

We turn now to unwrapping 4 elected but very actual KBMES in - Smart City, Autonomous Cars, Manufacturing and Health Care KBMES to show how Collaborative

Knowledge sharing and generation in MBMI can take place in a future world with 5 G technologies.

4.1. KBMES Case 1 - 5G Business Models in Smart Cities

5G will serve as the foundation for small-cell networks that will power the next generation of wireless network infrastructure in Smart Cities. 5G will upgrade human experience as it connect virtually everything and anybody at home and in all vertical and horizontal BMES.

Figure 6 5G in Smart Cities Adapted from T-mobile Youtube video [T-mobile]

5G will “power” everything from Smart Grid, utilities to Emergency, Smart Parking, realtime respond to natural floods. The connectivity and computing capacity that 5G enables will make smart cities a reality, as businesses can adopt the new technologies for smart city knowledge solutions. The major impediment to moving the smart city from the theoretical to the practical is the sheer speed and bandwidth to handle the amount of data generated by IoT and process it in to knowledge within real time. If this can be solve then all types of devises will be sending and sharing all types of data and knowledge to each other and to humans and businesses. However this requires a strong high speed relations based “backbone”. As Debra Amidon (Amidon 2008) claimed already in 2008 the real superhighways to “Knowledge Zones” will be extremely important – but the knowledge to where “relations” or as she called it “the superhighways” will be more important. This will be exemplified in everything and will bring us into the next era of the knowledge economy. Knowledge will become the main BM to most Businesses.

The cost savings that 5G knowledge is expected to generate to Smart Cities will be a huge. Smart city solutions applied to the management of vehicle traffic and electrical grids alone could produce \$160 billion in benefits and savings will be gained through reductions in energy usage, less traffic congestion and savings on fuel costs. This means that commute times will lessen, public safety will improve and significant smart grid efficiencies will be realized. For instance, in a smart city with 5G, there are several knowledge layers that can be added to something as simple as a smart streetlight with video cameras or gunshot detection sensor that will give information to public safety officials and machines so that they can respond faster. Video analytics can be quickly assessed and AI can be added on top of that to make the Smart city a safer place to live.

This will trigger much more BM's where income and other values will come from sharing knowledge and direct cost saving.

Millimeter wave 5G zones will emerge into Smart Cities, which will also allow for some new KBM's to be implemented - many of which have to do with public, private and business safety. 5G BM involving robots and drones can help with public safety. First knowledge responders – either machines or humans - can benefit from low-latency 5G video cameras and IOT devices spread around Smart Cities. 5G-connected ambulance can move freely through a Smart City by being connected to a network communicating “backbone” with traffic signals, and can also communicate with doctors at the hospital's trauma center en route. Who will pay for these benefits or values? Maybe not in beforehand but when the coincidence happens then businesses, humans and even machines will be willing to pay to get earlier to value fulfillment. The time perspective of KBM's becomes one of the very important value propositions in the future KBMES of a Smart City and it will not just be about “saving time but paying for time”.

4.2. KBMES Case 2 – 5G Business Models in Autonomous Car

There will be 23 million autonomous vehicles on US roads by 2035. It will represent \$25B decline in the individual insurance premium over the same period – in other words a disruption of the insurance BMES is expected – and not just in US but World Wide. Insurance providers need therefore to find new BM which will force them into KBMES they have not operated in before from 1) insuring against cyber threat, ransomware insurance, hacking insurance, etc. 2) insuring for autonomous vehicle liability from algorithm defect, software bugs, etc. 3) insuring autonomous and V2X infrastructure. According to and inspired by Professor Neeli Prasad ITU, San Jose California [Prasad 2019].

Figure 7.: Autonomous Vehicles adapted from Qualcomm presentation marts 2017

Connected autonomous vehicles require a massive network ecosystem for information and knowledge to flow, be processed and analyzed in only seconds. 5G moves the construction of smart traffic from the theoretical to the practical by underpinned the speed

and data flexibility of 5G. Smart traffic that can completely transform traffic systems and where ride sharing - due to Know How of where the vehicles and the customer are - will replace traditional transportation options. MIT found that New York City traffic could be reduced by 75 percent by ride sharing. Autonomous Vehicles and the algorithms that power them can create new efficiencies throughout all aspects of traffic life." Cost saving and efficiency are the main benefits and profit potentials at first sight – but many more are just ready to evolve. This is where businesses have to dig in – a kind of horizontal diversified Disruptive Multi Business Model Innovation evolution.

5G means also that the use of artificial intelligence to analyze the massive amounts of data being collected in and outside the autonomous vehicles will be possible – but importantly effective and efficient - to capture automatically and further process to useful and attractive knowledge. A number of BM's will be possible to reach out to – some that have never been profitable to invest in before. That can be

- controlling some kind of gate or barriers in the traffic
- controlling the infrastructure of road services
- controlling machines that sweep the roads

As cars become embedded with billions of sensors and become connected the car in itself becomes a browser [Prasad 2019]. This means that if users and customers accept it, there will be large BM potentials to penetrate these browser data inside and around the autonomous cars.

4.3. KBMES Case 3 - Manufacturing Businesses and circular economy 5G BM's

By 2020 IOT experts estimate that there will be 20 billion IOT devices connected world wide (Prasad 2019). In manufacturing BMES this means embedded devices in products, production and along business manufacturing processes. Plastic waste and recycling of plastic will be one BMES area, which will be able to take advantage of this development. Use of plastic in manufacturing businesses and the following waste plastic is a very hot topic to businesses and society today. For plenty of American and European businesses, recycling has been practically second nature. However it's now mandated by law in cities such as New York, San Diego, Pittsburgh, and Seattle, where apartment buildings, office spaces, restaurants must recycle plastics, cans, cardboard and glass. Unless their owners want to face a fine, they have to take care of and document recycling. In future the manufacturers have to help and support in this matter – otherwise they will not be chosen or be able to become/stay as supplier. Herein lay a billion Dollar Business - in a horizontal related KBMES that can provide a secure backbone system to track and trace the plastic, but also find out to sort and identify the different types of plastic. The technological business model innovation (TBMI) challenge would probably demand several knowledge partners to create and capture the BM's.

In European countries, recycling plastic is becoming more and more natural to do and even in cities - where it is not required by law - recycling is becoming mainstream. The challenge though, is that while recycling has become trendy it is also becoming harder to do. Firstly one of the biggest importer of recycled materials, especially for the US, China

stopped accepting most foreign recyclables just recently - as part of an effort to crack down on the China's pollution. As a result of this ban, the global recycling system has been crumbling, and plenty of cities in the US are now struggling to figure out what to do with their recycled goods- hereunder plastic. The global recycle BMES spans the globe and contributes to a \$200 billion BMES – but they are challenge on sorting the different types of plastic and it makes it very difficult to recycle plastic into new plastic that can be re used again. If this BMES could be transformed into a KBMES the potential business of this could be very attractive

Picture 1.: A worker sorts used plastic bottles at a plastics recycling mill in Wuhan of Hubei Province, China, in 2008. Adapted by |Getty Images

Recycling plastics also ensures that this waste doesn't go into landfills or incinerators. Burning plastic can be bad for the environment, because toxic emissions are released into the air in the process. Burning plastic, specifically, is known to release highly toxic compounds, called dioxins. But recycling is also expensive and time-consuming. It requires a tremendous amount of water and energy, in addition to money and effort to build the proper infrastructure. Due to the falling costs of oil prices, virgin plastic is actually cheaper to make than using recycled plastic and materials. Several businesses nevertheless are facing new very strict laws of recycling plastics, which means most manufacturing businesses have to take care and have to know how to recycle plastics used in their products or to protect their products differently by other types of packing material through transportation and handling. If these businesses want to prevent receiving a fine they have to build a KBMES together to document to the authorities, where the plastic is – anytime and anywhere. Herein lays both KBM's to help the manufacturing businesses but also the public businesses that want to track the plastic waste origin and manufacturer.

5G will by establishing these KBMES be able to push the recycling and the circular economy from a linear perspective/practice to a real circular practice by some new KBM's and KBMES. Hereby manufacturer products effectively and efficiently could be tracked to secure and control that they really handle and recycle their products and productions waste. Products impact to environment, humans and nature could hereby be

visualized physically, digitally and virtually in complete new ways. This would open a whole new agenda of knowledge based digitalized circular economy manufacturing– but only if 5G operator can provide reliable, trust full, secure and high capacity 5G networks and systems together with advanced sensor, navigation and communication technology.

4.4. KBMES Case 4 - Healthcare BMES and 5G BM's

Many Health care businesses especially public Hospitals have very large difficulties to run their business especially in these years when more advanced and more expensive health care treatments are turning up. One example is The Region Central Denmark who runs one of Denmarks largest health care businesses spread out on 11 destinations.

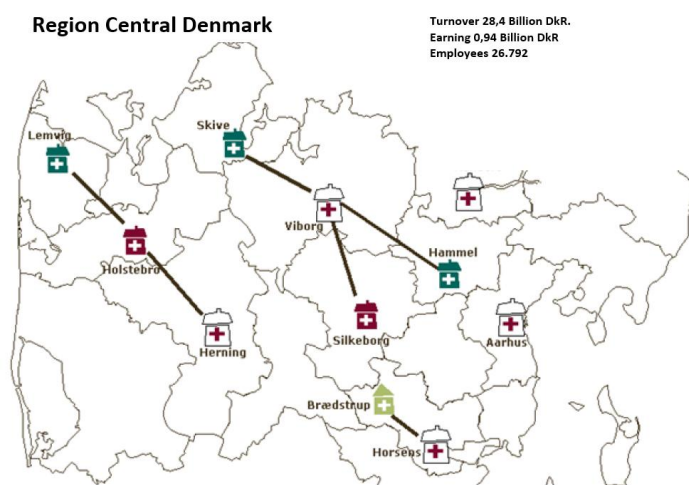

Figure 8.: Region Central Denmark's Health Care Business departments

Region Central Denmark is very interested in investing in 5G technology but finds it very difficult to calculate the business case of implementing 5G technologies. The cost savings that 5G is expected to generate to Health Care businesses and systems according to white paper from Accenture need heavy investment. 5G Health Care solutions applied to the management of Health Care logistics and health care medical consumption could produce billions in benefits and cost savings through increase productivity, better use of expensive health care technology, reductions in energy usage, increase in security of using medicine. However, the investment and documentation of the benefits while operating are much too high to commence this technology investment and innovation process for Region Central Denmark Business. Herein lays large potential of KBM's to those business that can create KBM's that can fulfill these demands. However different KBM typologies have to be created as a classical supplier customer BM would not release the potential. A KBM typology showing continuously the saving of cost and harvesting of other values would be possible solution. Different knowledge partners – including businesses from financial BMES's could release the BM potential.

5 Discussion

Today the MBMI supporting tools and environments for developing new persuasive and virtual BM's are limited and mostly non-digital in nature. The original proposed conceptual model, [Valter 2018] [Lindgren 2019], combined with the case examples in this paper is a first attempt in creating a conceptualized overview of the knowledge, insight and possibilities that lie within the digitalization of the MBMI concept and approach combined with a MBMI Knowledge Home/ Brain. The conceptual model has seven key sections interesting for knowledge society:

1. "Human Intermediary MBM Interaction"
2. "Machine Intermediary MBM Interaction"
3. "BMES Interrelated MBM Interaction"
4. "MBMI's patterns analysis"
5. "Artificial Intelligence"
6. "Deep Learning"
7. "MBM Library"

The "Human Intermediary Business Model Interaction" have four-different archetypes, which are describing the human as intermediary between the business reality and the BM or combination of more BM's.

Secondly, at the Interaction archetypes patterns in relation to the case examples:

1. "The Physical World", human computer interaction case example
2. "Augmented Reality", augmented reality case examples
3. "Virtual Reality", virtual reality case example

which are describing the interaction archetypes patterns between the human and the BM.

At the second section "Machine Intermediary Business Model Interaction", firstly we have the four-different archetypes, which are describing the machine as intermediary between the business reality and the BM. Secondly, we look at the interaction archetypes patterns in relation to the case examples:

1. "Internet of Things Sensing", monitoring case example
2. "Internet of Things Applying", applying case example
3. "Robotics & Drones" autonomous car case example

which are describing the interaction archetypes patterns between the machine and the business reality.

At the third section "Business Models patterns analysis with Artificial Intelligence and Deep Learning", we look at the three interaction archetypes patterns in relation to the case examples:

1. "Artificial Intelligence on Business Models and Ecosystems", cancer classification case example
2. "Artificial Intelligence to Human Intermediary", decision-making support case example [16]
3. "Artificial Intelligence to Machine Intermediary", No cases were found here.

which are describing the interaction archetypes patterns between artificial intelligence and the BM; human intermediary; machine intermediary.

Though, we fully recognize that further research would have the possibility to extent this model with different archetypes of artificial intelligence for MBMI and generation of new archetypes of BM's we already take the opportunity to add a Multi Business Model Library as a kind of "Knowledge Home for different BM's archetypes and constructions learned and adapted from business interaction with BMES's. On behalf of AI, deep learning, Multi Business Model library and Multi Business Model patterns analysis business can commence to build the foundation of a MBMI Brain as shown in figure 5.

Finally, at the last section "BMES Interrelated MBMI", we were currently not able to find any suitable case examples in relation to the BMES interrelated to BM's relationship archetypes:

1. "Interrelated BM Relationships"
2. "Shared BM Values"
3. "BM's Hierarchy Structures"

However, when persuasive and virtual business models grow, this will push the development of AI and Virtual Reality even more, together with the need and possibility to have machines taking over more part of the BM operations and MBMI.

6. Conclusions

Advanced technologies are and will be increasingly integrated in BM's and MBMI in the near future. This will create a new generation of BMs. These BMs can potentially be operated and innovated in different physically, digitally and virtually layers of MBMI and BMES's and will hereby create a completely new knowledge agenda and practice of MBMI interaction on behalf of Knowledge homes for MBMI – A MBMI Brain - with humans, machines and businesses interacting in new and different ways than what we have been able to do and know about until today.

The paper combined a conceptual model for a MBMI Brain with case examples/illustrations to show future MBMI Knowledge operation. The paper describes the conceptual relationships between the humans, machines and BM's and KBMES's embedded and interacting with advanced 5G and other technologies. The paper adds to previous developed research on Multi Business Model Library adapting knowledge from all known Business Model archetypes and learning from new BM archetypes that the business innovate and develop. Hereby it is possible to form the platform of a Multi Business Model Innovation Brain.

Ideally, we would have used concrete papers with MBMI empirical cases implementing each archetype in the proposed conceptual model. However, very early in the literature review it became apparent that such case does not currently exist, furthermore it seems that the current body of MBMI knowledge is very limited in regards of exploring the use of digital technology to support or enhance the MBMI process. Therefore we widened the scope of the literature review to other KBMES, where the use

of the technologies in the conceptual model is more intensely used in the quest to fulfil their goals and then relate that to the conceptual model instead.

Since our research with help of the proposed MBMI conceptual model has identified several key areas where the current conceptual body of the MBMI Brain needs to be extended, we decided to include a separate section for further research. On behalf of this knowledge we added a “MBM library model” to the model along with splitting up AI and Deep Learning.

7. Further Research

In our review of the current MBMI literature and the previous proposed conceptual MBMI Brain framework we found a gap in current body of knowledge, even in the current understanding of the MBMI process. It has not been investigated to its full extent yet. Therefore, we propose a further study, supported by the current technology and MBMI Knowledge, in understanding the MBMI environment and the success factors, before extending the MBMI process with any further digitalization factors. We propose to use the output of the previously suggested study in conjunction with the proposed MBMI Brain model and extend the MBMI process with further digitalization in the areas of interaction archetypes and interaction archetypes patterns as proposed in the the conceptual model. We will further investigate the impact of the exponential growth of these BM’s and advanced MBMI technologies discussed in our future research at the new CGC MBMI and Technology research lab.

Abstract

Today, the evolution of Information and Communications Technologies (ICTs) and the widespread use of mobile devices are pushing tourists to a continuous interaction among themselves and with service providers during every stage of the holiday experience. Therefore, the DMOs – the bodies responsible for tourism development and the tourist companies – must offer through the Web an increasing number of services, even in situ ones. Some of them have the aim of improving destinations' accessibility by means of geolocation marketing strategies.

The aim of our research is to show how the GPS geolocation of points of interest can become an instrument to promote destinations and to enhance their accessibility together with tourists' levels of satisfaction – improving tourist flows in a specific area through structured information.

Keywords – geolocation marketing, web accessibility, Google maps, GPS geo-location, Strava, Wikiloc

Type of paper: Academic research

1 Introduction

Today the Web is one of the most effective means of communication and promotion, and electronic marketing is rapidly transforming the way organizations communicate and operate (Ferrari, 2015). In tourism, customers are increasingly using the Internet for information and support (Buhalis and Law, 2008; Buhalis and O'Connor, 2005; Buhalis et al., 2011; Leung and Law, 2007; Navío-Marco et al., 2018). The Web is no longer merely a tool for promotion and commercial distribution: it is also a way to offer supporting and facilitating services during the trip.

Because of the evolution of Information and Communications Technologies (ICTs), the widespread use of smartphones and other mobile devices, and the increasing offer of Wi-Fi facilities, tourists can interact not only with service infrastructures in the destination but also with other people, obtaining and sharing information during every stage of the holiday experience (Baggio and Scaglione, 2017, 2018a and 2018b). Therefore, the DMOs and the tourist companies must offer through the Web an increasing number of services (Bai, 2015). Some of them have the aim of improving destinations' accessibility by means of geolocation marketing strategies (Florez and Aguilar, 2012; Palos-Sanchez et al., 2018; Salazar, 2005).

The aim of our research is to show how the GPS geolocation of points of interest can become an instrument to promote destinations and to enhance their accessibility, improving tourist flows in a specific area through structured information coming from Google Maps, Google My Business and other interpretive applications.

The object of this analysis is the area called Sila Grande – a part of Sila National Park that is a large mountainous area of Calabria, in Southern Italy. The research aims to understand which are the mountain trails Apps mostly used by tourists and in which ways visitors manage to share the maps created by themselves and the information gathered during the excursions on the trails. The purpose is to understand how tourists use the Apps to share and to get user generated contents and what kind of contents they are interested in. A distinction will therefore be made between purely tourist content (such as photos) and information useful for visitors' safety and security or helpful to improve the management of the park (like, for example, updated in real time situations of the trails, reporting of critical issues, such as landslides, avalanche snow or other types of disaster).

Furthermore, we would like to check whether the presence of the signal and therefore the possibility of using the Apps is a stimulus to visits, favouring tourism development.

The findings of the research could be useful information for park and DMOs managers. They could help to understand if increasing the accessibility of an area in terms of number of traceable and passable tracks and points of interest can enhance a destination's tourism competitiveness. Besides the findings of their research could be a starting point to study users' generated contests and their effects in experiential and marketing terms.

2 Literature review

2.1 Evolution in the tourism sector thanks to ICTs

Nowadays ICTs have substantially changed interpersonal communication also thanks to the spread of mobile devices (Benckendorff et al., 2014; Baggio and Scaglione, 2017; Yoo and Gretzel, 2016; Xiang et al., 2014). In tourism they represent a challenge and an opportunity for enterprises and operators, asking for important innovations in marketing and management systems. In fact, ICTs have totally changed the way in which destinations and firms offer experiences to visitors and consumers enjoy them. Today these experiences are increasingly mediated by ICTs, which have transformed the way

tourists program and live their holidays (Buhalis and Law, 2008; Buhalis and O'Connor, 2005; Buhalis et al., 2011; Frew, 2000; Leung and Law, 2007; Navío-Marco et al., 2018).

Thus, technological innovations had a deep impact in tourism industry in terms of both demand's and offer's transformations, especially regarding the increasing amount of information today available. Information has increased customers' power and independence, reducing contemporary that of enterprises, especially in the distribution sector (Buhalis and Jun, 2011). Moreover, the increasing popularity of social networks, user generated contents, reviews, rating web sites and blogs have enabled consumers to obtain without both costs and efforts a great amount of useful shared information before, during and after the holiday (Buhalis and Law, 2008; Gretzel and Yoo, 2013; Wang et al., 2014; Xiang et al., 2015). The result is that tourists communicate more and more with each other and co-create their own experiences with other tourists and local communities by means of ICTs, becoming out-and-out prosumers (McCabe et al., 2012; Navío-Marco et al., 2018; Tussyadiah and Fesenmaier, 2009; Wang et al., 2012; Yovcheva et al., 2013). During the tourist experience they can access to an increasing number of dynamic information and services (Neuhofer et al., 2015).

2.2 Geolocation marketing strategies

Geolocation marketing is considered part of mobile marketing. The last one is the set of marketing strategies that uses any device or mobile phone network (Florez and Aguilar, 2012; Palos-Sanchez et al., 2018; Ružić et al., 2012; Salazar, 2005). Geolocation marketing is a marketing instrument based on the use of GPS (Global Position System) technologies that puts consumers' geographical location in connection with their behaviour. Companies use this information for promotional purposes. For consumers, on the other hand, geolocation is a social networks' tool to encourage socialization (Palos-Sanchez et al., 2018). In the last decades, the development of geolocation has been strongly promoted by the growing popularity of social networks (Palos-Sanchez et al., 2018). That's how the so-called social geolocation and location-based social networks come up (LBSNs) (Buhalis and Sinarta, 2019; Beltrán, 2011; Zhao et al., 2012). In this case social networks users can check-in in a location and share location-related information (for example photographs, descriptions of places and activities in which they are involved).

Today tourists increasingly use mobile tourism applications (Blaser, 2015) in every different type of destination and during many diversified experience (museums and heritage visits, outdoor recreation and parks visits, trails, etc.). During their trip they need in-destination specific information (Slivar, 2018), whose quality could have important effects on the whole experience. This kind of information is different from the ones collected before the holiday, because they supply tourists with practical information but also tools to immerse themselves in the local atmosphere and in the trip experience. This is possible also because of the connections with local residents and other tourists. During the experience, they need information in three different stages (Klantel et al., 2004): the first one is the orientation phase (visitors acquire familiarity with the destination), the second one is the movement phase (visitors find the right way) and the last one is the

information perception phase (tourists have reached the searched attractions, absorbing information about them). They have numerous both on and offline sources of information. Among the online sources: tourist information and DMOs' web sites, social networks, tourist mobile applications, location-based offers sent to mobile devices by visitors and many others. Inside a natural protected area visitors require a guiding system and in-destination specific information. Today they are normally provided by electronic maps, GPS and multimedia technology. They offer a guide together with a real-time positioning and the possibility to share information and access LBS (Location Based Services) (Meng et al., 2014). Due to the rising use of mobile devices and the lowering number of parks rangers and guides, mobile guides are becoming indispensable for parks managers as tools for monitoring, interpretation and education (Nielsen, 2012).

3 Methodology

Our research consists in collecting tourist check-ins on geolocation Applications (such as Google Maps or specific tracks Apps).

In addition, the study includes in-depth interviews with 15 operators: Park guides (4), tour operators (4), managers of associations operating in the trekking and mountain biking (5), Park staff (2).

Table 1 shows the main subjects of the interviews.

Table 1 Main subjects of the interviews

Q1: What is the main tourists interest when they arrive in Sila Grande?
Q2: Do spending the night-tourists represent a good percentage?
Q3: Are they tourists that usually visit parks?
Q4: Are tourists returning?
Q5: Can tourists explore independently or do they always need guides?
Q6: Are tourists for most Italian ones or foreigners?
Q7: Which one is the longest trail in matter of travelling time?
Q8: Are these tourists interested in geolocation?
Q9: Do they usually download information material on their devices before the arrival (e.g. Trail maps)?
Q10: Then, do they upload data on the web?
Q11: Between mountain bikers and hikers, which one of them is more frequent in this area?
Q12: What kind of service would you offer in these areas?
Q13: Do tourists try to get information about the main attractions even before their arrival? How do they get them?
Q14: Which apps do they use and which sites do they visit?
Q15: How do guides intercept tourists?

The results of the interviews have been elaborated through a content analysis, which permitted to identify two key themes: behaviour during the visit (Theme 1) and use of geolocation Apps, social networks, GPS, electronic maps and similar supports (Theme 2).

In the second part of the research the main Apps and platforms that use GPS for the geolocation of users are analysed. In this research, since the area is in high mountain, the focus is on the collection of data on trails. Therefore the object is the route between the POIs and the not POIs.

The Apps that could be used in the area were scanned. In this study we considered: Wikiloc, Osm and Maps, View Ranger and Strava. These Apps have been chosen on the basis of the interviews results, the study of the literature and our professional experience. Besides, the recordings that are visible on the pages/place of Facebook have been listed in order to get even more general data.

4 Findings

The information collected through the interviews are useful to identify who are the tourists visiting Sila Grande (Theme 1).

In Table 2 you can find the answers to the questions Q1-Q11. The answers to the other questions, that are related to more in-depth issues, are presented later.

Table 2 Respondents' answers

	Q1 ¹	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11
R1	trekking	yes	yes	yes	no guide	Italians	9 hours	yes	yes	yes	trekking
R2	trekking	yes	yes	yes	no guide	Italians	8 hours	yes	yes	yes	trekking
R3	info	yes	yes	no	guide	Italians	11 hours	yes	yes	yes	trekking

R5	trekking	yes	no	yes	no guide	Italians	10 hours	yes	yes	yes	trekking
R6	maps	no	yes	yes	no guide	Italians	11 hours	yes	yes	yes	trekking
R7	food	no	yes	yes	no guide	Italians	12 hours	yes	yes	yes	trekking
R8	guide	yes	yes	no	guide	50-50	11 hours	yes	yes	yes	trekking
R9	trekking	yes	yes	yes	guide	Italians	9 hours	yes	yes	yes	trekking
R10	info	yes	yes	yes	no guide	Italians	9 hours	yes	yes	yes	trekking
R11	food	yes	yes	yes	no guide	Italians	11 hours	yes	yes	yes	trekking
R12	maps	no	yes	no	no guide	Italians	10 hours	yes	yes	yes	trekking

¹ Q: question, R: respondent

R13	info	yes	yes	yes	no guide	50-50	70 km	yes	yes	yes	trekking
R14	bikes	yes	no	no	no guide	Italians	105 km	yes	yes	yes	trekking
R15	bikes	yes	yes	yes	no guide	Italians	105 km	yes	yes	yes	trekking

About the question Q1, the interviewees stated that visitors' main interests are: trekking routes ("trekking", 4/15 answers), general information on the place ("info", 3/15 answers), map recovery maps of the place ("maps", 3/15 answers), taste the typical dishes ("food", 2/15), assistance and rental of mountain bikes ("bike" 2/15). Only one of the interviewee out of 15 declared that tourists are looking for an environmental guide ("guide" 1/15).

To Q2, 73.3% of respondents stated that the tourists who stay overnight are in good percentage, considering the proximity to a built-up area with an urban agglomeration that exceeds 100,000 inhabitants. The percentage of tourists who stay overnight is considered quite high (over 30%) by over the 60% of respondents.

To Q3 86.7% of the interviewees stated that they are tourists who regularly visit parks.

To Q4 73.3% of the interviewees replied that they are returning tourists and they often repeat the travel or excursion after a year or more.

To Q5 the respondents answered that in most of the cases tourists do not need to be accompanied by guides ("no guide", 12 / 15 answers).

About tourists' provenance, all the respondents agreed that unfortunately only a minority of tourists are foreigners. An interviewed (R#15) estimated this percentage at 35% all during the year and 50% during summer, that is the peak season in the area. Many people (12 among the interviewees) hope that this segment will grow in the future. Furthermore, the answers to Q6 show that the majority of tourists are Italian (86.7%). To Q7 some failed to quantify a route in terms of time, also because a peculiarity of the place is that the trails intersect each other. From Q8 to Q10 they all responded positively ("yes").

The answers to Q11 underline the fact that trekking is the prevailing interest among hikers. The identikit of the trails visitor is: a trekking expert (as all interviewees said), often a regular visitor (especially if he/she lives in the region) and in some cases he/she is also a biker. However, biking enthusiasts still represent a minority of visitors, as there are no services focused on their needs, an operator (R# 14) explained.

As to the last questions (Q12-Q15), we received different types of answers, suggesting the need to increase the range of services offered in the area to become more competitive. One respondent (R#1) told us that "he would offer mobility services, and therefore transport from the POI to the accommodation." Another (R#10) suggested that "bikers are rising and could reach trekking hikers' segment in the future. Having bike assistance services could be very useful." Furthermore another respondent (R#13) told that "in a territory where mobility is lacking, and sustainable mobility does too, a solution to reach some places could be car sharing." The same interviewed also highlighted that "some tourists also ask to operators or info points for paper maps, perhaps in the event that there are no GPS signals or the phones turn off."

The answer to Q13 by the respondent R#7 was: “Tourists from other regions are more demanding because they know how they should be welcomed. Local tourists are less informed about the territory”.

Regarding the Q15, they told us that guides intercept tourists in different ways, “on the net” (R#13) and “even in other places in Italy where excursions are made” (R#1). In addition R#10 explained that “The social networks are useful to bring together demand and supply, tourists and guides, then there is an interchange of tourists between the various Calabrian parks and in addition there are infopoints where they can be oriented and meet guides.”

In conclusion, the interviews allowed us to know better the tourists’ behaviour during the visits, also with reference to the use of the Apps. It results that Strava is the mostly used App in this area. It turns out to be considered more complete comparing to the others, also because it allows users to upload photos associated with the specific geographical coordinates of a place. Most of the respondents (70%) explained that hikers and bikers use specific Apps. At the beginning of this study we considered also other Apps, such as View Ranger, Osm, Maps Apps and the Facebook local place registration tool. Though, through this work, it was found out that these Apps are more useful for travellers in the broad sense rather than for trekking and biking hikers.

In light of the results of the in-depth interviews, it resulted clear that the two segments of typical users that emerged (trekking and biking lovers) use specific GPS Apps. These Apps – known also as ‘sport trackers’ in jargon – are the most advanced ones in terms of software; they may even link to other tools in order to achieve a better performance. In conclusion, the Apps considered in the analysis were: Strava and Wikiloc and in addition the Facebook local place registration tool. From the answers of the tourist operators it was revealed that only the half of the whole trail network of the Sila National Park (that offers a total of 600 kilometres of trails) is drawn by the two Apps together. Therefore, it is easy to understand that there is still a great work to do in order to increase the accessibility of the area in terms of geolocation.

In the second part of the research, related to the Theme 2, the main Apps and platforms that use GPS for geolocation of users were analysed.

In Table 3 are shown the three main Apps used for the survey (Facebook, Wikiloc and Strava), inserting the POIs deemed most suitable (always through the search on Apps and platforms). The selection and choice of these three Apps was based on the answers to the interviews, as well as on preliminary informal meetings with some stakeholders, which showed how these are the most used by the type of public under consideration in that area.

On the three Apps considered it was noticed that only Lake Cecita, Monte Botte Donato, the refuge of Monte Curcio, Lake Ampollino, the Cupone and Lake Arvo have check-ins on Facebook. Instead, on the other two Apps a considerable number of trails is included. Among those ones that do not have check-ins on Facebook, the following POIs stand out for the high number of trails: Lake Ariamacina, Serra Ripollata, Zarella, Cozzo del Principe, and Monte Volpintesta. These places are the most known and visited by tourists and users of the two Apps. Despite this, it can also be noticed that the POIs that

are not been checked-in on Facebook have trails on the other two Apps. Even though the Cupone is 6th in a ranking for the number of check-ins on Facebook, it owns the 1st place in terms of number of trails, considering only Wikiloc and Strava.

From the data observable in Table 3, more information is perceivable.

The respective positions in the map in Figure 1 are connected to the 18 dots in the table.

Table 3 Recordings in Facebook, Wikiloc and Strava in the area of interest

	POI	FACEBOOK	WIKILOC	STRAVA
1	MOUNTAIN BOTTE DONATO	3732 VISITS	11 TRAILS	24 TRAILS
2	REFUGE MOUNTAIN CURCIO	3642 VISITS	6 TRAILS	7 TRAILS
3	MOUNTAINS OF PORCINA	NOT FOUND	1 TRAIL	0 TRAILS
4	MOUNTAIN SERRA STELLA	NOT FOUND	3 TRAILS	0 TRAILS
5	MOUNTAIN CARLO MAGNO	NOT FOUND	0 TRAILS	0 TRAILS
6	MOUNTAIN TIMPONE BRUNO	NOT FOUND	1 TRAIL	0 TRAILS
7	MOUNTAIN VOLTINTESTA	NOT FOUND	1 TRAIL	4 TRAILS
8	MOUNTAIN PETTINASCURA	NOT FOUND	0 TRAILS	2 TRAILS
9	MOUNTAIN ZIGOMARRO	NOT FOUND	1 TRAIL	0 TRAILS
10	COZZO DEL PRINCIPE	NOT FOUND	2 TRAILS	2 TRAILS
11	SERRA RIPOLLATA	NOT FOUND	5 TRAILS	5 TRAILS
12	CUPONE	1311 VISITS	28 TRAILS	16 TRAILS
13	ZARELLA	NOT FOUND	4 TRAILS	3 TRAILS
14	LAKE CECITA	20.139 VISITS	10 TRAILS	3 TRAILS
15	LAKE ARVO	1.626 VISITS	8 TRAILS	1 TRAIL
16	LAKE AMPOLLINO	12.040 VISITS	13 TRAILS	6 TRAILS
17	LAKE ARIAMACINA	NOT FOUND	11 TRAILS	0 TRAILS
18	MACCHIA FRAGA	NOT FOUND	1 TRAIL	0 TRAILS

Google was used in order to create Figure 1, but two locations were missing: “Serra Stella” (POI 6) and “Macchia Fraga” (POI 18). Serra Stella can be found only through Strava, while Macchia Fraga is a wooden area – which means that Google GPS cannot find or define it – and it can be found only through Wikiloc. On the net, sport track Apps and GPS maps replace real life cartographers.

The POIs reported in all three Apps are six:

- Mountain Botte Donato
- Refuge Mountain Curcio
- Mountain Cupone
- Lake Cecita
- Lake Arvo
- Lake Ampollino

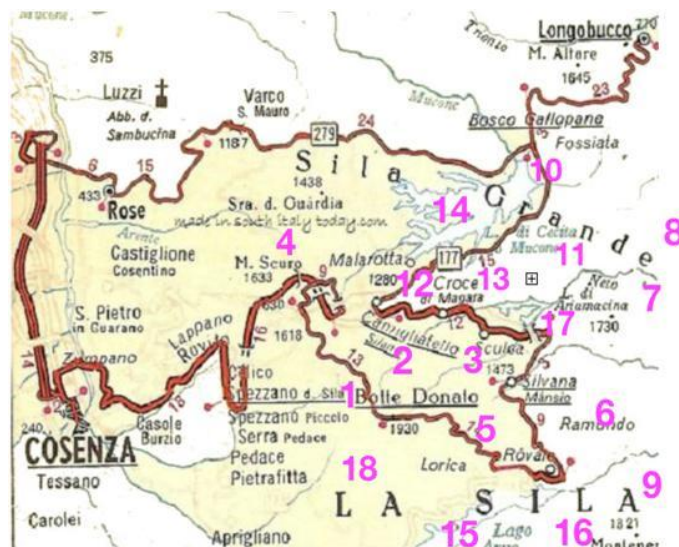

Figure 1 - Map of considered POIs in the Sila Grande

The place where a greater number of check-ins was carried out is Lake Cecita, which is one of the most popular places in the area. It is also where almost all of the main events of Sila Grande take place. The second one is Mountain Botte Donato, which is the highest peak of the Sila (altitude 1928 meters). In third position there is the refuge of Mountain Curcio, associated with a hospitality activity.

Regarding the number of check-ins registered individually by the Apps, Mountain Botte Donato is the first POI on Strava and on Facebook, while as far as Wikiloc is concerned, the primacy is an ex aequo between Mountain Botte Donato and Lake Ariamacina with 11 marked trails.

There are three areas with only one marked trail: Timpone Bruno, Zigomarro and the wood of Macchia Fraga. These ones can't be found even using the Google Maps satellite. Macchia Fraga is a wood, therefore one of those places where the GPS signal can hardly get.

5 Discussion and conclusions

The findings of the research show that the visitors of the area can be divided into two main segments, trekking and biking lovers. Both of them use specific geolocation Apps. The Apps play an important role from a social point of view in order to exchange information and share experiences with other tourists. Of course, they are also very useful to find specific information, also useful real-time news.

The results of the research regarding for example Macchia Fraga POI leads to the conclusion that if a place is not identified by the "Mountain View Giant" (Google), it could be difficult to consider it a tourist resource. In fact it is not accessible to users and travellers and this does not allow a complete trip to be planned. As a consequence we can say that if the GPS systems are not used at their full potential could create information asymmetries. These asymmetries are the opposite of the service that they should perform, that is the mapping an entire area.

An important aspect to consider in evaluating the findings of the research is that Calabria, the region where the research was carried out, has a great gap in terms of infrastructures compared to the rest of Italy and Europe (Ance, 2018; ISTAT, 2011). Therefore, the same research in another area would probably have allowed to verify the use of a greater number of Apps and the identification of a major number of POIs and recorded tracks.

The Apps and platforms that use GPS for user geolocation could represent the future of tourism marketing (Baggio and Scaglione, 2018a). They could become important marketing tools for local firms and destination management organizations. In fact they are only ones that can monitor tourists and track their movements. In addition, visitors can be intercepted during their holidays, offering them services and facilities. There are really interesting scenarios for marketers and enterprises, who could take advantage of these possibilities to propose visitors the most varied range of services in different moments and places.

Furthermore, the most used Apps work also as social networks, where users can exchange information, upload contents and also meet other tourists and enjoy parts of the holiday together. Focusing on the social network aspect, Facebook has been – albeit in a latent manner – the first social media to envelope the possibility of letting others know that a person is in a given place at a specific time. This gives the Internet's user, often subject to the vanity of being able to say "I was there", a tool to witness his/her presence in a place.

But Apps are also tools to improve the accessibility in tourism terms of specific areas and destinations. In fact, in a marketing strategy by creating checkpoints it is possible to trace the position of tourists or users in wild areas, offering services and increasing their safety in case of dangerous situations. This could be a way to monitor visitors, understand the critical points and offer services and support in case of need, for example creating checkpoint totems to contact relief.

Abstract

The rapid evolution of tourist demand pushes the tourism sector to innovate and to meet the requests of the most demanding customers, generating innovative and higher quality services based on authenticity. This is the philosophy of the innovative hospitality system called Albergo Diffuso (AD). The typicality of this new form of hospitality concerns services linked to the authenticity of the territory. This way, tourists, like temporary residents, can fully immerse themselves in the culture of the territory they are visiting. We aim to identify the business model of the AD that has influenced the development of sustainable tourism through the regeneration of historic villages and the recovery of cultural and territorial heritage. We used an exploratory analysis based on a multi-case. We analysed 19 ADs. An open questionnaire was administered to the managers. The questionnaire was then supported by a short interview with the manager. Our results confirm that the Albergo Diffuso is very appreciated by tourists and emphasize how this innovative model is leading a reversal of the current tourism business logics. The results show that the main factor of success is the experience that tourists experience in the territory, understood as a combination of local cultural traditions and knowledge. The key success factors of the operators' business models are the local area, its products and its best quality traditions but these are not sufficient to guarantee the sustainability of the AD model: solid management skills are also required. The ability to retain customers, invest in staff training and extensive communication channels are strategic management tools that companies must use efficiently to achieve success. This study identifies the main characteristics of business model of AD, pointing out how the rediscovery of the territory and its authenticity (socio-cultural and environmental), involvement and relationships with local communities are the key factors for the creation of a competitive advantage. It is critical for decision makers to know how own business is structured and which aspect are more appreciated by customers.

Keywords – Albergo Diffuso, Sustainability, Business Model Innovation, Tourism Experience, authenticity

Paper type – Academic Research Paper

1 Introduction

In recent decades, tourism demand has rapidly evolved into a form of conscious tourism geared towards deepening original values and personalized enjoyment. A generation of tourists has emerged characterized by greater experience, culture and a more lively critical and choice ability. They seek authenticity and perceive holidays as an opportunity to learn and increase their knowledge; they want to immerse themselves in the culture of places. They are always looking for new, original, unique destinations (Silberberg 1995). Finally, this new generation wants to experience together, to create friendship networks, to create bonds and to feel part of a community (Richards 2007). On the path of this change, the introduction of new accommodation formulas seems to be the best reaction to relaunch the tourist offer. In addition to traditional accommodation facilities, in fact, new forms of hospitality are becoming increasingly important, focusing on the revaluation of the territories and the enhancement of typical products. This is the philosophy of the innovative business of the Albergo Diffuso (AD), that is a structure that offers its guests rooms and / or apartments located not in the same building, as in the classic hotels, but in different buildings, within a hamlet.

The AD is proposed as a philosophical approach to authentic experience, to become a quality brand made in Italy, able to:

- launch sustainable development in the area;
- collect the needs of ever-widening market segments, relying on flexible solutions;
- act as a valid instrument for seasonal adjustment of the offer;
- promote each place in a unique and original way.

Authenticity is becoming the keystone of new generation tourism (Salamone, 1997). In the international debate, authenticity means "experience" or tangible "things" (Wang 1999). The AD seems to possess both characteristics of authenticity since it is located in a perfectly preserved hamlet with significant architectural features, the apartments are in historic buildings, and the rooms are furnished taking care to maintain the original historical period unchanged.

Moreover, what distinguishes the Albergo Diffuso from other forms of hospitality is the relational and experiential system, which involves the tourist so much that it becomes a "temporary resident" (Dall'Ara 2010).

Innovation is a crucial moment, which increases competitiveness and allows companies to develop (Williamson 1965). Innovation can concern either a new product or service or a new production system (Porter, 1990; Crossan & Apaydin, 2010).

The AD is innovative with respect to a traditional hotel both in terms of services provided and in terms of organizational system. Respect the first aspect, AD provides an integrated service, in a systemic logic with the surrounding environment. The services are closely linked to the natural, architectural and relational resources present in the area. To the traditional service, connected to hospitality, therefore accommodation, breakfast, specific hotel services, plus the services connected to the historical, artistic aspect of the architectural heritage present in the village. In addition, these are joined by participation in the life of the village and involvement in the traditional activities of the community.

These services are unique and are closely linked to the village that the tourist has chosen to visit. The activities side by side are closely connected with the cultural or naturalistic aspect that the tourist wishes to discover and learn about. Cultural curiosity is the first driver that encourages tourists to book an Albergo Diffuso in a village with specific artistic and architectural features, and the lively community and activities in the village represent the competitive advantage (Porter and Kramer 2007). The other innovative aspect is the organizational system (Senge, 1990). In the Albergo Diffuso the management performs a very complex function, since it does not have to manage only traditional presences and services, but must manage the entire village, in an integrated system. This means that the management must have superior knowledge, relating to the historical and cultural heritage, must be inserted in the community, must have knowledge of the natural and architectural heritage, must motivate the customers, and ensure unforgettable experiences. The management is not the owner of all the apartments, but there may be different owners, therefore it must also be able to manage the offer, guaranteeing the same high quality of services. For this reason, the AD represents an innovation in the tourism sector. Our study therefore focuses on the analysis of the Business Model Innovation (BMI) of the AD, in order to observe its peculiarity. A BM represents a general and holistic understanding of how an organization creates value through its activities and processes, involving several actors in its value chain and creating various interdependencies and dynamics with stakeholders (Massa & Tucci, 2013; Normann & Ramirez, 1992). For an innovative form of hospitality, like the AD, it is interesting to know what are the key success factors.

Thanks to this analysis, we will highlight the peculiarities of the AD and the main factors that generate value for the management but also for the territory. To conduct our research, we adopted a questionnaire as the main tool of analysis, and the following research question have been formulated:

- *R.Q.1: what are the key success factors of AD BMs?*

The paper is structured as follows: the next section illustrates the theoretical background of the AD and the BMI framework. The methodological design is presented in Section 3, while Section 4 offers a reading of the results achieved and the discussion. In the last section, conclusions and future research are presented.

2 Theoretical Background

2.1 Albergo Diffuso origin and current studies

The Albergo Diffuso concept appears for the first time, in Italy, in 1982, within a project planned by Leonardo Zanier, "Comeglians Pilot Project". In the 80s, after the term "Albergo Diffuso" came out, it was followed by other attempts of conversion of buildings, such as in Friuli (Sauri in 1982) and in other parts of the country; in Emilia Romagna, in Cal d'Enza around 1984, and in the small town of Vitulano, in the province of Benevento in 1987.

In these first attempts to create "Albergo Diffuso" model, the main objective was to use empty buildings and abandoned houses, to animate small village and to enhance artistic and significant sites with innovative marketing logic oriented to the experience, closely linked to the land (Dall'Ara, 2010). Only in the last 10-15 years, we can see the results and the effect, of this new model of hospitality, on the territory. The interest in the AD of many scholars of various disciplines has increased. At the beginning scholars were focused on the aspects and conditions for creating AD and its regulation (Droli 2013, Dall'Ara e Morandi, 2010; Paniccchia 2012). Later some studies focused on sustainability aspects, showing how AD can be considered a new sustainability-oriented hospitality model (Paniccchia and Leoni, 2017; Vallone, Orlandini and Cecchetti, 2013; Romolini, Fissi & Gori, 2017; Cucaria, Wankowicz, & De Falco 2019). Other contributions focused on a new model of competitiveness (Monge, Cattaneo, and Scilla 2015; Giampiccoli, Melville Saayman & Sean Jugmohan 2016). Others scholars began to see AD as a new model to preserve the traditional heritage (Silvestrelli, 2011; Vallone and Veglio 2018).

2.2 The AD Business Model Innovation

A business model is a conceptual tool to help understand how a firm does business and can be used for analysis, comparison and performance assessment, management, communication, and innovation (Zott et al, 2011; Osterwalder and Pigneur, 2005). Business models are interested in how the firm defines its competitive strategy by designing the product or service it offers to its market; how to pay for it, how much it costs to produce; how it differs from other competitor by the value proposition, and how the firm integrates its value chain with that of another firm in a network of values (Rasmussen, 2007). The quality of management is key because they determine the success of the business model through their capabilities, ability to acquire, combine and utilise valuable resources in ways that deliver a value proposition to customers.

Literature presents various perspectives on the business model. For some scholars business models are used to describe holistically "how a firm does business" (Zott and Amit, 2010; Beattie and Smith 2013). For others, the model explains how the firm will convert resources and capacity into economic value. (Teece, 2010). More specifically, Osterwalder and Pigneur, (2010) describe a business model as a series of elements: the value proposition (offering of products / services, customer segments, customer relations), activities, resources, partners, distribution channels (eg creation and delivery of value) and cost structure and income model (ie acquisition of value). Richardson (2008) proposes a consolidated view of the components of a business model such as: the value proposition (ie the offer and the target customer segment), the value creation and delivery system and the acquisition of the system value. Zott and Amit (2010) take an activity-based perspective, including the selection of activities ("what"), the structure of the activity system ("how") and who carries out the activities ("who").

The BM could be an important and additional tool of analysis in the tourism issue. (Hjalager & Madsen 2018). Studying the Ad business model means understanding which are the key factors, the decisive partners, which are its competitors; how it generates

value for the territory; which are the most relevant services, most sought after by customers; how important knowledge of places is; how important activities related to experience are. How it generates value.

This information can be used by management to better define its value proposition and better understand its potential and what are the limits of this new activity.

To be more precise, the value generation mainly occurs in a value network, which includes suppliers, partners, distribution channels and coalitions that extend the company's resources. In a BM there is a so-called "focal" organisation that manages value-added relations with a plethora of actors, who become strategic in the dynamic and interdependent process of value creation for the whole community. The collaboration between firms and other key stakeholders is very important and "value is no longer created by firms acting autonomously, but by firms acting together with parties external to the firm through informal arrangements or formal alliances" (Bocken, et al, 2014).

3 Methodology

The research focuses on AD located in Italy. Italy is a regionally administered country, with a general national legislative corpus for hotels, but in which each region decides to what extent the general criteria stated in national laws should apply to local needs in term of classification of hotel and characteristics of AD. In order to analyse the features of AD business model, a questionnaire-based survey was conducted among a sample of 19 AD businesses located in Italy. The sampling list was drawn from the National Association Alberghi Diffusi. In detail, the initial sample of 56 AD represented the whole universe and the questionnaire was sent by e-mail to all the accommodation facilities. A description of the research aims, a compilation guide and a link to an online questionnaire were sent to all the respondents. The compilation period was about 1 month, with several requests made by telephone in order to solicit the answers. The final sample was composed of 19 agritourism businesses, which corresponded to a response rate of 33%; this compares favourably with rates reported in previous online surveys among tourism and hospitality operators. The questionnaire included questions in the following areas of research: company profile, key financial data, type of services offered, type of customers, involvement of family/external managers, and key activities. Answers included both opened and closed questions, as well as a ten-point Likert scale. In addition, free spaces were given to the operators to write any additional comments about their experience with AD.

3.1 Sample

The sample is composed of 19 predominantly "young" AD, as they are mainly managed by the first generation of owners. These are companies average present on market by 8 years. Normally, the owner and the manager of the accommodation structure is the same. They are predominantly women, with degree and an age between 45 and 55. Also their role in AD was investigated, and the results are shown in Table 1.

Table 1. Role covered in AD.

Role Covered	Percentage
Management and coordination activities	11%
Operating activities	11%
Both	78%
Total	100%

The number of employees is on average between 6 and 10, although 35% of the sample has a number of employees between 1 and 5. The number of employees has remained unchanged over the last three years.

4 Results and Discussion

In order to answer the R.Q *what are the key success factors of AD BMs?*, we used the questionnaire responses and depicted the 9 key success factors identified by Osterwalder and by Osterwalder and Pigneur.

4.1 Key Activities

In order to identify the architecture of the companies and their network of partners (process management and key value drivers), we have compiled a list of activities that are carried out by the AD and we have asked to express an opinion in terms of key factor.

Table 2. Main AD activities and ranking.

Main AD Activities	Evaluation	Ranking
Relationship with the territory	7,67	1
Tradition and characteristics of territory	7,67	1
Service customization	7,33	2
Being an integral part of a historic village	7,00	3
Excursions and nature trails	6,83	4
Promotion	6,67	5
Human resources training	6,50	6
Target of customer	6,33	7
Denomination AD	6,17	8
Organization of guided tours	5,50	9
The diversification of the offer	4,83	10
The offer of complementary services	4,50	11
Cost leadership	4,33	12
The sale of agricultural products of the territory	3,60	13
Educational activities and learning workshops	3,17	14

Analysing this table, it emerges that the activities known as key success factors and considered as particularly relevant for the value creation, are represented by:

- the strong relationship with the territory and the natural environment, also highlighted by the offering of excursions and nature trails, discovering of history of the village and tradition;
- the ability to customize the service offered.

4.2 Partner Network

At the moment, the sample declared not to have key supplier partners; some AD are beginning to tighten collaborations regarding territorial revaluation projects with local institution (museum, etc).

4.3 Key Resources

The resources considered strategic by the respondents in order to run the AD are represented by the cultural and territory heritage and the human and financial resources to support the investments required to conserve the authenticity of the place.

A total of respondents declared that the manager's knowledge and the safeguard of the cultural heritage of village, carrying on the traditions, are the peculiarities that can make the difference in the business of the ADs.

From a financial point of view, it emerges a considerable involvement of the owners, indeed the key financial resources are mainly represented by financing of the owners, followed by the bank loans. Only 2% declared the use public sources and European fund.

4.4 Cost and Revenue Structure

Analysing the cost composition it emerged how the cost structure is represented mainly by the cost of personnel, the raw materials, the cleaning, energy and tax.

The percentage of annual average costs is between 50% and 70% of the company's turnover.

From the revenue point of view, the average turnover of the last three years (2016–2018) lower than 200,000 euros. Only 2% of the sample declared a turnover higher than 300,000 euros. This result confirms the limited development of AD in terms of revenues flows.

4.5 Value Proposition

We also investigated the perceived needs and the features behind the customer behaviour choice.

In particularly, it emerges that the elements perceived as the most important to address customer's behaviour are the maintain of an high and constant quality of service, the enhancing of the territory and the compliance with quality and certification standards.

4.6 Client Segments

To identify the customer composition we firstly distinguished three clusters by age: the first one is represented by young (18–35 years) customers; the second one by families (with parents and children) and the third one by customers over 65.

Analysing the customer composition, it emerges that the sample works with 27% of young customers, with 56% of families and with 17% of customers over 65 years. The foreign customers account for the 62% of the total. This highlights how the AD is particularly appreciated by foreigners who have the desire to immerse themselves in the Italian tradition and life style.

4.7 Client Relationships

The perception of the importance of maintaining and improving relations with customers was also investigated. The total of the sample declared they invested in activities to increase customer loyalty.

Discounts, compliments and promotional activities are some of the most used tool to maintain and improve customer loyalty. The capability to improve customer loyalty can, as well as communicating value and raising awareness for the safeguard of the environment, increase the well-being, not only of the AD owner, but also of the local community.

4.8 Distribution Channels

With distribution channels we point out the instruments used to communicate with customers.

The web site and social network are the digital communication channels used by the total of the sample. Some ADs have developed App.

5 Conclusions

From this first analysis, the business model seems to give some interesting information on this innovative form of hospitality. In fact, there are great differences with traditional models and innovative key factors. For the AD, the key factor for success is the link with the territory, being an integral part of a historic village.

This model in fact is perceived as the prerogative of a particular market segment for new tourists that are looking for innovation, innovative vacations that are also expressed in the choice of non-traditional accommodation but original and sustainable.

We examine the AD business model, focusing on the characteristics to be attractive and on the reasons that push tourists to choose it as a destination for their holidays.

Moreover, the internal employees are recognized as key partners and key resources; they support the core business and the key activities.

Another key factor is represented by the financing sources, mainly characterized by the owner's investments, showing the will to strengthen the economic development and support the durability of the business.

To improve value proposition, some actions of increasing the service offer have been implemented, generating customer satisfaction and enhancing the relationship with the territory and the community.

Finally, the ADs are aware of their customer segmentation, showing a prevalence of foreign clients.

Practical implications could be addressed to implement adequate policies for the development of AD as an instrument for the sustainability of the rural community. In fact the AD can change the economic development of a land. It can be seen as a model for preventing the depopulation of rural settings and for recovering abandoned villages.

This study could be very interesting for management to understand its potentiality and to be more attractive and competitive.

From the theoretical point of view, this study contributes to the national and international debate on peculiarities of AD.

Abstract

The paper intends to examine factors that mainly influence the creative process of celebrity chefs and culinary students. By using primary data obtained through an ad-hoc survey built by reviewing prominent literature focused on creativity and innovation in the haute cuisine context, we performed a discriminant analysis to compare the two different groups. Findings provide a better understanding of the origins and the main factors that drive creativity in haute cuisine. Outcomes of this study highlight the main differences that separate chefs in training from top chefs in terms of their creativity. Theoretical implications contribute to shed light on how creativity is influenced by both individual features and environmental/social components. Practical implications suggest which set of managerial capabilities chefs in training and, in turn, professional high schools of cooking have to develop in order to stimulate and sustain creativity in their educational programs. The study contributes to the academic debate on creativity and innovation in haute cuisine context, by suggesting key factors that effectively stimulate actions and behaviours leading to a continuous flow of novel and useful ideas.

Keywords – chef, haute cuisine, culinary innovation, creativity, cooking skills, students.

Paper type – Academic Research Paper

1 Introduction

Managing creativity to generate, develop and improve innovation is the key managerial challenge in today's economy and a critical determinant of firms' success and long-term survival (Anderson et al., 2014). Firms are forced to be creative and to introduce innovative products/solutions to ensure sustained competitive advantage (Lampel et al., 2000). Studies argue that creative ideas are effectively precursors of innovation (e.g., George, 2007). Creativity is variously influenced by three within-individual components: domain-relevant skills, creativity-relevant processes and task motivation (Amabile, 1988). Individuals are mostly creative when they feel motivated by passion, enjoyment, satisfaction, and challenge of the work (Amabile, 1988). Although individual creativity is the most relevant element for innovation activities, creativity may be seen as a particular confluence of a variety of components, so that is highest when an "intrinsically motivated person with high domain expertise and high skill in creative thinking works in an environment in supports for creativity" (Amabile, 2012, p. 3). However, the surrounding environment – i.e., the work or social environment – represents a component outside the individual that can be conceived as obstacle or stimulus to creativity (Amabile, 2012). Thus, it results relevant to understand how environmental conditions interact with individual characteristics to foster (or to discourage) creativity.

To deepen knowledge on creativity and innovation, the haute cuisine context is here investigated. In this context, creativity and innovation play a critical role due the reason that chefs are under pressure to generate original dishes, menus and proposals for customers seeking extraordinary gastronomic experiences. The haute cuisine is also characterized by increasing competitiveness (Stierand and Dörfler, 2012; Svejenova et al., 2010; Albors-Garrigos et al., 2013). Additionally, innovation has been identified as a significant impulse that can allow the development of an inimitable competitive advantage for chefs (Presenza et al., 2017). In effect, haute cuisine chefs can be observed as the benchmark for other sectors of activity. They are described as being "extraordinary chefs" (Stierand and Lynch, 2008), since they image and develop new ideas and/or combinations of existing ingredients, design and apply new processes, develop culinary scientific approaches, exploit talent and experiment continuously (Harrington and Ottenbacher, 2013; Messeni Petruzzelli and Savino, 2014; Vargas-Sanchez and López-Guzman, 2015; Presenza et al., 2017).

Such considerations imply that most of the success of haute cuisine restaurants is strongly linked to the chefs' creativity, by recognizing that heterogeneous components – both within and outside the individual – have an impact on their creative processes (Svejenova et al., 2010). However, there is considerable controversy surrounding the factors of creativity and innovation in haute cuisine context. It follows that a better understanding of those factors is strongly required.

The paper seeks to understand those factors that influence the creativity performance of top chefs, by investigating both within-individual components and social/environmental components. It performs a comparison between starred chefs and chef in training. Indeed, while the former have already gained success due to their ability

to be creative and innovative, the latter lack experience and are not subject to the pressures arising from a real work context. In turn, a comparison between the former and the latter allow to isolate factors related to experience and external conditions from factors related to chefs' personal characteristics.

The empirical analysis is based on a quantitative analysis. One hundred thirty-two questionnaires have been collected from Italian Michelin Stars Chefs and the same number of students attending professional high schools of cooking. Findings highlight the main factors and the origins of creativity in haute cuisine and emphasize the differences that separate chefs in training to top chefs.

The remaining of the paper is organized as follows. In Section 2, we review the relevant literature on creativity and innovation in the haute cuisine. In section 3, we describe the research methodology, by presenting the context of the study. In Section 4, we advance the key findings. Finally, in Section 5, we discuss the study and outline theoretical and managerial implications, by suggesting research avenues.

2 Literature review

Creativity is observed as a foundation of value creation in organizations (Amabile et al., 1996). Studies focused on the creativity concept argue that creative ideas are precursors of innovation (e.g., George, 2007). Creativity has been conceptualized as the generation of ideas that the socio-cultural environment judges as both useful and novel (Amabile et al., 1996, p. 1155). Differently, originality of ideas is judged on how extreme and unrealistic ideas are effectively perceived and whether they came at the right or wrong time (Amabile, 1996). In this respect, "new useless ideas and old useful ideas are not creative" (Bouty and Gomez, 2013, p. 5). Creativity can occur at different stages of innovation activities and with regard to a large variety of topics, from products and services, to processes, structures, work tools, and social progress (George, 2007). The creativity is influenced by three within-individual components: (i) domain-relevant skills (i.e., expertise, knowledge, technical skills, intelligence, etc.), (ii) creativity-relevant processes (i.e., cognitive style, personality process characteristics that are conducive to novel thinking, risk-taking, and taking new perspectives on problems), and (iii) task motivation (i.e., intrinsic motivation to engage in the activity out of passion, personal sense of challenge, enjoyment) (Amabile, 1996). Individuals are most creative when they feel motivated mainly by the passion, interest, enjoyment, satisfaction, and challenge of the work (Amabile, 1988). However, creativity needs of a necessary confluence of all components and, in particular, should be highest when an intrinsically motivated person with high domain expertise and high skill in creative thinking works in an environment high in supports for creativity (Amabile, 2012). In fact, while individual creativity is the most relevant element for organizational innovation, "it is not, by itself sufficient" (Amabile, 1988, p. 125). Beyond the individual components, the surrounding environment, generally work or social environment, represents a component outside the individual that can be observed as obstacles or as stimulants to creativity (Amabile, 2012). Thus, the outside component contemplates all of the extrinsic motivators and

factors that have been revealed to undermine or foster intrinsic motivation. For example, factors are the following: sense of positive challenge at work, top-management support to innovation processes, mechanisms for developing new ideas/solutions, mechanisms of sharing ideas and knowledge across organizational functions, etc. Research has distinguished two generic types of creativity: the everyday creativity inherent to the average person (Richards, 2007), and the creative genius linked to talents in certain fields (Simonton, 1997). In this perspective, haute cuisine is an example of creative and cultural industries where creative production plays a key role for firms' competitive advantage (Svejenova et al., 2010; Messeni Petruzzelli and Savino, 2015). In 2010, United Nations Educational, Scientific Cultural Organization (UNESCO) formally acknowledged haute cuisine as part of the creative and cultural industries by adding the French gastronomic meal to its "Representative List of the Intangible Cultural Heritage of Humanity" (UNESCO, 2010). In haute cuisine, the necessity of linking creativity, innovation and competitive advantage is becoming more relevant because creativity is strongly observed as determinant to develop appropriate and desirable products and obtain the highest levels of distinction. Lampel et al. (2000) assert that creativity in gastronomy can be used to introduce novelty for product differentiation and/or to develop a market innovation that may defy current norms and practices. New dishes and menu proposals are the concrete result of novel, original and atypical combinations, where old ingredients and innovative or familiar methods/techniques are expertly mixed in order to generate new proposals and unusual recipes that are constantly changing, and require working very long, intuitively and often anti-social hours (Capdevila et al., 2015). The creativity is primarily the result of hard work and study related to materials, tools, and techniques. The peculiarity is substituting, combining, adapting, rearranging and modifying ingredients of a dish and typically cooking several versions of it (Svejenova et al., 2010). Creativity in haute cuisine is extremely iterative and fluid. It requires efforts to screen, test, and validate activities and processes. The screening activity consists of the selection of criteria, such as product quality, seasonality, fit with the personal style of cooking, costs, pricing strategy, balance of the dish itself and fit with the rest of the menu, maintenance of standards, etc. Finally, testing, experimentation and validation are iterative activities that result in accumulating knowledge and determine the value based on customer acceptance. Several factors can influence the process of nurturing creativity in the haute cuisine context. Certain of these factors are directly connected to the chef, while others are related to the ecosystem in which the chef exists (Ottenbacher and Harrington, 2007; Pedersen, 2012; Vargas-Sanchez and López-Guzman, 2015). Chefs make use of personal experience, methods and techniques, as well as competences and capabilities to generate the idea for a new dish in their mind and utilize tacit knowledge to produce it. The development of new dishes, recipes and menus requires intuitive thinking, technical knowledge, cooking techniques, going beyond the rules and accepted processes, experimenting and searching for the best or better ingredients, making adjustments based on experimental results, and accepting mistakes and failures. These realities of creativity mean that successful products have to be continually improved by considering the chef's knowledge, accumulated experiences, and complementary technical skills (Ottenbacher and

Harrington, 2007). Albors-Garrigos et al. (2013, p. 2) assert that “these chefs usually have their own space and time for creativity and rely on networking with an extensive social context”, by underscoring the importance of external sources for obtaining information and inspiration that lead to innovative activities. Among the plethora of sources, most often cited is the involvement and interaction with customers (listening to their needs/preferences) as well as restaurant staff, colleagues, and suppliers of raw materials and ingredients (Bockelmann and Braun, 2014; Paris and Lang, 2015). Feedback can be obtained from presentations at gastronomy and culinary conferences, exhibitions and trade fairs as well as collaborating with scientists resulting in new textures and combinations of ingredients.

3 Methodology

3.1. Research setting

The research setting is the Italian haute cuisine, as defined by the Michelin Red Guide. The success of fine-dining restaurants is defined according to the restaurants' ratings by major guidebooks (Rao et al. 2003). Of these different guidebooks, the famous Michelin Red Guide is internationally acknowledged as the most thorough (Ottenbacher and Harrington, 2010), and is recognized as one of the most important culinary book (Bouty and Gomez, 2013). It is a series of annual publications addressing tourism and gastronomy, and represents the largest global benchmark for assessing the quality of restaurants (Di Stefano et al., 2015). The Michelin Guide provides a well-written description of each restaurant and a variety of other symbols to give readers insights into an establishment's ambiance, type of cuisine, specialty dishes, wine list, complementary services, etc.

Obtaining a Michelin star rating is a sign of creativity, quality and innovation, and it is considered one of the top achievements a chef can attain. The star symbols judge only what is on the plate, meaning quality of products, mastering of flavours and cooking, personality of the cuisine, value for the money and consistency of what the restaurant offers to its customers both throughout the menu and the year. Michelin star ratings are valued by the most relevant stakeholders, by including restaurant owners, customers and critics (Durand et al., 2007). The number of stars awarded assesses the chef's quality of craftsmanship (Svejenova et al., 2010). For this reason, the Michelin rating (expressed on a one- to three-star scale) can affect the reputation and economic well-being of a restaurant (Woodward and Stierand, 2014). Stars are given to the restaurant and not to the chef. However, the success of the restaurant depends largely on the chef's work. Hence, when a chef leaves a restaurant, the stars are “suspended” until the next examination by the Michelin experts. A major criterion for awarding stars to a restaurant is “renewal” - the ability to offer creative and new recipes on a regular basis. The study of Michelin star chefs is therefore akin to focusing on chefs who have engaged in frequent innovation as part of their professional success.

3.2. Research setting

To achieve research objective, an online survey targeting Michelin starred chefs and chefs in training was performed. A self-administrated questionnaire has been developed to examine the main components linked to individual and social/work environment that influence the creativity and innovation processes. It is based on and inspired by the study of Vargas-Sanchez and Lopez-Guzman (2015). To enhance external validity, the questionnaire was pretested by one Italian three-starred Michelin Chef (in two separated informal meetings ranging from 20 to 40 min) and four academic experts in the field of culinary industry. The survey was addressed to the chef of each Michelin starred restaurant and to the Managers of Chef Schools, with a detailed cover letter explaining the purpose of the study. The analysis was conducted over the period January 2016 to September 2017. The sample was composed of 132 Italian Michelin starred chefs. As the 2016 Guide includes 334 starred chefs (<http://www.scattidigusto.it/2015/12/10/guida-michelin-2016-tutte-le-stelle-dei-migliori-ristoranti-italia/http://www.scattidigusto.it/2015/12/10/guida-michelin-2016-tutte-le-stelle-dei-migliori-ristoranti-italia/>), the sample covers 39.52% of the entire population, of whom 88% are male. The number of the stars is represented as follows: 83% one star; 11% two stars; 6% three stars. Then, we contacted the Managers of Gastronomic Schools located in two Italian Regions to involve the same number of chef in training.

3.3. Measures

The study performs a discriminant analysis (DA). This is a statistical procedure, which allows to classify cases in separate categories (to which they belong) on the basis of a set of predictors/items and to assess how well the independent variables separate the categories in the classification. It is a linear combination of the selected items with the assumptions that predictors are normally distributed and that the covariance matrices for the predictors within each of the groups are equal.

With the analysis, the study aims at testing whether the set of predictors allows to correctly identify starred chefs and chefs in training and which factors make the difference between the two groups to understand the role of experience. DA linearly combines the predictors to estimate a discriminant function, that yields a discriminant score z , based upon the predictors' variables x_i , and the estimated coefficients α_i .

To assess the goodness of the analysis we rely on the Box's M test, that assess whether the covariances are equal across groups, and on the Wilks' Lambda (or U statistic) tests discrimination between groups. The latter is related to the analysis of variance; we check for the individual Wilks' Lambda for each of the predictors in the discriminant function and tests whether there are significant differences in the predictor's means between the groups. The p-value follows an F distribution. The Wilks' Lambda for the overall function indicate whether there are significant differences in the group means for the discriminant function; in this case the p-value is drawn from a Chi-square distribution

4 Results

Table 1 shows the standardized coefficient estimates for the discriminant function, which do not depend on the measurement unit, but coefficients with large absolute values correspond to the variables with greater discriminating ability. The most important predictor that allows one to discriminate between starred chefs and chefs in training refers to those who fight the imitation risk through a periodic reinvention and anticipating concurrent and adapting their supply (q5_3). It has the highest discriminant score and the largest positive impact followed by the item that accounts for the chefs who consider essential their experience with clients (q3_5) and by chefs who consider their participation at events, congresses etc. as important (q1_11). Instead, those who strongly believe that it is imperative to test a new product (q3_4) and who believe that the creative process is spontaneous and informal (q2_1), and that in creating new products they often start by trying to improve existing products (q1_9) have a negative sign and reduce the discriminant score.

From the group centroids – i.e., the means of the discriminant score for each of the two groups (Starred Chefs=-0.858; Chefs in training = 1.042) – we can understand that higher positive discriminant scores increase the probability to be classified into the student group since the average value for the student is positive while it is negative for the starred chefs.

Table 1. Standardized discriminant coefficients

Predictors		Function
Items	Codes	
As a technique for the generation of new ideas and products I use the combination, mixture, and fusion of ideas	q1_6	-.219
As a technique for the generation of new ideas and products I use analogy and camouflage	q1_7	.205
As a technique for the generation of new ideas and products I try to identify alternative uses	q1_8	-.039
As a technique for the generation of new ideas and products I use the analysis of areas for improvement of existing products	q1_9	-.298
Training, experience and learning are fundamental in our case	q1_10	.009
Participation in professional events (fairs, competitions, conferences, congresses, etc.) is very important	q1_11	.333
I have created a repository of ideas that I systematically improve	q1_12	-.092

In the process of transforming ideas into gastronomic products, testing new products through trial and error is imperative	q3_4	-.536
In the process of transforming ideas into gastronomic products, the accumulated memory (through learning and experience) on clients and their behaviour is a key factor	q3_5	.387
In the process of transforming ideas into gastronomic products, adapting to the circumstances of the moment (for example, crisis) is of primary importance when it comes to inserting a new product in the menu	q3_6	.300
In the configuration of a gastronomic experience, the business model (for example, the type of restaurant) is the determining factor	q4_1	.020
In the configuration of a gastronomic experience, the profile/personality of the entrepreneur is the determining factor	q4_2	-.157
In the configuration of a gastronomic experience, the profile/personality of the chef is the determining factor	q4_3	-.251
Imitation doesn't make me particularly worried, since not everything is imitable, such as skills in using a techniques or the personal touch in the kitchen	q5_1	-.019
Imitation doesn't make me particularly worried, since originality and differentiation of my gastronomic offering are obstacles to imitation	q5_2	-.238
I fight the risk of imitation through periodic reinvention, anticipation of competition and adaptation of my offering from time to time	q5_3	.628
I fight imitation by paying attention to customer relationship, strengthening his/her emotional component, also through his/her gastronomic education	q5_4	-.049

The classification results in Table 2 show the correctly classified cases: 85.8% of starred chefs are correctly classified, while 77.4% of chefs in training are correctly classified. Overall, 82% of the cases were correctly classified.

Table 2. Classification Results

	Predicted Group Memberships		Total
	<i>Starred Chefs</i>	<i>Chefs in training</i>	
<i>Starred Chefs</i>	97	16	113
<i>Chefs in training</i>	21	72	93
<i>Starred Chefs</i>	85.8%	14.2%	100%
<i>Chefs in training</i>	22.6%	77.4%	100%

The Box's M test shows that the covariance matrices are not equal, while the Wilks' Lambda test for the function as a whole displays that the overall discriminating power of the DF is good. The Wilks' Lambda for each of the predictors in the discriminant function tell us that not all of the predictors are relevant to discriminate between the two groups (Table 3). This test tells which variables contribute a significant amount of prediction to help separate the groups (in bold). Results strengthen the findings obtained with the standardized coefficients (Table 4) and add that an important difference between the two groups is due to the thinking that, during the transformation process, it is important to adapt to the current situation (e.g. the economic crisis) (q3_6) and that, in the imitation process, not everything is reproducible (q5_1).

The canonical correlation is the square root of the ratio between variability between and total variability is 0.69. The eigenvalue is the ratio between variances between and variance within groups (the larger the better) is 0.903.

Table 3. Wilks' Lambda for the single predictors

5 Discussion and conclusion

The study has explored the theoretical concept of creativity in the haute cuisine context. More specifically, it has empirically investigated the different factors that affect the creativity of top-chefs and chefs in training. Mainly, the comparison between these two groups of chefs has allowed us to isolate and distinguish between within-individual and social/environmental factors affecting creativity. Indeed, while a personal attitude towards creativity is likely to be present also in chefs in training, the latter differ from top-chefs since they miss experience in cooking and in facing the challenging conditions of a real work context. In turn, by comparing the two groups, this study has highlighted whether and which external (i.e., organizational and competitive) conditions affect creativity, along with individual skills and personal attitudes.

The empirical findings have underlined that the factors affecting the creativity of these two different groups are indeed diverse. The within-individual and environmental/social components assume a different relevance for top-chefs and for chefs in training. Specifically, the main difference is linked to the problems of the imitation risk that becomes particularly pressing for top-chefs. In this respect, top-chefs have to orient their energies, efforts and competencies to the search, combination and proposal of innovative offerings and experiences for their customers. New and old ingredients, new and traditional methods, continuous experimentation, novelty, sensory and experiential contents assume a critical role in the activities oriented to face the competitors. In line with Lampel et al. (2000), the creation of a new product/proposal results from the effort of searching and recombining those elements giving distinctiveness.

Other relevant difference is related to the experience with customers, observed as a relevant external source to innovate. Top-chefs underline that interactions and relationships with customers are necessary to acquire ideas, improve dishes and menu proposals, define quality services and create a sensory atmosphere/environment.

Additionally, the investigated groups assign different relevance to event participations. For top-chefs, events are observed as a useful moment of confirmation of their reputation, image and notoriety. Differently, chefs in training underline that events are a suitable opportunity to meet top-chefs and learn new culinary methods/techniques. This group highlights that the creative process is essentially spontaneous and informal, moving from the idea that the passion and motivation of chefs are key factors to develop new dishes and new methods.

The study contributes to existing literature in two ways. It extends knowledge regarding how creativity is influenced by different factors in cultural and creative industries. More specifically, in the restaurant sector and broader hospitality industry, creativity is increasingly attracting the interest of scholars because it is recognized as crucial determinant for maintaining a strong positioning in the market that must be sustained over time. As noted, creativity is the single most important factor contributing to the innovative outcomes of firms and the only necessary component of innovations (Stierand and Dorfler, 2012). Additionally, the study contributes to the academic debate on creativity and innovation in haute cuisine context, by suggesting key factors that

effectively stimulate actions and behaviours leading to a continuous flow of novel and useful ideas. Moreover, it empirically identifies factors that have a significant influence on the generation of creative ideas in the haute cuisine. These findings are aligned with those of Amabile (1983, 1996) who, in other settings, finds that the creative process is affected by within-individual components (i.e., experience, intuition, tacit knowing, sensitivity, etc.) and the surrounding environment (i.e., collaborators, customers, etc.).

The results of this research can also help us drawing some relevant managerial implications. Firstly, we should consider creativity and innovation from a strategic point of view. In fact, the creativity and innovation process has to be managed efficiently in order to develop successful and differentiated outcomes by anticipating direct/indirect competitors and to preserve novel dishes, culinary proposals and services from the imitations. Secondly, the results of our study stress the critical role of training and education in the formation of culinary skills and competencies. In addition, they suggest the opportunity to develop a set of managerial capabilities on which chefs in training and, of consequence, professional high schools of cooking have to stimulate and sustain concretely different creativity paths in their educational programs. In fact, creativity seems to flow more easily and concretely when it is stimulated and separated from the pressures of the workplace (Albors-Garrigos et al., 2013).

The study has also some limitations that might provide insights for further research. The analysis is effectively limited to the Michelin Star Chefs and chefs in training in Italy. Therefore, further research on haute cuisine and professional high schools in various countries could be useful to understand the geographic generalizability of the observed patterns and findings and to avoid size bias. Additional research could also include other hospitality sectors and the broader creative and cultural industry in order to assess the generalizability across industries as to what stimulates creativity and innovation processes and, consequently, the success of organizations in these settings.

Abstract

Interest for sustainability issues is rising in the business strategy and management disciplines. At the same time, sustainability-related practices are actualized by companies within economic, social, and environmental perspectives. For instance, enterprises working in the tourism industry are moving towards sustainability objectives, such as preservation of biodiversity and inclusive value creation.

The aim of this research is thus to develop a framework based on sustainable business model archetypes, to be applied in tourism industry. The research question is: Which sustainable business model archetypes could be developed and implemented by tourism enterprises and how?

At first, three archetype-based frameworks are compared to identify how a sustainable approach could be developed and adopted on the basis of company dimension and industry. Afterwards, a systematic literature review is conducted to collect examples of sustainable business model in tourism, with a special focus on practices oriented to business model innovation.

The research shows how former studies provide practices according to the three different lines of sustainability (i.e. economic, social, and environmental). The results display a variety of possible initiatives that may be adopted by tourism enterprises. Indeed, the study provides a new set of archetypes for sustainable business model innovation in tourism industry. As such, the paper contributes to the existent knowledge on sustainable business model by classifying and analysing actual chances of business model implementation from the sustainability viewpoint. The new set could be useful to both practitioners and academics in designing innovative paths for sustainable concrete enactments. Moreover, it offers the ground archetype-based framework for tourism management researchers to be tested in future studies.

Keywords – Sustainable business model, tourism sustainability, triple bottom line.

Paper type – Academic Research Paper

1 Introduction

Over last years, sustainability-related issues have entered in managerial studies with growing attention. For instance, according to Scopus database, papers on sustainable business models have more than quadrupled over the last five years. Nonetheless, tourism research has oriented its interest on sustainability from a macro perspective at large, i.e. considering a territorial development focus, rather than investigating the role of tourism enterprises in implementing sustainable practices. In particular, few studies (e.g., Jaafar and Maideen, 2012; Melissen et al., 2016) have deepened the knowledge on how sustainable business models may take form within tourism business context. Such studies highlight the difficulties that tourism enterprises face in considering sustainability according to the Triple Bottom Line, i.e. by attributing relevance to sustainable corporate performance on economic, environmental and social levels at the same time. Nevertheless, interest of tourists in the application of sustainable practices is growing (Buffa et al., 2018). Despite that, few studies (Mihalič et al., 2012; Høgevoid et al., 2015) consider the three aspects at the same time and very few studies (Battistella et al., 2018) clearly define specific applicative practices to obtain the Triple Bottom Line.

The aim of this study is to outline typical archetypes for sustainable business models in tourism. The archetypes describe “groupings of mechanisms and solutions that may contribute to building up the business model for sustainability” (Bocken et al., 2014: p. 42). Their goal is to facilitate the development of sustainable business models into the enterprises’ practices, and so far, some studies have adopted such tool for applying it into diverse contexts, such as global corporations (Ritala et al., 2018) and banks (Yip and Bocken, 2018).

The research question therefore is: *Which sustainable business model archetypes could be developed and implemented by tourism enterprises and how?*

Starting from the sustainable business model archetypes and importing recent literature on tourism sustainable business model, we detect and adapt examples of practices from tourism management area and we define specific sustainable business model archetypes in tourism. The final purpose is indeed to compose an updated set of archetypes for designing sustainable business models of tourism enterprises.

2 Materials and methods

2.1 Methodology overview

Following the methodological instructions in Yip and Bocken (2018), who studied the sustainable business model archetypes for the banking industry, we followed the next steps:

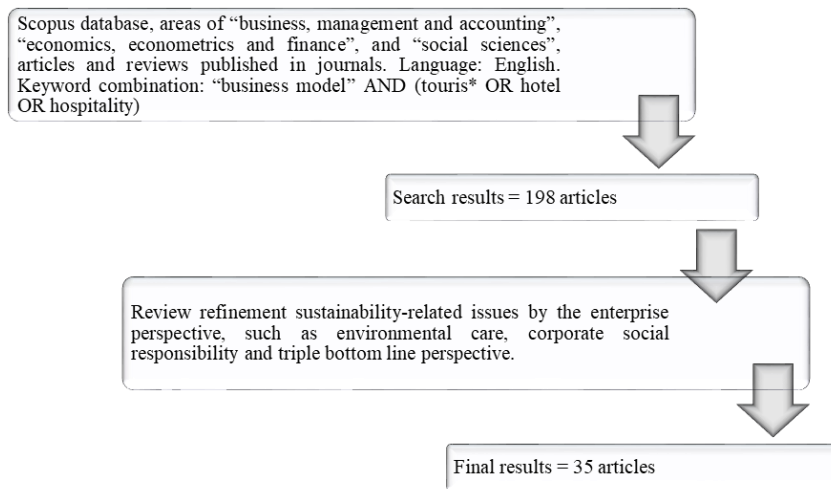

- From an initial literature review, we identified the studies adopting the archetype-based framework of sustainable business model.
- A systematic literature review was conducted according to methodological instructions by Jesson et al. (2011) in order to retrieve a collection of sustainable business models in tourism.
- Examples from business practice were collected from past studies to develop a new set of sustainable business model archetypes for tourism. The proposed set was drawn on the basis of the ones by Bocken et al. (2014), Ritala et al. (2018) and Yip and Bocken (2018) in order to enhance the comparability among existent frameworks and the reliability of the projected new one.
- Finally, practices were grouped to compose the set of archetypes, to be discussed in the final part of the paper.

2.2 The systematic literature review process on sustainable business model and practices in tourism

A systematic literature review was conducted according to methodological instructions by Jesson et al. (2011), with specification of a review protocol and of inclusion/exclusion criteria in order to guarantee the systematicity of the process. The review employed Scopus database, with selection within the areas of “business, management and accounting”, “economics, econometrics and finance”, and “social sciences”. Only articles and reviews published in journals in English were retained.

In order to collect the practices into the archetype-based framework, the search orientation dealt with studies on business models in tourism enterprises. For this reason, the research was developed with the keyword combination: “business model” AND (touris* OR hotel OR hospitality). The result was a collection of 198 articles retrieved by Scopus at the date of 7th October 2018. Articles were scanned in order to look for sustainability-related issues by the enterprise perspective, such as environmental care, corporate social responsibility and triple bottom line perspective. Articles solely based on destination management, public policies and regional development were excluded, since not coherent with the topic. By the methodological point of view, the review is functional to design a set of archetypes derived by previous review stream and dealing with the specific business area of tourism activities. The review led to a final group of 35 articles.

The following figure (Figure 1) sums up the systematic review process. Results are presented in the next section.

Figure 1 – The systematic review process

3 Literature review

3.1 The archetype-based framework for sustainable business model

The first objective of the literature review was to collect studies focused on sustainable business model. Here, the attention was driven to archetypes of sustainable business models, which could be helpful to support the design of the framework on sustainable business model even in a sector (i.e., tourism), which is different from the ones entailed in former studies. By the methodological point of view, the choice to focus on archetype-based framework only is functional, as the archetype-based framework by Bocken et al. (2014) and its following revisions and applications are drawn on past studies. This review process led to a final group of 3 articles, more specifically: the one by Bocken et al. (2014), who firstly outlined a framework based on the archetypes of sustainable business model, and two following applications, namely the study by Ritala et al. (2018) on large corporations and Yip and Bocken (2018) on banking industry. The following table compares the results of the three studies

Table 1 – The archetypes for sustainable business model

	Bocken et al. (2014)	Ritala et al. (2018)	Yip and Bocken (2018)
Technological/ Environmental	Maximise material and energy efficiency	Maximise material and energy efficiency	Maximize material and energy efficiency
	Create value from “waste”	Closing resource loops	
	Substitute with renewables and natural processes	Substitute with renewables and natural processes	
			<i>Substitute with digital processes</i>
Social	Deliver functionality rather than ownership	Deliver functionality rather than ownership	
	Adopt a stewardship role	Adopt a stewardship role	Adopt a stewardship role
	Encourage sufficiency	Encourage sufficiency	Encourage sufficiency
			<i>Inclusive value creation</i>
Organisational/ Economical	Re-purpose the business for society/environment	Repurpose for society/environment	Repurpose for society/environment
	Develop scale-up solutions	Develop sustainable scale-up solutions	
		<i>Inclusive value creation</i>	
			<i>Resilience in loan granting</i>
			<i>Sustainable financial products</i>

Source: own elaboration on Bocken et al. (2014), Ritala et al. (2018), Yip and Bocken (2018)

The founders of sustainable business model archetypes (Bocken et al., 2014) identified technological, social and organizational higher-level groupings, confirmed in the study by Yip and Bocken (2018). On the contrary, Ritala et al. (2018) categorized archetypes by environmental, social, and economical groupings, since the study considered the major innovation types as group criterium.

Moving towards the in-depth examination of the sustainable business model architecture by archetypes, as regards the technological/environmental grouping, “maximise material and energy efficiency” is common among the three studies and concerns the optimization of resources used. Ritala et al. (2018) substituted “Create value from ‘waste’” with “Closing resource loop”, in order to underline the reuse of products and materials, an archetype that was not entailed in the case of banking industry (Yip and Bocken, 2018). In the same study, the archetype “Substitute with renewables and natural processes” was turned into “Substitute with digital process” given the features of the service sector.

Regarding the social grouping, two archetypes “adopt a stewardship role”, i.e. referred to business responsibility/commitment to social and environmental issues, and

“encourage sufficiency”, i.e. reduced consumption by users/consumers, are common among the three studies. Ritala et al. (2018) adhere to the same typology by Bocken et al. 2014., while Yip and Bocken (2018) do not envisage “Deliver functionality rather than ownership” and add “Inclusive value creation”.

Interestingly, Ritala et al. (2018) consider “Inclusive value creation” archetype in the economical grouping, since they ascribe the meaning of sharing resources. The archetype “repurpose for society/environment” is common, since it expresses the business model innovation towards the prioritization of social and environmental benefits. “Develop scale-up solutions” is revised into “develop sustainable scale up solutions” in Ritala et al. (2018), in order to underline the delivery of sustainable alternatives at scale to maximize sustainability benefits. As regards organizational grouping in the banking industry in Yip and Bocken (2018), “Develop scale-up solutions” is lacking, whereas “Resilience in loan granting” and “Sustainable financial products” archetypes are added.

3.2 The results of the systematic literature review

The systematic literature review retrieved a group of 35 articles dealing with sustainability-related aspects of business models for tourism enterprises. The following figure (Figure 2) maps resulting studies according to their positioning within the sustainable business model.

Source: own elaboration

Figure 2 – The sustainable business model map in tourism literature

The map shows as almost the half of the selected papers (15 out of 35) consider the sustainable business model and related practices within a Triple Bottom Line framework, i.e. from the perspective of economical, environmental and social sustainability at the same time. All the papers were published from 2006 on, and in the last three years mostly (2016: 6 papers; 2017: 5 papers; 2018: 8 papers). This fact reflects the relatively recent development of the analysis on business model innovation towards sustainability.

The map is functional to identify reported business practices and group them in the new set of sustainable business model archetypes for tourism enterprises. Indeed, next section presents the outlined framework derived from the literature review.

4 Results

4.1 The outlined framework of sustainable business model archetypes in tourism

With the support of literature on tourism and business models, it is possible to outline a framework for the discourse on sustainable business model in tourism enterprises. The following Table 2 illustrates the overview on the sustainable business model archetypes. For each grouping of archetypes, it follows the detailed description of each one.

Table 2 – The sustainable business model archetypes in tourism enterprises

Grouping	Archetypes for SBM in tourism	Practices
Technological/ Environmental	Maximise material and energy efficiency	Energy saving with sensors and adjusting systems
		Energy saving with advanced alert systems
		Reduction of material use or transport
		Producing or using own resources
	Closing resource loops	Recycling
		Waste management
	Substitute with renewable energy sources and ecological products	Production with renewables
		Use and consumption from renewables
Social	Substitute with digital processes	Environmentally friendly products
		Digital process from users and consumers
		Use of social and web media
		IT safety
	Deliver functionality rather than ownership	Shared spaces
		Shared mobility
		Peer-to-peer Shared goods and services
		Training
	Adopt a stewardship role	Green protection and conservation
		Social protection
		Promotion of green and social measures
		Green and social events
		Ethics and transparency

Grouping	Archetypes for SBM in tourism	Practices
Organisational/ Economical	Encourage sufficiency	Education
		Capacity building
		Green activities for stakeholders
		Community involvement
	Promote inclusive value creation and community benefits	Communication
		Social entrepreneurship
		Charity support
		Openness to local community
	Re-purpose the business for society/environment	Activities for disadvantaged population (disabled, schools, etc.)
		Activities for workers
		Community-based enterprise
		Green and social strategy
	Develop collaborative approach	Reporting and communication
		Certifications
		Activities for employees benefits
		Responsible suppliers
	Provide sustainable quality services	Open innovation
		Cooperation with local community
		Cooperation with other actors, also public
		Cooperation with supply network and partners
		Cooperation with tourism partners
		Green cooperation
		Quality offer and services
		Quality staff
		Quality suppliers
		Customers programs

Source: own elaboration

4.2 The technological/environmental archetypes

More in detail, the technological archetypes of Bocken et al. (2014) have been revised acknowledging that tourism enterprises mostly deal with service provision rather than manufacturing activities. As such, to maximise material and energy efficiency is still clue for them, as well as the substitution with renewable energy sources. Indeed, energy saving with sensors and adjusting systems may take place through the use of energy-saving and LED light bulbs, water-saving showers and heating adjusting systems (Battistella et al., 2018; Høgevoid et al. 2015; Jones et al. 2014; Manaktola and Jauhari 2007; Melissen et al 2015; Sharma et al 2018). Advanced alert systems, as the case of water leakage, contribute to the maximise efficiency as well (Manaktola and Jauhari, 2007; Sharma et al., 2018). Moreover, the reduction of material use or transport, including building insulation or green construction standards (Buffa et al., 2018; Jones et al., 2014; Rylance

and Spenceley, 2016) and the production and the optimization of the usage of own resources (Broccardo et al., 2017; Sotiriadis and Van Zyl, 2017) are included as examples of business practices in this archetype. The production, use and consumption with/from renewables (Battistella et al., 2018; Buffa et al., 2018; Coles et al., 2017; Høgevold et al., 2015; Melissen et al., 2015; Mihalič et al., 2012; Yang et al., 2010), as well as the use of environmentally friendly products, such as cleansers (Høgevold et al., 2015; Jones et al., 2014; Manaktola and Jauhari, 2007; Sharma et al., 2018), compose the archetype “substitute with renewable energy sources and ecological products”. The archetype “closing resource loops” groups practices related to recycling activities and programs, as well as waste management, diffusely emerging from past studies (Battistella et al., 2018; Broccardo et al., 2017; Buffa et al., 2018; Coles et al., 2017; Høgevold et al., 2015; Jones et al., 2014; Manaktola and Jauhari 2007; Mihalič et al., 2012; Sharma et al 2018; Weeden 2015; Yang et al., 2010).

Taking inspiration by Yip and Bocken (2018), another archetype has been added: substitute with digital processes. Indeed, the use of digital management tools may allow an evolution towards technological, and thus environmental, sustainability. Examples are taken from practices on the use of social and web media (Akbar and Tracogna, 2018; Amersdorffer et al., 2012; Coles et al., 2017; Guttentag, 2015; Sotiriadis and Van Zyl, 2017; Tom Dieck et al., 2018), IT safety (Perić et al., 2016) and digital processes from users and consumers, such as the user-generated contents (Amersdorffer et al, 2012).

4.3 The social archetypes

Social archetypes by Bocken et al. (2014) could be applied to sustainable business models in tourism enterprises as well, with the inclusion of an archetype related to the inclusive value creation similarly to the case of Yip and Bocken (2018) referred to bank industry. More in details, to deliver functionality rather than ownership covers a group of practices, such as the sharing of spaces, shared mobility and peer-to-peer goods/services share (Battistella et al., 2018; Bohdanowicz and Zientara, 2008, 2009; Cheng, 2016; Guttentag, 2015; Sotiriadis and Van Zyl, 2017). To adopt a stewardship role in sustainable tourism practices may take several form, such as training programs, activities aimed at green protection and conservation, at social protection, at prompting ethical and transparent actions (Amoamo et al., 2018; Battistella et al., 2018; Bohdanowicz and Zientara, 2008; 2009; Broccardo et al., 2017; Buffa et al., 2018; Coles et al., 2017; Høgevold et al., 2015, 2016; Jones et al., 2014; Koelble, 2011; Mihalič et al., 2012; Mohamad and Hamzah, 2013; Tom Dieck et al., 2018; Yang et al., 2010). It could also be conveyed through the promotion of green and social events, for instance based on local culture (Koelble, 2011; Mihalič et al., 2012). Encourage sufficiency leverage sustainability through practices related to education, capacity building, green activities for stakeholders, and communication (Alrousan et al., 2015; Battistella et al., 2018; Bohdanowicz and Zientara, 2008, 2009; Høgevold et al., 2015; Manaktola and Jauhari, 2007; Mihalič et al., 2012; Mohamad and Hamzah, 2013; Perić et al., 2016; Weeden, 2015). In particular, it takes place with the involvement of the community and its empowerment towards sustainable actions as well (Høgevold et al., 2015; Koelble, 2011;

Mohamad and Hamzah, 2013; Rylance and Spenceley, 2016). Finally, the archetype “promote inclusive value creation and community benefits” groups examples related to practices of social entrepreneurship, charity support, activities for disadvantaged people and workers, such as forms of tourism social enterprises, donations and sponsorships, philanthropic activities (Alegre et Berbegal-Mirabent, 2016; Alrousan et al., 2015; Amoamo et al., 2018; Battistella et al., 2018; Bohdanowicz and Zientara, 2008, 2009; Fenclova and Coles, 2011; Høgevoid et al., 2015; Jones et al., 2014; Koelble, 2011; Melissen et al., 2015; Weeden, 2015; Yang et al., 2010; Zebryte and Jorquera, 2017). Moreover, openness to local community appears to be as particularly relevant in the tourism business context, providing examples such as the improvement of social security, the satisfaction of residents with tourism development and provision of facilities to residents (Battistella et al., 2018; Bohdanowicz and Zientara, 2008, 2009; Jones et al., 2014; Koelble, 2011; Mihalič et al., 2012; Rylance and Spenceley, 2016; Yang et al., 2010; Zebryte and Jorquera 2017).

4.4 The organisational/economical archetypes

Organisational archetypes are the ones presenting more differences compared to the original archetype-based framework by Bocken et al. (2014) and its latter applications (Ritala et al., 2018; Yip and Bocken, 2018). Indeed, on one hand to re-purpose the business for society/environment still plays a key role in determining an organizational implementation of the sustainable business model. For instance, tourist services may be delivered by community-based tourism enterprises (Amoamo et al., 2018; Jaafar and Maideen, 2012; Mohamad and Hamzah 2013), and may entail a green and social strategy and reporting (Broccardo et al., 2017; Buffa et al., 2018; Crick et al., 2018; Høgevoid et al., 2015, 2016; Jones et al 2014; Mihalič et al., 2012; Sharma et al., 2018). Enterprises may adopt environmental- and/or social-focused certificates/labels (Alrousan et al., 2015; Battistella et al., 2018; Bohdanowicz and Zientara, 2008, 2009; Høgevoid et al., 2015; Jones et al., 2014; Manaktola and Jauhari, 2007; Mihalič et al., 2012; Perić et al., 2016; Rylance and Spenceley, 2016; Sharma et al., 2018; Tom Dieck et al., 2018), provide benefits to employees (Alrousan et al., 2015; Battistella et al., 2018; Bohdanowicz and Zientara, 2008, 2009; Crick et al. 2018; Høgevoid et al., 2015, 2016; Jones et al., 2014; Manaktola and Jauhari 2007; Melissen et al., 2015; Mihalič et al., 2012; Rylance and Spenceley, 2016; Sharma et al., 2018) and choose responsible suppliers (Bohdanowicz and Zientara, 2008, 2009; Høgevoid et al., 2015; Jones et al., 2014; Manaktola and Jauhari, 2007).

On the other hand, the development of collaborative approach, as well as the provision of sustainable quality services are essential for leveraging sustainability in the business models of tourism enterprises. The archetype “develop collaborative approach” is newly inserted in the framework and groups examples, such as open innovation, cooperation with several stakeholders as local community, supply network, partners and also includes environment-based green cooperation (Akbar and Tracogna, 2018; Amersdorffer et al., 2012; Battistella et al., 2018; Berzina et al., 2017; Høgevoid et al., 2015; Kandampully and Promsivapallop, 2006; Manaktola and Jauhari, 2007; Melissen et

al., 2015; Mihalič et al., 2012; Rylance and Spenceley, 2016; Sharma et al., 2018; Sotiriadis and Van Zyl, 2017; Tom Dieck et al., 2018; Zebryte and Jorquera, 2017). Another archetype is proposed in the outlined framework, namely “provide sustainable quality services”. This archetype includes the provision of quality offer and services, highly-qualified staff, high-quality and fresh procurement of food (Alrousan et al., 2015; Battistella et al., 2018; Broccardo et al., 2017; Fuentes-Medina et al., 2018; Høgevoid et al., 2015; Koelble, 2011; Mihalič et al., 2012; Weeden, 2015). The archetype also considers customer programs aiming at customer fidelity and satisfaction (Alrousan et al., 2015; Battistella et al., 2018; Mihalič et al., 2012).

5 Discussion and conclusions

This section discusses the results in light of the peculiarities of sustainability in tourism and suggests future research directions in the field of sustainable business models in tourism. Services and servitization are rising attention of companies seeking to increase their competitiveness by moving towards a service-based business model. This implies a rising importance of re-assessing their business models.

This paper looked into tourism as one of the main industries where service is fundamental and where the companies and the tourists themselves consider the sustainable tourism for businesses a key role. The different nature of the service industry conducted the adaptation of the original archetypes by Bocken et al. (2014). In particular, tourism is characterised by:

- Direct customer contact is key; therefore, the archetypes cannot forget the key role of the customer to obtain social and environmental benefits as the role of tourism businesses can play in influencing the behaviour of tourists/guests is high.
- Value is created by a range of activities involving a number of stakeholders. As sustainable tourism is a multi-stakeholder issue, whose aim is to stimulate the balanced exploitation of natural resources at the local level and to limit the social and environmental impacts, many archetypes (e.g. “encourage sufficiency”) are strongly based on a strong community and local involvement.
- The businesses operating in the tourism sector mainly consist of SMEs. Their impact, although less significant if considered individually, are significant at the local level, particularly considering the cumulative effects produced by tourism businesses in a specific area. This impacts on archetypes such as “Promote inclusive value creation and community benefits” where the local aspect of the activities is the focus.

The research aims at contributing to the knowledge on sustainable business models by looking for solutions that could be delivered to tourism enterprises. The paper contribution is a revised set of archetypes of sustainable business models in tourism that categorizes the business models in the specific industry, that can facilitate a systematic and deeper analysis of sustainable tourism practices and that can be used to measure from the tourist point of view the most satisfactory archetypes and to help companies to inspire and facilitate the innovation process for sustainable business models in the future.

Coherently with the objectives of the study, the identification of archetypes of sustainable business model for tourism enterprises could support both researchers and enterprises in implementing sustainability. From the academic point of view, the research attempts to reduce the knowledge gap on sustainable business models, in tourism contexts especially. From the managerial point of view, the research proposes an initial set of solutions that could be adopted and implemented in real corporate environments.

This research has the following limitations. Firstly, the archetypes are developed through historical information and examples from literature review. As a result, it is necessary to add a practice view by means of interviews or questionnaires. Then this research focuses on the tourism industry that the results may not be relevant to other industries. Further studies may look at testing and implementing the proposed framework through both quantitative and qualitative methods, in order to strengthen the solutions for building up sustainable business models in tourism enterprises. Finally, we did not take a long-term view of possible transformations of the industry or of the sustainability in the industry, therefore the archetypes are related to the as-is situation and not to possible radical innovations.

Abstract

The paper discusses the bottom-up approach and PPPs in the creation of sustainable tourism products, with reference to projects managing the natural resources and protected areas of a typical community destination in northern Italy. We introduce the aims and features of a Reserves Network (RN) and analyse (1) whether and how stakeholder collaboration on projects aimed at conserving and valorising the destination's landscape and environment stimulate the creation of sustainable tourism initiatives; (2) the roles played by public and private actors in the definition of the projects; (3) if the projects' contribution - if any - to the destination's economic, social, and environmental sustainability.

The paper illustrates the results of a survey of 167 local stakeholders and 9 phone interviews with DMO members. We reconstruct the profiles of public and private stakeholders through multiple correspondence analysis and use content analysis to investigate the link between the RN and the development of sustainable tourism products.

The stakeholders recognise the RN's role, both in the creation of sustainable tourism products and in fostering/enabling local development. Differences, however, emerge between public and private actors regarding the economic, environmental and social sustainability of the RN projects.

The originality of the research lies in its managerial implications and contribution to the theoretical background.

Keywords – stakeholder engagement, collaboration, public private partnerships, sustainable tourism, Reserves Network

Paper type – Academic Research Paper

1 Introduction

The quest for innovation is a key challenge for tourism destinations seeking to increase their competitiveness (Hjalager, 2010; Carlisle et al., 2013) and is particularly complex for community destinations, i.e. territories in which the tourism offer depends on the collaboration of numerous stakeholders (Murphy 1985 and 1988; Murphy and Murphy, 2004; Beeton, 2006). In these territories private and public actors, as well as the local communities, are involved, with different roles and power, in decision-making processes regarding the development of the local tourism chain (Martini and Buffa, 2015). Natural resources are vital to this process, and are essential to the authenticity of the tourism offer. The tourism products offered by a particular community destination thus depend on the will and ability of its different stakeholders to coordinate their activities in ways that generate value not only for individual businesses, but for the destination as a whole (Simpson, 2008; Hung et al., 2011; Beritelli et al., 2016).

This paper presents the main results of our research, which focussed on the projects managing the natural resources and protected areas of a typical community destination. The main research questions are:

- Does stakeholder collaboration on projects aimed at conserving and valorising a destination's landscape and environment stimulate the creation of sustainable tourism initiatives?
- What roles do public and private actors play in the definition of the projects?
- Do the projects contribute to the economic, social, and environmental sustainability of the destination?

The area of research is the Reserves Network (RN), a new approach introduced in Trentino (Italy) to manage Natura 2000 areas. Our research highlights that, when local stakeholders actively participate in projects from the planning phase onwards, an RN becomes an effective natural resource management strategy. The stakeholders involved recognise the role of the RN, both in the creation of sustainable tourism products and in fostering local development. Differences, however, emerge between public and private actors in relation to the economic, environmental and social sustainability of the RN projects.

In the light of the empirical evidence, we discuss the opportunity offered by 'bottom-up' projects supported by private and public actors to effectively create value for the destination while also promoting sustainable tourism.

The paper is divided into four main sections. The following section illustrates the key points that emerge from the literature review in relation to the bottom-up approach and public private partnerships (PPP) in community-based destinations. The third section describes our fieldwork methods, and the fourth presents and discusses the most significant empirical evidence. In the final section, we highlight the managerial implications of our findings, and indicate further potential avenues of research.

2 Community based tourism, bottom-up approach and PPPs: a theoretical overview

As already mentioned, one of the main characteristics of community destinations is the presence of numerous (public and private) actors who play various roles in the definition of the territory's tourism offer. This complexity necessitates - on the one hand - the effective management of the actors involved, encouraging and enabling them to participate in specific development projects, and - on the other - the identification of an entity to coordinate the various activities and to mediate between the diverse interests, demands and expectations of the individual actors (Beritelli et al., 2016). To meet these challenges, the literature proposes the adoption of decisional processes based on *stakeholder consultation and participation* (Haywood, 1988; Simmons, 1994; Reid, 2004). Such strategies are crucial when important environmental decisions, which will entail the transformation of natural capital, are being made (Fennel and Dowling, 2003; Reed, 2008; Erkus-Ozturk and Eraydin, 2010), or when the historical/cultural patrimony of the destination is going to be impacted (Aas et al., 2005; Landorf, 2009). Participation ensures a broader, more responsible analysis of the economic consequences of development, and greater control over the ecological and socio-cultural aspects of sustainability for operators and local residents (Joppe 1996; Cooper and Wanhill, 1997; Timothy, 1999; Timothy and Tosun, 2003; Hwang et al., 2012).

The leading role of the local community is, of course, fundamental to any bottom-up approach. As underlined by Matarrita-Cascante et al. (2010, p. 738) "at the community level, formal and informal social mechanisms have a stronger capacity to promote the adoption of commonly desired values and attitudes. A community-level approach allows for the design of policies and practices sensitive to the opportunities, constraints and uniquenesses inherent to particular places (Bridger & Luloff, 1999; Cole, 2006; Maser & Kirk, 1996; Tosun & Timothy, 2003). Among such opportunities are goals associated with sustainability."

The decisions made by local communities involve a broad participatory process which, on the one hand, has the above mentioned advantages, but, on the other, requires the skilful coordination and harmonizing of interests and objectives which may seem - at least initially - to diverge considerably (Reggers et al., 2016). Bottom-up participatory processes can, therefore, take longer to achieve their goals than do the classic mechanisms grounded in hierarchical and/or market structures (Bieger et al., 2007).

While community involvement is undoubtedly essential for the development of participatory development projects, the presence of an effective coordinating - and guiding - entity is equally vital (Sakata and Prideuax, 2013). The bottom-up approach to sustainable development works well when there is broad community participation and dynamic social interaction (Matarrita-Cascante et al., 2010). Moreover, it has been shown that an initiative is much more likely to continue after the project which launched it has ended, when local people and their knowledge are deeply involved in the planning and implementation of the initial project (Pretty and Frank, 2000). In community destinations, therefore, the importance of the local community as a whole, and of the relationships

between individual (public and private) actors, is clearly evident. With regards to public-private partnerships (PPP) in community destinations, however, the data is not entirely unequivocal. Recent research emphasizes the strength of these relations, highlighting the contribution of PPPs' to the socio-economic development and valorisation of natural resources in the territories in which they have been operating (Ngilangwa et al., 2018). A study by Thiyane et al. (2018) reaches similar conclusions pointing to ways in which the involvement of PPP in development projects has been of socio-economic benefit in community destinations. De Almeida et al. (2018), who analyse the contribution of PPP to the development of sustainable tourism models in some protected areas in Brazil, concur.

Frost and Laing (2018), however, arrive at different conclusions: their research points to serious failures in the management - by PPP - of nature-based tourist attractions in Australia.

The above analyses clearly demonstrate the importance of local community, and both public and private sector, involvement in the valorisation of the territories investigated. Equally evident, however, is the extent to which the success of development projects depends on the specificities of each context.

3 Methodology

3.1 Area of study

The area of research is the Reserves Network (RN), established in Trentino (Northeast Italy) by the regional government to manage Natura 2000 areas. RNs were set up by the European project LIFE11/NAT/IT/000187 "TEN - Trentino Ecological Network" in order to create an ecological network within the territory. Most of the area covered falls under the Natura 2000 scheme, but it also includes a few locally protected areas (not part of either a national or a regional park) that are expected to benefit from the uniform management of the RN and the interconnection zones between the Natura 2000 areas.

The RN is not a newly protected area: within it, existing Natura 2000 areas are managed and enhanced in new ways, with a particular focus on the socio-economic dimensions of nature conservation and a bottom-up approach grounded in local stakeholder participation, responsible subsidiarity and integration between conservation policies and local sustainable development. Within the RN, the Natura 2000 conservation policy is explicitly linked to agriculture and tourism, integrating nature conservation measures and socio-economic development projects. The network is therefore not only concerned with defining direct measures for the protection of biodiversity - the maintenance of local economic activities (agriculture and handicrafts) and their integration with sustainable tourism is also an important focus.

Municipalities or other local governments set up the RN voluntarily and are responsible for its management, while the regional government directs management policies, and is responsible for auditing, and the relationship with the European Union.

3.2 Sample and data analysis

The field research was carried out in 2017 in five of the ten Trentino RNs. The research combined quantitative and qualitative methods. The first stage (qualitative analysis) consisted of face-to-face interviews with the coordinators of the five RNs. Our main objective was to identify the principal stakeholders involved in the creation of the RNs - both those whose approach was positive (proactive and collaborative) and those who adopted a critical approach (whether simply passively unenthusiastic about, or actively opposed to, the creation of the RNs, and who had, in some way, influenced and/or slowed the process). In this first phase, we also investigated the main activities, projects and initiatives promoted by the RNs to preserve and valorise the territory and the extent to which stakeholders had collaborated in their realisation. The collection of this information enabled us to plan the two subsequent research steps, analysed in this paper:

- The second stage (quantitative analysis) involved the local stakeholders identified in the previous research phase. We designed an online questionnaire and sent it to all the stakeholders identified as important by the RN coordinators, with the exception of the DMO directors, with whom we conducted ad hoc interviews (see *infra*). The online questionnaire was sent to the 167 stakeholders named by the RN coordinators, and 110 were returned to us (response rate 65.9%). The online survey collected data and information on the three topics upon which we have chosen to focus: the ways in which local stakeholders participated; their opinions of/satisfaction with the RN; their perception of the opportunities for and/or limitations on the territories' socio-economic development.
- The third research stage (qualitative analysis) was carried out through interviews with members of the DMOs in the territories containing RNs (9 phone interviews). We investigated the ways (if any) in which the tourist sector and the RNs were collaborating, and enquired into the former's perceptions of the opportunities and/or limitations linked to their RN in relation to the development of innovative sustainable tourism products.

The quantitative data collected in the second research stage was analysed as follows:

- a) Through a descriptive statistical analysis of the responses at the aggregate level ($n = 110$) and then a focus on the stakeholders involved in at least one of the RN projects. We observed the stakeholder participation in each type of project those primarily aimed at valorising natural resources *vs* those mainly focused on creating tourism products); participation in the different phases of the projects (i.e., planning *vs* realization); the type of stakeholder involved (public *vs* private actors).
- b) Using multiple correspondence analysis (MCA) to investigate the differences between public and private actors with regard to *a*) the type of project, and the project phase, in which stakeholders are involved; *b*) agreement on the contributions of RNs in terms of economic, social and environmental sustainability; *c*) the importance given to specific activities/aims of the RN.

Content analysis was used to analyse the interviews carried out with the DMOs in order to understand whether collaboration, involvement and agreement with certain RN

aims are considered to the development and sustainability of the tourism offer. This phase is still ongoing; in the next section we present our initial findings.

4 Main research results

4.1 RN projects and stakeholder involvement

Most (90%) of the (110) respondents to the questionnaire had participated in at least one RN project. About half of them were involved in nature conservation projects (local plant and animal biodiversity, preservation and restoration of habitat); more than 40% had taken part in projects related to the creation/restoration of paths, environmental education, organization of events/exhibitions for local residents, or guided tours to natural/artistic/cultural resources. Interest was also shown in the valorisation of local products and environmental education activities in schools (see Table 1).

Table 1 - RN projects in which stakeholders participated

Projects	Stakeholder participation	
	Yes (%)	No (%)
Nature conservation (local plant and animal biodiversity, preservation and restoration of habitat)	49.5	50.5
Creation/restoration of paths	43.4	56.6
Environmental education	41.4	58.6
Organization of events/exhibitions for local residents	41.4	58.6
Organization of guided tours to natural/artistic/cultural resource	39.4%	60.6
Promotion of local products	32.3	67.7
Organization of environmental education activities in schools	28.3	71.7
Valorisation of agriculture	26.3	73.7
Initiatives aimed at de-seasonalising tourism	23.2	76.8
Sustainable transport	22.2	77.8
Commercial development	5.1	94.9
Development of handicraft sector	3.0	97.0

Most of the stakeholders were involved in both the planning and the implementation stages of the projects, that is, they were active in the key decisional processes (Table 2).

Table 2 - Stakeholder involvement in RN projects

Project phases	%
Stakeholders involved in both the planning and the implementation of the activities	51.8
Stakeholders involved only in the planning	30.9
Stakeholders involved only in the implementation	5.5
Stakeholder not involved in any of the phases but had undertaken certain operation	1.8
Stakeholder never participated in a project	10.0

The MCA revealed an initial result which gives us an answer to the main research question i.e. the roles played by (public and private) actors in the RN projects. 56.6% of the questionnaire respondents were private stakeholders (this category includes actors involved in tourism, agriculture, industry, trade, handicrafts and support services for the private sector); 33.3% were from the public sector; 10.1% were students and/or pensioners. The analyses which follow focus specifically on the two predominant categories - private and public actors (n= 89) - illustrating their various profiles, which differ with regard to both the roles they played and their opinions on the RN contribution to the economic, social, and environmental sustainability of the destination.

4.2 Public and private stakeholder profiles

The MCA reveals a greater involvement of private actors in activities related to the valorisation of natural resources, whether conservation (nature preservation, path restoration), the valorisation of local products, or initiatives to promote de-seasonalization. There was also a certain involvement in sustainable mobility projects. In all of the above, private stakeholders were particularly involved at the planning stages (see Figure 1).

Public stakeholders, on the other hand, were more involved in educational activities (both in the community and in schools) and in the organisation of events (directed at both the local community and tourists). In all of the above, the public actors were involved in both the planning and the implementation stages of the projects/initiatives.

Figure 1 - Role and involvement of private and public stakeholders

Our research investigated if - in the opinion of the public and private actors - the establishment of the RN was increasing opportunities for socio-economic and environmental development and/or growth in the territory and for the local population. The MCA reveals that, as might be expected, the stakeholders vary in their opinions. In some cases (particularly in relation to the economic impact, *see below*), the public sector

seems to be more “cautious/timid” in its evaluation of the RN as a tool for the promotion and/or development of the territory, while private actors have higher expectations.

Figure 2 shows that the private sector is in general agreement that the RN has contributed - at least to some extent (slightly agree) - to the creation of jobs and the development/promotion of the territory. This group also believes that the RN has stimulated the creation of new economic activities (e.g. B&Bs, ‘agriturs’, outlets for the sale of local products, etc). However, private actors also agree more strongly than their public counterparts that the strict environmental regulations imposed within the RN have been an obstacle to (both arable and livestock) agriculture.

The public sector, however, seems to be more sceptical. As Figure 2 reveals, “slightly disagree” is its most common response.

Note: STA (strongly agree), SLA (slightly agree), SLD (slightly disagree), STD (strongly disagree), DK (do not know).

Figure 2 - The economic dimension

The MCA on the social dimension of the RN (see Figure 3) shows that public and private actors agree that the RN has increased community awareness of local environmental conservation, their own connection to their territory, and the importance of maintaining/rediscovers local traditions. Local stakeholders also believe that the RN has helped to decrease local conflicts. Within the public sector there is a greater tendency (than among private actors) to regard the RN as having had a noticeable impact on local society.

The MCA of the environmental dimension (Figure 4), in contrast, reveals that private stakeholders are more inclined (than those in the public sector) to accord importance to

the role of the RN. They tend to believe that the RN has enabled the requalification of abandoned/degraded areas, the creation or restoration of paths, and the valorisation of areas of particular natural value.

Note: STA (strongly agree), SLA (slightly agree), SLD (slightly disagree), STD (strongly disagree), DK (do not know).

Figure 3 - The social dimension

Note: STA (strongly agree), SLA (slightly agree), SLD (slightly disagree), STD (strongly disagree), DK (do not know).

Figure 4 - The environmental dimension

And lastly, the MCA of the variables related to the objectives associated with the creation of the RN (Figure 5) shows that these objectives were shared by all the local actors (with private stakeholders evincing the greater conviction). Aspects to which actors were sensitive included: the management of protected areas; stimuli for the innovation and identification/creation of new economic activities; opportunities to facilitate interaction between the various productive sectors; the improvement of the social climate through participation in collaborative projects/activities; territorial conservation; increased collaboration between public and private actors.

Note: V (very), F (fairly), S (slightly), N (no).

Figure 5 - Aims and Importance

Local stakeholder enthusiasm about the benefits and opportunities linked to the establishment of the RN is confirmed by an initial comparison with the content analysis of the interviews conducted with the directors of the relevant DMOs. Our specific intention is to investigate whether the findings of the quantitative analysis tally with what we are told by the actors involved in the organisations whose *raison d'être* is the development of local tourism. In this preliminary phase of the analysis, we have considered only the statistical measures of term frequency (represented in the word cloud in Figure 6) and the Tf/Idf (term frequency - inverse document frequency).

The results, examining the Tf/Idf measure, confirm that the DMO directors associate the RN with sustainability, and thus with the opportunity to organise related projects/activities – in some cases, the directors referred specifically to the existence of the territory's natural park (Parco Adamello Brenta). They also associate the RN with the contribution that it can make to *a)* the integration of activities within the local tourist offer and *b)* facilitating intracommunity cooperation.

Table 3 - Frequency and Tf/Idf of the content analysis

Word*	Frequency (%)	Tf/Idf
RN	18.83	0
projects	7.69	0
consortium	7.43	0.8109
activities	7.16	0
DMO	6.37	0.2513
sustainability	5.04	0
park	3.71	1.0986
topic/issue	3.18	0.1178
territory	2.92	0.2513
tourism offer	2.65	0.4055
stakeholders	2.39	0.4055
collaboration	2.39	0.4055

Note: For pragmatic reasons, Table 3 reports the list of top frequent words extracted from interviews.

activities and products). The fact that local actors are now acquiring these competences is likely to facilitate the future development of activities related to environmental education/interpretation (Skanavis and Giannoulis, 2009) which are becoming increasingly popular among some segments of the tourism demand.

With regard to the theoretical background, our findings confirm the importance of the involvement of local actors, right from the planning phase. This is borne out by our analysis of the projects and initiatives promoted by the RNs and appears to offer hope that these initiatives will prove resilient over time (Pretty and Frank, 2000). The research reveals constructive relationships between public and private actors which support the economic, social and environmental development of the territory. The establishment of the RNs proves to be an example of good bottom-up managerial practice, and is line with the positive experiences of the efficacy of PPPs reported in the literature (De Almeida et al., 2018; Ngilangwa et al., 2018; Thiyane et al., 2018).

In the light of the evidence and the implications that emerge from it, we believe that our research – while limited to one destination only - demonstrates elements of originality. Aware that this RN is - to date - unique in Italy, we nevertheless intend to extend our research to investigate whether or not the present results are confirmed by the experiences of other community destinations which have adopted the bottom-up approach to the management of natural resources.

Acknowledgement

The data presented in the paper come from a study (commissioned by the Province of Trento and conducted by the University of Trento) which examines the socio-economic impact of the Trentino RNs. The research is linked to the European project LIFE11/NAT/IT/000187 "TEN" - Trentino Ecological Network (D2 action).

Abstract

Sharing and collaborative economy concepts, based on product use optimization, are always more considered by enterprises as a potential eco-innovative and competitive factor. Those principles also match with circular economy EU goals of waste prevention, reduction and resources valorization and efficiency.

Present work attempts to build a theoretical framework for collaborative and circular business models (CCBM's) by integrating both circular and sharing purpose. Those models aim at overcome waste and inefficiencies of actual linear economy, encouraging the transition from a "thrown away society" to a "regenerative society" in which instead products seller we have a service provider and where goods became much more a dematerialized value though for a need satisfaction. While today different CBM's and sharing models have been arranged, their integration through CCBM's lack of a clear harmonization and schematization order to support all stakeholders (organization, consumer and policy makers) in its understanding, and implementation, especially producers who are claimed to make a disruptive change in their way of think at their business.

1 Introduction

The current production and consumption model is dependent on continuous growth and increasing resource consumption throughput (Gaudin, 2016). This model is so-called “take, make and dispose” or linear economy. A circular economy is a regenerative system in which resource input and waste, emission, and energy leakage are minimised by slowing, closing, and narrowing material and energy loops (EMF, 2012). Its main objective is to increase efficiency of resources by minimizing waste and resource extraction by closing the loops in terms of resources and materials (EC, 2014). Similarly, sharing economy principles, according which “an underutilized product is a lost product” (Gansky, 2010), can be considered strictly connected to circular economy issues. Actually, collaborative initiatives based on sharing strategies allow to overcome wastes and inefficiencies of linear economy and support the transition to circular economy (Bocken et al., 2016). According to the “European agenda for the collaborative economy” (EC, 2016), the term “collaborative economy”¹ refers to business models where activities, also facilitated by collaborative platforms, create an open marketplace for the temporary usage of goods or services often provided by private individuals. In particular, the European agenda states that collaborative economy involves three categories of actors:

- **service providers** who share assets, resources, time and/or skills — these can be private individuals offering services on an occasional basis (‘peers’) or service providers acting in their professional capacity (“professional services providers”);
- **users** of the services;
- **intermediaries** that connect providers with users and that facilitate transactions between them (‘*collaborative platforms*’ in case of online tools).

Although the sharing economy has its first appearance as a bottom up phenomenon and it was originally intended as an exchange among “privates” (Botsman and Rogers, 2010), it has grown and has been spread also in the private organizations and companies with interesting advantages in economic and environmental terms (Cohen, 2015). According to a study of Price Waterhouse Cooper (Lancefield et al. 2015), it is necessary to bring the collaborative practices within the organizations since many of them have underutilized potentials and capabilities. The application of the sharing and/or collaboration practices through B2B and B2C agreements, would allow a more efficient functioning of the enterprises (Bocken et al., 2016). The same goes to intangible assets such as intellectual property or company brands, which can be easily shared through the use of new technologies. This is the reason why flexible business models which change the workers expectations and stimulate process innovation, are emerging (Chesbrough, 2010). In particular, collaborative platforms can be used to help companies to develop new activities, by reducing costs and developing new income flows.

The shift from the linear economy to the circular economy has produced innovative

¹ In this paper the term “collaborative” and “sharing economy” will be used alternately

ways to do business and new business models have deeply changed the industrial sector (EMF, 2015). The literature defines a business model as a set of procedures that the organization puts in practice to create, deliver and capture values. (Osterwalder and Pigneur, 2010). The integration of the Circular Economy in the strategic management ground remains weak and insufficient and it is needed additional theoretical and empirical research on how this is adopted and implemented by the companies. On the other hand, evidence show that there is a lack of public awareness on the advantages of the Circular Economy approach, therefore the importance of additional research and scientific literature is also bigger (Su et al., 2013;). Sharing economy practices, which have grown rapidly in recent years thanks to new ways of contact such as platforms, often present elements that contribute to the transition to the circular economy (Demailly and Novel, 2014). Literature is lacking for this aspect, despite its strongly innovative footprint and the virtuous circle that it encompasses.

This paper wants to explore business models that use collaborative trends and tools and also comply with the circular economy approach.

2 From Linear to Circular and collaborative business model

The term *Business Model* refers to the conceptual logic of how the firm creates and appropriates economic value by charging the customer (user) a price for the solution to a problem (Teece, D. J. 2010). A **Circular Business Model** (CBM) as conceptual logic for value creation is based on the production of new offerings utilizing economic value retained in products after its use for (Carbon Trust. 2017). It therefore integrates principles of circular economy such as resource efficiency and waste preventions.

It is possible to detect the following **collaboration schemes** (Sposato et al. 2017) (fig. 1):

- **P2P (Peer-to-Peer)**, where the collaboration occurs among individuals intended as "private",
- **B2C (Business-to-Consumer)** among companies and single consumers,
- **C2B (Consumer-to-Business)** among single consumer to companies,
- **B2B (Business-to-Business)** among companies themselves.

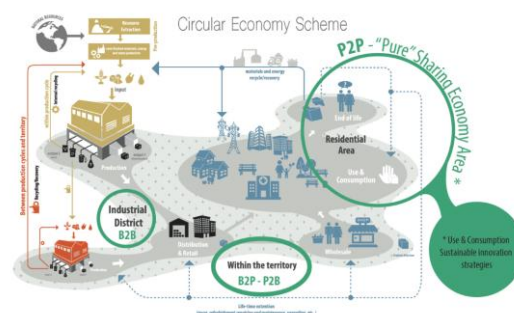

Fig.1. Shared and collaborative economy actors (P2P, B2P, B2B) within circular economy scheme. Source: ENEA

The intersection between circular business models and collaborative business models forms the Collaborative Circular Business Models (CCBM). The CCBMs focus on relationships and agreement among more stakeholder who are necessary to “recapture and recirculate” the value of the resources at different life cycle stages. CCBM’s aims at life-time extensions, use optimization of products and resources valorization. All actors involved in the product value chain cooperate and collaborate to maximize the value contained in products (both economic and material value) not only at production stage, but also during and after the use phase.

The Figure 2 outlines circular business models in relation to the life cycle stages of a product or service and detects which of them can also be classified as sharing and/or collaborative business models.

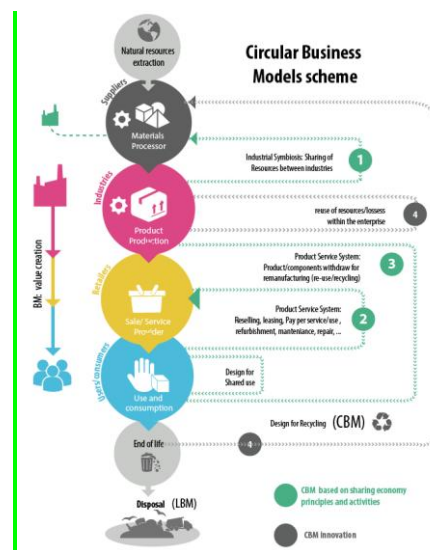

Fig.2. Circular and Collaborative Business Models. Source: ENEA

Collaborative practices imply a return flow to the producer from users/producers or between users, often including intermediaries between the two parties (Linder et al. 2013). In most cases intermediation and collaboration can be based on collaborative on-line platform..

3 Materials and Methods

The present work is a qualitative analysis of different collaborative circular business models (CCBM). The analysis is based on a holistic approach and tents to give a conceptual answer and hints on how to develop them further.

CCBM have been analysed by considering:

- the *type of relationships* between “collaborators” (who produces the value , who uses it , who delivers and recaptures it);
- the *drivers* for the circular and collaborative business model implementation by

considering the role of the main involved actors including the *different types of collaboration based on digital platform* or on more conventional agreement between the stakeholders involved.

4. Results

The CCBMs can be divided in two big groups: B2B and B2C.

4.1 Business-to-Business(B2B) CCBMs: the case of Industrial Symbiosis

Industrial symbiosis (IS) is an important collaborative circular economy business models (CCBM) which implements “closing the loop strategies” at the production stage through the collaboration between two or more companies in order to exchange, share or jointly manage resources, with both economic and environmental advantages for all parties and the possibility of creating new business opportunities. This integrated cross-industrial system is based on resource efficiency of underutilised resources (such as materials, energy, water, by-products) together with the shared use of assets, logistics and expertise capacity.

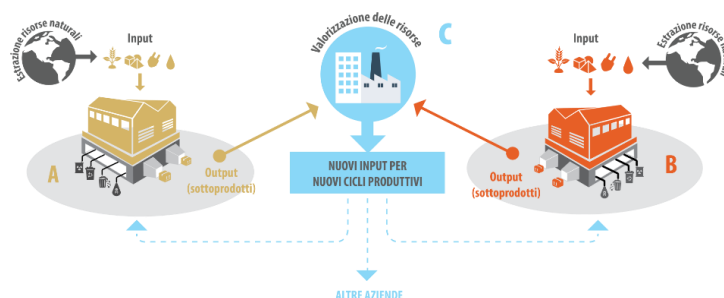

Fig.3. Industrial Symbiosis scheme. Source: ENEA

As shown in Figure 3, collaboration occurs between the “offering companies” that produce by-products and residues and “receiving companies” that receive those resources as a return flow and recapture its economic value, avoiding the utilization of other more cost expensive raw materials; depending of IS pathway, also intermediaries can act between the two parties (e.g. for potential residues treatment process). Therefore IS acts in networks of companies operating in different sectors of providing a mutual benefit or symbiosis for residues/by-products transactions. (Cutaia et al. 2014).

The enabling technology for IS implementation are the emerging on-line platforms for resources sharing (materials, energy products, water, services and expertise) among companies. An example is the Industrial Symbiosis platform developed by ENEA where companies can share their available and needed resources in in order to find potential collaboration with other companies interested in their exchange/valorization. The platform consist in a database of geo-referred input-output resources (uploaded by each company) and technologies (managed by ENEA) useful for the identification of potential

symbiosis pathways. In this case, the platform provides support to collaborate and work with companies for finding industrial symbiosis opportunities.

4.2 Business to Consumer (B2C) CCBMs: the case of Product Service System

The “product-service systems” (PSS) has been defined by Goedkoop et al. (1999) as “a marketable set of products and services capable of jointly fulfilling a user’s need. The product/service ratio in this set can vary, either in terms of function fulfilment or economic value”. Thus, more traditional material intensive ways of product utilization are replaced by the possibility to fulfil consumers’ needs through the provision of more dematerialized services, which are also often associated with changes in the ownership structure (Tukker, 2015). Business to Consumer (B2C) collaborative models offer a disruptive change in the producer/consumer relationship and behavior, switching from the concept of goods ownership to the concept of goods use (Mont, 2002). Customers are now individuals (users) who cooperate with companies for their needs satisfaction. It is based on the value of utilization, where products are no more consumable (material goods), but a performance where the consumer pays for its utilization to fulfill a need. In line with this, products are just a media to provide a function and the “costs of production is only a very small part of the costs involved in making a product available to the customer” (Giarini et al. 1998). This new, more service-oriented model of manufacturing growth has some key competitive factors such as the capability for continuous innovation, improved design and quality and customized goods, rather standardized products than the production of large volumes of goods (Reim et al., 2015; Valencia et al., 2015). Moreover, these new practices require a higher level of customer involvement and mindset change of the producers. The producers need to be capable of sensitizing the consumer on opportunities that environmental renovation bring. They encourage the update and are responsible of the “education” of the consumers on how to use the product.

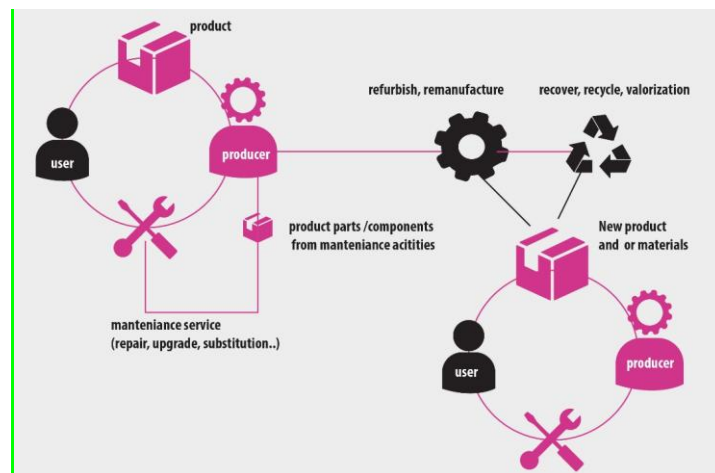

Fig.4. Pay-per-service scheme (PPS). Source: ENEA

As shown in the figure 4, the producer is the owner of the products and provides the users with the maintenance function through repairing, upgrading, substitution services etc. in this case the good is often delivered to the users for a long period. Collaboration between user and producer is iterative and continuous and determines constant product innovation in technological and environmental terms (i.e. domestic appliances that continuously update their energy efficiency class). This model brings radical changes not only in the use and post-use phase, but also in the product design. Also in this case the owner remains the producer (including the end of life management) but, to better maintain and capture the value of the return flow (which are more continuous than in a PPU model), the product needs to be conceived as a good that can be disassembled in smaller components in order to be able to repair it rather than throw it away. In a PPU, in fact, the main revenues for the company arise from the intensification of the product use (and the payment for its use), based on the principle that the sharing use imply the sharing cost among users of the product value. Otherwise, in a PPS, where the relationship not necessarily imply a shared use (or a high frequency), ecodesign strategies are not only more convenient, but indispensable for the business. In fact, each component should have materials and life-length that are coherent with its function and it should also be easily disassembled and repairable in order to favour the maintenance and material recovery (ecodesign strategies). Since the material value of the product is just a capital asset, producers are encouraged to take back their products, or some of its parts, remanufacture or refurbish them and offer them again when possible, or valorize its materials for new applications or products. In other terms, the closure of the loops becomes a cardinal point in the construction of the business model based on the PPS where the economic value of the materials is not entirely charged to the consumer.

5. Drivers for the CCBMs implementation

5.1 The role of the producers

The producers have a major role in the penetration of the circular and collaborative business models in the market. In fact, according to the discussion above, the extension of the producer responsibility in all life cycle phases of the product, covers the latter with a significant importance in changing the trends (Montalvo, 2016). This new responsibility is also a source of important opportunities and advantages. In fact, through the implementation of the CCBMs, the producers can increase the perception of the total value to the consumers or other producers thanks to an increased and continuous flow and exchange of information about their needs and preferences. This can consolidate the fidelity through time. They can specifically intervene in

- innovating the market (from both production and consumption point of view), particularly in sectors where industry is mature.
- anticipating the implications of future take-back legislation and materials /waste management
- being more flexible and prepared to changes in market demand and materials

price fluctuations.

5.2. The role of the platforms (intermediaries)

Concerning intermediaries role, they can support the whole innovation process (Kanda et al., 2015): from the innovation development phase to the innovation diffusion phase (Mignon, 2016). Intermediaries generally differ in recipient targets providing services to supply-side actors, i.e. innovation developers, or supports to demand-side actors, i.e. innovation adopters (Kanda and Mignon, 2017). In case of collaborative platform, its intermediary role provides support to both supply-side and demand-side actors, establishing continuity in the support. Collaborative platforms offer the potential for environmental benefits by providing the possibility to share resources more widely than in the past. The development of these platform can support circular business models and allow companies to get through the constraints of linear zero-sum thinking and to gain a circular advantage fostering new consumption models to be adopted by consumers.

From the preview experiences, it emerges that strategies for unlocking the Circular Economy potential include either bottom-up and top-down actions. Both these approaches need robust, clear and transparent information based on technical and scientific studies (evaluations, innovations and tools/models). The collaborative platforms can also be used to help companies develop new activities by reducing costs and developing new entrance flows.

5.3. The role of consumers

The European Strategy for the resource efficiency indicates that improving resource efficiency is not only a top-down objective, but it can also be a bottom – up approach. Local administrators have a consistent role in the citizens' participation but also their involvement and role is crucial for the adoption of measures that can improve resource efficiency. The PWC (Lancefield, D., et al. 2015) reveals that companies should pay attention to the consumers who can, in a near future, become direct competitors. The companies should assess if their consumers can found a P2P network and take over their market share by developing similar services. This is more often in contexts where certain services are widely requested by the population and are offered with high fixed prices and present an underutilization. For this reason, collaborative economy models are deeply changing the interactions between consumers and business world, passing from the user concept of sharing economy and evolving in the actual concept of “prosumers” (producer + consumer) of the collaborative models, by spreading and developing the concept of “co-creation” and “co-design” of products.

5.4. The role of policy and governance

A significant contribution to boosting the CCBMs is given by the public and institutional thrust which can spur their implementation by concrete actions such as favorable regulation and incentives. The intervention of the public sector can be justified for the aforementioned reasons and advantages that the CCBMs bring to the society.

Furthermore, it has also been argued that by offering market – based solutions, CCBMs are able to respond and contrast the market failure related to information asymmetry (Vitkovic 2016). Indeed, the “peer review” practice through platforms and feedbacks on the quality of a service or good, contributes on the reduction of the information asymmetry.

Nevertheless, due to its intrinsic difference in the way its business is developed, the sharing economy models are very difficult to frame under a traditional and standardized regulation. Busch et al point out how the existing regulatory framework is focused and designed after “bipolar” transactions between businesses and consumer and it does not provide solutions for the new situation that comprises not only business and consumers, but also platforms, (“triangular transactions”). In this regards, it is also argued that the sharing economy businesses are subject to less ex – ante regulation (Vitkovic, 2016) than the traditional ones, breaking this way the assumptions of the competition law.

These particular aspects have been an obstacle to the design of adequate policies that can favor the penetration of the CCBMs in the market and consequently help changing the market trends and the mindset towards a concrete transition to the circular and sharing economy practices. On the other hand, the EU has widely recognized the importance of the collaborative economy and has also actively worked in this direction. The EC (2016) has adopted the “European Agenda for the collaborative economy” which foresees orientation for the Member States on how to deal with the EU laws in application to the business models generated by the collaborative economy. The indications of the Commission concern focal points of the sharing economy, in particular: market access requirements; liability regimes; protection of users; self-employed and workers in the collaborative economy; taxation and monitoring. Through this Communication, the Member States are pushed to facilitate and spur the sharing economy practices by simplifying procedures for the peer to peer practices, recommendations on a favorable taxation without letting aside standards for service and product quality, consumer protection and workers’ rights.

The European Commission has also adopted an ambitious Circular Economy Package which consists of an EU Action Plan for the Circular Economy (EC, 2015) to help European businesses and consumers to make the transition to a stronger and more circular economy. This document underlines among others, the contribution of the sharing economy to the reaching of the circular economy objectives. Specifically “Innovative forms of consumption can also support the development of the circular economy, e.g. sharing products or infrastructure (collaborative economy), consuming services rather than products, or using IT or digital platforms” (EC, 2015) The foreseen actions are conceived following the life cycle approach: from the design to production (by minimizing the resourced used), to consumption (use, re-use and regeneration) and the management of the end of life (disposal, recover and recycle).

In March 2017, the European Commission and the European Economic and Social Committee (EESC) launched a joint European Circular Economy Stakeholder Platform (ECESP). The platform’s 24-member coordination group has now been chosen and the list of participants published. Selected through an open call for expressions of interest, the

coordination group will contribute in a crucial way to the ECESP's activities for the next 3 years. The group brings together circular economy stakeholders, with representatives principally from: civil society; business; trade unions; think tanks; public bodies. The ECESP also has a website to serve as a virtual meeting place where all members of the circular economy community can interact. In this way, stakeholders can work together to deliver results – sharing good practice and expertise, as well as strategies and pledges for the circular economy.

6 Conclusions

Applying the concept of collaborative approach to CBM, it is possible to point out how people organize in new assets and how the interaction between service provider and users is changing in an optic of global optimization of the resources. This approach contrasts the trends of the last decades where the economic value contained in a good has progressively diminished in relation to its function by opening the path to a system in which repairing an object has resulted to be more burdensome than buying it new. This has intuitively weighed on materials use and consumption, affecting severely environmental balances and boosting hardly the resource exploitation. On the other hand, material provision has a quite important cost in the total accountability of companies, therefore thinking of an economic valorization of the materials in a plurality of ways and methods may also become a competitive factor for the enterprises. Together with the rising concern of the society over environmental issues and the rising awareness on social issues, turning business practices in circular and collaborative ones, strongly confirms to be a wise strategy for being more innovative and consequently more competitive in the new markets.

The role of services in providing value is even more important. Not long ago, most of a product's added value came from the production processes that transformed raw materials into products. Now added value is created by technological improvements, intellectual property, product image and brand names, aesthetic design and styling; all of them nonmaterial aspects of products. These will help producers to differentiate and diversify their products to better respond to customers' demands.

Abstract

A business ecosystem that plays an important role in the transition towards a circular economy is the supply chain. Performance measurement of supply chains is a key enabler for this transition.

Studies addressing performance measurement of circularity at a supply chain level appear to be scarce. Therefore, this paper aims to develop a performance measurement system for supply chains in a circular economy.

To develop this performance measurement system, a design science research methodology is applied. First, the requirements for an effective performance measurement system were identified. Subsequently, a performance measurement system that meets these requirements was developed. Finally, the performance measurement system was tested in a case study.

To the best of our knowledge, this paper provides the first and only tested performance measurement system of circular supply chains. The test showed that the performance measurement system meets most of the requirements. Additional tests will have to be performed to determine whether the performance measurement system meets all requirements.

Keywords – Supply Chain Management, Circular Supply Chain, Performance Measurement, Closed-loop supply chain, SCOR, Case study

Paper type – Research Paper

1 Introduction

A circular economy focuses on “... reducing, reusing, recycling and recovering materials in production/distribution and consumption processes” (Kirchherr et al, 2017). To date, performance measurement in the circular economy has primarily focused on measuring circularity at the level of products, companies or economies (Kirchherr et al, 2017; Saidani et al, 2018). However, studies addressing performance measurement of circularity at a supply chain level appears to be scarce (Elia et al, 2017; Saidani et al, 2018). Jain et al (2017) and Kazancoglu et al (2018) present frameworks for performance measurement. However, it is unclear if their frameworks meet the requirements of an effective performance measurement system (PMS).

The scarcity of performance measurement systems (PMS) for circular supply chains is remarkable, since supply chain management plays an important role in the transition towards a circular economy (van Buren et al, 2016). Performance measurement is a key enabler of supply chain management within this transition by reporting, controlling and improving the performance of supply chains (APICS, 2017; Bendoly et al, 2007; Bourne et al, 2005; Gunasekaran et al, 2004). Therefore, it is important to develop a PMS for supply chains in a circular economy, hereafter referred to as circular supply chains.

This paper contributes to existing literature by developing and testing a PMS for circular supply chains. To develop this PMS, a design science research methodology is applied (Peffers et al, 2007). The methodology is described in the next section, section 2, which is followed by the results from this research in the sections 3, 4 and 5. The PMS is evaluated via a case study, which is part of the iterative improvement approach of a design science research methodology. The evaluation is described in section 6. Finally, the paper ends with the conclusions in section 7.

2 Methodology

To develop a PMS of circular supply chains, the design science research methodology as described by Peffers, et al (2007) is used which includes the phases: (1) Problem identification and motivation (section 3) (2) Definition of requirements for the solution (section 4) (3) Design and development (section 5) (4) Demonstration and evaluation (section 6). The methodology applied in these phases is described in the following sections.

Figure 1: Design Science Research Methodology, adapted from Peffers et al (2007)

To identify the requirements for an effective PMS, a literature review was conducted. This literature review followed the approach as described by Webster and Watson (2002). Subsequently, the taxonomy of circularity indicators by Saidani et al (2018) was used to identify circularity indicators on micro -, meso – and macro level. These circularity indicators served as the base to identify three performance attributes of circularity: profitability, material efficiency and value retention. Finally, per performance attribute metrics were developed. A key requirement of PMS appeared to be the integration of multiple interlinked and interdependent metrics. Therefore, the metrics were developed so that they have mutual relationship and thus form an integrated PMS.

3 Problem identification and motivation

A PMS is used to compare current performance levels with targets, to facilitate an improved understanding of supply chain processes and encourage continuous improvements (Bendoly et al, 2007). Despite the growing importance of the circular economy, PMSs that enable the transition of supply chains towards a circular economy are still scarce.

4 Requirements for an effective PMS

In the 1910s, at the start of industrialization, performance measurement mainly focused on measuring the productivity per employee. In the 1950s, with the rise of quality control, more sophisticated productivity measurements were introduced. Subsequently, the focus moved to financial measurements to be able to better serve the interests of shareholders. Moreover, in the 1980s, measurements for customer satisfaction and efficient internal operations were introduced to recognize the importance of these stakeholders. With the introduction of multiple stakeholders, the importance of balanced decision making was also recognized. To enable this balanced decision making, different measurement were integrated in a PMS, such as the Balanced Scorecard (Kaplan and Norton, 1996). Finally, the focus moved to performance measurement of supply chains and performance measurement in context (use and change in the context of specific organizations), named performance management (Bititci et al, 2012).

PMSs should meet the following requirements to be effective:

- Multiple dimensions of performance. The PMS should capture the perspectives of multiple relevant stakeholders (Beamon, 1999; Caplice, 1995; Gunasekaran, 2004; Jensen, 2000; Neely, 1995) by providing a balanced portfolio of different dimensions of performance (Gunasekaran, 2004) and covering long-term and short-term objectives (Neely, 1995).
- Trade-offs. The PMS should recognize and allow for trade-offs between different dimensions of performance by providing insight in the interdependencies among metrics (Caplice *et al*, 1995).
- Drivers of performance. Rather than just financial metrics, the PMS should also include non-financial metrics that drive financial metrics (Bendoly, 2007; Caplice *et*

al, 1995; Gunasekaran, 2004; Maskell, 1989) and track activities that influence future, as well as current performance (Caplice, 1995).

- Horizontal integration. The PMS should contain metrics that are aligned along processes (Caplice *et al*, 1995; Gunasekaran, 2004; Neely, 1995).
- Vertical integration. The PMS should contain metrics comprised of levels of connected hierarchy (APICS, 2017). This enables to link strategy to decision making at each level in the organization (Beamon, 1999; Bourne, 2002; Caplice *et al*, 1995; Maskell, 1989; Neely, 1995). Moreover, it clarifies and translates vision and strategy into goals and actions (Jensen, 2000; Kaplan and Norton, 1996; Neely, 1997) and covers long-term, medium-term and short-term decision making and control (Bourne, 2002; Gunasekaran *et al*, 2004).
- Communication. Communicate to employees of all organizational levels the current organizational performance and how their individual efforts contribute to organizational success (Gunasekaran, 2004; Jensen, 2000).
- Limited range of metrics. The PMS should contain only critical performance metrics that represent key attributes (Bendoly, 2007; Bourne, 2002; Gunasekaran, 2004).
- Reward structure. The PMS should be consistent with the reward structure (Caplice, 1995; Neely, 1995).
- Network. The PMS should depict the organization's key components, partnerships and collaborations (Gunasekaran, 2004; Jensen, 2000).
- Benchmark. The PMS enables benchmarking across time, location and organizations (Beamon, 1999; Gunasekaran, 2004; Neely *et al*, 1996; Neely, 1997).
- Learning. The PMS stimulates learning, action and continuous improvement (Caplice, 1995; Gunasekaran, 2004; Kaplan and Norton, 1996; Maskell, 1989; Neely, 1996; Neely, 1997).

5 Design and development

In this section the design and development of the PMS will be described. This section follows the structure of the requirements for an effective PMS as described in section 4.1.2. First, the multiple dimensions of performance of the PMS are motivated. Subsequently, the trade-offs, drivers of performance, horizontal integration and vertical integration of the PMS is described.

5.1 Multiple dimensions of performance

The multiple dimensions of performance of a circular supply chain can be subdivided into economic, environmental and social performance, which is also referred to as 'triple P' (People, Planet and Profit) (Ahi and Searcy, 2015, Hassini *et al*, 2012). In the PMS, the economic performance and environmental performance will be included. The social performance will be excluded from the PMS. Social performance is still relatively underexposed in literature on circular economy (Ghisellini *et al*, 2016; Kirchherr *et al*,

2017; Saidani et al, 2018) and requires further research in order to be able to design a measurement of social performance.

5.1.1 Economic performance

The economic performance represents the profitable use of resources in the supply chain (Ahi and Searcy, 2015). Resources in the supply chain can be subdivided into costs and assets (APICS, 2017). Costs occur when the resources materials, water and energy are purchased and converted into an end product. Assets are resources that are used to support the conversion of materials, water and energy into an end product and for the distribution of this end product to the consumer. Assets are, for example, trucks, warehouses and machinery. Moreover, performance attributes for supply chains focus on cost reduction and an efficient use of assets (APICS, 2017). Therefore, a metric that measures the economic performance should include costs and assets. A metric that contains costs and assets is the well-known Return on Supply Chain Fixed Assets (APICS, 2017). Return on Supply Chain Fixed Assets represents the return an organization generates with its invested capital in Supply Chain Fixed Assets (land, warehouses, trucks and machinery)(APICS, 2017).

Return on Supply Chain Fixed Assets = (Supply chain Revenues – Total cost)/Supply Chain Fixed Assets

5.1.1 Environmental performance

This paper aims to develop metrics for circularity of supply chains. The relationship between circularity and environmental performance of supply chains is still unclear (Ahi and Searcy, 2015) and requires further research. By developing metrics for circularity of supply chains, this paper aims to contribute to a better understanding of the relationship between circularity and environmental performance. This paragraph will motivate the claim that circularity can be subdivided into two performance attributes: Material Efficiency and Value Retention.

The first performance attribute of circularity is Material Efficiency. Resource scarcity creates a clear need for material efficiency in supply chains (Alonso et al, 2007). Several authors stress the importance of material efficiency (Braun et al, 2018), reduction of waste (Yang et al, 2018) and collection of waste as a characteristic of circular supply chains (Batista et al, 2018; Braun et al, 2018). Circularity metrics on a product level (Saidani, 2018), such as the Life Cycle Assessment (Lieder and Rashid, 2016), Material inputs per unit of service, Material Flow Analysis and Substance Flow Analysis (Elia, 2017), The Circular Economy Indicator Prototype (Cayzer et al, 2017) and Ecological Rucksack (Spangenberg et al, 1999) all focus on material efficiency. Moreover, circularity metrics on an macro-economy level (EASAC, 2016; Mathews and Tan, 2011) focus on material efficiency. Material efficiency on a macro-economy level is determined by domestic material input, net additions to stock and total domestic output. This supports the relevance of material efficiency as part of the circularity metric on a supply chain level.

In line with the formula of material efficiency on a macro-economy level, the formula

of material efficiency on a supply chain level is determined by input of materials, inventory mutation of materials and output of products. The difference between input of materials and output of products is waste (Pearce and Turner, 1990). Waste can occur during production, consumption and recovery (Pearce and Turner, 1990).

For production, a certain weight or volume of materials is sourced (APICS, 2017). These materials are either placed in inventory or used to produce an end product. End products are either placed in inventory or sold to a consumer. Therefore, waste during production is (weight or volume of materials sourced (MS)) minus (weight or volume of inventory mutation (IM)) minus (weight or volume of total supply chain products sold (PS)).

During the process ‘consumption’, end products are used by a consumer and, after consumption, the products are returned or not. Therefore, waste during the process ‘consumption’ is (weight or volume of total supply chain products sold (PS)) minus (weight or volume of products returned (PR)).

During the process ‘recovery’, a certain weight or volume of the products returned is indeed recovered into recovered materials that can be used during production or during consumption. Therefore, waste during recovery is (weight or volume of products returned (PR)) minus (weight or volume of recovered materials (RM)). A metric of waste in the circular supply chain arises by adding the measures of waste for the three processes of the circular supply chain.

$$\text{Waste} = (\text{MS} - \text{IM} - \text{PS}) + (\text{PS} - \text{PR}) + (\text{PR} - \text{RM}) = \text{MS} - \text{IM} - \text{RM}$$

Finally, this metric is presented as Material Efficiency, a percentage of weight or volume of recovered materials in relation to the weight or volume of materials sourced.

$$\text{Material Efficiency} = (\text{MS} - (\text{MS} - \text{IM} - \text{RM})) / \text{MS} = ((\text{IM} + \text{RM}) / \text{MS}) * 100\%$$

The second performance attribute of circularity is Value Retention. Value is created during production and needs to be retained during consumption and recovery, so that during recovery a minimal amount of resources needs to be added in order to arrive at a new end product. Ellen Mac Arthur Foundation (2013a) refers to value retention as the power of circling longer. Yang et al (2018) describe value retention as slowing resource loops which aim to extend or intensify the utilization period, resulting in a slowdown of use of resources. Batista et al (2018) refer to prolonged life cycles as an fundamental aspect of a circular supply chain. Circularity metrics on a product level, on a company level and on an macro-economy level refer to value retention (Saidani et al, 2018). Usually this is expressed in principles such as, reuse is preferred over recycling, or is calculated as the percentage of reused over recycled as in the Material Circularity Indicator (Ellen Mac Arthur Foundation, 2018) and The Circular Economy Toolkit (Evans and Bocken, 2017). This supports the relevance of value retention as part of the circularity metric on a supply chain level.

In a similar way to the previous metric, the metric for value retention is also based on three processes of a circular economy: production, consumption and recovery (Ellen Mac Arthur Foundation, 2013a). The value retention is at its maximum under two conditions:

- the value created during production (SC cost of production) is retained during

- consumption with minimal cost to Maintain and Repair (SC cost of MR);
- it requires minimal cost to recover (SC cost of recovery) to create maximal revenues of recovery (SC revenues of recovery).

Value retention =

$$\left(\frac{((SC \text{ revenues of recovery} - SC \text{ cost of recovery} - SC \text{ cost of MR}))}{SC \text{ cost of production}} \right) * 100\% \text{)}^{NRF}$$

NRF = Number of recovery flows

A recovery flow is one sequence of production, consumption and recovery, in which the product is manufactured, consumed and recovered. Recovery flows can occur multiple times (Ellen Mac Arthur Foundation, 2013a). In case production and consumption occur and there is no recovery, the number of recovery flows equals 0. Following the formula described above, the value retention then equals 0.

5.2 Trade-offs

Environmental performance and economic performance can have a positive and a negative relationship (Wu and Pagel, 2011). The PMS developed in the current study aims to integrate environmental performance with economic performance to provide insight in possible trade-offs. See for a description of the integration paragraphs 5.4 and 5.5.

5.3 Drivers of performance

PMSs usually consist of performance attributes that focus on internal operations and customer satisfaction (APICS, 2017). The PMS in the current study focuses solely on performance of internal operations: an efficient use of assets and cost reduction. Performance on customer satisfaction, such as reliability, responsiveness and agility (APICS, 2017; Kaplan and Norton, 1996) are excluded from the PMS. Circular supply chains will continue to strive for reliability, responsiveness and agility of their processes to accomplish customer satisfaction. A circular supply chain does not differ on these performance attributes from any other supply chain. Therefore, performance on customer satisfaction will be excluded from the remainder of this research.

5.4 Horizontal integration

The requirement of horizontal integration indicates that a PMS should contain metrics that are aligned along processes (Caplice et al, 1995). The circular supply chain consists of three processes: production, consumption and recovery (Batista et al, 2018). Horizontal integration is accomplished by including metrics for profitability, material efficiency and value retention for all three processes.

5.5 Vertical integration

The requirement of vertical integration indicates that a PMS should have different connected levels within a hierarchy of metrics (APICS, 2017). These connected levels are

not present within the current PMS, which could be an interesting next step in the development of this PMS.

6 Demonstration and evaluation

The PMS is tested via a case study. The first paragraph will describe the company in which the PMS is tested. The second paragraph will describe the various performances of the company, as presented by the PMS. The third paragraph will describe the evaluation of the PMS by the company.

6.1 The company

The company produces plastic flooring in one central production facility in Western Europe from where it delivers the plastic flooring to distributors all over the world. These distributors sell the plastic flooring to the end consumers which are companies and private persons. The company's markets are: China, Asia, Africa, North-America, South-America, Oceania and Europe. The main market is Europe. The assortment consists of many products due to the wide choice of colours and designs of the floors. The assortment can be subdivided into 3 main product groups: clicked floors, glued floors and loose-laid floors. In clicked floors the floor consists of tiles that are clicked together. The glued floors are glued to a concrete subsurface. Loose-laid floors consists of tiles that are laid on the subsurface, without the use of glue. The main raw materials are various plastics, binders and pigments which are purchased from different suppliers all over the world.

6.2 Results

The PMS was applied for the supply chain of every product/market combinations. A product/market combination is a combination of a product group (clicked floors, glued floors or loose-laid floors) with a market (China, Asia, Africa, North-America, South-America, Oceania or Europe). The company assumed that the product/market combination of loose laid floors Europe provides the most interesting opportunities for circularity. For this supply chain the current and future performance with recovery will be presented in this paper.

Table 1: current performance supply chain loose laid floors Europe

Metric	Production	Consumption	Recovery
Return on Supply Chain Fixed Assets	-	-	-
Total Cost	100	-	-
Material efficiency	99%	0%	0%
Value retention	0%		

It appeared that Return on Supply Chain Fixed Assets was very time-consuming to determine. Therefore, only total cost was presented in the PMS. The total cost is presented as an index, due to confidentiality reasons. The company currently has no

returns of used products and therefore no recovery activities. This leads to a material efficiency of 0% in consumption and recovery and a value retention of 0%. The value of the product is lost after one flow.

Subsequently, the future performance of the supply chain with recovery was determined.

Table 2: future performance supply chain loose laid floors Europe with recovery

Metric	Production	Consumption	Recovery
Return on Supply Chain Fixed Assets	-	-	-
Total Cost	100	-	30
Material efficiency	99%	100%	99%
Value retention	70%		

It is assumed that all products sold are being returned after consumption, in other words: the material efficiency of ‘consumption’ is 100%. Recovery of returned materials leads to materials with the same quality as virgin materials. Therefore, the revenues of recovery are assumed to be equal to the Total Cost of production. This leads to a value retention of 70%. Furthermore, it is assumed that there is one recovery flow and the company does not have to pay the customer for their used product.

6.3 Evaluation of the PMS

The results were discussed with a focus group discussion with representatives of all departments. Furthermore, an expert interview was conducted with the supply chain manager. The results from the focus group discussion and the expert interview are categorized based on the requirements for effective PMSs, as described in section 4.

Multiple dimensions of performance

The company has experienced the PMS to be relevant to provide an overview of the company’s performance on circularity. Although social performance is excluded from the PMS, the company believes that a metric for social performance would be a valuable addition. Moreover, use of energy in production, in particular fossil fuels, seems to be lacking in the PMS.

Trade-off

For the company the possible relations between metrics is unclear. It is expected that improvement on one metric may lead to deterioration of performance on another metric. However, this relationship is not apparent based on the metrics.

The PMS measures the performance via multiple metrics. On the one hand it is helpful and relevant to have insight in these metrics. However, the question also rises which metrics should have priority.

Horizontal integration

Because the company currently has no returns, the results show material efficiency

and value retention of 0%. The company questions whether these numbers are relevant for supply chains with no returns. Due to the long lifetime of their products it is expected that these metrics will remain zero for many years to come. A PMS with future performance with recovery appears to provide more insights.

Communicate to employees of all organizational levels the current organizational performance

The PMS has helped to provide insight in the current state. The PMS has provided insight in the business case to return – after use – flooring, shred the flooring and use this as input for the production process. The business case has showed that returning loose-laid floors from customers in West Europe, transport costs and making it suitable to use in production, costs about 30% of the price of virgin raw materials. The market of Western Europe is in particular interesting because it is the main market and return transport costs will then remain relatively low. For other markets the quantities delivered are relatively low and therefore the quantities to be returned are also relatively low and the return transport costs will be higher which causes the business case to be less interesting. Recycling local-to-local and not returning the product to the production facility in Western Europe then seems a more interesting venue. Cooperation with competitors to recycle local-to-local also seems an interesting opportunity to increase the utilization of recycling facility.

The PMS has provided insight in the business to return – after use – glued flooring. Removing these floors from a building results in that not only the floor, but also the glue, equalizer and concrete are removed. Separating the flooring from the glue, equalizer and concrete leads to high costs and high use of energy and water. Therefore, for now recycling glued flooring is not a viable business. New developments to improve these removal processes are underway that may lead to a viable business case in the near future.

The PMS has provided the insight that the clicked floors currently have a low market share and therefore low quantities to return. Therefore, clicked floors are not a viable business case to return.

The PMS confirmed that amount of waste in the company is rather minimal. Throughout many years the company has developed a lot of knowledge in ways to minimize waste and to recycle waste to raw materials for its own production.

The term of circularity was still unclear to many employees in the company. A positive consequence of applying this PMS has been that it helped to discuss and promote circularity among employees and to create a better understanding of circularity and its opportunities for the company.

Enables benchmarking across time, location and organizations

Since there is not a benchmark available of previous time periods or from other organizations, the company found it difficult to evaluate the outcomes of the PMS. For some measures the outcome is 99%, which seems like a good score. For other measures the outcome is 30% which raises the question how much room for improvement there is and if this improvement is easy or difficult to accomplish. A benchmark tool together

with the PMS would be very helpful.

7 Conclusions

The current study presents a PMS in which economic and environmental performance is integrated. The test showed that the PMS provides insight in the business case of recovering products after consumption. Moreover, the PMS enables to discuss the topic of circularity and thereby provide a better understanding of circularity amongst employees.

In the use of PMSs there is a trade-off between usability and completeness. Return on Supply Chain Fixed Assets seemed to be a complete measure. However, the test showed that this metric is not very usable. Total cost appeared to be a better usable metric, although future case studies should test if this metric is complete.

Hierarchical integration of metrics on multiple levels still needs to be developed. Furthermore, opportunities to benchmark the results appear to be relevant. Information technology seems to be an essential tool to enable this benchmark, although data sharing between companies leads to various issues of confidentiality and trust.

Some requirements for effective PMSs could not be tested by this single case study. Therefore, more case studies are relevant.

Abstract

This paper proposes a linear programming model to design industrial symbiosis synergies in eco-industrial parks based on the exchange of waste energy among different companies. The model allows to fill two important limitations of previous studies: (1) it uses a multi-objective optimization perspective that considers economic and environmental issues simultaneously; (2) the integration of two decision-support tools, the former able to assess the amount of waste that can be effectively exchanged among companies, the latter able to suggest how to share the infrastructural costs arising from symbiotic synergies so that the economic benefits are fairly shared among the involved companies. A numerical case example is presented to show how the model works. The case highlights several applications of the model, which contribute to confirm its usefulness for companies, industrial symbiosis facilitators, and policymakers.

Keywords – Industrial Symbiosis, Eco-Industrial parks, Optimization problem, Decision-support tools

Paper type – Academic Research Paper

1 Introduction

1.1 Industrial Symbiosis

Industrial symbiosis (IS) is a subfield of industrial ecology that engages separate industries in a collective approach to competitive advantage, involving physical exchange of materials, energy, and services (Chertow, 2000). The IS practice refers to replacing production inputs required by a generic production process with wastes generated by other production processes, thus helping to close the loop of manufacturing processes. Companies adopting IS can reduce the amounts of both wastes disposed of in landfills and primary inputs used in production processes (e.g., Jacobsen, 2006). As a result, they can enhance production efficiency and decrease production costs (e.g., Yuan and Shi, 2009). Hence, the IS approach is able to create environmental benefits for the society and economic benefits for companies, simultaneously. For this reason, several countries are endorsing IS by promoting the development of IS networks (ISNs), i.e., networks of at least three firms involved in exchanging at least two wastes (e.g., Fichtner et al., 2005). The literature distinguishes two creation mechanisms for ISNs: these networks can emerge from the bottom, as the result of a spontaneous process undertaken by companies, or be designed by adopting a top-down approach. Examples of bottom-up ISNs are the so-called “self-organized ISNs” (e.g., Chertow and Ehrenfeld, 2012; Doménech and Davies, 2011) whereas eco-industrial parks (EIPs) are examples of top-down ISNs (e.g., Massard et al., 2018; Tudor et al., 2007). This paper focuses on EIPs.

1.2 Eco-industrial parks

In EIPs, companies can be involved in exchanging materials (i.e., wastes and by-products), water, energy, and services. A central authority – usually, one of the involved companies, a third company, an IS facilitator, or a research center – is in charge for designing and managing the IS exchanges among companies belonging to the park (Fraccascia et al., 2019). These exchanges are designed by adopting mathematical optimization models (for a detailed review of optimization models used to design eco-industrial parks, the readers are referred to Boix et al., 2015). While the design of material-based and water-based IS exchanges has been widely investigated by the literature, there are relatively few studies that deal with energy management in an EIP through mathematical optimization. When designing energy-based exchanges, several energy-specific issues must be considered: (1) energy is hard to store, hence it is critical ensuring the quantity match between demand and supply (Kikuchi et al., 2016), which is recognized as one of the most important conditions for developing IS (Fraccascia and Yazan, 2018); (2) energy exchanges require specific investments (e.g., the construction of pipelines) that increase the dependency on the symbiotic partner (Fichtner et al., 2005); and (3) companies need to be close enough because investments and heat losses increase with the length of pipelines (Korhonen, 2001).

1.3 Literature gaps

When considering optimization models for energy-based exchanges, two strong gaps in the literature can be identified. The first gap concerns the lack of multi-objective optimization studies that consider economic and environmental issues simultaneously. In fact, the existing optimization models for designing energy-based exchanges are devoted to maximize the economic performance or to minimize the environmental impact of the EIP. The second gap is related to the fact that the existing models focus on optimizing the EIP “globally”, without taking care of “local” aspects. For example, these models allow to minimize the overall investment costs in pipelines; however, they do not indicate how investments costs have to be shared among companies. In order to design and manage EIPs effectively, local issues must be taken into account. In fact, cost-sharing issues are critical for the establishment of IS relationships. In this regard, when independent companies should cooperate to pursue a common goal but the benefits of cooperation are unevenly shared, a misalignment incentive problem arises (Narayanan and Raman, 2004). In this case, companies gaining the scant part of economic benefits might be not willing enough to establish the cooperation, thus impacting on the overall EIP (Albino et al., 2016).

1.4 Outline of the paper

In this paper, we design a linear programming model to design energy-based exchanges in EIPs. The objective function takes into account both economic and environmental issues simultaneously. Technical and economic constraints are considered. The optimization model is integrated with the following tools, aimed at: (1) assessing the amount of energy that can be exchanged among each couple of companies, due to fluctuation in energy production and demand; (2) sharing investment costs among the involved companies. The first tool allows a better estimation of the environmental and economic benefits potentially created by IS cooperation, thus enhancing the reliability of the model. The second tool provides useful suggestions to the EIP managers on how to fairly share investment costs of infrastructures required to exchange energy, so that an incentive alignment toward cooperation occurs. A case example is used to test the model and to describe the usefulness in practice.

The rest of the paper is organized as follows. Section 2 presents the optimization model. Section 3 addresses the numerical case example. The paper ends with discussion and conclusions in Section 4.

2 The optimization model

This Section is divided into three subsections. Section 2.1 presents the hypothesis and the main features of the model. Section 2.2 addresses the design of infrastructures supporting energy exchanges. Finally, Section 2.3 concerns the tool for sharing the investment costs.

2.1 Hypothesis and main features

Let us consider that a given number of firms, I waste producers and J waste users, are located in the same EIP. Each waste producer is characterized by an annual production of the generic waste k , denoted as S_i^k , which can be discretized as the sum of the amount of waste produced in N temporal periods. Similarly, each waste user is characterized by an annual requirement for the input replaced by waste k , denoted as D_j^k , which can be discretized as the sum of the amount of waste produced in N temporal periods. Accordingly, it follows that:

$$S_i^k = \sum_{t=1}^N S_i^k(t) \quad (1)$$

$$D_j^k = \sum_{t=1}^N D_j^k(t) \quad (2)$$

The highest amount of waste k that can be exchanged during one year between waste producer i and waste user j , denoted as X_{ij}^k , can be computed as follows:

$$X_{ij}^k = \sum_{t=1}^N \min \left\{ S_i^k(t); \frac{D_j^k(t)}{\rho^k} \right\} \quad (3)$$

where ρ^k denotes how many units of input can be replaced by one unit of waste. Here, it is assumed that waste energy cannot be stored. Therefore, if at generic time t the amount of waste produced by firm i is higher than the amount of waste required by firm j and firm i does not have other symbiotic partners, the waste producer has to dispose of $S_i^k(t) - \frac{D_j^k(t)}{\rho^k}$ units of waste.

2.2 The mathematical formulation for designing the infrastructures

Let $i \in I$ be the set of waste producers, $j \in J$ the set of waste users, and $k \in K$ the set of wastes to be exchanged. Table 1 shows all the parameters used in the model.

Table 1 Parameters used in the model.

Technical parameters	
D_j^k	Annual amount of waste k demanded by firm j
S_i^k	Annual amount of waste k produced by firm i
L_{ij}	Distance between firms i and j [Km]
x_{ij}^k	Annual amount of waste k exchanged between firm i and firm j
T	Project lifetime [years]
ρ^k	Amount of input replaced by one unit of waste k
Unitary costs	
CC^k	Construction cost of pipeline to exchange waste k [€/Km×unit of waste]
CM^k	Annual maintenance cost of pipeline to exchange waste k [€/Km×unit of waste]
CT^k	Annual treatment cost for waste k [€/unit of waste]
DC^k	Disposal cost for waste k [€/unit of waste]
Cmp^k	Purchase cost for input replaced by waste k [€/unit of input]
Environmental costs	
τ^k	Environmental cost for disposing of waste k [€/unit of waste]
ϑ^k	Environmental cost for using the input replaced by waste k [€/unit of input]

The objective function to be maximized is as follows:

$$f = \text{ceasing costs} - (\text{infrastructural costs} + \text{additional operational costs}) \quad (4)$$

Ceasing costs can be modeled as follows:

$$\text{ceasing costs} = \sum_{k=1}^K \sum_{i=1}^I \left[(DC^k + \tau^k) \sum_{j=1}^J x_{ij}^k \right] + \sum_{k=1}^K \sum_{j=1}^J \left[(Cmp^k + \vartheta^k) \rho^k \sum_{i=1}^I x_{ij}^k \right] \quad (5)$$

where the first addend – i.e., $\sum_{k=1}^K \sum_{i=1}^I [(DC^k + \tau^k) \sum_{j=1}^J x_{ij}^k]$ – denotes the avoided costs related to waste disposal and carbon tax and the second addend – i.e., $\sum_{k=1}^K \sum_{j=1}^J [(Cmp^k + \vartheta^k) \rho^k \sum_{i=1}^I x_{ij}^k]$ – denotes the avoided costs related to the input purchasing. Note that environmental issues are included in the objective function by means of the parameters τ and ϑ .

Infrastructural costs are related to the building and maintenance of pipelines. They can be modeled as follows:

$$\text{infrastructural costs} = \sum_{k=1}^K \sum_{i=1}^I \sum_{j=1}^J \left(\frac{CC^k}{T} + CM^k \right) L_{ij} x_{ij}^k \quad (6)$$

Finally, additional operational costs are related to waste treatment. They can be modeled as follows:

$$\text{additional operational costs} = \sum_{k=1}^K \sum_{i=1}^I \sum_{j=1}^J CT^k x_{ij}^k \quad (7)$$

The objective function is subjected to the following two constraints:

- (a) $0 \leq x_{ij}^k \leq X_{ij}^k \quad \forall k, i, j$
- (b) $\{DC^k + \tau^k + (Cmp^k + \vartheta^k) \rho^k - \left[\left(\frac{CC^k}{T} + CM^k \right) L_{ij} + CT^k \right]\} x_{ij}^k > 0 \quad \forall k, i, j$

The former is a technical constraint, which imposes that the waste flows among companies must be not negative and not higher than the respective maximum amount of waste that is possible to exchange. The latter is an economic constraint, which imposes that each waste exchange must be economically feasible.

2.3 The mathematical formulation for sharing the investment costs

In this paper, we adapted the methodology proposed by Yazdanpanah and Yazan (2017), which is based on the concept of Shapley value (Shapley, 1953). Accordingly, in IS relationships costs are fairly shared when all the involved companies gain the same economic benefit from the symbiotic synergy. In this case, there is no incentive misalignment among the involved companies, since none of the involved companies can gain only a scant part of the total economic benefits created. In this regard, let α be the percentage of infrastructural costs and additional operational costs that the waste producer has to pay. Let us denote as α^* the value of the parameter α so that both of the involved

companies gain the same economic benefit from the IS relationship. It can be computed as follows¹:

$$\alpha^* = \frac{\sum_{k=1}^K [DC^k + \tau^k + (Cmp^k + \vartheta^k)\rho^k - \left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k]}{2 \sum_{k=1}^K \left[\left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k\right]} \quad (8)$$

The value of α is defined between two extremes α^{\min} and α^{\max} , which correspond to the scenarios where the economic benefits from the IS practice are equal to zero for the waste user and for the waste producer, respectively. The values of α^{\min} and α^{\max} can be computed according to the following equations:

$$\alpha^{\min} = \frac{\sum_{k=1}^K \left[\left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k - (Cmp^k + \vartheta^k)\rho^k\right]}{\sum_{k=1}^K \left[\left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k\right]} \quad (9)$$

$$\alpha^{\max} = \frac{\sum_{k=1}^K (DC^k + \tau^k)}{\sum_{k=1}^K \left[\left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k\right]} \quad (10)$$

According to the value of α^* , five cases can be highlighted: (1) $0 < \alpha^* < 1$, i.e., costs are shared between companies; (2) $\alpha^* = 0$, i.e., all the costs are paid by the waste user; (3) $\alpha^* = 1$, i.e., all the costs are paid by the waste producer; (4) $\alpha^* < 0$, i.e., all the costs are paid by the waste user, which also pays an additional compensation to the waste producer; and (5) $\alpha^* > 1$, i.e., all the costs are paid by the waste producer, which also pays an additional compensation to the waste user.

3 Case Example

Let us consider nine waste producers and nine waste users spread in a given geographic area as depicted in Fig 1. For the sake of simplicity, let us assume that only one waste is produced by firms (i.e., $K=1$) and that the waste can replace only one input. The annual amounts of waste produced and input required by each company are depicted in Table 2. For the sake of simplicity, let us assume that both the demand and potential supply of waste are constant in all periods, i.e., that $S_i^k(t) = S_i^k(t+1) \forall i = 1 \dots I, t = 1 \dots 11$ and $D_j^k(t) = D_j^k(t+1) \forall j = 1 \dots J, t = 1 \dots 11$. Technical and economic parameters are displayed in Table 3. Numerical results concerning the amount of waste to be exchanged between each couple of waste producers and waste users are depicted in

¹ This results from imposing the following equality:

$$\begin{aligned} \sum_{k=1}^K (DC^k + \tau^k)x_{ij}^k - \alpha \sum_{k=1}^K \left[\left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k\right]x_{ij}^k \\ = \sum_{k=1}^K (Cmp^k + \vartheta^k)\rho^k x_{ij}^k - (1 - \alpha) \sum_{k=1}^K \left[\left(\frac{CC^k}{T} + CM^k\right)L_{ij} + CT^k\right]x_{ij}^k \end{aligned}$$

Table 4. A graphical solution is highlighted in Fig 2 (squared distances are used).

Fig 1 Geographic location of companies considered in the case example. Waste producers are depicted in red, waste users are depicted in green.

4 Discussion and Conclusions

This paper proposes a linear programming model to design energy-based exchanges in EIPs. This model provides some useful advances compared to the existing models. First, the objective function takes into account both economic and environmental issues simultaneously. In fact, environmental issues are modeled through the environmental

costs τ and ϑ . Second, the model is able to assess the amount of energy that can be effectively exchanged among companies because it considers fluctuations in waste energy production and demand, then not just considering the annual amount of waste produced and required. In fact, it might happen that, even in case of a perfect match between the annual amounts of waste produced and required, these amounts are produced and required in different periods and therefore the match cannot be ensured in the same period. In this regard, the example in Table 5 highlights that, despite the annual amount of produced and required waste is equal (i.e., 400 units), the actual amount that can be effectively exchanged is lower (i.e., 210 units) because of quantity mismatch occurring in each period. Finally, the optimization model is integrated with a decision-support tool able to propose the optimal policy for sharing costs arising from IS so that the economic benefits are fairly shared between each couple of involved companies. This is useful in order to avoid the problem of incentive misalignment, which is recognized as a strong barrier to the establishment of IS relationships.

Table 5 Example of a mismatch between demand and supply of waste.

Period	$S_i^k(t)$	$D_j^k(t)$	$X_{ij}^k(t)$
1	100	50	50
2	50	40	40
3	50	200	50
4	10	50	10
5	190	60	60
Total	400	400	210

A case example is presented, in order to show how the model works and to highlight its usefulness in practice. According to the numerical solution displayed in Table 4, a mismatch between demand and supply still remains. For example, the waste receiver 3 can replace only 6% of its input. Hence, in order to reduce such a mismatch, other waste producers should be added to the area. To this aim, the model can be used to identify where to locate the new plant(s), so that the economic benefits are maximized, via launching the optimization algorithm for different locations of the new plant(s).

From the numerical case, it can be highlighted that the value of α^* is higher than zero for all the IS relationships, ranging between 0.10 and 0.29. This means that in all cases the infrastructural costs should be shared between the involved companies, so that the economic benefits are fairly shared. This feature of the model can be particularly effective for managers in charge of designing the EIP, since avoids that companies put in practice opportunistic behaviors when negotiating the cost-sharing solution.

Finally, the model can be used to assess the impact of policy measures affecting environmental costs, waste disposal costs, and input purchase costs. For example, it can be useful to discover policy measures useful to make feasible IS opportunities that are currently not economically convenient.

There are some limitations that should be acknowledged. In fact, the model assumes that one waste can replace only one input. Furthermore, the model does not take into account the treatment processes that waste might require in order to be used as input. These issues are a driver for future research.

Abstract

In this paper, we provide practical decision support to managers in firms involved in Industrial Symbiotic Relations (ISRs) in terms of strategy development and test the hypothesis that in the long-term, playing a fair strategy for sharing obtainable ISR-related benefits is dominant. We employ multi-agent-based simulations and model industrial decision-makers as interacting agents that observe their history of cooperation decisions in ISRs. The agents are able to: learn from their past, deviate from relations in which their partner plays unfair, and change their strategy to reach higher long-term benefits. Results show that in a long-run industrial decision makers learn to play fair in ISRs. In addition to managerial support for developing long-lasting ISRs, our work introduces the concept of learning as a notion that links the micromotives in ISRs to their macrobehavior.

1 Introduction

Industrial symbiosis (IS) is a subfield of industrial ecology that engages separate industries in physical exchanges of waste materials, water, and energy (Chertow, 2000). Two companies implement an IS relationship (ISR) when at least one waste produced by the former is used to replace production inputs by the latter. By exchanging wastes for inputs, companies can reduce the amounts of wastes disposed of in landfills and the amounts of primary inputs purchased by traditional suppliers, thus generating environmental benefits for the collectivity and reducing their production costs at the same time (Jacobsen, 2006). Thanks to such a reduction, companies implementing IS can gain competitive advantage compared to their competitors not adopting IS (Esty and Porter, 1998). For these reasons, IS is recognized as a key practice to support the transition towards circular economy and policymakers are pushing companies to adopt such a practice (European Commission, 2015).

However, implementing an ISR requires that companies pay additional costs compared to their main businesses, i.e., costs to transport wastes from the producer to the user and costs to make wastes available to be used as inputs. In fact, some wastes may require a treatment process before being used as input, e.g., filtration, sorting, grounding processes, etc. Companies interested in an ISR have to negotiate how to share these additional costs among them which is a crucial phase for the creation of the ISR because determining how the total economic benefit created is shared among companies. In fact, a minimum economic benefit exists that motivate companies to symbiotically cooperate. Such a benefit depends on idiosyncratic features of companies, such as the desired return on investment (Mirata, 2004). In this regard, the literature provided several models proposing how the economic benefit overall created by ISR can be fairly shared between the involved companies, so that both of them are motivated enough to cooperate (Albino et al., 2016; Yazdanpanah and Yazan, 2017). However, real cases investigated by the authors showed that companies might adopt opportunistic behaviors during the cost-sharing negotiation phase, aimed at capturing the greatest part of the economic benefit overall created while leaving a scant part to the other company. In such a case, an incentive misalignment problem may arise (Narayanan and Raman, 2004), i.e., the company gaining the scant part of the benefit might be not motivated enough to cooperate with the symbiotic partner and it might prefer to reject the relationship. Furthermore, even if the relationship is not immediately rejected, such a misalignment may be responsible for reducing trust in the symbiotic partner, which can hamper the stability of the relationship in the long period (Lambert and Boons, 2002). In fact, high trust between the involved companies is recognized as a key facilitator for ISRs (Hewes and Lyons, 2008). Hence, the IS practice can be conceptualized as a form of ‘coopetition’, i.e., something in between pure cooperation and pure competition (Osarenkhoe, 2010). In fact, companies have to cooperate aimed at creating an economic benefit at the ISR level (which cannot be created unilaterally) but then they have to compete in appropriating such a benefit. So far, the literature focused on assessing the economic benefits overall created (i.e., on the

cooperation phase) but scant attention has been devoted to investigate how companies share such a benefit (i.e., to the competition phase).

This paper is aimed to fill this gap. First, we use non-cooperative game schemes (Nash, 1951) to model strategies that companies can adopt for benefit-sharing. Second, we employ agent-based simulation (Axelrod, 1997) to explore the iterated game and its evolution over time. Our aim would be to investigate how firms develop long-term and whether their potential to observe previous rounds of the industrial symbiosis game affects the evolution of their strategies.

The paper is organized as follows. Section 2 presents the game theory model developed. Section 3 presents the agent-based model and the simulation results. The paper ends with discussion and conclusions in Section 4 and Section 5, respectively.

2 Game-theoretical model

In this section, a non-cooperative game scheme (Nash, 1951) is used to model and predict the behavior of industrial firms in ISRs.

Let us consider two companies, the waste producer (P) and the waste user (U), which try to establish an ISR. The total economic benefit that can be created from such a relationship (π_{max}) can be computed by the following equation:

$$\pi_{max} = CW + CI - AC \quad (1)$$

where CW denotes the reduction in waste disposal cost gained by the waste producer, CI denotes the reduction in input purchase costs gained by the waste user, and AC denotes the additional costs stemming from the ISR, i.e., waste treatment and transportation costs (Fraccascia and Yazan, 2018). Companies have to negotiate how to share these additional costs and such a negotiation affects how the total economic benefits are shared between them. In this regard, let λ be the share of additional costs that is paid by the waste producer and let $1 - \lambda$ be the share of additional costs that is paid by the waste user. Hence, the economic benefits gained by waste producer (π_P) and the economic benefits gained by waste user (π_U) can be computed as follows:

$$\pi_P = CW - \lambda \cdot AC \quad (2)$$

$$\pi_U = CI - (1 - \lambda) \cdot AC \quad (3)$$

where $\pi_P + \pi_U = \pi_{max}$. According to the literature, a minimum net economic benefit exists for each company that makes the ISR convenient enough from the economic perspective. Let us denote the minimum benefit for the waste producer and user as ε_P and ε_U , respectively. When trying to establish an ISR, the waste producer (user) may play two strategies:

- A *fair* strategy, where he/she settles for gaining its minimum benefit ε_P (ε_U). So that the strategy can be considered fair, ε_P (ε_U) should be lower than $0.5 \times \pi_{max}$. In

such a case, the waste producer (user) will be willing to cooperate $\forall \lambda \leq \frac{1}{AC} [CW - \varepsilon_P]^1$ ($\forall \lambda \geq \frac{1}{AC} [\varepsilon_U + AC - CI]^2$);

- An *opportunistic* strategy, where he/she tries to capture the greatest part of the economic benefit created, leaving that the waste user (producer) gains its minimum benefit ε_U (ε_P). Hence, the waste producer (user) will be willing to cooperate for $\lambda = \frac{1}{AC} [\varepsilon_U + AC - CI]$ ($\lambda = \frac{1}{AC} [CW - \varepsilon_P]$), so that he/she will gain an economic benefit of $\pi_{max} - \varepsilon_U$ ($\pi_{max} - \varepsilon_P$)³.

The single-shot ISR game can be modeled as a non-zero-sum game⁴ simultaneously played by the two above-mentioned companies. Payoffs are evaluated as the net benefits for each player. The resulting payoff matrix is shown in

Table 4. Accordingly, the ISR will arise in three of the four scenarios:

- Both companies play the *fair* strategy. In such a case, they negotiate the value $\lambda^* \in \left[\frac{1}{AC} (\varepsilon_U + AC - CI); \frac{1}{AC} (CW - \varepsilon_P) \right]$, so that $\pi_P \geq \varepsilon_P$ and $\pi_U \geq \varepsilon_U$, simultaneously. Hence, the payoff of the waste producer is $CW - \lambda^* \cdot AC$ and the payoff of the waste user is $CI - (1 - \lambda^*) \cdot AC$;
- The waste producer plays the *fair* strategy and the waste user plays *opportunistic* strategy. In such a case, the waste producer gains the minimum benefit ε_P while the waste user gains $\pi_{max} - \varepsilon_P$;
- The waste producer plays the *opportunistic* strategy and the waste user plays *fair* strategy. In such a case, the waste producer gains $\pi_{max} - \varepsilon_U$ while the waste user its minimum benefit ε_U .

Finally, if both companies play the *opportunistic* strategy, the ISR does not arise and companies do not gain economic benefits.

Table 4 Payoff matrix for the proposed game theory model.

		Waste User	
		<i>Fair</i>	<i>Opportunistic</i>
Waste Producer	<i>Fair</i>	$CW - \lambda^* \cdot AC$ $CI - (1 - \lambda^*) \cdot AC$	ε_P $\pi_{max} - \varepsilon_P$
	<i>Opportunistic</i>	$\pi_{max} - \varepsilon_U$ ε_U	0 0

As can be noticed from Table 1, no dominant strategy exists for any of the actors. The game results in two Nash equilibria⁵, i.e., cells *fair-opportunistic* and *opportunistic-fair*. To verify this, we elaborate on the fact that in both these cases, none of the players can

¹ This comes from the following constraint: $CW - \lambda \times AC \geq \varepsilon_P$.

² This comes from the following constraint: $CI - (1 - \lambda) \times AC \geq \varepsilon_U$.

³ Under the assumption that $\varepsilon_P < 0.5 \times \pi_{max}$ ($\varepsilon_U < 0.5 \times \pi_{max}$), it results that $\pi_{max} - \varepsilon_U > 0.5 \times \pi_{max}$ ($\pi_{max} - \varepsilon_P > 0.5 \times \pi_{max}$).

⁴ While in zero-sum games the total benefit to all players in the game, for every combination of strategies, always adds to zero, in non-zero-sum games outcomes can have net results greater than zero, so that a gain by one player does not necessarily correspond to a loss by another.

⁵ A situation would be seen as a Nash equilibrium if neither of the involved players can benefit by deviating from it.

unilaterally increase its payoff by deviating. In this regard, let us consider that the waste producer (user) plays the *opportunistic* strategy and the waste user (producer) plays the *fair* strategy. In such a case, the waste producer (user) would have no interest in changing its strategy, since such a change would reduce its economic benefit, while the waste user (producer) cannot change its strategy because the relationship would be rejected by the waste producer (user). Therefore, the game stays in either of the two cells. This form of strategic play is also known in the non-cooperative games literature (Aumann and Shapley, 1994) as the max-min approach where a player P reasons about its strategies—to maximize its own utility—with the assumption that the opponent player O has the same goal (i.e., O aims to maximize its own utility and accordingly minimize P 's utility). Due to the non-cooperative setting of the game, from P 's point of view, it should select the strategy that maximizes its utility among all the O 's minimizing strategies.

All the above is about strategic choices is firms play once. In real-life situations, firms may get involved in multiple resource exchanges hence have to play the ISR game plenty of times. To understand the dynamics and evolution of ISRs (over time), we model ISRs behavior in the long run using an iterative ISR game among the involved firms. In this regard, the literature recognizes that path dependence plays a relevant role in long-term ISRs, i.e., that companies are influenced by the historical accumulations resulting from previous operations when taking decisions (Arthur, 1994; Boons and Howard-Grenville, 2009). Accordingly, possible behaviors that emerge in the long period can be highlighted. First, a company that is cooperating in the *fair-fair* scenario might start to adopt an opportunistic behavior by changing its strategy from *fair* to *opportunistic*, aimed at increasing the amount of economic benefits from the ISR, being confident that the symbiotic partner will continue to play *fair* strategy. However, opportunistic behavior is responsible for reducing trust between companies (Sako, 1992), which is considered as a key element for the stability of ISRs (Hewes and Lyons, 2008). In fact, the literature reports cases where ISRs were interrupted because of the lack of trust among the involved companies (Lambert and Boons, 2002). We model such a situation as the possibility for the company that is playing *fair* in the *fair-opportunistic* scenario to defect from the ISR. In the next section, long term game is explored by employing agent-based simulation.

3 Agent-Based Simulations for long-term IS relationships

In this section, we simulate multi-round games among multiple industrial firms, where each firm is modeled as an agent. The generic i -th agent is characterized by the following three idiosyncratic parameters:

- $\varphi(i)$ is the probability that the agent i plays the *fair* strategy when starting a new game;
- $\omega(i)$ is the probability that, if at time $t - 1$ the agent i was cooperating playing *fair* strategy with its partner, at time t the agent i changes its strategy and plays *opportunistic* strategy;
- $\delta(i)$ is the probability that agent i interrupts its current relationship because it is playing *fair* strategy and its partner is playing *opportunistic* strategy.

We consider two sets of resource-provider and resource-receiver agents. In the initial stage, for each agent the parameters φ , ω , and δ are randomly assigned between 0 and 1. For any arbitrary time-step t , the generic agent i can be: (1) currently cooperating with another agent j , where both of them played *fair* strategy at time $t-1$; (2) currently cooperating with another agent j , where i played *fair* and j played *opportunistic* strategy at time $t-1$; (3) currently cooperating with another agent j , where j played *fair* and i played *opportunistic* strategy at time $t-1$; (4) currently not cooperating with other agents.

We simulate 100 waste producers and 100 waste users interacting amongst each other for 1,000 runs. At the end of the simulation, we collect the values of parameters φ , ω , and δ of each company for each time step. In particular, the higher the value of φ , the more firms learned that adopting *fair* strategy is convenient for long-term ISRs. Alternatively, the higher the value of ω , the more firms learned that opportunistic behaviors resulting from changing strategy from *fair* to *opportunistic* strategy when the partner is playing *fair* strategy is detrimental for long-term ISRs. Finally, the higher the value of δ , the more firms learned to defect the relationship if its partner is playing *opportunistic* strategy. Simulations are replicated 10,000 times and values of φ , ω , and δ are averaged across the replications.

Simulation results are shown in Fig 1. Let us first consider the parameter δ . It grows from 0.5007 at $t=1$ to one at $t=449$ and keeps this value until $t=1,000$. Such a growth denotes that, in case a waste producer (user) plays *opportunistic* strategy, in the long term the waste users (producers) that are in relation with it learn that they can benefit more by defecting the relation. In fact, they can establish new ISRs with other firms playing *fair* strategy and gain higher economic benefits. Such a collapse of relation might be costly for the waste producer (user) because immediately reduces the economic benefits it gains from the ISR. As a result, firms learn that playing *fair* strategies is beneficial in the long term. In fact, the values of φ and ω support such an issue. In particular, as can be noticed from the parameter φ , in the long period the probability that companies play the fair strategy when starting a new game increases: φ grows from 0.4997 at $t=1$ to one at $t=414$ and keep such a value until $t=1,000$. The parameter ω shows two opposite trends over time: it grows from 0.5003 at $t=1$ to 0.5442 at $t = 153$ and then decreases to 0 at $t = 1,000$. This is representative for the fact that, initially, firms try to take advantage from adopting opportunistic behaviors, in particular by changing strategy from *fair* to *opportunistic* when both players are adopting *fair* strategy. In fact, the company changing strategy increases its own economic benefits from the ISR if its partner is available to keep the relationship despite its economic benefits are reduced. However, as the values of the parameter δ show, in the long period such a partner is more willing to interrupt the ISR with an opportunistic player because it learns that it can benefit more by defecting the relation. As a result, firms learn that opportunistic behaviors aimed at taking more advantage from existing ISRs are detrimental for their economic results.

Fig 1. Simulation results.

4 Discussion

Our findings show that companies enter in a learning process on how to develop business strategies while assessing IS opportunities. Changing from *fair* to *opportunistic* strategy is not a long term and stable solution for companies as it only provides short term benefits and the challenge of finding a *fair-playing* partner increases over time. Changing from opportunistic to fair behavior enables companies to find a *fair-playing* partner quicker and thus, implementing IS business is easier. This also indicates a *fair-play* for companies when they first launch the negotiation phase. So, achieving collectivity while contributing to sustainability goals in a profitable manner is possible to learn by companies.

These results are in line with the literature highlighting the key role of collaboration for the success of the IS practice in the long period (Chertow, 2000; Lambert and Boons, 2002). Despite results show that the willingness to adopt opportunistic behavior is reduced in the long period, they also show that such a willingness increases in the short-medium period. In this regard, opportunistic behavior can be discouraged by developing trust between the companies involved in ISRs (Hewes and Lyons, 2008).

From the methodological perspective, agents learn because path dependence is recognized as a driving factor of current decisions of companies (Doménech and Davies, 2011). Considering the two presented ISR strategies in the former section, i.e., *fair* and *opportunistic* strategies, we test the hypothesis that in long-term, firms learn to implement the *fair* strategy. This is because in case a firm A applies opportunistic strategies, in long-term other firms that are in relation with A learn that they can benefit more by defecting the relation. Such a collapse of relation is costly for A as it has to establish new ISRs and pay corresponding costs, e.g., transaction costs. Such a framework is in line with the role of *path dependence* in the context of IS. In fact, firms are strongly influenced by their past ISRs in taking decisions about their current relationships (Boons and Howard-Grenville, 2009; Domenech and Davies, 2011). Considering Table 1, in any time-step, ISRs either take place in a *fair-fair* form or in a *fair-opportunistic* form (and never in an

opportunistic-opportunistic manner). As we discussed above, while in single-shot ISRs an opportunistic strategy results in higher benefit for industrial firms, in the long-term the opponent firms (on the other side of the relation) may defect the relation and establish new relations. Thus, the proposed ABM is considered to be an efficient tool to analyze network behavior. Such a tool can also be particularly useful for the managers of industrial clusters as well as regional policy-makers to push companies through sustainable behavior. A similar approach can be also adopted for different purposes of policy-making, e.g., to minimize energy consumption, carbon emissions or resource use as well as to produce socially sustainable solutions such as employment creation.

5 Conclusions

This paper has theoretical, managerial, and policy implications. In terms of theoretical implications, the integration of ABM with game theory for analyzing ISRs is an innovative approach, as to our knowledge no studies took place in the literature integrating two approaches in the field of IS. Organizational learning for (particularly self-emergent) IS networks is not in-depth analyzed in the literature of IS; so, this paper extends the applicability of game theory integrated ABM for organizational learning of companies to achieve sustainable behavior.

With regard to managerial implications, this paper highlights different dynamics that can take place in the construction of ISRs explaining them through a game model. This model is useful for managers to take more precise decisions with as much information as possible referring to cooperation between ISR companies.

The transaction between ISR firms results in undoubted environmental benefits, in the form of reduction of landfill saturation, as well as decrease in the environmental impacts related to the use of conventional raw materials. However, since the transaction is highly dependent upon actors' behavior (or simply IS additional costs do not allow better payoff), policymakers may encourage the establishment of the transaction, providing incentives to the involved actors (either to both of them or just to the one with the lower contractual power that could be more motivated to not enter or leave the transaction). In this way positive externalities could be internalized by actors contributing to the improvement of environmental benefits. Taking into account the *local* character of sustainable supply chains, such incentives may also be used within regional and inter-regional environmental policies frameworks. However, there is still need for efficient tools which can integrate the accounting of externality reduction in the computation process in decision-making. In this sense, this paper might be a leading one to indicate research need for such tools facilitating the application of environmental accounting and (economic-oriented) decision-making simultaneously.

This paper proposes also a novel business strategy development as *circular economy* calls for new business models that would facilitate the operation of the waste-based businesses to gain value-added while preserving primary resources.

Further research may include the optimization of the payoffs of the ISR firms taking into account the instable character of reusable end-of-life products (whose supply chains

structurally differ from ISR-based supply chains), in terms of quality level and continuity of supply. Moreover, in future agent-based simulations, we aim to take into account other operations-oriented dynamic parameters, e.g. physical quantity of resources, presence of environmental regulations, and alternative buyers/suppliers. Such factors may affect the contractual power and willingness to cooperate of companies. Our future research avenue is modeling actors' behavior through multi-player iterative games, when firms are involved in multi-dimensional Industrial Symbiotic Networks (ISNs).

Abstract

Traditional intellectual capital (IC) frameworks are often too broad to provide actionable recommendations for managers. To overcome this limitation, it has been suggested that more contextually informed frameworks could be developed. Accordingly, the aim of this paper is to identify and classify the knowledge resources that shape IC in the marketing function, as well as to test the content validity of the proposed framework, and to diagnose the strengths and weaknesses of Spanish firms in terms of marketing-related knowledge resources. To identify and classify knowledge assets in the field of marketing, we followed a literature-grounded approach. More precisely, we set out from the IC categories identified in the global IC literature (namely, human capital, organizational/structural capital and social/relational capital) and tried to identify the specific content of each of them in the marketing function, based on its characteristics and recent evolution. Afterwards, we tested the content of the new framework in a group of companies with different profiles (manufacturing/service, B2B/B2C, high-tech/low-tech, large/mid-sized) and carried out a survey in a representative sample of Spanish firms with at least 100 employees to diagnose their situation in terms of marketing-related IC. As a result, this paper presents a marketing-related IC architecture made up of three main categories, nine subcategories and eighty items. Moreover, the survey results demonstrate that marketing-specific human capital is the most developed knowledge resource in Spanish firms, followed by marketing-specific relational capital.

On the contrary, marketing-specific structural capital presents the lowest level of development.

Keywords – Intellectual capital, Knowledge resources, Marketing, Spain.

Paper type – Academic Research Paper.

1 Introduction

According to the knowledge-based view (Grant, 1996; Spender, 1996), knowledge is the most strategically important resource of the firm and the cornerstone of competitive advantage and value creation. Thus, managers must focus on producing, acquiring, retaining and utilising knowledge (Spender, 1996). The overall set of knowledge resources of an organization constitutes its intellectual capital (IC) (e.g., Edvinsson and Malone, 1997; Sveiby, 1997; Bontis, 1998).

The influence of IC on performance has been widely studied in previous research (e.g., Bontis *et al.*, 2000; Wang and Chang, 2005). However, most of the studies adopt a very aggregated approach, classifying knowledge resources at a very broad level (e.g., human capital, structural capital and relational capital of the whole company) and without reaching enough level of detail that could give rise to actionable recommendations. For example, human capital is grasped by means of indicators such as “our employees are highly skilled”, or “our employees are considered the best in our industry” (e.g., Bontis *et al.*, 2000; Subramaniam and Youndt, 2005) which do not clarify the specific skills and knowledge that employees should master. Similar general level aggregation takes place with structural capital and relational capital. As a result, IC-performance studies provide managers with very vague and general advice about what knowledge resources they need to promote to enhance performance (Chiucchi and Montemari, 2016; Kianto *et al.*, 2018).

In this regard, addressing the specific needs and configurations of IC in different functional areas of the firm represents a further step that may help overcome the above problem. In this study we have chosen to focus on the marketing function, which represents quite distinct, but still broadly relevant contextual domain for firms’ IC. This constitutes a relevant area to focus on, given its key role in attracting and retaining customers, and in shaping innovation and value creation efforts, which all are essential for company survival. Moreover, the numerous and rapid changes in the marketing field considerably affect the knowledge resources needed to successfully perform this function. New technologies cause the interaction between individuals and firms to occur through different channels, devices and touchpoints. As a result, new types of data and analytic approaches are emerging, as well as new marketing models, concepts and tools.

Considering this, the aim of this paper is (1) to identify and classify the knowledge resources that shape IC in the marketing function, (2) to test the content validity of the proposed framework, and (3) to apply it to diagnose the strengths and weaknesses of Spanish firms with at least 100 employees in terms of marketing-specific knowledge resources.

2 Disentangling marketing-related IC

2.1 Intellectual capital

As stated by Martín-de-Castro *et al.* (2011), providing an unified or unique definition of IC is almost impossible, considering the countless definitions that can be found in the literature. Nevertheless, Aramburu and Sáenz (2011) established that most of them can be classified into two groups: knowledge-based and holistic. While the knowledge perspective conceives IC as the sum of all knowledge resources that firms utilize for competitive advantage (Youndt *et al.*, 2004; Subramaniam and Youndt, 2005) the holistic perspective defines IC as the sum of the ‘hidden’ assets of the company not fully included on the balance sheet (Roos and Roos, 1997). This includes knowledge, but also employees’ attitudes, loyalty, motivation and flexibility (Marr, 2006), corporate culture (Brooking, 1997), relationships with customers and suppliers, brand names, trademarks and reputation (Sveiby, 1997), to name but a few. In this research, we adopt the first perspective, and thus we equate IC to “knowledge capital” (Reed *et al.*, 2006).

Whichever the perspective adopted, IC is split up into different components. The most widespread classification distinguishes between three main categories: human capital, organizational/structural capital and both internal and external social/relational capital (Reed *et al.*, 2006). From the knowledge perspective of IC:

- *Human capital* refers to employees’ knowledge, skills and abilities (Youndt *et al.*, 2004). The challenge of human capital is that firms have no complete control and management of employees and their knowledge (Roos, 1998).
- *Organizational/structural capital* consists of the institutionalized knowledge and codified experience stored in memory devices such as databases, manuals, routines, patents and the like (Youndt, *et al.*, 2004; Subramaniam and Youndt, 2005). Unlike human capital, structural capital is completely owned by the organization (Sveiby, 1997).
- *Social/relational capital* refers to the knowledge resources embedded within, available through, and derived from a network of relationships (Youndt *et al.*, 2004). These networks of relationships could be both internal to the firm (e.g., internal networks among employees, supervisors and between departments) and external (e.g., connections with customers, suppliers and other external partners; Edvinsson and Malone, 1997; Sveiby, 1997; Bontis, 1998).

Additionally, some studies have included other categories in an attempt to expand the traditional IC framework. Some of these ‘new components’ are: renewal capital, defined as the “actualized learning capability of the firm” (Kianto *et al.*, 2010) and entrepreneurial capital, conceptualized by Erikson (2002) as the individuals’ ability to pursue opportunities regardless of the resources they control. However, our study focuses on knowledge viewed as a stock rather than as a capability, and renewal capital and entrepreneurial capital are of the latter kind. Given this fact, this paper focuses only on the first three categories explained above, which are also the most widely utilized in the IC literature.

2.2 From IC at the company level to IC in the marketing function

Setting out from the knowledge perspective of IC, we define marketing-specific IC as *all the valuable marketing-specific knowledge resources that an organisation has access to and manages in order to develop its marketing capabilities and achieve its marketing-related goals*.

Notice that an organization does not need to own a resource to be able to utilize it (Helfat *et al.*, 2007). For instance, firms do not own their employees, but they benefit from their knowledge and expertise. Likewise, external alliances may enable them to have access to certain resources that they do not possess, such as market knowledge regarding a specific geographical context or knowledge regarding some type of technology.

It should be noted that in the above definition, marketing capabilities fall outside the scope of marketing-specific IC. Rather, marketing capabilities are seen to be grounded on the knowledge stocks that integrate marketing-specific IC (Kogut and Zander, 1992; Grant, 2010). These capabilities contribute to market performance and company growth by enabling the acquisition of new clients, the retention of existing ones and increased sales to already existing customers.

To build up the IC architecture of the marketing function, we need to identify the main knowledge objects that marketers need to deal with in order to perform their job, and see how they spread in individuals, the organization itself, and internal and external relationships (i.e., the main categories that make up IC in a company).

In the next paragraphs, we discuss the logic that gave rise to the identification of these knowledge objects (i.e., the different entities people in the marketing department should know about):

- *Customers* – The definition of marketing provided us with the first knowledge object. According to Kotler and Armstrong (2018), “marketing is the process of engaging customers and building profitable customer relationships by creating value for customers and capturing value in return” (p. 53). Therefore, *customers* constitute the first knowledge object of the marketing function. Marketing professionals must understand them in order to fulfil their mission.
- *Products and/or services* – Second, building and maintaining profitable customer relationships depends on delivering superior customer value and satisfaction, which in turn depends on product/service performance relative to customers’ expectations (Kotler and Armstrong, 2018). Thus, *products and/or services* (i.e., the company’s offering) constitute the second knowledge object of the marketing function. People in the marketing department must know the firm’s offering and ultimately contribute to improve it and/or to develop it.
- *Market(s)* – On the other hand, “marketing involves serving a market of final consumers in the face of competitors” (Kotler and Armstrong, 2018; p. 34). Accordingly, understanding the marketplace constitutes the first step of the marketing process, which gives rise to the third knowledge object of the marketing function: the *market* or markets in which the company operates. Marketing professionals must understand the market to adequately differentiate and position the company’s offering.

- *Internal context* – This view of the external context needs to be complemented with knowledge about the *internal context* of the firm (i.e., its mission and vision, overall constraints, interdependencies between different organizational units...) to guarantee that the decisions adopted, and the actions promoted are consistent with the overall setting.
- *Disciplinary knowledge* – So far, we have argued that marketers must know about customers, products and/or services, markets, and the internal context of the firm. However, to perform their job, marketing professionals also need a set of marketing-related concepts and theories (i.e., *disciplinary knowledge*; Rossiter, 2001) that help them to develop and implement a successful marketing strategy and address different work situations.
- *Know-how* – All the above knowledge involves “information-type” (Kogut and Zander, 1992) or “knowing about” knowledge (Grant, 2010). In other words, knowledge about traits and characteristics; facts and figures; ideas, concepts, theories and propositions. However, this type of knowledge constitutes only one side of the coin. The other side is *know-how* or knowledge about how to do something (in our case, a marketing task or activity). This kind of knowledge can only be partially captured by means of statements, diagrams and/or images that describe a method, process or practice, and is mainly tacit (Kogut and Zander, 1992). “It involves skills that are expressed through performance” (Grant, 2010; p. 163). Nevertheless, these personal skills are distinct from organizational capabilities. The latter “involve coordination between organizational members such that they integrate their skills with one another and with a variety of other resources” (Grant, 2010; p. 154).

Thus, once the knowledge objects of the marketing function have been presented, in the next sections we will show how they fit into the three types of “knowledge containers” that are considered in the IC literature (employees, the organization itself and relationships).

2.2.1 Marketing-specific human capital

Marketing-specific human capital (HC) refers to *all the knowledge residing among the marketing and sales people*. In other words, it consists of what employees of the marketing department know.

Unlike other IC categories (i.e., organizational/structural capital and social/relational capital), in which different subtypes of knowledge containers could be identified (see the next sections), in the case of HC, employees are the only “knowledge recipients”. Thus, within this IC category, specific subcategories will be mostly related to the knowledge objects previously described. Putting aside knowledge about the internal context of the firm (which we think is mostly embedded in internal relationships between the marketing department and other departments in the company), the IC subcategories considered in this domain are: customer knowledge; product/service knowledge; market knowledge; educational background (which constitutes the main source of disciplinary knowledge) and experience (which could reinforce disciplinary knowledge, but also others); and marketing-related skills (i.e., know-how-related knowledge).

Based on performance literature regarding marketing and sales staff, we have then identified the specific knowledge items to be considered within each subcategory:

- *Customer knowledge* – It refers to employees' knowledge about customers which allows satisfying their needs better than competitors (Saxe and Weitz, 1982; Rapp *et al.*, 2006). This subcategory is made up of 6 key aspects that people in the marketing function should know about their clients: needs, expectations, satisfaction levels, personality, behaviour and circumstances.
- *Product/service knowledge* – It refers to employees' knowledge about product specifications, applications and customer use situations (Cravens *et al.*, 1993; Rapp *et al.*, 2006). It encompasses 5 key issues that marketers should know about the company's offering: product/service specifications; product/service applications and functions; differences from competitors; potential causes of operating failure; and the firm's latest product and/or service developments.
- *Market knowledge* – It refers to employees' knowledge about the industry in which the company operates (Schillewaert and Ahearne, 2000; Rapp *et al.*, 2006). It is made up of 4 elements that show employees' knowledge about the industry: information on industry trends and relevant events, and information on competitors' activities and strategies.
- *Educational background and experience* – It refers to the formal educational background of employees in the marketing domain, to their updated knowledge in this area, and to their professional experience in the marketing and sales field, as well as in the industry in which the company operates. As already mentioned, the first two aspects included in the definition are tightly connected to disciplinary knowledge, while experience could also reinforce the other three types (i.e., customer-, product/service- and market-related-knowledge), as well as know-how. This subcategory is made up of 5 items gathering the different aspects included in the definition.
- *Marketing-related skills* – It refers to those skills that are deemed relevant for a professional in the marketing and sales field. Thus, it represents the know-how embedded in individuals. After a literature review, we have come up with 10 skills that are deemed relevant for a marketing professional (e.g., Schillewaert and Ahearne, 2000; Rapp *et al.*, 2006; Piercy *et al.*, 2009; Guesalaga, 2016): targeting skills, adaptive skills, problem solving skills, communication skills, planning and organizational skills, expenditure management skills, IT skills, social media management skills, teamwork skills, and creativity.

2.2.2 Marketing-specific structural capital

Marketing-specific structural capital (SC) refers to *all marketing-related knowledge residing in information systems, databases, documents, manuals, routines and procedures, as well as in any other physical and/or digital artefact*.

Given the plethora of marketing-oriented IT solutions that already exists (e.g., CRM, customer experience management software, customer journey tracking software, social media management software, marketing intelligence software and the like) and the

tremendous possibilities offered by data analytics, it seems reasonable to distinguish between organizational knowledge generated by means of different computer-based data processing tools, and more traditional forms of “organizational memory” (Walsh and Ungson, 1991), which do not involve data processing. Hence, according to the origin of the knowledge resource and its container, we distinguish between marketing-specific IT capital and marketing-specific organizational memory. Each subcategory will encompass several items regarding different knowledge objects:

- *Marketing-specific IT capital* – This subcategory focuses on marketing-related knowledge generated by different types of IT solutions. Based on an analysis of existing solutions in the market, a group of 12 knowledge resources has been identified, of which 7 refer to customer knowledge (knowledge regarding potential new customers, customers’ interests and concerns, customers’ sentiments and emotions, customer behaviour, customers’ journey stage, customers’ profitability, and existing customer groups and/or segments); 2 refer to product/service-related knowledge (product and/or service performance, and opportunities for product/service improvement and/or development); another 2 correspond to market knowledge (knowledge about top industry insiders and influencers; and about market trends); and 1 relates to know-how (performance of the marketing and sales staff).
- *Marketing-specific organizational memory* – It refers to different types of stored knowledge related to marketing that employees can access physically and/or digitally. Based mainly on the knowledge management literature (e.g., Argote, 2006; Dalkir, 2011; O’Dell and Hubert, 2011), 7 items have been proposed within this subcategory, of which 1 corresponds to customer knowledge (relevant and easily accessible information records about customers); another 2 to market knowledge (relevant and easily accessible records about competitors and market trends); another 1 to the internal context (“who knows what” directory) and 3 to know-how (availability of well-established routines and procedures, best practices and lessons learned, and information records on key projects, deals and/or campaigns).

2.2.3 Marketing-specific relational capital

Marketing-specific relational capital (RC) refers to *all marketing-related knowledge generated, transferred and preserved through interpersonal relationships*.

Depending on the actors involved and on their internal or external nature, these relationships could be grouped into four subcategories, each of them including knowledge items from different knowledge objects. The four subcategories are:

- *Internal relational capital (department level)* – It refers to the knowledge generated, transferred and preserved through interpersonal relationships within the marketing department. Given that, in the case of social/relational capital, the existing IC literature tends to focus on the relationships themselves, rather than on the knowledge generated through them, we have been unable to base on past research to propose the content of each subcategory. In the case of department-level relationships, we suggest that personal interactions between people from the marketing function could give rise to relevant insights about customers (1 item),

markets (3 items) and know-how (3 items). From a more general perspective, we also think that these personal interactions could give rise to new perspectives that challenge existing assumptions regarding any type of knowledge object (1 item).

- *Internal relational capital (inter-department level)* – It refers to the knowledge generated, transferred and preserved through interpersonal relationships between people from the marketing department and people from other departments or functions. In the case of this subcategory, we think that personal interactions between people from different departments contribute to a large extent to reinforcing knowledge regarding the internal context of the firm. Altogether, 4 knowledge items have been proposed for this knowledge object, which refer to a shared understanding of the overall firm setting (company vision, interdependencies between departments, problems and challenges, and system constraints). Customer knowledge (1 item) could also be strengthened through these relationships (for instance, people from other departments such as engineering can also interact with customers and gain relevant information for the marketing department), as well as some know-how related aspects (2 items regarding how to better integrate and/or coordinate work from different functions and departments, and problem diagnostic and solution). As in the previous subcategory, 1 more item has been included regarding the possibility of generating new perspectives that could challenge existing assumptions.
- *External relational capital (customers)* – It consists of the knowledge generated, transferred and preserved through interpersonal relationships between marketers and customers. Of course, personal interaction with customers will improve customer knowledge (2 items), but also product/service knowledge (2 items regarding the discovery of unsolved problems and of improvement opportunities), market knowledge (1 item regarding relevant insights about competitors) and know-how (1 item related to effective ways to diagnose and solve problems). As in the previous subcategories, 1 more item has been added about the generation of new perspectives that could challenge existing assumptions.
- *External relational capital (other external actors)* – It consists of the knowledge generated, transferred and preserved through interpersonal relationships between marketers and other external actors. This type of personal interactions could give rise to substantially increased knowledge about the market in which the company operates (5 items), but it could also provide the marketing department with some know-how related insights (2 items), as the discovery of new and relevant practices that could be adopted by the company, and effective ways to diagnose and solve problems. Like in the other subcategories, 1 more item has been included regarding the generation of new perspectives that challenge existing assumptions.

2.2.4 Content validation

Once the marketing-specific IC model with all its subcategories and items was developed, a pre-test was carried out to verify whether the proposed framework was comprehensible for the companies, and to identify whether either possible relevant elements were missing, or whether some of the knowledge stocks included could be left

over. Six companies participated in this validation test, which were carefully chosen to ensure diversity between different combinations of manufacture/service, B2B/B2C, high-tech/low-tech and medium-sized versus large-sized companies. The pre-test resulted in the confirmation of the proposed model about marketing-specific IC.

3 Diagnosing marketing-related IC in Spanish firms

After the pre-test validated the content of the marketing-specific IC framework, a representative survey was carried among Spanish firms in order to diagnose their strengths and weaknesses in this respect.

3.1 Methods

3.1.1 Sample and data collection

The population of the research was made up of Spanish companies with at least 100 employees. This threshold number was established to guarantee that companies had a well-established marketing and sales function. SABI database (Sistema de Análisis de Balances Ibéricos; System of Iberian Balance Sheet Analysis) was utilised to identify the companies that configured the population involved in the research. The total population was made up of 2,346 firms, which were classified into different groups according to different combinations of manufacture/service, B2B/B2C, high-tech/low-tech and medium-sized versus large-sized firms.

Once the sample size to carry out a representative study was calculated (342 firms), the target population was contacted by phone and a follow-up system was put in place to guarantee that proportions of the above-mentioned groups were preserved. The final sample was made up of 346 companies that answered the emailed or phone survey, for which total confidence was guaranteed. Given space limitations, details about the composition of the sample are omitted.

85.26% of the respondents held a managerial role in the marketing domain, and several of them highlighted the fact that the measurement instrument revealed to be a very complete self-assessment tool that allowed them to carry out an in depth-analysis of their strengths and weaknesses as a marketing department under a new and extremely relevant light. Thus, this also supported the content relevance of the proposed framework.

3.1.2 Measures

The items utilized to analyse the marketing-related IC categories were measured by means of 7-point Likert scales (1 = strongly disagree, 7 = strongly agree; or 1 = not at all, 7 = very satisfactorily), and were based on the above described framework.

3.1.3 Statistical analysis

Descriptive analysis of the data collected were performed using SPSS software version 25. The following section shows the results obtained.

3.2 Findings

For space reasons, only findings regarding the summary item of each of the marketing-related subcategories are presented. As can be seen in Table I, the most developed subcategories of marketing-specific IC in Spanish firms are those related to human capital, while those regarding structural capital constitute a clear weakness. On the contrary, relational capital occupies an intermediate position.

Table I. Descriptive analysis – Summary items

<i>Variable</i>	<i>N</i>	<i>Mean</i>	<i>SD</i>
Marketing-specific HC customer knowledge	346	5.58	1.13
Marketing-specific HC product/service knowledge	345	6.05	1.01
Marketing-specific HC market knowledge	344	5.29	1.23
Marketing-specific HC educational background and experience	342	5.77	1.09
Marketing-specific HC marketing-related skills	344	5.75	0.96
Marketing-specific SC IT capital	345	4.66	1.45
Marketing-specific SC organizational memory	345	4.60	1.47
Marketing-specific internal RC department level	342	5.10	1.30
Marketing-specific internal RC inter-department level	343	5.04	1.34
Marketing-specific external RC customer-related	343	5.44	1.20
Marketing-specific external RC other external agents	339	5.12	1.27

4 Conclusions

This paper constitutes a relevant contribution to the IC literature, as is among the first ones that tries to deploy the general IC framework into a particular functional area of the firm (namely, the marketing function), which allows a more in-depth and meaningful assessment of a company's knowledge resources. Indeed, the model developed represents a complete self-assessment tool that allows marketing managers to carry out an in depth-analysis of the strengths and weaknesses of their department under a new and extremely relevant light. It also opens the way towards a more fine-grained set of IC-capability-performance studies that will allow to discover the very specific knowledge resources that managers should promote in order to enhance organizational capabilities and performance.

Reflecting on the Intellectual Capital Literature: Is the Field at another Crossroads Point?

Andreea Bordianu

Leeds University Business School
United Kingdom

Abstract

The paper reviews, reflects on and critically analyses the intellectual capital (IC) accounting literature to examine whether the way we conceptualize IC is a possible cause for the stalemate in the field. Future avenues of research are suggested by looking into the practices of integrated reporting and big data technologies for pragmatic solutions to IC problems.

The literature review takes a structured approach and uses Alvesson and Deetz (2000) critical framework for analysis in order to reveal the hidden structures behind the literature and to bring further insights into the different dimensions of IC.

Two types of literature review are brought together to deepen the analysis and provide an account of what is already known within IC accounting literature and map what is yet to be uncovered, while reflecting on the limitations of past efforts. The study identifies gaps of knowledge where more research would be useful by grouping the literature into specific themes of interest that problematizes the IC research: knowledge, classification and categorization, accounting measurement and performance.

The paper is relevant to researchers working within the IC field and connected areas, such as integrated reporting and sustainability accounting. Various avenues for resolving the issues which have placed IC at a cross-roads point are suggested to revive the field and to prevent others from facing the same problems.

1. Introduction

The demand to better understand and to account for intellectual capital (IC) has never been more acute. In order to gain competitive advantage in the digital era of knowledge and information, companies have to rely on IC resources as most forms of physical and financial assets are commodities which have been deemed unable to achieve further economies of scale (Alcaniz et. al., 2011; Jeny & Moldovan, 2018). The new “Industrial Revolution 4.0” (Schwab, 2017), characterised big volumes of data, fast developing digital technologies and large social media spread, all of which generate intangible value, has further increased the reliance on IC resources.

In an economy that emphasizes its reliance on IC to achieve high levels of performance, it is important to understand the mechanisms through which this resource adds value to a company, to uncover the unseen and untapped intangible value created by

companies of the digital era (Alcaniz et. al., 2011; Bonacchi et. al., 2011). However, the emerging picture of IC is somewhat confusing (). In reflecting on the theory and practice of IC, one of the founding fathers, Lief Edvinsson (2013), states that “*IC remains invisible fuzzy dimension*” and he asks whether “*in grappling for meaning of IC, we are suffering a kind of learned blindness*”. There are both academic and practice issues that contribute to the confusion around IC.

From an academic perspective, a multitude of definitions, models and frameworks for IC abound. The literature appears to have reached agreement on IC consisting of three elements: human, relational and structural capital (Secundo et.al., 2017). Nevertheless, what each one of these elements comprise of in their turn is less consistent between authors. Therefore, researchers have yet to agree on a holistic and comprehensive understanding of this concept (Abhayawansa, 2014). Additionally, the complexities of all IC dimensions highlighted by the multiple frameworks are not acknowledged and reflected into empirical research (Andriessen, 2004a; Dumay & Garanina, 2013).

Albeit being considered central to value creation, researchers still have difficulties explaining the exact mechanisms through which IC adds value. Is IC an input or an output in the process of value creation? Is the synergy created by the interaction of its components IC or added value? Some researchers argue that the measurement of IC could aid the understanding of the value creation process (Neely et. al., 2004).

Unsurprisingly, there are still no solutions to the measurement of IC. Mouritsen (2006) suggested that IC measurement problems cannot be addressed through ostensive research which concentrates on developing classification frameworks and, consequently, it focuses on stocks of IC and answer questions of “*what*”. Instead, he asserted that performative research, which offers an understanding of IC in action from a flow perspective is more appropriate because it answers questions of “*how*” (Dumay, 2009; Guthrie et.al.,2012). Despite the call for action research to better understand IC, Dumay (2013) observes that, “*many IC researchers are stuck in an evaluatory trap*”. They continue to develop further frameworks rather than providing a performative and critical research on IC. The focus on the practice of IC approaches and models rather than on its theoretical conceptualization (Secundo et.al.; 2015) created a gap between the theoretical and practical developments in the field, further confusing the meaning of IC (Edvinsson, 2013). Furthermore, through Mouritsen’s (2006) call IC has become a management issue rather than an accounting issue. This shuffled the debate from accounting for IC to business models, strategy and integrated thinking all of which still haven’t solved the problem of measurement and performance implications of IC. Additionally, it brought confusion on whether IC is a management system, at best a management accounting system, or an accounting tool to measure and create value.

From a practice perspective, companies initially found value in the IC frameworks to help them reflect their worth beyond financial outcomes. Multiple IC disclosure projects have been launched such as RICARDIS, EFFAS, WICI, Wissensbilanz, InCas, CADIC. Recently, companies and countries which have embraced the disclosure and management of IC are slowly starting to give up this practice with its pioneer Skandia leading the way (Dumay, 2016). In support, recent studies which investigate IC in action have found that

managers who are actively managing this resource are not making use of the IC terminology (Chiucchi, 2013). Instead they resonate much better with concepts such as the “*balanced scorecard*”, “*key performance indicators*” or “*human capital*”. In Denmark companies are quoting “*low perceived value of IC statements, both internally from a knowledge management perspective and externally in relation to the disclosure practice*” as the main reason behind their decision to abandon IC disclosure (Schaper, 2016 p.52). IC statements have been morphed into the new accounting initiatives of integrated reporting and sustainability accounting which struggle to gain momentum and be adopted by companies.

Adding to academic and practice issues, there have been limited recent theoretical developments and the scarce publications on the topic are not optimistic about the future of IC as a field of research (Dumay, 2016). On these accounts, after more than three decades of research, there would seem important differences between researchers’ and practitioners’ conceptualisation and understanding of IC still exist (Abhayawansa, 2014). Mary Barth (2018, p.7) explains it better: the issue of accounting for IC is not new but fixing it “*never seems to get traction*”. Similar to what Chatzkel was observing back in 2004, IC is in search of clarity and continues to fight for its legitimacy as a field of research. Hence, the field finds itself yet again at another cross-roads point. The need for a renewal of theoretical work within the IC field is apparent in order to resolve the impasse. Providing some clarity into our understanding of this concept, its characteristics and its evolution as a concept would be timely and provide a firmer foundation on which to build future research.

This paper advocates taking a step back into IC literature to examine whether the way we conceptualize this term is a possible cause for the current decline. It builds on previous important literature reviews on the subject, such as Petty and Guthrie (2000), Guthrie et. al. (2012), Dumay and Garanina (2013). However, compared to the previous studies, this one is theoretically oriented in that it does not only focus on the meta-analysis of the literature corpus according to well-established categories, but it delves into theoretical contribution up to date. Subsequently, it systematically reviews and reflects on what is already known within the IC literature, maps what is yet to be uncovered, while critically examines the limitations of past efforts. As a first attempt in the field, the study adds another layer of analysis by grouping the literature into themes overlapping the current issues surrounding IC as previously presented in the paper. As such, it identifies common threads, inconsistencies and gaps in the conceptualization of IC across the following themes:

1. **Knowledge theme** groups research which focuses on explain the knowledge and information characteristics of IC
2. **Classification & categorization theme** comprises of studies which have dealt with the IC division into separate elements and the creation of classification frameworks.
3. **Accounting measurement theme** concentrates on accounting measurement and reporting of IC
4. **Performance theme** consists of studies which aim to explain how IC is involved into the value creation process.

Finally, the paper suggests future avenues of research by investigating whether the practices integrated reporting and big data technologies can provide pragmatic solutions to IC problems and move the field past the cross-roads point or, by contrast, they suffer from the same fallacies. The rest of the paper is organized as follows. First, the method used to review the literature is presented next. Second, we describe the findings of the structured literature review and the critically analyse the research under each one of the themes of interest identified. Third, we investigate the lessons which can be learned from the current research into integrated reporting and big data. Finally, the paper presents futures avenue of IC research to move the field past its crossroads point.

2. Method

In order to identify the relevant IC literature to be included in the study we composed a list of journals which published papers in the field of IC by bringing together the lists of journals previously included in literature reviews on the topic. We identified twenty-five peer-reviewed journals known to be IC centric. We chose to go beyond accounting journals to include management one. While the focus of the review is on the accounting discipline, management has contributed greatly to our understanding of intellectual capital. As such, we consider it is essential to include these papers to have a better grasp of IC conceptualization and its implication for the accounting profession. The complete list of journals included in the review can be found in the appendix.

We performed a keywords based search via Web of Science using keywords such as intangible asset (Sveiby,1997), goodwill (Luthy,1998), immaterial asset (Edvisson&Malone,1997) or human assets (Andriessen & Tiessen,2000), strategic-firm resources (Barney,1986), invisible assets (Itami,1987), strategic firm-specific assets (Dierickx & Cool,1989), intangible assets (Hall,1992), core competencies (Prahalad & Hamel,1990; Kaplan & Norton,1992), firm capabilities (Nohria & Eccles,1991), knowledge assets (Teece,1998), knowledge-based resources (Wiklund & Shepherd,2003), dynamic capabilities (Teece et. al. ,1997) and intellectual capital.

The resulting number of articles have been grouped into the proposed themes by examining their titles and the abstracts. Within each theme we used Guthrie et. al. (2012) classification system for categorizing the articles. During this pilot stage two authors read the papers based on both abstracts and full text of the articles to discuss and make preliminary classifications. This resulted in a slightly modified coding scheme as outlined in Table 1. Then one author manually coded all the papers while the second and third author checked the coding for consistency. Occasionally, when there was coding ambiguity, the authors discussed the contents of the article until they agreed on the same codes. The advantage of manual coding is when words with similar meaning such as ‘human capital’ and ‘employees’ are encountered, they can be understood in their true sense and coded accordingly. Thus, manual coding allowed the researchers to use implicit knowledge of the situation so they could effectively interpret idiomatic and metaphorical text and complex subordinate phrases.

Finally, we utilised the classifications to establish a range of descriptive statistics for each theme, allowing us to understand the patterns emerging from the reviewed articles. This provides the basis for our meta-analysis and discussion of the IC field over the period in question. The following section outlines the meta-analysis and is followed by an open discussion of our findings.

2.1 Knowledge theme

Researchers have formulated identification criteria to indicate which organizational resources can be acknowledged as intellectual capital. Knowledge definitions link IC to knowledge as an identification criterion.

The first stage of IC research argued that only resources which have a knowledge component and produce value for the company can be classified as IC (Edvinsson & Malone; 1997). As such, Edvinsson and Malone (1997) define IC as *“knowledge that can be converted into value”* and Stewart (1997) states IC is *“packaged useful knowledge”*. At this point in time, knowledge is an attribute of the individual (Nonaka & Takeuchi, 1995). The IC definitions reflect this aspect. Hudson (1993) presents IC as *“a personal asset of individuals, a combination of genetic inheritance, education, experience, and attitude about life and business”*. Similarly, Edvinsson and Malone (1997) see it as *“combined knowledge, skill, innovativeness and the ability of the company’s individual employees”*. From this perspective, organizational resources are passive and centred around the human capital which enacts them. Subsequently, IC is about employee creativity, ideas and intuition, their ability to make sense of their work world and make appropriate decisions. In Nonaka and Takeuchi’s (1995) terms it is about the tacit knowledge which resides in the mind of the employees. As such, how to unpack an individual’s tacit knowledge and share it with others becomes the key organisational problem (Mouritsen & Larsen, 2005).

The second stage of IC research tries to solve this problem by putting forward the idea that IC represents only formalized knowledge which is visible in the organizational routines and procedures (Mouritsen et al., 2001). Luthy (1998) states that IC is *“something that is knowledge based, captured in an identifiable form, and useful in organizations”*. Ernst & Young (cited by Wall et al., 2004) view IC as *“intellectual material that has been formalised, captured and leveraged to produce a higher-valued asset”*. The process of formalizing knowledge decentres the individual and puts an emphasis on the *“knowledge and knowing capability of a social collective, such as an organization, intellectual community, or professional practice”* (Nahapiet and Ghoshal, 1998). Consequently, IC *“should not be person centred, but centred on collective processes and procedures”* (Mouritsen et al., 2001).

Decentring the role of human capital is a two-fold issue. On one hand, it suggests that in a collective human capital is one among several networked resources. Subsequently, other elements of IC, structural and organizational capital, can be equally important in the mix (Mouritsen and Larsen, 2005). On the other hand, the management of the networked knowledge resources and their effects become the new organisational problems to be questioned.

The latter issue evolved into the focus of the third stage of IC research which analysed how managers mobilize the bundles of knowledge resources to achieve high levels of performance in an organisational context. Specifically, it looked at where and how the management identifies, how much it invests, how it categorizes and how it makes decisions based on IC information (Mouritsen & Larsen, 2005). From this point of view, the management is the entity which is supposed to know the relation between individual and organizational knowledge and separate the two to make them manageable in the value creation process. As such, the third stage of IC research was concerned with the disentanglement of knowledge resources. However, the individual is part of the collective (organisation) and, by interacting with it, knowledge is continuously gathered, shared and transformed. Therefore, it is difficult to set boundaries to knowledge and it is widely diffused within the organisation and beyond it.

As a consequence of knowledge being so diffuse and without boundaries, IC is partially controlled or owned (Lev, 2001). Partial ownership and control imply that IC has only partial excludability, in other words, it is very difficult to legally prevent others from appropriating this resource or drawing economic benefit from it (Kim & Mauborgne, 1999). These characteristics are a two-edged sword with respect to the possible effects of IC on the organizational life.

On one hand, possessing a resource with these characteristics could be beneficial for a company because it makes IC a non-rival resource, meaning that it can be simultaneously used by many users without reducing its value (Lev, 2001; Andriessen, 2004b; Roos et. al., 2005). An obvious illustration of this characteristic is a database which can be used by different people at the same time without losing its value. Moreover, taking into consideration that information could be added to this database, its value could be enhanced. On the other hand, it could be detrimental to a company because it provides opportunities for free-rider effects. For example, the technology innovated in a research and development process can be used by other companies to develop other products, as patents are usually obtained for products and not for the technology itself (Flostrand, 2006). Therefore, partial ownership and excludability characteristics show that the concept of IC is not synonymous with value creation. There are as many opportunities to lose value through IC as there are opportunities to add value. Also, it explains why some researchers are susceptible to accepting the notion of competitive advantage as an equivalent to intellectual capital.

Knowledge definitions reduce the area of organizational resources which can represent IC by advocating “*knowledge*” as an essential identification criterion. Implicitly it had to provide philosophical explanations and take epistemological stances (Roos & Roos, 1997). Questions such as “*what is knowledge?*”, “*what do we mean by knowing?*” and “*how is knowledge developed?*” which, for a long time, have represented key concerns in philosophy, have been transferred to the understanding of intellectual capital. Answering these questions showed that IC is a bundle of networked knowledge resources which can equally create and destroy value. Also, it raised concerns about the volume, quality and even the existence of IC (Spender et.al., 2013).

2.2 Classification and categorization theme

The definitions discussed previously describe IC as the new factor of production capable of deriving competitive advantage due to its knowledge component, but only if it is leveraged and formalized. These definitions highlight that if IC is the key value driving resource at a company's disposal, managers need to be able to identify and measure it in order to achieve high levels of performance. One cannot manage what cannot be described (Andriessen, 2004b; Spender & Marr, 2006). Classification definitions have tried to address this concern. Projects such as the Danish IC Statement Guidelines (2003), PRISM (2001), MERITUM (2001) or DATI (2000) classified and categorized IC components and provided a series of instructions about what each IC element should comprise of and how they can be "*measured*" (Youndt et.al., 2004). However, for these projects, the purpose of measuring IC is not to accurately represent the value of intellectual capital, but to make it more accessible to managers and markets to make investment decisions. As such, they make use of non-financial indicators, narratives, visuals and diagrams to indicate the potential value of intellectual capital.

At first, researchers developed classification definitions which divided IC into individual elements and separately defined each one of them. At this stage, researchers were not concerned with explaining the performance implications of IC, they were merely acknowledging the existence of this resource within organizations. As such, the majority of classification models in the first stage take a static perspective on IC (Kianto et. al., 2014) and consider it a stock of knowledge accumulated at one moment in time (Bontis, 1998). The static- stock angle, allows for the IC elements to be stable and separable entities. Nonetheless, as mentioned in the knowledge definitions the focus was falling on the individual and the human capital component.

The second stage of IC research highlighted that IC elements are interrelated and sometimes integral to each other (Mouritsen et. al, 2001). Consequently, researchers started to explain through classification models how the various IC elements interact with one another into value creation chains. For example, Edvinsson (1997) describes this process in the following way: "*The financial focus is the roof. The customer focus and process focus are the walls. The human focus is the soul of the house. The renewal and development is the platform.*" (Edvinsson, 1997: p. 371). Bollen et. al. (2005) show theoretically that the more human capital companies possess the more structural and relational capital is created, while Nazari and Herremans (2007) argue that structural capital and relational capital cannot be created without human capital. Hence, human capital is the foundation of the value creation process, but similar to the knowledge definitions it is not IC's centre.

Despite studying the dynamics of IC elements interactions, the classification definitions in the second stage are still taking a static perspective on IC (Kianto et. al., 2014). By contrast, the third stage of research approached the IC from a dynamic perspective and was concerned with its value creation implications. It argued that IC is not only about what the organization possesses (stocks of resources), but also what the organization does (flows of resources) (Kianto, 2007). As such, IC comprises both the

value of its individual elements and the production output of their interaction which gets mobilized through knowledge management activities (Heisig, 2010; Veltri et.al. 2014).

For instance, Andreou et.al. (2007) empirically identify the following components of IC - market capital, human capital, decision effectiveness, organizational capital (technology and process capital) and innovation and customer capital. This categorization of IC components implies that, in practice, managers do not perceive IC only as a stock of resources which contribute to the value creation process, but also as a flow of knowledge described by management processes and mechanism, such as decision effectiveness.

In practice, it is difficult to separate stock and flow without establishing a time boundary. The value creation process is clearly complex, based on interactions between assets and elements and requires a continuous feedback between knowledge stocks and flows. Hence, similarly to third stage process definitions it suggests the performance implications of IC cannot be separated from its management.

Across the three stages of research many classification models have been developed which raises questions about how many components IC has and what each of these components in turn comprises (Youndt et. al., 2004). Also, the high number of classification models casts some doubt on the usefulness of defining IC component by component (Dumay, 2009).

Some pundits assert that the models are different only in appearance. As such, they reveal a similar structure for intellectual capital; however, they make use of different terminologies in order to highlight the perspective they are taking on IC (Bontis, 2001). Some of the models have been developed for auditing purposes, others for benchmarking purposes and commercial purposes etc. (Andriessen, 2004b). For example, Brooking's Technology Broker was developed for auditing purposes. The infrastructure assets component of IC in this model is very similar with structural capital element in Stewart's model developed for managerial purposes. In the same way, the renewal and development perspective in Edvinsson's model is similar to Kaplan and Norton's learning and growth perspective.

Nonetheless, there are differences between these models at a deeper level of analysis as the authors assign similar organizational resources to diverse IC components (Andriessen, 2004b). To illustrate, infrastructure assets in Brooking's framework contain only resources which are easily identifiable, while Sveiby (1997) includes in the internal structure not only this resource, but also elements which are not necessarily identifiable, such as organizational culture. Furthermore, the third stage of IC research has revealed that managers classify the components of IC into different categories than the theoretical frameworks. Subsequently, the categorization of IC into components is fragile and may not stand the test of practice.

From this standpoint, separating IC into components would not bring any additional information about its influence and contribution to organizational life (Andriessen, 2004b). In effect, it attempts to create superficial boundaries between elements which in practice are inseparable. "*It puts assets on hold*" while IC works in action through various complementarities between its components and other organisational resources (Mouritsen, 2009).

However, without separating IC into components it would be impossible to explain how IC derives value within an organization. Supporters of separating IC into components assert that the value of a classification resides in its *“ability to function as a heuristic device, as a help construction for interpretation”* (Grojer, 2001: p. 696). Therefore, IC classifications are useful as long as they allow a better understanding of the intellectual components’ behaviour. More specifically, the main interest surrounding IC is how each of its elements is able to create value by itself and together with others. The irony is that in order to understand synergies between IC elements, we need to separate them and in this was pause a process which is supposed to be dynamic. In effect, via measurement and classification resources are put on hold and required to stop interacting and thus required to stop working. In contrast, when resources work in the process they cannot be distinguished from each other and when resources are in action oversight is hampered.

Overall, categorizing IC might have the disadvantage of separating elements which operationally are inseparable, because it takes a stock perspective on intellectual capital. It has, on the other hand, the advantage that it allows a better identification of IC inside an organization and it divides it into elements which are sufficiently different between themselves to justify their separation. Hence, classifying IC into components allows a better conceptualization of this element and a better operationalization for research purposes (Roslender & Fincham, 2004). Some features of IC can be derived from the classification models: the potential value of IC is achieved in action and it is a dynamic resource with an idiosyncratic nature. As regards the first feature, the potential value of IC, IC components have to interact with each other and with tangible factors. Furthermore, the dynamic nature implies that IC is a concept in evolution, which undergoes changes across time and which must be constantly understood and interpreted (Kianto, 2007). The implication for researchers and practitioners is that an exhaustive list of IC components does not yet exist, due to these constant changes of classification (Grojer, 2001). The idiosyncratic nature of IC also implies that IC indicators are specific for each individual organisation, sector, industry, typology, size of organisation, etc.

2.3 *Accounting measurement theme*

The increased gap between the market and book value of a company and the “dot com” bubble are two important phenomenon which have been put down to the fact that the total value of IC is not shown in financial statements (Lev, 2004). In order to explain why the value of IC is not reflected in the financial statements, authors started to define IC by comparing it with a seemingly similar resource – intangible assets – already present in the balance sheets.

In accounting, intangible assets are defined as: *“an identifiable non-monetary asset without physical substance. An asset is a resource that is controlled by the entity as a result of past events (for example, purchase or self-creation) and from which future economic benefits (inflows of cash or other assets) are expected.”* (IAS 38 “Intangible assets”). The three stages of IC research have concentrated on different parts of this definition according to their main research objective.

In the first stage of IC research, accounting like definitions were limited to highlighting the intangible nature of IC and the various characteristics which follow from this. They presented IC as the *“invisible assets that include a wide range of activities”* (Itami, 1987) or as a resource which is *“valuable, yet invisible”* (Heisig et. al., 2001). By putting an emphasis on its *“invisibility”* researchers imply that IC has the same characteristics as the intangible assets in the sense that it is a non-monetary asset without physical substance.

As the research moved to the second stage focus on IC and performance, accounting like definitions followed suite and highlight the *“future economic benefits”* which can be derived from intellectual capital. Hence, IC at this stage of research is represented by *“not embodied financial goods. Their nature is not monetary, and they are an economic advantage for the company”* (Kreigbaum; 2001). Andriessen (2004b) believes that IC resources represent *“nonmonetary resources without physical substance that in combination are able to produce future benefits for the company”*.

In an economy that emphasizes its reliance on IC to achieve high levels of performance, it is important to understand the mechanisms through which this resource adds value to a company (Alcaniz et. al., 2011; Bonacchi et. al., 2011). For this reason, the third stage of IC research, highlighted the need to capture IC in order to aid the understanding of how it produces value-added inside an organization. Nazari and Herremans (2007) provide the following definition *“IC is intellectual material (which) if formalized and utilized effectively, it can create wealth by producing a higher value asset”*. They imply that in order to be able to classify a company’s intellectual capital, to identify how it supports a firm’s goals and to quantify the contribution this resource is making to the organizational performance, managers and shareholders need to measure it (Dumay, 2009; Spender et. al., 2013). In short, *“what you can measure you can manage, and what you want to manage, you need to measure”* (Roos et. al., 1997).

Therefore, the accounting like definitions expose the need to reduce the level of ambiguity in the conceptualization of IC and, by comparing it with the accounting terminology of intangible assets, they imply IC should be measured and captured in the same manner as traditional accounting assets. Hence, they require the same level of objectivity and certainty in the valuation of IC as in the valuation of traditional assets (Spender et.al., 2013).

However, this ambition is problematic for various reasons. As noted previously, most IC components cannot be recognized in the balance sheet as intangible due to restrictive accounting criteria (Lev et.al.; 2005). Specifically, IC can only be recognized in the financial statements if it can be clearly identified, is under the firm’s control, and its value and future financial benefits can be correctly determined (Jerman & Manzin, 2008).

However, the abstract nature of IC makes it very hard to capture and formalize and ultimately very difficult to identify. Furthermore, most IC components, as presented in the knowledge definitions section are not controlled by the company (Roslender & Fincham, 2004; Alcaniz et. al., 2011). Finally, when it comes to valuing assets two accounting methods are currently practiced: (a) identifying what they cost to create, or (b) determining their current market value. Nonetheless, IC is generally non-tradable which

makes it hard to estimate its cost. The current market value is usually determined by calculating the present value of the cash- flows generated by a specific asset. This is equally difficult to achieve as the components of IC are synergetic and interact with one another and with other assets making it difficult to identify them and the associated future cash flow streams.

Thus, accounting like definitions underline its immateriality and its potential for future economic benefits. The immateriality dimension makes IC an abstract resource, uncertain and hard to capture. For this reason, accounting definitions argue there is a necessity to measure IC if we are to comprehend the extent of the benefits for the organisation. Nonetheless, accounting faces considerable challenges in measuring IC due to restrictive accounting regulations.

2.4 Performance theme

Starting from the observation that traditional production factors are not able to generate abnormal returns anymore, researchers suggested that IC is the “new” untapped force for economic prosperity (Lev et.al., 2009; Spender, 2011). Process definitions have built on this observation and defined IC by its ability to represent the new strategic factor for creating value.

The first stage of IC research focused on raising awareness on the successful involvement of IC in the production process alongside other organisational resources. For example, Smith (1994) states that IC(IC) represents “*all the elements of a business enterprise that exist in addition to working capital and tangible assets...that make the business work*”. Brooking (1996) believes that IC represents “*the combined intangible assets, which enable the company to function*” highlighting the intangible nature of intellectual capital. At the same time, the first stage definitions emphasized the strategic importance of IC in a company and its significance as a source of organizational competitive advantage. Hall (1992; p. 136) states that IC is the “*value driver that transforms productive resources into value-added assets*”. In a similar vein, Viedma (2001) sees IC as the “*company’s core competencies, the key resources at its disposal*”. In line with this characteristic of intellectual capital, researchers believed that IC leads to greater levels of performance (Dumay,2012). This grand theory has been widely embraced and reiterated in the literature and in so doing forms the foundation of the second stage which sought to find causality between the different elements of IC– human, structural and relational capital - and organisational performance.

At an empirical level, the second stage of IC research concentrated on finding the direct and linear link between the three separate IC elements and performance. While at a theoretical level, it recognized that these IC elements interact and should be contextualised by other physical and financial resources in order to add value. As such, the theoretical arguments of the second stage hold the general belief that human capital is the building block for value creation, with structural and relational capital following. Simultaneously, it asserts that the competitive edge of IC rests on its ability to bond the organizational resources into a unique value-added chain. IC “*is merely providing a mechanism that allows various assets to be bonded together in the productive process of*

the firm” (Mouritsen, 2004). Daum (2002) claims that IC components “*often show network effects*” while Mouritsen and Larsen (2005) assert that IC should be “*understood as a bundle of knowledge resources that produce network effects*”. In other words, IC components are synergetic - when combined they produce more value than the sum of their individual parts (Bradley, 1997; Bontis et. al., 2000; Lev, 2001; Bontis & Fitz-enz, 2002).

The interactions between the elements of IC are a noteworthy theoretical progression. However, definitions in the second stage of IC research do not explain how IC leads to higher levels of performance, how IC is mobilised in this process, nor what trade-offs should be made. In an attempt to fill in this gap, the third stage of IC research focused on explaining these processes by studying IC in action.

It finds “*uncertainties*” in the roles and consequences of IC in firms. On one hand, it refutes the grand theory formulated in the first stage by showing IC can be a liability for the firm and it can destroy value as well as creating it. Murthy and Mouritsen (2011) assert that “*not all elements play a role because certain combinations of elements will favour either human or technology centered organisation*”. Simultaneously, IC is found to be more fluid than initially thought, the boundaries between its elements not well defined and the relationships between them very dynamic. To be specific, there are many possible variations for the interactions between the elements of IC depending on which one of elements the organizational strategies rely on.

On the other hand, the third stage of IC research shows that the causality between IC and performance is not linear as modelled in the second stage of IC research. The connection between IC and performance is more complicated acting both as inputs and outputs in the value creation process.

Process definitions start with placing IC at the centre of the value creation process considering it as key to a company’s competitive advantage. In the second stage of research, this type of definition brings further clarity into the competitive advantage capability of IC. They explain that the competitive advantage characteristic of IC manifests only through interactions between its elements and in conjunction with other resources. The third stage finds that, in the process of value creation, IC elements can contribute to a different extent and can both add and subtract value.

3. Integrated reporting and big data lessons – section under development

4. Conclusions and future avenues of research – section in progress

The arguments above show that IC is highly idiosyncratic and the way it is measured itself could reveal things about its attributes. It is hardly possible to develop measures that fill up IC since the boundaries between the elements of IC are loose and do only little to explain their various possible underlying logics. It is equally difficult to measure human creativity in a way that it has the same referent for companies which are

strategically different. This means that developing an exhaustive classification to fit all organisations is both not possible and not advisable. In consequence, IC becomes a very wide concept which can comprise of an infinite number of elements which could be measured in various ways.

Two possible approaches could be taken to “fix” IC as a concept in the next stages of research. On one hand, we could narrow down the concept of intellectual capital. Researchers could lead research on finding an IC definition which is widely accepted by the academic community and practitioners. This might seem an unachievable task, but one must not forget about the fact that we have achieved agreement before on abstract things such as the metric system or the gravitational force. We have agreed on these concepts because they have the same functionality for everyone. Hence, the question to be asked is what functionality does IC have? What does it serve us for? Nonetheless, if agreement at a general level is impossible, a list of most important IC elements and their fixed associated indicators could be developed at the industry level. This would partially solve measurement issues and would enhance a better understanding of the performance implications because we would know exactly what we measure and manage. Due to increased comparability we would be able to tell more about specific areas of IC that we are interested in.

On the other hand, we could embrace and celebrate the diversity surrounding IC. In line with the current conceptualization of this term, we could accept it is a wide boundless concept and treat it as an eco-system which. This means that we should concentrate less on measurement issues and more on performance implications. Specifically, measurement could be done using non-standardized, non-comparable indicators with the goal of making visible the “hidden” IC for managerial decision making. In this case, IC performance evaluation issues could be transferred to the managerial performance. Managers are the ones who are able to see the realities of an ever changing and dynamic value-creation process which links IC and performance. Thus, IC performance will be more about the appropriateness of the decision making, adaptability to the environment, response to opportunities and less about the direct links between IC and performance. This means that future research could test whether the managerial perceptions of the links between IC and performance hold during and after the decision-making process. This would tell us whether managers successfully mobilize IC towards organizational performance goals.

Note

The paper is at an incipient stage of development, but the author(s) believe(s) it has potential to become a good literature review paper. The paper needs to be considerably tightened up. Meta-analysis of the literature for each theme needs to be added in order to gear the paper towards the purpose described in the abstract. Also, a whole section on lessons to be learned from integrated reporting and big data research needs to be written up as well as the concluding section. Any recommendations and comments more than welcome.

Abstract

This study aims to examine the relationships among intellectual capital, customer value creation, employee job satisfaction, and market performance of firms in the Chinese context. A questionnaire survey was administrated with data collected from email, field visits, and an online platform. The hypotheses test and analysis were conducted with structural equation modelling. Human capital is significantly related to structural capital and structural capital positively influences both internal and external relational capital. There is a positive relationship between internal relational capital and employee job satisfaction. A positive relationship exists between external relational capital and customer value creation as well. Both customer value creation and employee job satisfaction positively affect the market performance of firms. This is one of few studies that explore the relationship between intellectual capital and market performance through internal factor: employee job satisfaction and external factor: customer value creation.

Keywords – Intellectual capital, market performance, customer value creation, employee job satisfaction, structural equation modelling

Paper type – Academic Research Paper

1 Introduction

Since the reform and the open door policy was initiated in 1978, the economy of China has developed dramatically and become the second largest economy in the world after the US (Claus and Oxley, 2014). It is predicted that China will probably replace the US in terms of economic aggregate around 2020 (Fouré et al., 2012). However, the unprecedented success of China in the past several decades has mainly depended on economies of scale in labor-intensive industries rather than knowledge-based approaches: invention and innovation (Fan, 2014). Therefore, it is urgent for China to transform its model of economic growth pattern from resource based to knowledge based. It is essential to seek further potential of Chinese firms to utilize their intangible assets to sustain the whole economic prosperousness in this knowledge-intensive era.

Intellectual capital (IC) is considered as a critical asset of knowledge-based business because the key attributes of products and services become invisible as wireless connections. The intangible asset, such as knowledge, is the most distinctive factor of manufacture and production under the current economic atmosphere (Leadbeater, 2000; Castilla Polo, 2007). The information networked environment and innovation as fundamental factors for competitiveness drive the importance of IC (Petty and Guthrie, 2000) in determining a nation's economic performance or business success (Castilla Polo, 2007; Zhu, 2009). Thus, it is interesting to explore the association of IC and firm performance, especially, in the developing countries (Kanchana and Mohan, 2017), such as China.

IC management is acknowledged as a powerful weapon to create value and innovation of firms (Roos et al., 1997; Al-Ali, 2003; Hussinki et al., 2017) when the basic resources are no longer capital, labor or natural resources but are knowledge workers (Drucker, 1993). In addition, Nonaka and Takeuchi (1995) investigated Japanese firms in the 1990s and found that their success depended on the ability to create knowledge and apply it to produce products and services. However, previous studies mainly focused on the IC and financial performance of the firms, for example, Bontis et al. (2000) and Liu et al. (2017), little attention has been paid to relationship of IC and internal factors, such as employee job satisfaction, external factors, such as customer valuation creation, even for a specific performance measurement of the firms, such as market performance. Thus, this paper tries to investigate the relationships among IC, customer value creation, employee job satisfaction, and market performance of the firms to address the above-mentioned issues.

2 Literature review and hypotheses development

According to Sullivan (2000), IC is defined as the hidden value of an organization that can be transformed into profit. In general, IC can be classified as human capital (HC), structural capital (SC) and relational capital (RC) (Kwee, 2008). HC related to the skills, competence, and knowledge of employees of an organization (Sveiby, 1997) cannot be owned by the organization (Edvinsson and Malone, 1997; Stewart, 1997). SC is about knowledge which can remain in the organization when employees leave (Sveiby, 1997).

RC relates to the relationships with all the stakeholders of an organization (Kwee, 2008). RC can be classified as internal relational capital (IRC) and external relational capital (ERC). IRC refers to all the relations within an organization, while ERC refers to all the RC concerned with all stakeholders outside the organizations, such as vendors, customers, and governments. However, the relationships among IC elements are varied and mixed. For instance, it reported that positive relationships existed among HC, SC, and RC (Bontis et al., 2000; Wang and Chang, 2005), but insignificant relationships among them can also be found (Zhang and Wan, 2006; Cheng et al., 2010). Therefore, it is essential to further assess the relationships among HC, SC, and RC. It is believed that people and their knowledge are the most important resources of firms (Liu and Lee, 2016). Staff members develop the SC of firms. Thus, hypothesis 1 is developed as follow.

H1: There is a positive relationship between HC and SC.

SC, such as business processes, collaboration tools, and databases, facilitates the communication of employees, suppliers, and customers. Then, hypothesis 2 and 3 can be formulated as:

H2: There is a positive relationship between SC and ERC.

H3: There is a positive relationship between SC and IRC.

Overall, an examination of the studies on IC and firm performance shows that the relationships among HC, SC, RC and firm performance in empirical studies are inconsistent, though some studies disclosed all of them were essential in determining firms' performance (Kamukama et al., 2010; Zhang and Wan, 2006). The indicators of firm performance were varied from research to research, which brings difficulties in comparisons. In particular, little attention has been paid to examine the association of RC with customer value creation and employee job satisfaction.

Customer value creation is one of the competitive advantages that can distinguish a firm from others, which is important for firms to focus on (Ulaga, 2001; Wang et al., 2004). ERC is an indicator of relationships with external stakeholders of firms. There might be a link between ERC and customer value creation. Thus, hypothesis 4 is proposed.

H4: There is a positive relationship between ERC and customer value creation.

Since Hawthorne studies in the late 1920s and 1930s, it has been believed that employee job satisfaction has a notable impact on individual performance (Petty et al., 1984), which finally results in status of firm performance (Robbins et al., 2013). Support and encouragement from internal colleagues could enable staff members to improve their job satisfaction and performance (Kianto et al., 2016). Therefore, hypothesis 5 and 7 are formulated as:

H5: There is a positive relationship between IRC and employee job satisfaction.

H7: There is a positive relationship between employee job satisfaction and market performance.

Most of the previous studies focused on the relationship between IC and financial performance of the firms. Fewer of them were conducted to investigate firms' market performance directly. Hussinki et al. (2017) argued that superior market performance of firms could result from the higher level of IC and knowledge management practices, but

clear quantitative relationships are missing. It suggests that knowledge and collaboration of customers significantly affect the marketing effectiveness of firms (Fidel et al., 2015). Therefore, hypothesis 6 is developed as:

H6: There is a positive relationship between customer value creation and market performance.

Figure 1: Research model

3 Research methodology

To address the research questions, a questionnaire from Professor Aino Kianto (Kianto et al., 2015) was applied to collect data from Chinese firms. The original English questionnaire was translated into Chinese and retranslated back into English to check if there was any misinterpretation in the translation process. The questionnaire was trial run in several firms before implementation and any possible misunderstanding was rectified. The primary sample was drawn from a list of companies in the database of Ningbo University who were either their alumni or collaborators. In addition, an Internet-based survey was conducted to supplement the data collection across China to collect more data.

In total, there are 139 valid responses which meet the requirement of sample size for data analysis. Around one third (34 percent) of them are managers and directors, the rest are from various professionals at various positions. Of the geographical locations, more than a half (66 percent) of the respondents are from Ningbo, 14 percent of them are from Shenzhen, six percent and two percent of them come from Shanghai and Beijing respectively. The rest of them are from other cities. As for the respondent's firm size, both large firms with more than 1000 employees and medium-size firms with 300 to 1000 employees represented around one-fifth (22 percent) each; small size firms with less than 300 employees accounted for another 14 percent; the size of the left firms remains unknown because of anonymous respondents

4. Empirical results

Based on the data collected from Chinese firms, SEM was adopted to test the hypotheses. Multivariate normal distribution of data underlies the ML methods in path analysis of SEM; thus, it is mandatory to test if the data is approximately normally distributed. Skewness and kurtosis are used to justify that the data conforms to normal distribution when the value of skewness should be within the scope of -1 to 1 (Coakes and Steed, 2009). Meanwhile, the value of kurtosis should fall within the range of -3 to 3 (Balanda and MacGillivray, 1988). Assessment of normality was conducted by AMOS (version 21) for the model in this study. The Mean, standard deviation (SD), skewness and kurtosis were presented in the following Table 2. The values of skewness and kurtosis of all the variables were within the recommended scope so that the data was approximately in the normal distribution, which could be used to apply ML estimation in SEM.

Table 2: Data descriptive statistics

Variable	Min	Max	Mean	SD	Skewness	Kurtosis

It is impossible to gain scientific acceptance on empirical studies if data is neither reliable nor valid, in hence, data reliability and validity should be analyzed first before testing the hypotheses. In this study, all the values of alpha calculated by SPSS (Version 21) were varied from 0.809 to 0.913 as shown in the following Table 3 for all constructs indicating that reliability of measurement was convinced.

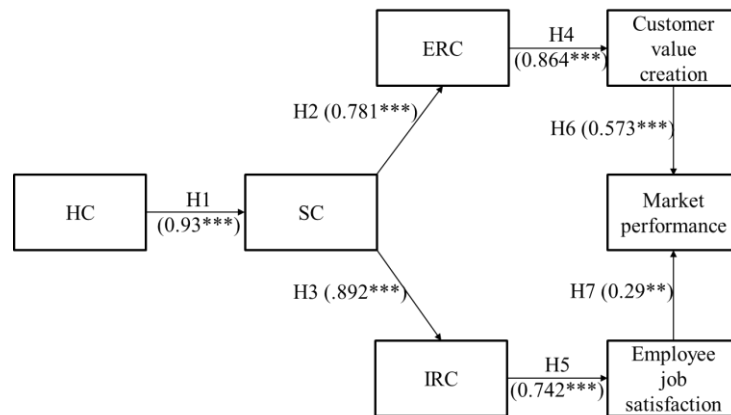

Table 3: Data reliability

Construct	Cronbach's Alpha (≥ 0.7)
Market performance	0.812
Customer value creation	0.913
Employee job satisfaction	0.838
IRC	0.809
ERC	0.858
SC	0.847
HC	0.823

Data validity can be measured by average value extracted (AVE) and composite reliability (CR). AVE measures the amount of variance that is captured by the construct in relation to the amount of variance due to measurement error, which should be more than 0.5 indicating that the constructs can explain most of the variance (Fornell and Larcker, 1981), whereas the value of CR should be no less than 0.6 (Bagozzi and Yi, 1988). All the values of AVE were more than 0.5. Meanwhile, the values of CR were above 0.8 as shown in Table 4 demonstrating the data validity is acceptable in this research.

Table 4: Data validity

Construct	Item	SE (≥ 0.5)	AVE (≥ 0.5)	CR. (≥ 0.7)
IRC	IRC01	0.749	0.591	0.8116

Figure 2: Path coefficients and effects of research model

The fit statistics ($\chi^2=429.964$, $df=244$, $p=0.000$, $\chi^2/df=1.762$ RMSEA=0.074, SRMR=0.0688, NNFI=0.904, CFI=0.915) in Table 5 showed that the model was in an acceptable level in total. Hypothesis H1 (C.R.= 7.894, $p<0.001$) was supported and confirms that HC is the fundamental element to enhance SC. In addition, SC positively influences both IRC (C.R.= 9.835, $p<0.001$) and ERC (C.R.= 9.255, $p<0.001$), which accepted the assumptions of H2 and H3. ERC was positively related to customer value creation because of the significance of H4 (C.R.= 8.942, $p<0.001$) and IRC was beneficial to employee job satisfaction due to the significance of H5 (C.R.= 8.742, $p<0.001$). It also suggested that better market performance originated from customer value creation (supporting H6, C.R.= 5.174, $p<0.001$) and employee job satisfaction (supporting H7, C.R.= 2.871, $p<0.01$) in this model as shown in Table 6 and Figure 2.

Table 5: Goodness-of-fit statistics of research model

Fit index	$\chi^2(freedom)$	P	χ^2/df	RMSEA	SRMR	NNFI	CFI
Result	429.964(244)	0.000	1.762	0.074	0.0688	0.904	0.915
Recommended cut-off value	/	$p \geq 0.01$	≤ 3	≤ 0.08	≤ 0.1	≥ 0.9	≥ 0.9

Table 6: Results of hypotheses test for research model

	Estimate	S.E.	C.R.	p	Result

*** p<0.001(two-tailed) **p<0.01 (two-tailed) *p<0.05 (two-tailed)

Regarding the effect analysis, HC, SC, and customer value creation were more effective factors to influence market performance than IRC and ERC, which demonstrated that the market performance would grow to the magnitude of 0.538, 0.579, and 0.573 respectively if HC, SC, and customer value creation increased 1 magnitude. However, IRC ($0.742 > 0.662 > 0.616$) was the most influential factor to affect employee job satisfaction in terms of both direct and indirect effect. While ERC ($0.864 > 0.675 > 0.627$) was the strongest indicator to influence customer value creation among all the IC components. The details about direct, indirect, and total effect analysis are shown in Table 7.

Table 7: Direct, indirect and total effect analysis

Effect	Dependent Independent	SC	IRC	ERC	EJS	CVC	MP
Direct effect	HC	0.93	0	0	0	0	0
	SC	0	0.892	0.781	0	0	0
	IRC	0	0	0	0.742	0	0
	ERC	0	0	0	0	0.864	0
	Employee job satisfaction	0	0	0	0	0	0.29
	Customer value creation	0	0	0	0	0	0.573

	Customer value creation	0	0	0	0	0	0.573

5. Discussions

According to the empirical results, one of the most significant findings in this study is that HC is the foundation of IC, which echoes studies in other regions conducted by Bontis et al. (2000); F-Jardón and Martos (2009); Mahmoodsalehi and Jahanyan (2009); Wang and Chang (2005). Meanwhile, it also reveals the relationships among HC and SC, IRC as well as ERC. But unlike the results of Bontis et al. (2000), SC plays a mediated role between HC and IRC as well as ERC in the tested research model, which indicates SC is beneficial for building stronger IRC and ERC. In fact, IT tools, business processes and the like belonging to SC facilitate the relationships for both internal and external stakeholders who are comprised of the RC of an organization as shown in the research model.

HC is fundamental for firm performance (Wang and Chang, 2005; F-Jardón and Martos, 2009; Bontis et al., 2000). In this study, it suggests that HC significantly affects the market performance of firms through the mediating factors, SC, IRC, ERC, customer value creation, and employee job satisfaction.

Based on Figure 2, it discovers that the correlations between customer value creation and market performance, employee job satisfaction and market performance are significantly positive. It reveals that firms with a higher value of customer creation would enhance their market performance, which is in accordance with the reality that customers and markets are inseparable. As more customers consume the firms' products or services, the probability of better market performance for the business increases. Employee job satisfaction should never be underestimated in its role on market performance, although total effects are less than customer value creation in terms of influencing market performance. In summary, those firms who create more HC, SC, IRC, and ERC for the higher level of customer value creation and employee job satisfaction could outperform their competitors about the market development.

All the studies have their own limitations, including our study: First, it is a common problem in organizational-level studies about individual report data that whether the response of each subject is representative of firm-level situations (Ferraresi et al., 2012). Second, the empirical findings depend on the data. Most of the samples come from East China where the economy is robust than West China. Though there are some overlaps of these two areas, such as Chinese culture, rules, and regulations, it is still preferable to limit generalizing the findings across China. Since China has significant variances between different regions, it would be interesting to observe the differences between Eastern and Western China in the future. Third, firms with different sizes, years of foundation, capital structures, and industries operate distinctly, especially towards IC management. It is necessary to consider the diversity of these firms in detail for future research.

Despite the aforementioned limitations, this research contributes to theory development in the following ways. This study revealed the associations of IC elements (HC, SC, IRC, ERC) from the background of the largest developing country, China. This is one of few studies investigating the relationship between IC and market performance directly. It implies that HC is the foundation of a firm from the empirical analysis and discloses the positive relationships of IC elements, namely, HC, SC, IRC, and ERC.

Acknowledgment

The authors of this study would like to thank the Research Committee of The Hong Kong Polytechnic University for the provision of a scholarship (project code: RUNQ) to conduct this research.

Abstract

Sustainable development requires the creation of sustainable innovation ideas (SIIs), but also that these ideas are selected and implemented into new products and services that are more sustainable than the products and services they substitute. Although the increasing use of online idea management system (IMS) enables firms to have more opportunities to search and develop SIIs, the survival of these ideas appears to be highly uncertain due to the diverse contributors and complex contributions to ideas. Arguably, effective organizing of the search of SIIs is potentially critical but firms face significant challenges to advance the searched SIIs across various innovation processes in online IMS due to the far limited extant knowledge. This study aims to explore the role of different online search patterns for SIIs. It does so through an empirical study based on data from an online IMS in a large Swedish company. On this basis, several types of analyses are performed in order to identify different types of SIIs and explicit search patterns, as well as the role of different explicit search patterns in the management of different SIIs. The results show that the different explicit search patterns along one or more different dimensions of sustainability have influence different types of SIIs differently. The study contributes to both the literature on innovation and sustainability, shedding new light for management on knowledge search patterns, and thereby offering potential improvements to the approaches used to manage SIIs in online IMS.

Keywords – Innovation, Sustainability, Knowledge search, Ideas, Idea management system.

Paper type – Academic Research Paper

1 Introduction

As innovation is a driver for sustainable development (Silvestre and Țîrcă, 2019), there is a clear need for firms to foster innovation in order to reach the economic, environmental and social goals of the sustainable development agenda (Lupova-Henry et al., 2019; Boons et al., 2013; Dyck and Silvestre, 2018; Silvestre and Țîrcă, 2019). Previous literature notes that actions on an idea are of great potential for innovation as well as sustainability (Cluzel et al., 2013; Tyl et al., 2014). However, it has been found that SIIs with a high level of environmental and societal ambition (Tyl et al., 2016), to some extent have more difficulty to be selected than other types of ideas, and thus have to be more carefully supported (Tyl et al., 2016). This poses challenges to firms to advance SIIs through various stages of their innovation process due to their limited capabilities to handle the specific needs and requirements of sustainable innovation ideas. In particular with the widespread use online IMS, this challenge becomes even more substantial as most firms turn to be open to capture different types of ideas from an online community and sustainable innovation ideas may come from diverse sources who might also take on different roles, such as volunteers, peers or managers. Summarizing the above, the need to focus explicitly on the management of SIIs in online IMS stands out as an urgent and important issue to empirically investigate.

One key aspect tackled in the innovation management discourse concerns knowledge search (van den Ende 2015; Lopez-Vega et al., 2016). Given that different types of ideas are openly called for in IMS, it can be indicated that whether SIIs are explicitly sought after or not may potentially impact the creation and acceptance of these ideas. However, most literature on knowledge search has this far focused on where to search (internally or externally) (Lopez-Vega et al., 2016), whereas much less attention has been paid to how to search for ideas with a specific cognitive purpose. In order to fill this research gap, this study aims to *explore the role of explicit online search for SIIs*.

In order to fill this aim, we investigate the role of explicit online search based on data from IdeaBoxes, an online IMS in a Swedish multi-national telecom company. In the extracted data set, tags of ideas and IdeaBoxes such as cost saving and energy efficiency, were used to categorize different types of SIIs and sustainable IdeaBoxes with regards to the observed explicit search patterns. The results show that the explicit search on the different dimensions of sustainability has different influences on the different SIIs. For example, the explicit search on economic value ideas has a negative effect on the idea acceptance of environmental/or economical innovation ideas, while the explicit search on sustainability integrating environmental, social as well as economic concerns positively influences the acceptance of environmental innovation ideas. It is indicated that the SIIs asked for are sometimes not the needed ones, and then particularly when the economic value is taken into account. To our best knowledge, this is the first study that investigates how an online IMS is used to foster sustainable innovation and the effects of the knowledge search strategies used. The study contributes to both the literature on innovation and sustainability, shedding new light for management on knowledge search and providing a specific business approach to manage SIIs in a more fruitful way.

2 Theoretical background

2.1 Innovation for sustainability

With increasing awareness of the economic-social-ecological crisis the world is currently facing (Boons et al., 2013), sustainability concerns are increasingly incorporated into the research attention of scholars, the agendas of policy-makers and the strategies of companies (Geissdoefer et al., 2017; Silvestre and Țircă, 2019).

Innovation with an explicit focus on sustainability aspects is not a new phenomenon, but given the global challenges the world is facing, this type of innovation has attracted more attention than before. It can be noted that so-called "eco-innovations" or "green innovations" focusing on environmental and economic challenges have been widely discussed during the last decade as the outcome of special interests (Ardito et al., 2018). However, given the global sustainability challenges, decision-makers increasingly take ecological, economic and social sustainability aspects into account in their operations (Geissdoefer et al., 2017; Silvestre and Țircă, 2019). One crucial factor in succeeding in managing sustainability challenges is getting more and better sustainable innovations (Dyck and Silvestre, 2018), both of a technical nature, but also in the form of new products and services that enable reduced material and energy use by creating new patterns of action.

Therefore, there is a clear need for sustainable innovations that enable more sustainable ways of living (Lupova-Henry et al., 2019; Boons et al., 2013; Dyck and Silvestre, 2018; Silvestre and Țircă, 2019). Compared to the other types of innovations, the development and implementation of sustainable innovation are arguably equally complex, dynamic and uncertain. However, the purpose and direction of outcomes of sustainable innovations are often different in terms of their holistic trade-offs of environmental, social and economic performance. This has led previous research to emphasize that sustainable innovation is a process in which trade-offs regarding ecological, social and economic aspects need to be integrated into business activities, from idea creation to commercialization of new products and services (Charter and Clark, 2008).

2.2 Idea management for sustainable innovation

As the socio-ecological roles of products are largely determined by decisions during early product development phases, it is important to introduce a socio-ecological sustainability perspective early in the product innovation processes (Hallstedt et al. 2017), and particularly in the process of sustainable innovation idea management. Just like other types of innovations, also all sustainable innovations begin as ideas. Previous literature notes that actions on an idea are of great potential for innovation as well as sustainability (Cluzel et al, 2013; Tyl et al., 2014).

However, compared to other types of innovation ideas, SIIs, with a high level of environmental and societal ambition (Tyl et al., 2016), to some extent appear to be more difficult to be selected than other types of ideas, and thus need to be more carefully

supported (Tyl et al., 2016) in order to eventually be realized. This poses challenges to firms to advance SIIs through various stages of their innovation process due to their limited capabilities to handle the specific needs and requirements of SIIs. Although idea generation has recently been improved in many companies, e.g. through the introduction of tools supporting the construction of sustainable business models (O'Hare et al., 2014), the management of SIIs has received less attention. Therefore, in order to be able to create more and better sustainable innovations, increased knowledge is required about how these innovations should be handled, beginning with the generation, development and selection of SIIs.

2.3 Online search for SIIs

Idea management in companies is increasingly taking place in completely new ways, where the use of online IMS enables firms not only to search locally for good ideas, but seek ideas from both external experts and hobbyist volunteers through open calls, contests, or Internet-enabled communities (van den Ende et al., 2015). This creates a situation where many more can contribute to innovation with different skills and in different roles. At the same time, the management of ideas has become much more extensive and decentralized, which can lead to good ideas not being captured and realized for various reasons. In particular, with the holistic trade-offs of environmental, social as well as economic performance, SIIs that in some respects offer new and different combinations of values and thus run a particularly high risk of being treated prodigiously in these online IMS.

Thus, we contend that there is much room for new research contributions in how firms organize their online search for SIIs. An important practice to set direction of online search is related to idea selection. More specifically, SIIs can be captured through explicit search either for "known unknowns" (i.e. with explicitly stating a "tacit" need to solutions), or for "unknown unknowns" (i.e., through more ambiguous scanning for ideas in areas) (Lopez-Vega et al., 2016; van den Ende et al., 2015). Although it has been argued that "selection knowledge" and thus cognitive attention with explicit search are needed in order to enable firms to pick quality ideas (Kester et al., 2011; van den Ende et al., 2015), the role of explicit search in the management of SIIs is unclear due to the limited extant knowledge.

3 Research questions

Given that different types of ideas are openly called for in IMS, it can be indicated that whether SIIs are explicitly sought after or not may potentially impact the creation and acceptance of these ideas. However, the real role of explicit search patterns is not clear as the question how such search patterns influence the selection of different types of SIIs has not yet been thoroughly investigated. More specifically, as most of the previous literature in the field of innovation management and sustainability focuses quite myopically on only one goal at a time (Ardito et al., 2018), extant knowledge about the management of SIIs comprehensively integrating economic, environmental and social dimensions is limited.

For example, although scholars recently have started to focus on the development of innovation for sustainability, the literature is this far primarily aimed to concurrently meet environmental concerns through exploring the methodologies and tools of eco-ideation (e.g. Tyl et al., 2015), as indicated for instance by the concept of eco-innovation (Ardito et al., Kiefer et al., 2017). Furthermore, in terms of the literature related to organizing search pattern for ideas, most attention has been paid to where to search (internally or externally) (Lopez-Vega et al., 2016), whereas much less attention has been paid to how to search for ideas with a specific cognitive purpose.

In order to fill this research gap, this study aims to explore the role of explicit online search for SIIs. On this basis, and taking different dimensions of sustainability into account, two research questions are addressed:

RQ1: What different types of SIIs can be identified in online IMS?

RQ2: What is the influence of explicit search patterns on different types of SIIs?

4 Research methodology

4.1 Research setting

This empirical study was conducted based on data from an internal online idea management system called IdeaBoxes used in a Swedish multi-national telecom company. IdeaBoxes was set up in 2008 using crowdsourcing principles to capture and collectively develop innovation ideas globally from employees. This is performed through the use of non-competitive idea boxes for different specific problems, managed by one or more voluntary innovation managers. More specifically, in non-competitive idea boxes, more opportunities are provided not only for distributed and diverse employees to share their different sets of knowledge and experience, including sustainable development, but also for innovation managers to virtually search SIIs with the focus chosen for their idea boxes. As ideas are claimed by managers for interest, action or implementation, this signals that further resources will be assigned for actions related to the further idea implementation. This type of idea acceptance can be considered as a measurement of idea quality in this system.

4.2 Data collection and measurement

In this study, data about ideas generated during two years (from the 1st of December 2014 to the 1st of December 2016) were collected from open and collaborative non-competitive idea boxes in the IdeaBoxes system.. Although the collected ideas were addressing all types of innovation and not only SIIs, tags in the system labelled to ideas and idea boxes, e.g. cost saving, energy efficiency, power reduction, etc. could be used to define the types of ideas and idea boxes with respect to environmental, economic and social issues. On this basis, this empirical study was performed in three steps, where the results from the first step serves as an input to the analysis of the first and second research questions in the next two steps.

Step 1: Data collection and analysis at tag level

In this step, all tags used on ideas and idea boxes in this system were firstly collected from the database of IdeaBoxes. Thereafter, tags were classified into different dimensions of sustainability based on the sustainability criteria argued in previous literature (see e.g. Joung et al., 2013; Sikdar, 2003). During the coding at tag level, a systematic classification requires a coding framework for different dimensions of sustainability. The coding framework in this study was developed firstly based on the argued sustainability metrics, something which includes three groups corresponding to environment, economic as well as social aspects (Sikdar, 2003). The three groups summarized in Table 1 are one, two and three dimensional aspects of sustainability, respectively. Furthermore, sustainable development with its seven sub-dimensions was included as a coding framework regarding the normally used words in this concept. For example, for the environmental aspect in group 1, indicators such as pollution, emission, global warming (Joung et al., 2013; Sikdar, 2003) were collected.

Table 1 Coding framework for the types of tags

Types	Aspect	Indicators for coding	Example of coded tags
Group 1: One dimension	Environmental	Pollution, Emission, Environmental friendly, Global warming etc.	Emission reduction (Carbon, green gas, etc.) Reduce pollution (air, noise, etc.) Recycling, reuse paper, materials, phones, etc. Green energy, environment, electricity, etc.
	Economic	Cost, Value-added, Profit, Investment, Efficiency	Cost saving; More profit with less effort, increase profitability Optimized investment, investment strategy Save effort, time. Earn value, value added, etc.
	Social	Employee/Customer/Community benefits, Safety, Health, Satisfaction, etc.	Employee, customer and end user satisfaction; Healthy employee, insurance and environment, etc.
Group 2: Two dimensions	Environmental- Economic	The combination of environment and economic indicators, ecological footprint, eco-efficiency, resource saving/optimization, etc.	Save/Optimize fuel, power, electricity, energy, Save cost and reduce waste, save nature and save money, Recycle environment and cut costs, optimization of resource etc.
	Economic- Social	The combination of environment an social indicators, etc.	Socio-economic activity, safety and efficiency,
	Environmental- Social	The combination of environment an social indicators, etc.	Health and reduction of Co2
Group 3: Three dimensions	Environmental- Economical- Social	Sustainable, Sustainability	Sustainable development, sustainable world, sustainovation, etc.

Step 2: Data collection and analysis at idea level

This step is mainly to classify the ideas based on the coded tags in Table 1 with respect to the first research question. Firstly, ideas published in the non-competitive idea boxes were selected. Secondly, tags to the selected ideas were extracted. Thirdly, the number of different tags to ideas was calculated based on the results of Step 1. By doing so, ideas were classified into seven types with three dimensions as well. For example, if

tags to an idea are about environment and economy, this sustainable innovation idea is classified as the environmental-economic type. If tags to an idea are not about any dimensions of sustainability, ideas would be removed from the collected dataset.

Step 3: Data collection and measurement at idea box level

In terms of the second research question, as different types of sustainable idea boxes and other types of idea boxes were analyzed with regard to the observed explicit search patterns, the classification of idea box types was mainly undertaken in this step. Similar to Step 2, idea boxes where the selected SIIs were submitted were firstly collected. Thereafter, tags to the selected idea boxes were collected and the types of idea boxes were identified based on the number of different tags to idea boxes. On this basis, with respect to the seven types of tags, seven types of explicit search patterns for different SIIs can be identified. However, if there are no sustainable tags of idea boxes, the idea boxes are classified into the one without an explicit search for sustainability.

Furthermore, in order to test the influence of the explicit search patterns, a linear regression at idea box level was conducted. More specifically, the numbers of different accepted ideas in different types of idea boxes are measured as dependent variables and the numbers of different submitted ideas are added as control variables. The type of idea box with respect to the explicit search pattern is the observed categorized independent variable.

5 Result and Analysis

5.1 Data description

After data collection, measurement and analysis in the three steps above, focusing on the classified types of tags, ideas, and idea boxes, respectively, are summarized in Table 2.

Table 2 Types of tags, ideas and idea boxes

Tags types	Idea types	IdeaBoxes types
Environmental	Idea1: Environmental innovation idea	Ideabox1: Explicit search for Idea 1
Economical	Idea2: Economic innovation idea	Ideabox2: Explicit search for Idea 2
Social	Idea3: Social innovation idea	Ideabox3: Explicit search for Idea 3
Environmental – economic	Idea4: Environmental-economic innovation idea	Ideabox4: Explicit search for Idea 4
Economic-social	Idea5: Economic-social innovation idea	Ideabox5: Explicit search for Idea 5
Environment-social	Idea6: Environmental-social innovation idea	Ideabox6: Explicit search for Idea 6
Environment-economic-social	Idea7: Environmental-economic-social innovation idea	Ideabox7: Explicit search for Idea 7
Others		Ideabox8: Non explicit search for sustainability

Based on the classification of ideas and idea boxes, the number of different ideas submitted and accepted in different types of idea boxes was calculated and shown in Table 3.

Table 3 The number of different ideas submitted and accepted in different types of idea boxes

Idea box types	Idea activity	The number of different ideas submitted and accepted						
		Idea1	Idea2	Idea3	Idea4	Idea5	Idea6	Idea7
Ideabox1	submitted	0	1	0	1	0	0	0
	accepted	0	0	0	0	0	0	0
Ideabox2	submitted	5	25	26	6	1	0	1
	accepted	0	1	2	0	0	0	0
Ideabox3	submitted	12	17	51	6	1	2	3
	accepted	1	0	4	0	0	0	0
Ideabox4	submitted	0	2	0	0	0	0	0
	accepted	0	0	0	0	0	0	0
Ideabox5	submitted	0	2	0	0	0	0	0
	accepted	0	0	0	0	0	0	0
Ideabox6	submitted	0	0	0	0	0	0	0
	accepted	0	0	0	0	0	0	0
Ideabox7	submitted	6	2	13	2	0	0	12
	accepted	1	0	0	0	0	0	1
Ideabox8	submitted	152	261	103	51	16	3	41
	accepted	19	61	8	6	2	0	3

From Table 3, it can be seen that most SIIs address one specific dimension of sustainability, and the largest number of ideas address economic aspects. Furthermore, it is interesting to notice that most of them have been submitted to idea boxes without an explicit search pattern for sustainability while the idea boxes with an explicit search for only environment has received only very few environmental innovation ideas.

For the influence of explicit search patterns, the percentage of accepted ideas in each type of idea box, with different explicit search patterns, was measured and the result is shown in the form of radar cart (see Figure 1).

In Figure 1, the acceptance probability of different SIIs in different IdeaBoxes was represented in the center. More specifically, Different sustainable innovation ideas are separated by different colours and shapes, while different IdeaBoxes are shown in different axes. Thus, different data points at different axes represent the acceptance probabilities of different SIIs in different IdeaBoxes.

The results show that there are quite different idea acceptance probabilities in different idea boxes in terms of different types of SIIs. More specifically, Idea2, namely ideas addressing economic aspects, have the highest idea acceptance probability in idea boxes without an explicit search pattern on sustainability, as compared to others. Similar to Idea2, Idea4 and Idea5 have higher idea acceptance probability in idea boxes without an explicit search pattern. Moreover, we see that there are no accepted environmental-social innovation ideas in any idea boxes. For the Idea1 and Idea7 types, the idea acceptance probability in idea boxes with an explicit search along three dimensions of sustainability is higher than the ones in idea boxes without an explicit search. By contrast, Idea3 has almost the same idea acceptance probability in idea boxes with an explicit search on economic or social aspects of sustainability and idea boxes without an explicit search on sustainability.

5.2 Regression results

With respect to the second research question, the influence of an explicit search on different SIIs was tested by the number of accepted different ideas. Model 1 is to test the influence of explicit search patterns on Idea1. In model 2, their influence on Idea2 was tested. In the same way, the influences of explicit search patterns on Idea3, Idea4, Idea5, Idea6 and Idea7 were tested in Models 3, 4, 5, 6, and 7, respectively. The regression results are shown in Table 5.

The 7 Models in Table 5 show that the explicit search on the different dimensions of sustainability has different influence on different types of ideas. More specifically, Model 1 and Model 2 show that both environmental innovation ideas and economic innovation ideas were negatively influenced by the explicit search focusing on economic aspects, but positively influenced by the explicit search focusing on three dimensions of sustainability. In Model 3, it is seen that the explicit search pattern focusing on economic aspects has a negative influence on the acceptance of social innovation ideas whereas the social explicit search pattern has a positive influence. Model 2 shows that both the explicit search on economic aspects and the combination of all three dimensions of sustainability have a negative influence on the acceptance of environmental-economic innovation ideas. Other ideas and explicit search patterns do not show any statistically significant relationships. There is no result for the explicit search of social-environmental ideas because of the lack of ideas of the Idea6 type in the Ideabox6 type of idea boxes in the collected sample.

6 Discussion and conclusions

Since the use of online IMS enables firms to search ideas from more and diverse contributors with different skills and in different roles, ideas run the risk of being treated prodigiously, and this in particular applies to SIIs. Although the organizing of online search is arguably critical for idea management (van den Ende et al., 2015), questions regarding how explicit search patterns influence the management of different online SIIs have not yet been thoroughly investigated. This paper, with respect to this, aims to explore the role of explicit online search patterns in the management of SIIs. In order to fill this aim, two research questions have been addressed. They are: 1) What different types of SIIs can be identified in online IMS? 2) What is the influence of explicit search patterns on different types of SIIs?

With respect to the first research question, seven different types of SIIs in online IMS have been identified, including search foci addressing each one of the economic, ecological and social dimensions of sustainability, as well as their possible two- and three-dimensional combinations. Hence, we distinguish between environmentally-focused innovation ideas, economically-focused innovation ideas, social innovation ideas, environmental-economic innovation ideas, economic-social innovation ideas, environmental-social innovation ideas, and environmental-economic-social innovation ideas.

For the second research question, the results show that the different explicit search patterns have different influences on both the generation and the selection of SIIs. More specifically, in terms of the influence on idea generation, it shows that most SIIs have been submitted to idea boxes without an explicit search focus on sustainability while the idea boxes with an explicit search focus on environment have not received many environmental innovation ideas. This result on the one hand indicates that an explicit search focus on sustainability to some extent constrains the number of generated SIIs and there appears to be more creative space for creators to generate SIIs when not having an explicit search for sustainability. On the other hand, it also indicates that the creators concern the survival of their ideas and prefer to submit them to the more open system with less knowledge control. For the influence on the selection of SIIs, it is interesting to notice that there are no SIIs accepted in the idea box explicitly addressing environmental concerns. One possible explanation for this has been put forward by Bocken et al. (2011), namely that the early evaluation of ideas from an environmental perspective is likely to eliminate more radical ideas. Furthermore, it is found that the explicit search along the economic value dimension has a negative effect on the idea acceptance of environmental/social/economic/environmental-social ideas. By contrast, the explicit search for overall sustainability, integrating environmental, social as well as economic concerns, positively influences the acceptance of environmental/social/environmental-social ideas.

To our best knowledge, this is the first study that investigates how an online IMS is used to foster sustainable innovation in terms and the effects of related knowledge search strategies. The results theoretically contribute to the recent calls about better

understanding of sustainable innovation (Ardito et al., 2018), by showing the different types of SIIs, different explicit search patterns and the roles of different explicit searches in the generation as well as selection of different SIIs. Furthermore, this study deepens the knowledge about organizing online search in the field of digital innovation and sustainable development, extending the attention on the issues from “where” to “how” to search by providing a more comprehensive understanding of different explicit search patterns on different dimensions of sustainability.

In addition, this study also provides implications to manage SIIs in terms of knowledge search patterns in online IMS. With the investigated results about the submission as well as acceptance of SIIs in terms of different online search patterns, one of the important managerial aspects concerns the organizing search pattern for idea generation and selection. More specifically, the result that more ideas generated without the explicit search pattern than the ones with the explicit pattern on sustainability suggests that more open discussion environment without the settled knowledge search on sustainability is needed for the generation of SIIs. While in terms of the selection of SIIs, detailed explicit search patterns are suggested to be considered. In particular, for the SIIs emphasizing the environmental issues, it is suggested that environmental, economic as well as social performances are taken into account in the search pattern. However, the economic value is suggested to be carefully considered in the explicit pattern if it is a merely goal in the management of SIIs, as the early consideration economic value would result in the high risk of being treated prodigiously or rejected early.

To summarize, the results open for a discussion that the sustainable innovations ideas asked for might not be the ones actually wanted or needed. However, this study bears some limitations as well, for example, the limited generalizability of research findings to other firms due to the limited data from a single company, the ambiguity of idea success and the related possible variation in the definitions of idea success used in different idea boxes, etc. Despite the limitations, this research offers substantial insights for both scholars and practitioners into the micro-foundations of SIIs’ management, contributing to both the literature on innovation and sustainability, shedding new light for management on the role played by knowledge search patterns in idea creation and selection, and thereby offering potential improvements to the approaches used to manage SIIs in online IMS.

Acknowledgement

We gratefully acknowledge helpful advice and assistance by Professor Sofia Ritzén, Glenn Johansson, and Sophie Hallstedt during the course “Sustainability in Engineering Product Development (SEPD)”. We also thank Professor Yu Yang at Chongqing University, China, the joint supervisor of the first author, for providing support on this research project. Finally, we would like to thank the financial support partly from Stiftelsen IMIT and China Scholarship Council (CSC) under the Grant CSC No.201506050060.

Abstract

The paper contributes at the debate on circular economy as emerging paradigm aimed to promote sustainable development patterns, by focusing on the issues of the innovation ecosystems and quintuple helix. Despite the topic of innovation results to be intrinsically linked to the paradigm of circular economy and the dimension of environmental sustainability is more and more recognized crucial into the debate on innovation ecosystems through the quintuple helix, the exploration of their meaning and dynamics in the perspective of circular economy is under-researched and calls for a deeper comprehension. Framed in the above premises, this paper presents the evidences of a single and extreme case study related to the Italian Circular Economy Stakeholder

Platform (ICESP), as good practice of a digital platform for stakeholders' engagement supporting the creation of an innovation ecosystem focused on the circular economy.

Keywords: Circular Economy, Innovation Ecosystem, Quintuple Helix, Digital Platforms, Stakeholders, ICESP

Nature of the proposed paper: Academic Research Paper

1. Introduction

Circular Economy is one of the most relevant trend topics in the public debate (Urbinati et al., 2017). As a branch of sustainability science aimed to reduce environmental impacts and promote sustainable patterns of development (Miliute-Plepiene & Plepys, 2015; Schneider, 2015; Haas et al., 2015), Circular Economy is recalling the interest of a large community of scholars and researchers interested into the exploration of its meaning and dynamics both at level of companies (Mylan et al., 2016) and governments (Grundel and Dahlström, 2016; Geng et al., 2009).

According to Ellen MacArthur Foundation (2015), Circular Economy aims to redefine patterns of growth, focusing on positive society-wide benefits, by gradually decoupling economic activity from the consumption of finite resources, and designing waste out of the system. It is strongly recognized as a way of sustainable growth in respect of environmental, and societal patterns with several implications also for regional and industrial development (Ghisellini, et al., 2016; Urbinati et al., 2017).

It is in this perspective that the conception and execution of actions and strategies of circular economy by private and public organizations recall the contribution of a plurality of stakeholders and this requires collaboration and shared values.

Despite the topic of innovation results to be intrinsically linked to the paradigm of Circular Economy, very few studies have explored its meaning and dynamic in the perspective of systems of innovation.

In the meantime, while the dimension of environmental sustainability results to be well recognized into the debate on innovation ecosystems (Etzkowitz, and Ranga, 2015), such as into the Quintuple Helix model through the helix of natural and environmental transitions (Grundel and Dahlström, 2016; Romano et al., 2014; Carayannis and Campbell, 2009), the research in this field has missed to understand how innovation ecosystems can support the development of processes of value creation in line with the principles of Circular Economy. As knowledge intensive and collaborative heterogeneous networks of actors supporting the creation of sustainable innovation (Etzkowitz and Ranga, 2015; Romano et al., 2014; Carayannis and Campbell, 2009), innovation ecosystems can play an important role in catalysing flows of knowledge in the domain of circular economy, also thanks to the embracement of virtual platforms. Web technologies and digital platforms have enhanced the opportunities of value creation into the innovation ecosystems by making more effective and rapid the processes of knowledge

creation, absorption and diffusion (Romano et al., 2014; Muntaner-Perich and de la Rosa, 2007).

In allowing the creation of a bridge between knowledge inside the organisations and knowledge outside the organisations, innovation ecosystems are favourable locus for value creation (Borin and Donato, 2015; Dumay, 2013). Also in this perspective, it is necessary to investigate which are the main characteristics and in which way a digital platform can support the creation of an innovation ecosystems for the achievement of goals related to the Circular Economy.

Framed in the above premises, this paper aims to offer an integrated reading and a contribution of systematization at the intersection of the research on Circular Economy and Innovation Ecosystems in the perspective of Quintuple Helix through the study of the Italian Circular Economy Stakeholder Platform (ICESP), as extreme case study of a platform based ecosystem of stakeholders specialized into the domain of circular economy.

The paper presents several elements of original contribution in terms of an integrated reading of well debated issues, such as Circular Economy and Innovation Ecosystems, as well as of the empirical evidences of ICESP, as relevant empirical context of analysis related to collaborative dynamics of innovation inspired at the model of Quintuple Helix and focused in the domain of Circular Economy.

The remaining of the paper is structured as follows: the literature background presents the theoretical pillars of study in terms of Circular Economy, Innovation Ecosystems and Quintuple Helix. In the section 3, the methodological approach is presented; the section 4 presents the evidences related to the case study at ICESP and in the paragraph 5. the conclusions and implications for theory and practice are presented.

2. Literature background

2.1 Circular Economy and stakeholders' involvement

Circular Economy is one of the most actual issue of the current public debate (Urbinati, et al., 2017). It has been identified as a promising source of solutions at the challenges associated to the sustainable development goals identified by the United Nations (Geissdoerfer et al., 2018), since it is based on the assumption that products and resources continue to circulate in closed loops by minimizing waste, emission, and costs (Ellen MacArthur Foundation, 2013; Ranta, et al., 2018). Indeed, circular economy suggests the shift from linear model of production and consumption to circular ones able to preserve environmental and economic value within the system (Nußholz, 2018).

Different schools of thought have inspired the current theorization of the Circular Economy (Geissdoerfer et al., 2018), such as the regenerative design (Lyle, 1994), Industrial Ecology (Graedel and Allenby, 1995), Ecosystem metaphor (Su et al., 2013), Looped and performance economy (Stahel, 2010), Industrial symbiosis (Chertow, 2000). The debate on Circular Economy continues to be fluorescent and populated by different perspectives of studies aimed to deepen meaning, dynamics and implications of circular economy at level of single companies, industries, public organizations, urban areas and

territories (Innella et al., 2017; Cappellaro et al., 2019). In such a context, the study of the business model for the circular economy is one of the most actual, mainly for what concerns the value creation and its determinants (Urbinati et al., 2017; Ranta, et al., 2018). A circular business model incorporates all the “elements that slow, narrow, and close resource loops” (Geissdoerfer et al., 2018, pp. 191). As result of the application of Circular Economy principles into the functioning of a business model, it requires to reserve a particular attention at some sustainable issues such as the sustainable nature of value, a long term perspective and the growing role of stakeholders (Urbinati, et al., 2017; Geissdoerfer et al., 2018). The involvement of stakeholders within the organizational ecosystem has been identified by other authors (Lewandowski, 2016; Antikainen and Valkokari, 2016; Nußholz, 2018) as crucial for the successful implementation of a circular business model. Despite this the full comprehension of the role of stakeholders for the successful implementation of a circular economy strategy is still under-research and calls for more research. Specifically, it is necessary to understand which are the mechanism more suitable for their active involvement as well as to explore the role and contribution that digital platforms can have in enabling the creation of an innovation ecosystem focused on the challenges of circular economy.

2.2. Innovation Ecosystems and Digital Platforms: a Quintuple Helix perspective

The issue of innovation ecosystems has been a topic largely debated with different contributions shaping from the regional development to the open innovation. The premises at the basis of the systemic view on innovation ecosystem is that innovation is not more a linear but a systemic process that grows within a network of inter-organizational relationships (Zajac and Olsen, 1993; Powell et al., 1996) able to promote the interrelation and integration of different knowledge sources and providers (Romano, et al., 2014). Designing and managing of these complex network of actors, also defined as innovation ecosystems, become mandatory to assure the achievement of innovation goals by assuring participation and user-centrality for the sustainable, inclusive and intelligent growth of individuals, companies and territories (Passiante and Romano, 2016). Innovation ecosystems are institutional infrastructures supporting networking and collaboration among a plurality of stakeholders by activating virtuous and knowledge-intensive flows of knowledge (Asheim and Gertler, 2005; Romano et al., 2014). The debate on innovation ecosystems identifies the attribute of sustainability within its main characteristics (Passiante and Romano, 2016). The inbound and outbound flows of knowledge activated by the interaction of the stakeholders within the ecosystems, make these environments as sustainable contexts to booster the process of value creation, in its larger definition. A useful framework for mapping and managing the dynamics undertaken in such contexts is identifiable into the Quintuple Helix model (Carayannis and Campbell, 2011). Inspired at the logic at the most well-known framework of the Triple Helix model (Garner and Ternouth, 2011; Etzkowitz, and Zhou, 2006), representative of the fruitful and knowledge relevant interactions between governments, academia, industries and institutions, the Quintuple Helix model embeds the Quadruple Helix (Carayannis and Campbell, 2009), that included the media based and culture based

public, with the context of the natural environment, by demonstrating a more visible attention at the sustainability dimension. In such a process, universities and research centers, large and small companies, institutions and governments are called to collaborate and cooperate each other, by sharing knowledge and exchanging experiences, with a more direct and active involvement of users in all the stages of the innovation process.

Despite the topic of innovation results to be intrinsically linked to the paradigm of Circular Economy, very few studies have explored its meaning and dynamic in the perspective of systems of innovation.

In the meantime, while the dimension of environmental sustainability results to be well recognized into the debate on innovation ecosystems (Etzkowitz, and Ranga, 2015), such as into the Quintuple Helix model through the helix of natural and environmental transitions (Grundel and Dahlström, 2016; Romano et al., 2014; Carayannis and Campbell, 2009), the research in this field has missed to understand how innovation ecosystems can support the development of processes of value creation in line with the principles of Circular Economy. The process of value creation into the innovation ecosystems arises from the interactions and flows of knowledge activated by a plurality of actors that can be physically and virtually connected. In allowing the creation of a bridge between knowledge inside the organisations and knowledge outside the organisations, innovation ecosystems are favourable locus for value creation (Borin and Donato, 2015; Dumay, 2013). Web technologies and digital platforms have enhanced the opportunities of value creation into the innovation ecosystems by making more effective and rapid the processes of knowledge creation, absorption and diffusion (Romano et al., 2014; Muntaner-Perich and de la Rosa, 2007). Also in this perspective, it is necessary to investigate which are the main characteristics and in which way a digital platform can support the creation of an innovation ecosystems for the achievement of goals related to the Circular Economy.

3. Methodology

This paper employs an exploratory qualitative approach based on the methodology of case study (Yin, 1994, 2003) and research in action (Argyris, and Schön, 1989). As suitable investigative tool for the analysis of a contemporary phenomenon in its natural setting, case study is preferred when the boundaries between phenomenon and context are not clearly evident (Yin, 1994, 2003). As for the research in action, the active involvement of researchers into the development of the study has allowed to access at a privileged and rigorous sources of information.

The case analyses the Italian Circular Economy Stakeholder Platform - ICESP, as extreme case study of a platform based ecosystem of stakeholders specialized into the domain of circular economy.

Conceived as a virtual environment supporting the processes of networking, knowledge sharing and collaborative partnership, ICESP is the Italian Circular Economy Stakeholder Platform, a mirror Platform of ECESP, the European Circular Economy Stakeholder Platform. ECESP is a joint initiative by the European Commission and the

European Economic and Social Committee and was born to foster the transition towards a circular economy bringing together stakeholders active in the broad field of the circular economy as action included in the 2015 EU Action Plan for the Circular Economy actions, concept enforced in the last Communication COM (2019) 190 final (Bruxelles, 4.3.2019).

ICESP has been launched in May 2018 by ENEA, the Italian National Agency for New Technologies, Energy and Sustainable Economic Development.

For its characteristics and features, ICESP is clearly identified as an extreme case study.

The case of ICESP is here addressed toward the comprehension of the dynamics and processes of an innovation ecosystem built around a digital platform and populated by a community of actors, that in coherence with the framework of Quintuple Helix, will promote processes of fertilization and promotion in the field of the circular economy.

More in detail, the case study analysis has been organized around three main areas, related to the its strategic, functional-organizational, and technical model.

4. Findings

Focusing on the pillars of the theoretical background (circular economy, innovation ecosystem through digital platforms, and quintuple helix,), the analysis of ICESP has to be address toward the comprehension of its strategic, functional-organizational, and technical model.

About the strategic model, the study has allowed to understand as ICESP exists because the European Commission, in order to support the Circular Economy Action Plan strategies and future related funding, has launched the *European Circular Economy Stakeholder Platform* – ECESP. ENEA has been selected in ECESP Coordination Group as representative of the Research sector, and in consideration of this three-year assignment, it has been enrolled by the Commission to act as a national hub for the circular economy. Therefore, ENEA promoted the realization of an ECESP national Italian interface, by the constitution of the “*Italian Circular Economy Stakeholder Platform* - ICESP”. Both are initiatives for deepening and stakeholders’ engagement, to overcome sectorial activities and highlight inter-sectorial opportunities and challenges through a meeting point where stakeholders can share their solutions and work together to address specific challenges, linking existing initiatives and supporting the circular economy at national, regional and local level, to support its implementation.

ICESP main goal of short-medium-long term is to create a point of national convergence on initiatives, experiences, critical issues, perspectives and expectations on the circular economy that the Italian system wants and can represent in Europe with a single voice, promoting the *Italian way for circular economy*, to overcome the fragmentation of Italian initiatives on Circular Economy and to establish a permanent instrument promoting the dialogue, knowledge and Italian best practices diffusion.

As for the linkage with the ECESP, ENEA will transfer the information derived from the participation in the ECESP Coordination Group towards ICESP members and at the

same time it will disseminate in Europe the Italian good practices in the field of circular economy gathered through ICESP.

Furthermore, ECESP inputs will be fed in ICESP to ensure continue and fruitful connection (Figure 1.)

About the functional-organizational model, ICESP's stakeholders are currently represented by institutions, industries and business associations, research, civil societies. In particular, the ICESP platform follows two different and complementary ways to contribute. It is possible to sign the ICESP Charter to become effective member and/or contribute to working groups. The effective members are distributed as follows:

ORGANIZATION TYPE	NUMBER
Institutions	8
Industries and business associations	28
Research Centres and Universities	11
Civil society	2

ICESP subscribers agree on the relevance and the common interest regarding:

- eco-innovation, research, development and technology transfer;
- regulatory, financial and market instruments;
- enterprises and supply chains organizational models;
- measurement tools and indicators;
- guidance and support to businesses;
- promotion of new cultural approaches and lifestyles;
- role of territories and cities in guiding the transition from global to local and vice-versa

However, many other organizations are involved in working groups even if they have not signed the Charter, reaching an approximate number of 100.

ICESP 's work is organized in the following six working group (see also table XX):

- WG1: Research and eco-innovation, knowledge diffusion and education
- WG2: Policy and Governance tools

- WG3: Instruments for measuring circular economy
- WG4: Systems and models for sustainable and circular design, production, distribution and consumption
- WG5: Cities and territory
- WG6: Best Practices and Integrated Approaches

Within the WG5 “Cities and territory” stakeholders are classifiable according to the quintuple helix, because citizens, social entrepreneurs and activists are engaged in the platform too.

Furthermore, some good practices linked to WG5’s activities are classifiable within the frame of the quintuple helix, in which citizens and city makers are the main actors, together the other representatives of the quintuple helix, and a few best practices in which citizens are become co-governors of city commons have been collected, too.

All them are involved in periodic consultations in relation to the ECESP Coordination Group meeting. Additionally, the operational and consultation activities realized by the Working Groups are aimed to produce position papers, recommendations and guidelines to be presented in ECESP and will be useful for the promotion of the Italian way for circular economy and with various topics of interest including:

- Research and eco-innovation
- Dialogue and good practices collection
- Dissemination of knowledge and training
- Regulation
- Financial instruments
- Circular economy measurement
- Improvement of public awareness on sustainable consumption models

Finally, the WGs are also involved into the organization of events dedicated to communication and dissemination of results.

As for mechanisms adopted for activating cooperation, each Working group has 2 or 3 coordinators (see table 2), engaging to set up periodical meeting to activate cooperation and deliver the expected results.

Table

<i>Working Group</i>	<i>Coordination</i>
WG. 1 - Research and eco-innovation, knowledge diffusion and education	CNA, Puglia Region-ARTI, University of Bologna
WG. 2 - Policy and Governance tools	Minister of Environment DG-RIN, Minister of Economic Development, Unicircular
WG. 3 - Instruments for measuring circular economy	ENEA, Minister of Environment –DG SVI
WG. 4 - Systems and models for sustainable and circular design, production, distribution and consumption	ENEA, ENEL, Intesa Sanpaolo Innovation Center
WG. 5 - Cities and territory	Agency for Territorial Cohesion , ENEA
WG. 6 - Best practices and Integrated approaches	ENEA, Puglia Region-ARTI, Unioncamere

The platform includes a strong work from the coordination team for ensuring the achievement of results in line with the platform aim. Moreover, the General assembly sets the annual plan for the Working Groups (WGs) work. The activities are carrying out both in offline mode as well as online by using the interface available on the website www.icesp.it.

The outcomes are published in the website and are available for free download. Another offline/online work has been developed for the contribution on Good Practices (GPs). Indeed, the GPs can be directly uploaded in the website (function foreseen by June 2019) but also they can be uploaded by coordination team (the manager of website) that collects them in the WGs activities through stakeholders' involvement, using a specific format. All those GPs are the basis for implementing the ICESP GPs database that is then implemented on the ICESP website and has a specific interface for the users. The GPs format takes into account all mandatory fields required by the European Platform ECESP in order to make possible for the contributors to make easier the submission also in ECESP website, increasing the visibility and the GP dissemination.

Different stakeholders are expected to contribute in different way and these expectations are reflected in working group. For example, research (RTO and Academy) is more engaged in Research and Ecoinnovation working group, while industries in Design, Production and Consumption system working group. However, all the sectors are involved in all working group to ensure the "ICESP closing the loop".

As for the technical model, ICESP has a website aiming to become an interactive way for stakeholders' communication. Other National platforms exist, with similar approach even if with different internal mechanism. However, every platform is configured as voluntary work supporting ECESP work through Coordination Group. Standard does still not exist

5. Conclusions

Aimed to provide a contribution of systematization at the intersection of the research on Circular Economy and Innovation Ecosystems in the perspective of Quintuple Helix, the study has analysed the case of ICESP, as institutional initiative aimed to support the development of circular economy. As extreme case study of a platform supporting the creation of an innovation ecosystem, the analysis of ICESP has been addressed toward the comprehension of its strategic, organizational and technological model.

In allowing to demonstrate how the availability of a digital platform, conceived in the frame of larger and institutional strategy, can positively impact on the creation of an innovation ecosystem, the case of ICESP has offered interesting insights on the different categories of stakeholders involved in and their characterization according to the model of quintuple helix.

Implications for theory arise in terms of replication of the study, also through the embracement of investigative tools aimed to monitor the role and centrality of stakeholders, the foresight and the dynamic analysis of their behaviours, the comparison of similar initiatives in different national and regional contexts. Additionally, the study

offers several implications for the agenda of policy makers, in terms of sustainable and collaborative innovation processes for supporting the development of circular economy.

Abstract

The issue of urban waste has become a priority from a social and environmental point of view and in literature there are various papers studying technological and economic solutions to overcome these problems. For this reason, important strategic choices are needed, with the goal to increase the recovering of waste separate collection (to reduce waste landfilled) and to increase energy recovery from waste value chain. The aim of the paper has been to assess the environmental impacts of a pilot plant from RDF (refused derived fuels) to syngas, through the LCA methodology to create innovative network of sustainable business closing the loop in terms of circular economy. Syngas is a gas obtained from a pyro gasification process, which converts carbonaceous material into simpler molecules of CO, CO₂, hydrogen and methane (syngas) to be reused to feed small engines or to produce other chemical intermediates. The case study presented, offers the possibility to evaluate an alternative option to reduce waste landfilled, creating in the same time new business and a new model of “share” in knowledge ecosystem perspective. Considering the circular economy aspect, the use of RDF to produce syngas, can represent a goal to be pursued. The environmental analysis shows that a small plant to produce syngas, if well managed, can represents an important choice for the environmental performance. On the basis of data and considering that a percentage of 20-30% has lost in the Biological and Mechanical Treatment, in Puglia there is potential RDF-end of waste in the range of 374 – 428 millions of kilograms per year. Hence, according to the provincial areas of Apulia, almost six plants would be implemented, creating replicable models with the final aim to “quickly” re-use waste and re-invent industry.

Keywords – Circular economy, Syngas production, eco-innovation, sustainability,

Paper type – Practical paper

1. Introduction

Recently the European Union promoted the new economic system that has been also based on the valorisation of secondary raw materials, to reduce waste generation and create new materials and commodities from waste within a continuous economic cycle. This aim can certainly be pursued by reducing urban waste amount to be sent to landfills, increasing both the recovery of materials and energy. The issue of urban waste has become a priority from a social and environmental point of view and in literature there are various papers studying technological and economic solutions to overcome these problems. From a circular economy perspective, a possible option could be “waste to energy” that is to create a value supply chain using Refused Derived Fuels (refused derived fuels) obtained from urban waste to produce synthetic gas (syngas) avoiding fossil fuels use. According to the Italian law, the RDF labelled as “end of waste” are only produced in authorized plants certified UNI En15358 or registered Emas (Environmental Management Audit Scheme). A declaration of conformity by the manufacturer sanctions the status of end of waste, and it must be compiled according to specific scheme attached to the regulation.

The RDF gasification is sustainable from a social and environmental point of view: from social point of view, it integrates waste separate collection into the supply chain, enhancing a more careful verification of undifferentiated waste and, in the same time, allowing to trace the matter flows from the various production processes. This last aspect guarantees an effective control of management in each of the management phases, certifying it as non-hazardous waste. From an environmental point of view, because it allows to recover energy that could be reused to power production plants that are fuelled by fossil fuels.

In Puglia the problem of waste is becoming an urgent issue to be solved and the priority is to find efficient technical and managerial options. For this reason, important strategic choices are needed to increase the waste separate collection, which rate (47%) is not high enough, and the energy recovery from waste value chain. In this direction, innovative small power plants could be used to produce syngas, a synthesis gas obtained from a pyro gasification process, which converts carbonaceous material into simpler molecules of CO, CO₂, hydrogen and methane (syngas) to be reused to feed small engines or to produce other chemical intermediates.

For this reason, important strategic choices are needed, with the goal to increase the recovering of waste separate collection (to reduce waste landfilled) and to increase energy recovery from waste value chain. For example, small power plants could be used to produce syngas, a synthesis gas obtained from a pyro gasification process, which converts carbonaceous material into simpler molecules of CO, CO₂, hydrogen and methane (syngas) to be reused to feed small engines or to produce other chemical intermediates.

The aim of the paper has been to assess the environmental impacts of a pilot plant from RDF (refused derived fuels) to syngas through the LCA methodology to create innovative network of sustainable business closing the loop in terms of circular economy. The case study presented, offers the possibility to evaluate an alternative option to reduce

waste landfilled, creating in the same time new business and a new model of “share” in knowledge ecosystem perspective. Moreover, based on the results, a potential implementation at territorial level of this approach has been considered.

2. Materials and methods

The LCA analysis has been performed to verify from environmental point of view whether the production of syngas can be considered a strategic initiative to be used in long- and medium-term choices at territorial level. After calculating the environmental impacts, the successive step has been to validate the hypothesis to implement in Apulia region different small plants of syngas production for developing a circular economy model. From these analyses a useful location for the plants could be the provincial area. The territorial level has been chosen, because the local approach allows for avoiding and/or reducing the economic and environmental cost of the waste transport. In the hypothesized model, percentage of mixed waste treated to become input for the syngas production has been analyzed. In 2018 over $1,750 \cdot 10^6$ kg of solid urban wastes have been produced in the region Apulia (Regione Puglia, 2018). About 47% of the total urban waste have been collected separately, while the remaining part, about $922 \cdot 10^6$ kg were mixed waste, that is not sorted at source and that needs to be managed. It usually treated in Biological and Mechanical Treatment plant to separate and manage waste according to chemical and physical characteristics. From these plants, which are eleven in Apulia, about 58% was disposed of in landfills (ISPRA, 2018). In the hypothesized model, percentage of mixed waste treated to become input for the syngas production has been analyzed. Furthermore, the LCA analysis has assessed the environmental impacts to understand the validity of the approach from the environmental point of view.

2.1 Syngas production

Before illustrating the hypothesis, a briefly information related to the syngas is given. Syngas is a mixture of gases comprising carbon monoxide (CO) and hydrogen (H₂), methane (CH₄) and carbon dioxide (CO₂). Biomass such as agricultural wastes, forest products, grasses, residual waste and other cellulosic material may be converted to syngas. Syngas, furthermore, is an intermediate in the chemical and bio- refining industries and has a vast number of uses because can be converted into alkanes, olefins, oxygenates, and alcohols, such as ethanol and it is also used as an intermediate in producing synthetic petroleum as a fuel or lubricant via the Fischer–Tropsch synthesis or can be used to produce organic molecules, such as synthetic natural gas (SNG-methane). In the last years, syngas has been studied to produce from waste materials that would otherwise need to be discarded. Instead of placing waste products in landfills, these waste products can be used to generate a useful, energy rich product. This makes the syngas conversion process both an efficient means of producing energy and an environmentally friendly option for the recycling of waste products, in the light of circular economy. Syngas is obtained by a thermo-chemical reaction process named gasification. Gasification transforms the carbonaceous material (biomass, waste, coal,

etc) into a mixture of combustible gases, containing 20-40% hydrogen (H₂), 35-40% carbon monoxide (CO), 0-15% methane (CH₄) and 25-35% carbon dioxide (CO₂).

During the process, the material is heated at a high temperature of approximately 850°C with a controlled amount of oxygen, air and/or steam (gasifying agent) and limited combustion to supply thermal energy and sustain the reaction. The gasification process takes place inside a reactor and can be divided into two stages: the first stage – pyrolysis, where the volatile components of the fuel are released by means of a series of complex reactions at temperatures below 600°C (Cherubini and Stromman 2011).

2.2 The studied process analysis

The LCA analysis has been carried out to a pilot plant that has been operative for a period of six months, as experimental phase, to produce Syngas from RDF. The production of the RDF is developed in the following phases:

- waste collecting;
- bio- stabilization
- mechanical separation of the inert and metallic fraction

The incoming waste undergoes a process of shredding that reduces the volume to less than 250 mm to be subsequently loaded in specific boxes for the stabilization of organic residues. The bio stabilization phase goes on for about a week and is carried out by injecting air allowing the mass to be uniformly oxygenated, favouring a temperature of around 40°C. During this phase, the weight is reduced by about 30%. Starting from a ton of urban waste, about roughly 700 kg of RDF are obtained, and this has been the result of plant, as well. The average waste transport for this study was calculated at 150 km and it was hypothesized to produce biochar that varies from a minimum of 3% (with the production of syngas equal to 97%) to a maximum of 33% (with the production of syngas equal to 67%). Biochar is formed from ashes (inert material) and a carbon residue. Biochar has a good calorific value, and this means that can be reused in the plant (Arena 2012; Arena et al, 2014; Field et al., 2013).

Table 1 shows the product percentage of the waste that results from the production process (as underlined above, 1.95 kg for 1 kg of syngas produced has been calculated. A preliminary screening of the relevant parameters of the waste for RDF has been necessary.

Table1: Waste average composition

Wood	12%	0.23
Paper	41	0.80
Organic matter	2.5	0.05
Metals non-ferrous	2.5	0.05
Glass	1.5	0.03
Plastic	29	0.57
Textiles	11.5	0.22
<u>RDF</u>	<u>100</u>	<u>1.95</u>

Considering the indications of the UNI EN 15359: 2011 standard, considering the intrinsic characteristics of the RDF, such as the calorific value, the content of chlorine and mercury, the RDF was suitable for the plant experiment. During the operation of the plant, a massive loss has been recorded, probably due to cellulose and plastics decomposition. The process is technically feasible with different material used during the experimental phase as plastics residual of industrial treatment and paper waste (Materazzi, 2016)

Table 2 illustrates a summary of the main characteristics of the plant.

Table 2 Characteristics of powerplant of Syngas production

Main technical features	
Operation plant	1000 kg/h
Average temperature	800 °C
Gassifier agent	Nitro
Biochair production	Between 3% up to 33%
Energy input	2,5 kW/h
Syngas density	1,1 kg/Nm ³

To have a correct operative functioning of the plant it is important to take under control different parameters as gasifier agents, temperature, fluidizing speed.

3. Results and Discussion

The first hypothesis has been to assess the environmental factors to verify the opportunity to proceed with this plant technology. According to the LCA methodology, the study has been split into upstream, core (mainstream), and downstream. with the Ga.Bi software (Ecoinvent v. 3.3 of Ga.Bi software v. 6.6). Data have been collected from literature and primary data collected from the power plant. The functional unit is normalized to 1 kg of syngas produced (Schreiber et., 2012; Sebastian et al., 2011). Figure 1 highlights the preliminary analysis of the study (showing only the results of global warming, the eutrophication and the acidification).

The upstream phase is the more critical between environmental emission. This is important because correct management of the collection phase and the management of the arrival of the input for thermo-chemical conversion represent the most important aspects to consider for environmental emission. During the core phase, the emissions are very low, as compared to the upstream phase, and this is a confirmation that a strategy based upon the syngas can play an important role in the circular economy approach. However, it is necessary to create the preconditions to make the RDF suitable, considering that it is the most problematic aspect of the supply chain. Emissions are strictly imputable to the movement of waste within the site, because of the bio-stabilization and selection process to create RDF. The intermittent steps between the different phases of the pre-treatment phase need to be improved, such as the handling of waste before the loading phase, which occurs by means of mechanical shovels. Inside the gasifier, the main problems are related to the erosion and corrosion phenomena which can make the gasifier stop. In many cases, the problems of corrosion are due to alkaline compounds, such as potassium, which can be found both in the biomasses and in the organic waste fraction, which can react with the silicon forming silicates creating encrustations on the walls of the gasifier. This problem certainly is more enhanced because the gasifier is a small plant, but in any case, it has caused different problems.

4. Conclusion

Sharing innovation, technologies and resources within this case study moves towards the closing of the loop and circular economy. It can reduce the amount of waste landfilled and exported recovering material and energy otherwise lost creating, in the same time, new sustainable business and better environmental performance.

Considering the circular economy aspect, as underlined above, the use of RDF can represent a goal to be pursued. The environmental analysis shows that a small plant, if well managed can represents an important choice for the environmental performance. On the basis of data shown in the previous section and considering that a percentage of 20-30% has lost in the Biological and Mechanical Treatment, in Puglia there is potential RDF-end of waste in the range of 374 – 428 millions of kilograms per year.

Hence, according to the provincial areas of Apulia, almost six plants would be implemented, the greatest one in Bari, for the total production of syngas in the range of $190 - 218 \cdot 10^6$ kg per year.

It must be underlined that Region Apulia provided for a waste management perspective up to 2020-2025, in which the separate collection would be increased to 65%, the landfill disposal reduced. In this waste management outlook, the role of production of RDF end of waste should be improved. In this direction the RDF use could be one of the possible options to decrease the still high (355,000 t in 2017) amount of mixed waste exported by our country.

Other consideration is represented by the technological aspect. Has underlined, the syngas conversion from RDF input has good environmental performance indicators. Consequently, co-gasification processes can also be designed to broaden the possible

technology usage scenarios. The syngas produced can be used in different applications, depending by the level of purity obtainable by input selection after the preliminary treatments. The main alternatives are the use as an energy carrier or as a building block for the synthesis of different chemicals (from hydrogen with methanol, ammonia, liquid fuels, etc.). The latter is very important as, unlike from incineration process (waste-to-energy), a technological approach based on the production of syngas can have a multiplicative effect as it can feed new value production chains and not only be used for energy production. These considerations can help a significant reduction of wastes to landfill, avoiding environmental problems and enhancing a policy based on the shifting to circular economy approach.

This kind of more sustainable approach to manage the waste could be successfully implemented in the different Italian regions creating replicable models made available by local network (all actors involved) with the final aim to “quickly” re-use waste and reinvent industry. Indeed, the case study has been analyzed also with a knowledge ecosystem perspective the opportunity to create a cohesive and dynamic system within all the actors involved.

Abstract

The improvement of knowledge worker performance with reference to the workload is a great challenge to most economies and their firms. In many knowledge-intensive organizations, the key cost component is the worker's worktime. Recent research has demonstrated that a worker's dual temporal experience gives rise to an unconditional Cognitive Time Distortion (CTD), understood as the relation between perceived time and physical time, for a given event. By reducing and controlling for CTD significant knowledge worker performance improvement can be achieved. We have, however, little knowledge about how to decrease the knowledge worker's level of CTD while doing knowledge work. In this study, we test different feedback techniques in a laboratory experiment aiming at influencing and controlling the CTD of individuals. The context of the experiment is worker performance feedback, with regard to worker's self-assessment of worktime for a given work conducted. One group (n=32) receives performance feedback contenting monetary reward information only, whereas a second group (n=31) receives performance feedback containing only information on the level of worker's CTD. The results show that the provision of feedback of CTD produces different self-assessments of worktime, as compared to the group that only received monetary-related feedback. The group with feedback information about the level of CTD manifests a significantly lower variance of CTD in their time assessment than did the group that received monetary reward information only. These results suggest profound implications for the performance feedback practices for knowledge workers performance.

Keywords – Cognitive time distortion, Feedback of error of time assessment, Knowledge worker, Temporal workload, Worker performance management.

Paper type – Academic Research Paper

1 Introduction

The activity and success of today's economic organizations such as software and data processing companies, recruiting firms, financial, businesses, consulting and accounting services firms to a large extent depend on the performance of knowledge workers and the volume of this workers is increasing in developed countries (Salas-Vallina et al., 2018; Sawant and Jain, 2017; Sørensen and Holman, 2014; Turriago-Hoyos et al., 2016). In current work environments, these workers often experience high workload and time pressure (Froehle and White, 2014; Škerlavaj et al., 2018). Hence, the improvement of knowledge worker performance and productivity with reference to the workload is a great challenge for most organizations.

For many knowledge-intensive organizations, the key cost component is the worker's worktime. Previous cognitive science literature demonstrates a significant difference between a worker's cognitive time and physical clock time. The Temporal Workload Equation suggests that a worker's dual temporal experience gives rise to an unconditional CTD, understood as the relation between perceived time and physical time that significantly affects key economic indicators such as profit, productivity, workload and risk (von Schéele, 2001; von Schéele and Haftor, 2013; 2015; 2018; von Schéele et al., 2018). It is also established that the reduction of a knowledge worker's CTD contributes to a higher efficiency of the workload (von Schéele and Haftor, 2018). Previous experimental studies on time prediction and assessment demonstrate the importance of experience and training (Block et al., 2010; Halkjelsvik and Jørgensen, 2012; Roy et al., 2008; Roy and Christenfeld, 2007; Thomas et al., 2003; 2007; Tobin and Grondin, 2012; 2015), yet without showing how CTD can be controlled so that its detrimental influence on economic indicators is suppressed. Particularly, it is unclear what feedback mechanism is recommended for controlling CTD.

Over the last decades, different management techniques were advanced with the aim to provide higher efficiency of workers' workload (Sawant and Jain, 2017, Sørensen and Holman, 2014). Yet, the idea of "nudge" interventions and behavioral science techniques for changing individual behaviour and performance has achieved particular attention (Benartzi et al., 2017; Thaler et al., 2014). The nudge theory proposes to affect individual performance by the choice architecture that alerts people and directs behaviour in a predictable way (Thaler and Sunstein, 2008). One of the tools of the choice architecture is feedback provided to an individual (Thaler et al., 2014). Many organizations provide monetary-based feedback to affect performance of their employees, yet without achieving desired outcomes (Lourenço, 2015; Kosfeld et al., 2017). This evidence calls for additional research on feedback techniques in relation to knowledge worker performance.

This study presents a comparison of “nudging” the knowledge worker behavior so as to reduce CTD in a laboratory experiment with the aim to understand how CTD can be controlled. The here presented laboratory experiment evaluates two different performance feedback information for individual knowledge workers aiming at influencing and thereby controlling the CTD of individuals. The context of the experiment is worker performance feedback, with regard to worker’s self-assessment of worktime for a given work conducted. One group received performance feedback contenting monetary reward information only, whereas a second group received performance feedback containing only information with the level of worker’s CTD.

The results of the laboratory experiment demonstrate that unlike monetary-related feedback, time-related feedback of CTD significantly reduces error in time assessment (von Schéele, 2001) and soften the lever effect of the distorted time assessments. The provision of feedback of CTD produces different self-assessments of worktime, as compared to the group that only received monetary rewards. The group with feedback information about the level of CTD manifests a significantly lower variance of CTD in their time assessment than did the group that received monetary reward information only. These results suggest profound implications regarding the performance feedback as a tool for nudging where we demonstrate the importance of information on the worker’s level of CDT. The successful outcome of the time-related feedback is here suggested to be considered and further studied from the perspective of the nudge theory.

The paper is structured accordingly: Section 1 presents a summary of research on current nudge interventions together with a mathematic definition of CTD in section 2. Section 3 informs the reader about the details of a laboratory experiment, in which different modes of controlling the CTD is tested. In section 4 the results from the laboratory experiment are presented. The paper concludes with a discussion of the obtained results together with remarks about further research.

2 Theoretical background

Below, we review studies that explore the role of nudging via feedback on individual behavior, describe CTD definition and summarize current empirical evidence on individual time perception and time assessment.

2.1 Nudging through feedback

Although the concept of feedback is a fundamental factor for both manual and knowledge workers (Frey and Osterloh, 2002), current motivation systems including feedback are shown to just partly affect knowledge worker behaviour and improve performance (Hopp et al., 2009; Markova and Ford, 2011; Pink, 2009; Salas-Vallina et al., 2018). Over the last decades, the idea of “nudge” interventions for changing individual behaviour and performance has achieved particular attention (Benartzi et al., 2017; Thaler et al., 2014). The nudge theory proposes to influence individual performance by the choice architecture that directs behaviour in a predictable way significantly

changing incentives (Thaler and Sunstein, 2008). One of the tools of the choice architecture is feedback given to an individual (Thaler et al., 2014).

Feedback is defined as an action taken by external party to provide information regarding aspects of the conducted task performance (Kluger and DeNisi, 1996). Feedback is often mentioned as one of the most powerful influences on individual behaviour and performance improvement (Molloy and Boud, 2014). Feedback provision and its relevance is supported by different theoretical traditions. In psychological literature, feedback is demonstrated to have positive effects on motivation, attention and learning (Kluger and DeNisi, 1996). In behavioral economics, feedback is considered as a means to nudge individual behaviour in a desired direction (Thaler and Sunstein, 2008). Although a number of studies demonstrate how feedback can improve individual performance (Garbers and Konradt, 2014; Song et al., 2017), they also show the complexity of feedback techniques that do not always have positive results. For example, monetary-based feedback does not always positively affect knowledge worker behaviour and performance (Lourenço, 2015; Kosfeld et al., 2017). Therefore, in this paper we seek for a special type of feedback that will nudge knowledge workers towards efficient workload and performance.

For knowledge-intensive organizations worktime is a key cost component. Recently, it was demonstrated that CTD (the relation between perceived time and physical time for a given event) significantly affects key economic indicators such as profit, productivity, workload and risk (von Schéele, 2001; von Schéele and Haftor, 2013; 2015; 2018; von Schéele et al., 2018) and a reduction of a knowledge worker's CTD contributes to a higher efficiency of the workload (von Schéele and Haftor, 2018). However, we still have a lack of knowledge on how to control CTD and what feedback technique is recommended to manage CTD. Below, we explain in more detail the definition of CTD and review studies that provide empirical evidence on factors that can significantly affect individual time prediction and time assessment.

2.2 Cognitive time distortion, temporal prediction and assessment

Psychological literature that addresses human cognition provides clear evidence that there is a difference between physical clock time and worker's cognitive time (Block and Eisler, 1999; Levin and Zakay, 1989; Nembhard and Uzumeri, 2000). Moreover, humans experience temporal duration differently (von Schéele and Haftor, 2014, von Schéele and Haftor, 2018). CTD denoted as τ_i is understood here as the ratio between *cognitive time* (t_c) and *physical time* (t_p) which can be formalized accordingly:

$$\text{Time Distortion: } \tau_i = (t_c / t_p)_i \quad (1)$$

The operationalization of CTD focuses on measuring a deviation of the cognitive time with reference to a certain reference point, or event. In equation 1, “ i ” may be a process, project, or a service contract. Both t_c and t_p must in the definition refer to the same event,

in order to give sense and meaning to CTD. CTD in the assessment of 1 cognitive hour may vary between 1.08 and 2.14 physical hours (von Schéele et al., 2018).

Previous literature on temporal assessment investigated time assessment from two perspectives. On the one hand, studies focused on the predicted time assessment before the task was performed (Roy and Christenfeld, 2008; Tobin and Grondin, 2012). On the other hand, time assessment was also studied after the task was completed (Tobin et al., 2010; Bisson et al., 2012). For example, it was established that prior experience with a task has a positive effect on predicted time of task performance (Block et al., 2010; Halkjelsvik and Jørgensen, 2012; Roy et al., 2008; Roy and Christenfeld, 2007; Thomas et al., 2003; 2007; Tobin and Grondin, 2012; 2015). It was found that simple short task practice of 2 minutes significantly increased the accuracy of temporal prediction of individuals in task performance (Thomas et al., 2003). Moreover, it was shown that the number of trials positively affects the accuracy of temporal prediction (Roy and Christenfeld, 2007). Tobin and Grondin (2012) also demonstrated that prior task duration knowledge can improve the accuracy of temporal prediction significantly.

Some studies investigated the question of time assessment when time assessment is done after the task is performed and demonstrate mixed results (Tobin and Grondin, 2015). Boltz et al. (1998) found it difficult to find time assessment differences between experts and novices. Other studies demonstrate a significant difference in time assessment between these groups of participants, demonstrating that experts are better in time assessment than novices (Roy et al., 2008; Tobin and Grondin, 2015) and thus highlight the importance of prior experience and training with a task on the perceived duration of the task.

Although prior experience and training is shown to positively affect temporal prediction and time assessment after the task was performed (Roy et al., 2008; Tobin and Grondin, 2015) and there is also empirical evidence that temporal feedback about the duration of the task may positively affect temporal prediction of the task (Roy et al., 2008; Ryan and Fritz, 2007), the question of how CTD can be managed and what feedback mechanism can improve time assessment precision has not been addressed. To address this gap, a detailed laboratory experiment was conducted to understand how time precision assessment can be managed with time-related feedback of CTD in comparison to monetary-related feedback.

3 Method

A laboratory experiment was designed and conducted to fulfill the following criteria: (a) participants chosen are appropriate for the experiment, (b) participants performed a knowledge-intensive task to mirror real work settings, and (c) sample size is sufficiently large to provide statistical power.

3.1 Participants

The laboratory experiments comprised of 63 participating students (n=63) at the Royal Institute of Technology, Stockholm. They were divided into two groups, where

each group received different modes of feedback. One feedback mode was based on bonus (*Monetary-related feedback*), while the other feedback mode was based on information about the CTD (*CTD-related feedback*). Each group had to assess time durations five times consecutively, and the result of the mean values and the variance of the time assessments were compared. Before feedback to each group, there were no significant differences in mean values of CTD, and no significant difference in variance of CTD. Table 1 demonstrates distribution between feedback mode and gender.

Table 1 Crosstabulation between feedback mode and gender

			Gender		Total
			Male	Female	
Feedback mode	Monetary-related	Count	20	12	32
		Percentage of total	31.7	19.1	50.8
	CTD-related	Count	8	23	31
		Percentage of total	12.7	36.5	49.2
Total		Count	28	35	63
		Percentage of total	44.4	55.6	100.0

The participants in the experiment were 44.4% male and 55.6% female. Among participants with male gender, 20 (31.7%) received monetary-related feedback and 8 (12.7%) received CTD-related feedback. Among participants with female gender 12 (19.1%) received monetary-related feedback and 23 (36.5%) received CTD-related feedback respectively.

3.2 Procedure and material

Each participant performed an independent work task (putting a jigsaw puzzle together as soon as possible) in a room without any clock and assessed the duration of five-time intervals. The puzzle consisted of 60 pieces and was enough complicated to guarantee that an adult person would need at least 15 minutes to finish the puzzle. During the experiment all five intervals had the same time duration of 2 minutes and 26 seconds. The participants were not informed about the length of time intervals and received only information when an interval started (participants received a message: “*time interval starts now*”) and ended (participants received a message: “*time interval ends now*”). Directly after finishing time interval, the participants were asked to assess its duration as accurate as possible. After that the participants received feedback and continued work by indicating that the next time interval starts now. The procedure was repeated five times and the experiment was finished by informing the participants about the aim of the research.

The monetary-related feedback was designed in a way to imitate certain management strategies that favour “bonus system” and monetary reward. The participants were orally informed that they will receive a reward of 500 SEK if they make the most accurate time assessment. After each assessment the participants received the following feedback

message: “Good work! Well done! If you continue to make even better assessment next time, you may earn money bonus”.

The CTD-related feedback was designed to investigate how individuals react on being informed about their cognitive time distortion. The participants were orally informed that they will receive feedback indicating how their time assessment complied with the objective duration in percent. After each assessment the participants received the feedback message: “Good work! Well done! However, your time assessment was xx % too high or too low.”, depending on the true value in percent of how much his/her time assessment deviated from the objective time. For each time interval, the physical time, subjective time assessment and CTD were registered.

4 Results

The experiment was designed to investigate how the mode of feedback: monetary-related versus time-related feedback on CTD affects time assessment after tasks were completed. The results of the experiment demonstrate that the mode of feedback produces different time assessment of worktime (see Figure 1).

Figure 1. Box plot of different modes of feedback mode's influence on time precision assessment.

As depicted in Figure 1, the five-time assessments divided into groups of feedback modes. The group that received feedback about their CTD, exhibit significantly lower standard deviation as compared to the group that has feedback about monetary-related feedback. These results are supported by Levene's test of homogeneity of variance (Table 2).

Table 2. Levene's test of homogeneity of variance

		Levene Statistic	df1	df2	Sig.
Time precision assessment 1	Based on Mean	.240	1	61	.626
	Based on Median	.222	1	61	.639
	Based on Median and with adjusted df	.222	1	60.160	.639
	Based on trimmed mean	.242	1	61	.624
Time precision assessment 2	Based on Mean	.885	1	61	.350
	Based on Median	1.021	1	61	.316
	Based on Median and with adjusted df	1.021	1	56.105	.317
	Based on trimmed mean	.916	1	61	.342
Time precision assessment 3	Based on Mean	8.765	1	61	.004
	Based on Median	7.163	1	61	.010
	Based on Median and with adjusted df	7.163	1	43.496	.010
	Based on trimmed mean	8.265	1	61	.006
Time precision assessment 4	Based on Mean	15.016	1	61	.000
	Based on Median	12.473	1	61	.001
	Based on Median and with adjusted df	12.473	1	41.615	.001
	Based on trimmed mean	15.037	1	61	.000
Time precision assessment 5	Based on Mean	21.232	1	61	.000
	Based on Median	18.920	1	61	.000
	Based on Median and with adjusted df	18.920	1	39.294	.000
	Based on trimmed mean	21.089	1	61	.000

The results in Table 2 demonstrate that from time assessment no 3, there is a significant difference between the variance of the two groups with different feedback modes. The group with time-related feedback manifests a significantly lower variance of CTD in their time assessment that did the group with monetary-related feedback. Time-related feedback reduces the variance of time assessments to less than half of the variance in comparison to monetary-related feedback.

The Hawthorne effect of the experiment was minimized by anonymous and voluntary participation (Campbell and Stanley, 2015). The threat of the construct validity such as hypotheses guessing (Cook et al., 2002) was minimized by informing participants about the aim of research at the end of the experiment. The internal validity was ensured by a

short duration of the experiment. Students who participated in the experiment performed knowledge-intensive tasks and are representative of the target population.

5 Discussion and Conclusion

In many industries, knowledge workers' worktime represents the key cost component of a firm's cost structure. Recent studies demonstrate that CTD can cause time leakage and thus affect knowledge worker performance. Yet, we know little how to decrease the level of CTD while doing knowledge work to ensure improved performance. The present study presents a comparison of "nudging" the knowledge worker behavior so as to reduce CTD by providing time-related feedback.

The results of this study show that unlike monetary-related feedback time-related feedback on CTD is more effective at managing individual time assessment and its precision. Key theoretical implication of this study is the empirical evidence that CTD can be controlled if managed correctly. Moreover, we demonstrate that a nudge technique (Thaler et al., 2014), in our case time-related feedback is very relevant as a management technique in individual time assessment. This technique is shown to significantly reduce CTD and contributes to a higher efficiency of the workload (von Schéele and Haftor, 2018) and thus improve knowledge worker performance.

Although a significant body of studies shows the role of previous experience and training in temporal prediction and time assessment (Block et al., 2010; Tobin and Grondin, 2012; 2015), there is also some evidence that temporal feedback about the duration of the task may positively affect temporal prediction of the task (Roy et al., 2008; Ryan and Fritz, 2007). However, no studies have demonstrated how time-related feedback affect time assessment after the task was performed. In this study, we addressed this gap and demonstrate in experimental settings that time-related feedback on CTD can significantly improve time assessment.

The results of the study also demonstrate that monetary-related feedback does not significantly affect time assessment and thus can be incorrectly used by managers in adjusting individual workload. In contrasts, the results of this experiment enable managers with a technique on time-related feedback of CTD that can be used to improve the efficiency of the workload. Applying this technique may improve the precision of time assessment, optimize the workload and thus, improve knowledge worker performance.

The results of this study also provide recommendations for future research. First, during the experiment all five intervals had the same time duration. Future research can change time duration of intervals to avoid the learning curve effect. Second, in our experiment time duration of 2 minutes and 26 seconds was used. Longer durations of more than only some minutes would provide more detailed evidence on how time-related feedback affects time assessment. Third, between experimental intervals were no brakes and thus future research could investigate time assessment with longer pauses. Finally, actual knowledge-intensive practices could reflect real-world practices by providing a more detailed consideration of CTD and time assessment.

Abstract

We have in this paper looked into what forms the knowledge worker in the future both on a corporate level and a societal level. We have interviewed researchers working with these issues in the Swedish telecommunication company Telia and the Norwegian telecommunication company Telenor. These are both companies making their living of understanding the future both on a corporate level and a societal level.

We have concluded that robotics and AI will be more advanced, but neither the way we are working nor the way we are organizing work will change much in the years to come. The processing of information will be an even more critical work task either in itself or integrated into every work task. Every knowledge worker will have to try to see and think through what will be happening today and tomorrow. The past, present, and future will merge into a working reality. There will be dynamic scenarios together with the corporate, team and individual networks. Those grasping and understanding the situations working in professional and organizational networks will be the winners. They will be the bottom-up needed for corporate success still working in a top-down hierarchy delivering products and services through a global logistics.

We have found that the one key for any organization in the future will be an analytical eye-toward-the-future where anything happening is analyzed and reported to the top management and coordinated into future deliveries. The key employees will be those implementing AI-based products and services on demand to advances customers. They will have a bottom-up understanding that is not needed in the eye-towards-the-future system and the top management system. The problematic issue for future work is the need for bottom-up understanding, sideways understanding and senior management based strategy and organizational coordination where project teams are coordinated working in collaboration.

The main finding is the slow change in Telia and Telenor towards a real knowledge worker using more of his working time to significant business issues. We will get a framework where a professional knowledge worker is using his qualifications or what he is educated for and where his professional experiences and attitudes are used in a positive way for delivering excellent results. The framework for the future will be

ordinary people achieving extraordinary results in teams owing to their education, experiences, and attitudes.

According to Telia and Telenor, we will take the environmental issues much more seriously, and large corporation together with the dominating economic powers will make the necessary starting steps to save the world. The saving of the earth represents a concentration of both corporate and national power. Neither Telenor nor Telia plan to reduce the number of employees, but will deliver higher profits and much higher sales per employee. Neither Telia nor Telenor look upon the AI technology as a threat only as many possibilities.

This study concludes that there will be many small positive corporate and societal steps for each year towards 2030 improving the way we are living and working together with environmental improvements. The reconstruction of the middle class is also emerging — neither a perfect nor imperfect world.

Keywords: Future knowledge work, Innovation, Fourth industrial revolution, Robots, Automation, Artificial intelligence

1. Introduction

In today's increasingly, knowledge-intensive and turbulent economy organizations are facing new levels of uncertainty and ambiguity. To survive many businesses must become more flexible and adaptive of the future. However, they face an oxymoronic situation where efficiency calls for standardization and routinization, while effectiveness calls for flexibility and tailor-made solutions. In the literature, these considerations often are treated as separate streams of knowledge. For example, the KM literature has a bias in considering knowledge as a "thing" that should be distributed through digitalized processes, gaining efficiency through standardization (Beck 2016).

On the contrary, the literature about professional service firms (PSFs) pays attention to expertise and knowledge as social constructions. The workplace of the future is not a concrete "thing" but a creation based upon subjective speculations about the consequences of globalization and technology for how we are organizing work in the future. The first industrial revolution started in England (Taylor 1911); the second one began in the US with the birth of standardization and the mass market, globalization, technology, and logistics drove the third one while the fourth one will incorporate the second and the third revolution by adding workable artificial intelligence solutions, as well as life science inventions (Bravermann 1974).

This literature is about how robots and artificial intelligence will transform working life. Our purpose is to understand what the workplace of the future will be. The researchers investigating these issues are writing about substantial changes where robotics and AI will take over the work and where we will get a well-educated elite of 20-30% succeeding and where the job of the masses are threatened and where a sizeable portion of the workforce will be without possibilities for work. The erosion of the middle class is described as the future.

Once the dust has settled from the fourth industrial revolution, workplaces and professions might be unrecognizable. A new class is seeing the light of day: the precariat (Dignan 2019). We will live side-by-side with the "working poor" – people who have several jobs, but still can't make ends meet (Ehrenreich, 2001). There will be a small salaried elite consisting of innovation and knowledge workers. Workplaces will be unrecognizable. Robots will have destroyed bureaucratic hierarchies, and torn apart the middle classes. What will remain will be contract workers with insecure jobs. Concurrently, we are seeing the emergence of a new level of knowledge pajama-workers – people who can do their jobs in bed or at a café table. Slightly further into the future, we can see a significant transformation in professional environments. Doctors will be medical engineers; nurses will be nursing assistants accompanied by robots. Robots and holograms might be replacing teachers. Moreover, taking this scenario further, we see the downfall of the great dinosaurs. Robots might diagnose and prescribe.(Susskind 2016).

While the industrial society caused the middle classes to grow and live in greater comfort, there is much to suggest that the Fourth Industrial Revolution will decimate the middle class. The decimation of the middle class might lead to that power and authority takes over the arena of knowledge management.(von Hippel 2003)

We know that most jobs will change rapidly. Until now, educated people have been able to find employment. In the future, many educated people will not find jobs. It seems likely that most jobs will be those either at the bottom or the top of the wage scale. We will see the development of the precariat and the working poor, but also well-paid innovation workers and knowledge workers.

Robots and informants are causing changes in employment structures. Old jobs disappear, and people are laid off. The public and corporate sector are creating fewer fulltime jobs, but more part-time jobs. The experience will be a disrupted and transformed work life. These trends are a direct outcome of the transition to the fourth industrial revolution.

The increasing informational and knowledge-related content of jobs is an expression of the emergence of a new organizational logic, with its specific characteristics; Lego-flexibility. Lego flexibility means that the production chain is outsourced to several countries by a cost-, quality-, innovation-and-competence logistic. Experience design is an innovative management and organizational model, where the focus is on user experience in the processes and the coupling between the customers and the workers who do what the organization is designed to do, i.e., the people in the front-line. Also backoffice may be attended to from a design perspective on organizational work(Von Krogh 2000).

Any social system that fails to balance between stability and change and at the same time being innovative will not be able to steer the ship at a time of increasing complexity. We see the transition from information and intensive knowledge jobs, to an increasing demand for innovation intensive jobs (West 2018)..

Robots, nano-computers, and information will interact with each other permeating all areas of employment. We figuratively, imagine this as neurons communicating in the human brain. Familiarity with contexts and a direct "hands-on" contact required by

traditional industrial production will be less critical. The implications for educational institutions and their educational programs and methods are already apparent.(Zsiska 2018).

The robots, nano-computers in networks and informants, will be characterized by a tripartite organization. Firstly, the market is developed for robot operators who will not need background knowledge other than experience in the work they perform, i.e., they are skilled production workers and will receive the appropriate training. The traditional knowledge professions will secondly be developed by reinforcing and translate their knowledge base about the design and development of the informants. Thirdly, new disciplines and trades will be generated that model, build and maintain robotic machines, informants and nano-computers. Robots, artificial intelligence, and informants are giving rise to such momentous changes that it is difficult to envisage how working life will develop in the future(Turner 2000),

We have in this paper looked into what forms the knowledge worker in the future both on a corporate level and a societal level. The future might be 2025, 2030 or 2035. We have interviewed researchers working with these issues in the Swedish telecommunication company Telia and the Norwegian telecommunication company Telenor. These are both companies making their living of understanding the future both on a corporate level and a societal level. The researchers investigating these issues are writing about substantial changes where robotics and AI will take over the work and where we will get a well-educated elite of 20-30% succeeding and where the job of the masses are threatened and where a sizeable portion of the workforce will be without possibilities for work. The erosion of the middle class is described as the future.(Tuschmann 2011).

We have concluded that robotics and AI will be more advanced, but neither the way we are working nor the way we are organizing work will change much in the years to come. The processing of information and its meaning will be an even more critical work task either in itself or integrated into every work task. Every knowledge worker will have to try to see and think through what will be happening today and tomorrow. The past, present, and future will merge into a working reality. There will be dynamic scenarios together with the corporate, team and individual networks. Those grasping and understanding the situations working in professional and organizational networks will be the winners. They will be the bottom-up needed for corporate success still working in a top-down hierarchy delivering products and services through a global logistics. (Zuboff 1986, 2018).

We have seen the car industry produce three times as many cars with one-third of the workers in the last generation. There is a dismissing return in how much we can reduce the numbers of workers for AI, robotics, and logistics. Delivering education and health care will anyhow be a work demanding human employees. Providing services might be more automated, but will still be work demanding. There is no reason to believe that we neither have come to an end of the middle class nor the number of people working. There might be more flexibility in the work life, but in 2030 there will be more people working

than at any time and more people than anytime will be educated at all level(Tsoukas 1996)-).

Our proposition is the opposite of the literature:

- (1) The corporate changes owing to AI, robotics and new information and communication technology(ICT) will be much smaller than anticipated and done by a step by step change with more knowledge workers than ever implementing the changes over time
- (2) The environmental issues will be handled much more seriously both by larges corporations and large nations and global cooperating agencies starting the reducing of the global temperature and CO2 gases.

2. Originality and value of the study

The originality of the work is to set the agenda for a discussion of societal and corporate driving forces. The consequences for the future work will be described, analyzed and explored. The future knowledge scenario gives a platform for what might be the future for work and the implications of the development already in action. The idea of this paper is rooted in doubt about an essential part of the literature describe as happening towards 2030. We wanted to look into if these opinions about the future compared to how the frontrunners look into the future. We have identified the telecommunication companies as frontrunners of the future.

The research question of this paper is:

What forms the knowledge work towards 2030 on a societal and corporate level?

3. Design/methodology

The study is an explorative study using a survey study together with the literature along with own imagination and intuition. We have interviewed five professionals in the future research division of Norwegian Telenor (The world 7th largest telecommunication company) about their views of the workplace of the future. We have also conducted two interviews at the Swedish telecommunication company Telia. Future work-life department (The world 12th largest telecommunication company). The interviews were conducted in March 2019. We are comparing the empirical data with the results from the literature.

4. Corporate findings

We can summarize the findings from Telenor and Telia in three sections. Both companies state the need for knowledge about different future scenarios, a dynamic understanding of the market, and the importance of corporate and professional networks.

4.1 The dynamic sharing economy of the future

1. Scenarios of the future. The future scenarios are including a plot of continuing as before, the worst scenarios and the best situations and the consequences of these scenarios. The scenarios are the eye towards the future every company needs.
2. A dynamic understanding of the market and the development of the market. There will be different aspects of the market, and there will be a reused market supporting the sharing economy. There will be a high-end delivery on demand of the most advanced solutions where the key employees form the future together with key customers. The communication here will be a bottom-up connection both to the eye-of-the-future department and the top management group.
 - (a) A product-network-service delivery as today.
 - (b) Second-Hand product delivery is reusing products. The reused and sharing part will be made to meet the demand for reusing smartphones and tablets.
 - (c) An on-demand market delivering advanced tailored products and services, The key employees will be working with them on the demand market, and their understanding of the offerings and customers will be essential for Telenor.
3. Networking platforms where there will be many individuals, team, corporate and professional networks relating to each other. The systems will both be including and excluding members.

Grounded in these three premises – of scenarios, dynamic markets and networking platforms, we elaborate why and how they may unfold in the future work organizations.

4.2 The future corporate systems

1. The eye towards the future or data analyzing as information and knowledge will be extreme essential to survive.
2. Bottom-up key employees are working for the on-demand market.
3. Kaizen team system is linking system 1 and 2 to mode 4.
4. Top-down managers are making the right decisions, choices, and strategies. The engaging story is needed to make the strategy into reality.
5. Coordination of all activities
6. Specialization for on.demand deliveries of high-tech products and standardization for traditional products and services working hand-in-hand.
7. A second-hand market of products and services reusing products
8. Networking platforms are linking Telenor and their professional employees together with a global political, economic, social and technical trends.

4.3 The future workplace

The employees in the foreseeable future will be working smarter and greener accepting new technology like robotics, and digitalization AI solutions. The findings on individual level may be summarized in 22 issues.

The future in this kind of portrayal is brighter for knowledge workers than anything seen or documented anytime. Zooming into what is already in the making, according to informants in Telenor and Telia, we may capture brighter and darker sides, which both are worth unveiling.

1. Most employees in Scandinavia will be educated Bachelor, Master and Doctoral degrees. The whole workforce will be well educated, and there will be a collaboration with the best global educational institutions for employing and training the best students.
2. The employees will be working in teams either on-site or virtually. The collaboration will be a critical success factor.
3. There will be an administrative and a professional pipeline not as today to secure only the best management, but to secure that the professionals have their pipeline.
4. The working language will be English, but employees with foreign languages and different cultural backgrounds will be in demand.
5. The employees will be working greener including traveling less and thinking greener and smarter for all services and products. The critical professional story will be working smarter and greener.
6. Loyalty, trust, engagement, and discipline will be even more critical than today. To both keep and recruit professionals with these attitudes will be important.
7. The employees may need more leadership (follow up and directions along which to work) and less management (control), but it may unfold in virtual and distributed ways. The leaders must both be charismatic and visionary and have authority. To be able to tell the corporate story of the future, pictures and animation will be an essential leadership attitude.
8. The working hours will be more flexible with the possibility to work at different sites and hours.
9. Solution and results will be a reward in itself where the team will be more rewarded than today. The conclusion is that more knowledge-based employees perform on itself, but are more satisfied with a team performance reward.
10. The employees will have to be able to govern their availability to avoid out burn and stress.
11. There will be no (or less) single offices, but common workspaces for sharing and collaboration.
12. There will be more single women and single men working for Telenor while there will at the same time be more possibility for parents concerning daycare and flexible hours.
13. There will be no (or less) parking spaces, but everything will be based upon walking, biking and traveling through public transportation.
14. Continuous internal and external executive education will be demanded. There will be certificates for finished executive education.
15. The workplace will be more aesthetics and artistic decorated for inspiration. Art management will include well-decorated workplaces.

16. There will be entrepreneurial and innovative corporations in the company circulating employees through creative work sites.
17. The managers will be recruited through internal success and less through external success.
18. Social and emotional competence will be in higher demand.
19. Solution oriented team project working people will be necessary.
20. Telenor and Telia will be open for more and more nationalities and diverse backgrounds.
21. There will be more women as middle managers and top managers. Women are dominating all professional educations in Scandinavia, and by 2030 they will have passed the 30% level both as middle managers and senior managers.
22. Change and transformation leadership will be more important than transaction leadership.
23. The project organization form will dominate with less permanent organizational forms and more short-term organizational forms.
24. The top management team will be a temporary task force trying to use the task force form to be more innovative.

Concluding the 22 changes, adaption and adjustments there is nothing revolutionary in any direction. Work life will slowly adjust to a changing reality. We will see knowledge workers concentrating on their knowledge, experiences, and attitudes. We will see ordinary knowledge workers deliver extraordinary results.

The future of knowledge work design and content is brighter than at any time.

4.4 The future world perspective

Schein (1993) is pointing to the foundational but difficult to grasp world view in any organizational culture. Telenor and Telia have divided their world views into four possibilities for 2030. The four chances are brief scenarios with powerful consequences for Telenor and the world:

1. The red digitalized world dominated by small entrepreneurs and innovators stretching the AI possibilities beyond anything seen so far. Telenor will need to identify these smart corporations for understanding, cooperation, and buy-ups.
2. The blue corporate world dominated by large corporations like Apple, Microsoft, Amazon, and Telenor. These corporations will both define the future, take all benefits and through global governance dominate regions and nations. The smaller corporations will be mergers and buy-ups.
Telenor is the 7th largest telecommunication corporation in the world today and will have to work to become one of the five dominating corporations in telecommunication.
3. The yellow human world where ethics, sustainability and sharing with local, regional, national and over national agreements for a more rational and democratic society. The humanistic perspective.
4. The green world with over governmental units (EU, UN, OECD, IMF, WTO, etc.) and large nations supporting environmental and climate issues. Green

decisions will bind both corporations and countries. The decisions will be needed to bring the climate issues under control.

5. Discussion

Telenor and Telia like most of the literature reported have no clear cut opinion of the future defined as 2030. There is insecurity with a lot of options or possibilities. Perhaps we will be continuing doing more of what we are doing today. Most of the technology development and AI literature are saying the opposite.

We might be seeing the industrialization of knowledge work with stronger control systems at all levels. There will be many people without work through the phase of robotics, and according to traditional Marxististic analyses, they will press down the wages. The globalization will make the competition for job stronger.

On the other hand, the more technology and AI-based the economy become the more knowledgeable employees we need. We will need people with knowledge (i.e., excellent education), experiences and the right attitudes. The robotics and AI might give a working market where there will be a higher demand for perhaps one-third of the workforce.

One-third of the workforce will provide us with manual production and services. One third might be without work and as the best solution paid a form of low public salary.

Telenor's solution will be a blue corporate world producing and delivering more than anytime with a green world taking care of the climate and public services. A yellow world with humanity and dignity together with a green world might be a utopia. A red world with smaller entrepreneurs and corporations delivering frontend technology changing the power of the large corporations might be a solution. We have concluded that the work of the future might not be as different from today as many predict.

Loyalty, discipline, trust, and engagement will still be in high demand. Project organizing and agility have been working well for a generation, and we have seen the less and less permanent organizational structure, as already suggested by Mintzberg (1979).

We have on one side literature describing the coming changes as a revolution for the way we are working and organizing (Dignan, 2019) while the more empirical research work from researchers living the differences tell us about a future very much like the situation today. There are not any changes in the development of larger global corporations with more power and more employees, although Chinese data-bases are reaching a critical mass of data, expertise, talent, and capital. The concentration called blue development by Telenor will continue.

The dominating economic blocks and countries will probably still be China, USA, EU, Japan, South Korea, and the UK. There will however be a more significant focus upon environmental issues including global decisions relating to the global temperature and the carbon use. The larger corporations will support these issues to a greater degree and contribute to a greener world for all of us if alerted and also enabling practices to find new ways.

Concluding highlights

The future looks bright from a perspective of the two leading Scandinavian telecommunications corporations. We will gradually adjust step by step towards 2030. The consequences of AI, robotics and information technology will be manageable. Scandinavia already works as a testing ground for new technology and knowledge intensive products/services due to its high penetration of education, distributed wealth, technological adoption and expected trust towards others. The individual qualifications are increasing for knowledge (formal education). Experiences and most of all the right professional work attitudes. Social and emotional skills for teamwork will be even more critical. We will at the Scandinavian arena have more than 50% women as middle managers and top managers-

The eye-towards-the-future analyzing the future will be crucial for all corporations.

Bottom-up communication from those handling the most advanced customer needs will also be crucial.

The future analytical studies must be linked to the bottom-up and top-down management to be able to coordinate all the activities of the corporation. More and more of this coordination will be organized in temporary teams and projects. Less and less of the organization will be permanently organized, and even the leader teams might be temporary task forces.

The large corporations like Telenor and Telia will be much more concerned about environmental issues. Working greener and smarter will be important issues. The cooperation with regions, nations and over national units will be much stronger trying to improve the environmental matters for customers and their organization.

6. Future framework

We have found that one key for any organization in the future will be an analytical eye-toward-the-future where anything happening is analyzed and reported to the top management and coordinated into future deliveries. The key employees will be those implementing AI-based products and services on demand to advances customers. They will have a bottom-up understanding that is not yet common in the eye-towards-the-future system and the top management system. The problematic issue for future work is thus the need for bottom-up understanding, sideways understanding and senior management based strategy and organizational coordination where project teams are coordinated working in collaboration.

The main finding is the slow change in Telia and Telenor towards a real knowledge worker using more of his/her working time to significant issues. We will get a framework where a professional knowledge worker is using his/her qualifications or what s/he is educated for and where his/her professional experiences and attitudes are used in a positive way for delivering excellent results. The framework for the future will be ordinary people achieving extraordinary results owing to their combinations of education, experiences, and attitudes, as well as becoming part of a right project. It will however also be creative specialists ("talents") and entrepreneurial groups meeting in workshops,

cafes, coworking spaces and elsewhere, in and across organizational boundaries. The future of knowledge work is giving people the opportunities to deliver excellent results and to be rewarded for these results as a part of their team. To make ordinary people as well as talents actually produce extraordinary results in groups is the future and knowledge work.

7. The way ahead

The research needs to be expanded to different sectors within production and services. Tele- and communication corporations are representing a knowledge-intensive service that might be compared to future views within finance, shipping, property, consulting and ICT service corporations. The results might be different or similar. There are many opinions about the future and all changes that will be made by AI and robotics

Abstract

In the modern society organization's ability to manage its information and knowledge resources is critical. The purpose of this study is to design and test a profiling model for information and knowledge management, which can be used both for frequent monitoring for trend analysis and in-depth analysis of factors supporting contemporary knowledge and information management practices of the organization. The proposed model combines the aspects of knowledge-based management and information management and it is developed by following design theory principles. The model is designed for public sector, especially for those organizations, which purchase and are responsible for the provision of public services. These organizations are in a critical role in developing and aligning information and knowledge management practices of regional ecosystems. They also serve as employer for great number of knowledge workers regionally. It can be argued that this kind of maturity model can also support the performance of knowledge workers operating in the public sector as it offers a route towards the development of more functional information and knowledge management practices within and across the public organisations.

Keywords – Knowledge management, Maturity model, Performance, Information management, Public sector

Paper type – Academic Research Paper

1 Introduction

In the recent decades, maturity models have been presented in many different managerial fields such as information management, strategy management, and performance management (e.g. Aho, 2012; Becker et al., 2009; Jääskeläinen and Roitto, 2015; Kruger and Johnson, 2010; Van Aken et al., 2005; Wettstein and Kueng, 2002). These models have been designed both for managerial and academic purposes. At best, maturity models can increase the understanding on the status of current management practices and supports in identifying strengths and most critical development areas (Jääskeläinen and Roitto, 2015). They are also powerful tools supporting benchmarking between organizations or networks with comparable criteria. There is indication in the literature that maturity models can improve the performance of organizations (Bititci et al., 2015) by presenting desirable characteristics for operating, leading usually also to better work satisfaction and work performance. Maturity models may also evaluate the ability of organizations to manage knowledge in networks and ecosystems.

There are a few existing maturity models for knowledge and information management (e.g. Hsieh et al., 2009; Pee and Kankanhalli, 2009; Poepplbush et al., 2011, Teah et al., 2006). This study contributes by combining the existing models and linking them to the established information process management model by Choo (2002). Consequently, the paper adds to the literature by balancing the technical aspects of information management and performance measurement (cf. Van Aken et al., 2005; Wettstein and Kueng, 2002) with factors supporting organizations and ecosystems to adopt new knowledge-related technologies as well as factors supporting the actual usage of those technologies.

The purpose of this study is to design and test a maturity model for information and knowledge management. The evaluation part of the model is based on a survey, which can be implemented through both interviews and a questionnaire. The model is designed for public sector, especially for the organizations, which purchase and are responsible for the provision of public services. These organizations are in a critical role in developing and aligning information and knowledge management practices of regional ecosystems. They also serve as employer for great number of knowledge workers regionally. It can be argued that this kind of maturity model can also support the performance of knowledge workers operating in the public sector as it offers a route towards the development of more functional information and knowledge management practices within and across the public organisations.

2 Methodology

This study utilizes design science approach in which the intention is to both develop scientific knowledge and solve practical problems (Andriessen, 2004; Van Aken, 2007). In design science, the effectiveness and validity of proposed solutions are evaluated both by researchers and users in the field of model application. The study follows process model for designing maturity models based on design science approach (de Bruin et al., 2005) presented in the figure 1. This research follows the first four steps of the figure.

In the first phase, decisions regarding purpose and focus of the model are made. The model is developed to support the information and knowledge management of public sector organizations organizing service provision in social and healthcare sector. Thus, the focus of the model is domain specific, focusing on information and knowledge management process in public sector. The main purpose of this model is to provide description about the state of information and knowledge management in organizations operating in this sector, i.e. the model is viewed as a diagnostic tool in order to identify development needs. Thus, the model is not just descriptive, but entails also prescriptive elements.

Figure 1 Main phases in constructing a maturity model (adapted from de Bruin et al., 2005)

The design phase includes the decisions regarding audience and respondents, and methods of application. In this research, managers and experts responsible for information and knowledge management in organizations purchasing public services were chosen as a target informants of the research. Because the major purpose of the model is to provide understanding about the state of information and knowledge management of an organization in order to support internal development (by identifying development targets), self-evaluation including 5 point Likert scale was chosen as method of application.

In the third phase it is necessary to identify what needs to be measured in the maturity assessment (content) and how this can be measured. In this phase, the construction of the model proceeds with the definition of evaluation main perspectives and variables of the model and implementation plan. The evaluation variables identified were classified into two main perspectives: information and knowledge management and user satisfaction regarding the main components of information and knowledge management. The design and content of the model synthesizes earlier literature. The basic framework extends the information process management model by Choo (2002). The framework established focal themes of information and knowledge management. This section is described in more detail in sections 3.2. and 4.1.

This paper will also report the testing phase of the model, which is conducted by the potential users. First, a web-based survey based on the profiling model was carried out in nine organizations in three different Finnish counties in order to evaluate the state of the information and knowledge management. Second, the results of the analysis and feedback related to the model and its usability was collected in focus group interview in one large participating organization. This phase is described in section 4.2.

3 Theoretical premises of the profiling model

3.1. Maturity models

The maturity model idea has been widely spread to different management areas, such as process management and performance management (Bititci et al., 2012). Maturity model can be seen as an umbrella concept, which is divided into three different parts (Jääskeläinen and Roitto, 2014). The maturity model framework defines the evaluation variables to be measured. Maturity model instrument defines how these variables are measured. The maturity profile is the overall status of an organization, which combines the information gathered through the maturity model instrument.

Maturity concept is often considered ambiguous. When formal systems such as information systems are examined, similar terms include the level of sophistication (e.g. Evans, 2004), the level of completeness and scope (e.g. Evans, 2004; de Waal et al., 2009) and the evolution-phase of the examined systems (e.g. Speckbacher et al., 2003). Another viewpoint to maturity is the relevance of examined processes or systems for managers (Hatry, 2006) which is the eventual test for the usefulness of information and knowledge management systems, practices and models. This also relates to the context in which the examined process or system is used. Therefore, it has also been proposed that employee satisfaction towards the examined system or process should be included in the maturity analysis (Jääskeläinen and Roitto, 2014).

Since the model design considers maturity as a multidimensional concept, we decided to use the term profiling model instead of maturity model in order to emphasize the importance of combining the dimensions of maturity level and employee satisfaction. This approach is also in alignment with the performance measurement profiling model by Jääskeläinen and Roitto (2014).

This research considers the maturity of information and knowledge management as a three-way phenomenon consisting from the level of scope, sophistication, and satisfaction towards the system. These aspects combined give an extensive overview of information and knowledge management in the organization. However, these three aspects cannot be ranked in order of importance. In this study, the scope is defined according to the original framework (Choo, 2002). Sophistication is related both to the information system sophistication (Salleh et al., 2010) and the possibility to provide and utilize information in a more detailed way (Schläfke et al., 2013).

3.2. Information and knowledge management framework

The profiling model takes into account the whole spectrum of information and knowledge management. Thus, it includes the more technical side of information handling and the softer side of humans related to knowledge, but it also takes into account both the viewpoints of the employees and the organization. In other words, we define information and knowledge management as systematic process that support both the employee's work and the competitiveness of the organization by integrating technology and human aspects together. As Lake and Erwee (2005) have stated, information and

knowledge management is about of finding, selecting, organizing, distilling, and presenting information in a way that improves an employee's understanding within the work context. Furthermore, it also enhances organizations to gain insight and understanding from its own experience and data sources, and support utilization of knowledge in problem solving, decision making and strategic planning. (Lake and Erwee, 2005)

In order to follow this rather comprehensive definition of information and knowledge management, main framework as the bases for the model was defined. Firstly, the general information process management model (Choo, 2002) was selected as the backbone of the framework in order to capture the information processing phases of employees. This model is generally applied in information management field as it includes general phases that are needed in information handling, such as gathering, organizing, storing and utilization. Secondly, this information management process viewpoint was supplemented by the general guidelines of master data management (MDM) in order to include more organization level goals for insights and understanding to support decision making and strategic planning (Lake and Erwee, 2005). The main framework for the profiling model construction is presented in figure 2.

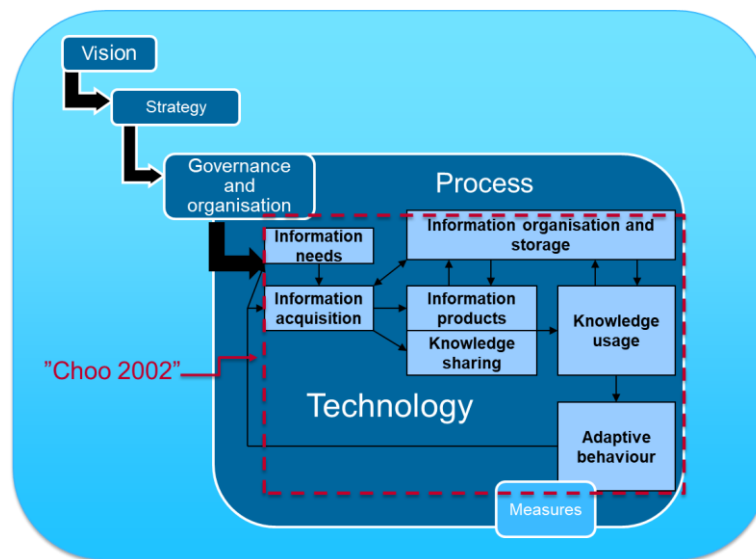

Figure 2. Main framework of information and knowledge management used as the bases for the profiling model construction. (Based on Choo, 2002)

3.3. Overview of existing maturity models in information and knowledge management

The reviewed models vary in their background, research fields, and implementation areas. This section overviews the models by presenting their varying characteristics.

The scope of the model was intentionally large since this paper aims at presenting an overarching maturity model of information and knowledge management. However, even within a more specific sub-field such as performance management the scope of models

varied from the content of measurement systems (Cocca and Alberti, 2010; Van Aken et al., 2005; Wettstein and Kueng, 2002) to the use of measurement information in management (Aho, 2011). Most of the models appear to be segmented to any organization – with a few exceptions such as the model by Cocca and Alberti (2010) intended for SMEs and the model by Brooks et al. (2015) designed for health care.

The execution of the models is designed either for interactive assessment in a small set of firms (e.g. Khatibian et al. 2010; Teah et al. 2006) or large surveys for the self-assessment of employees (e.g. Tung et al., 2011; Jääskeläinen and Roitto, 2014). The evaluation instruments varied between the reviewed models. 9 studies utilized a traditional survey with likert scales, 6 studies presented a maturity grid for the evaluation of maturity levels in selected areas (typically 10 or less) and 2 relied on the hybrid of the two former evaluation approaches. Some of the studies did not clearly present how the presented aspects should be evaluated.

Half of the presented models were not tested in practice. Notably, none of the reviewed information management/system models was tested in practice. The way of testing varied from single case studies to large scale surveys. Studies implementing and testing the presented models included the following:

- Aho, 2011, Jääskeläinen & Roitto, 2015, Marx et al. 2012; Wettstein & Kueng, 2002; Tung et al. 2011 (performance management models),
- Hsieh et al. 2009; Khatibian et al. 2010; Kruger and Johnson 2010; Pee and Kankaanhalli 2009, Teah et al. 2006 (knowledge management models),
- Lahrman et al. 2011, Popovitch et al. 2012 (business intelligence models).

This study intentionally concentrated on the models presented in the academic literature since the aim was to design an overarching model which could be utilized as a survey. This excluded several models with consultative background, such as Capability Maturity Model (CMM and CMMI) in information management. The consultative models typically present a concise list of assessment factors (up to ten) which are then evaluated by using grades with written descriptions fitting into one A4 page.

4 Defining the design and content of the model

4.1 Selecting critical variables from the existing literature

The design work started by reviewing the literature. Google scholar search was used to identify existing maturity models in the area of information and knowledge management. Search terms maturity, maturity model, effective, effectiveness were used in different fields. These fields included information management, information systems, knowledge management, knowledge-based management, performance management and business intelligence. 24 suitable publications were found in the following fields:

- information management (1 article)
- information systems (1 article)
- knowledge management (7 articles)
- knowledge-based management (no hits)

- performance management (9 articles)
- business intelligence (6 articles)

The analysis of articles was conducted by three researchers. Both the characteristics of the articles and their content were analyzed. The descriptive analysis included the type of the article (literature review, empirical analysis, model presentation) and evaluation type of the model (e.g. maturity grid, likert-scale). Content wise the main task was to identify critical variables included in the existing models which could fit into the main research framework. In the first phase the fit between the framework and the reviewed models were analyzed. It was found that the framework can be successfully used to select and focus the variables from the existing literature, although the concepts and terms were sometimes different. Adjustment of the terminology to the original framework was carried out jointly by the three researchers. It is notable that not all of the identified studies were eventually used since they did not always present a framework for maturity analysis, the model did not fit properly in our framework, or the article did not present the actual content of the model. It was found that of 16 studies presented a new model, 3 used an evaluation tool for empirical analysis related to information and knowledge management, 4 were purely literature reviews (eventually not presenting any model) and 1 examined the benefits of maturity models in management. It was a bit surprising how few studies openly presented the content of the discussed models.

The variables were selected based on their recurrence in the reviewed studies, empirical testing, and the diversity and extent in the light of the perspectives of the framework. It was deemed important that a balanced number of evaluated aspects can be identified for different perspectives of the model. The three researchers first carried out independent work followed by the synthetization of results. Overlapping variables were combined and the correct perspectives for each variable was determined. At this stage 54 different variables were identified. Although, the list of variables was deemed as mostly appropriate, it was seen as too extensive to be implemented in the practice. Next phase was to prioritize the list of variables. After the commentary of larger researcher group (total of 8), the number of critical variables narrowed down to 25. The end result is presented in table 1.

Table 1 Main perspectives and variables of the model

Main perspective of the framework	Critical variable	Source
Vision and strategy	Existence of knowledge management strategy and targets	Aho, 2011; Brooks et al. 2015
	Strategic alignment of knowledge management	Aho, 2011; Lahrman ym., 2011
	Extent and significance of knowledge management	Lahrman ym., 2011; Teah et al., 2006
	Systematic approach to the development of knowledge management	Aho, 2011; Lahrman ym., 2011; Van Aken et al., 2005; Teah et al., 2006; Wettstein ja Kueng, 2002
Administrative structure and organization	Top management support	Brooks et al. 2015; Jääskeläinen & Roitto, 2015; Lahrman ym., 2011; Pee and Kankaanhalli 2009; Teah et al. 2006, Tung et

		al., 2011
	Commitment of employees	Jääskeläinen & Roitto, 2015; Tung et al., 2011
	Expertise and knowledge of employees	Aho, 2011; Becker and Knacksted, 2009; Lahrman ym., 2011; Popovic ym., 2012
	Resources	Van Aken et al., 2005
Information needs	Identification of information needs (e.g. link between technology and management needs, needs of different stakeholders)	Aho, 2011
	Understanding of information needs	Aho, 2011
Information acquisition	Information gathering and availability	Teah et al. 2006; Van Aken et al., 2005
	Availability of information	Aho, 2011; Jääskeläinen & Roitto, 2015; Popovic ym., 2012
	Overall satisfaction towards the main perspective	
Information organization and storage	Enterprise architecture	Aho, 2011; Lahrman ym., 2011
	Data storage in information systems	Aho, 2011; Jääskeläinen ja Roitto, 2015; Wettstein & Kueng, 2002
	Data integration	Becker and Knacksted, 2009; Brooks et al. 2015; Marx et al., 2012; Lahrman ym., 2011, Popovic ym., 2012
Information products and services	Information systems supporting reporting and analytics	Aho, 2011; Jääskeläinen & Roitto, 2015; Marx et al., 2012; Popovic et al., 2012
	Overall satisfaction towards the main perspective	
Information distribution	Communication of information	Aho, 2011; Wettstein & Kueng, 2002; Teah et al., 2006; Van Aken et al., 2005
	Real time delivery of information	Aho, 2011; Popovic et al., 2012; Van Aken et al., 2005
Information use and adaptive behavior	Performance management process	Aho, 2011; Marx et al., 2012; Popovic et al., 2012; Wettstein and Kueng, 2002
	Information use in decision-making	Aho, 2011
	Information use in resource allocation	Jääskeläinen & Roitto, 2015
Performance measures	Link between measures and strategy	Aho, 2011; Jääskeläinen ja Roitto, 2015; Van Aken et al., 2005
	Scope of measures	Aho, 2001; Jääskeläinen ja Roitto, 2015; Marx et al., 2012; Tung et al. 2011; Van Aken et al., 2005; Wettstein ja Kueng, 2002, Pee and Kankaanhalli, 2009
	Quality and reliability of measurement information	Aho, 2001; Jääskeläinen ja Roitto, 2015; Popovic et al., 2012
Outcomes	Performance outcomes of knowledge management	Lahrman et al. 2011

It can be seen that not all of the perspectives include the same number of variables. It was especially difficult to identify variables for the information needs perspective.

Satisfaction towards each perspective was added to the model due to the definition of maturity for the designed model. It was not included in the variables of the reviewed models, although the model by Jääskeläinen and Roitto (2014) included the same idea of evaluating the satisfaction for the two main perspectives of their maturity model.

4.2 Testing the model

First, the model was tested with a self-evaluation survey. A web-based survey based on the profiling model was sent to 109 upper managers (excl. political management), middle managers responsible for information and knowledge management and ICT-expert respondents in 9 Finnish public sector organizations, mainly in social and healthcare sector. Altogether 37 persons responded to the survey, resulting in the response rate of 34%.

In the survey, respondents were asked to evaluate statements related to critical variables of the profile model by 5-point Likert scale. Survey included 95 statements. In the survey, respondents were not forced to choose option in Likert scale, but they had possibility to select 'not able to answer' or '?' if the evaluated aspect appeared ambiguous. In addition, in each section, respondent were asked to give feedback about each section of the survey (open-ended sections).

Around 9-30% of respondents gave feedback about the survey, either concerning main perspectives or the survey as a whole. The authors analyzed the open-ended feedback, and made some modifications to the survey. Based on the feedback, sections 'Information use' and 'Adaptive behavior' were combined into one section 'Information use and adaptive behavior'. This modification needs to be acknowledged when analyzing results, since originally each main perspective is based on the framework of the model. In addition, focal concepts of the survey (data, measure, measurement, measure information, knowledge management) were defined more specifically and the phrasings of couple of questions were modified. Two questions were also removed from the survey.

Respondents had opportunity to assess the overall usability, validity, relevance, clarity and practicality of the model. Most of respondents (65%) regarded the survey as comprehensive and valid tool for evaluating the state of KM. However, usability, relevance and clarity scored lower (41 – 46%). Based on comments, this was due to the length of the survey, and lack of shared definitions of central concepts as mentioned earlier. However, the average response time was 15 min as planned, and it can be regarded as rather normal for a survey-based tool.

In the second phase, testing was carried out in a focus group interview in one large participating organization. Altogether 6 persons in managerial positions (either top management or middle management) in the field of information and knowledge management, ICT and general management participated the focus group interview, where the results of the analysis and feedback related to the model and its usability was collected.

According to participants, the survey forms a solid picture of information and knowledge management in an organization and specifies various competence areas needed for knowledge and information management, i.e. ICT, measurement and

management. Results described the KM state of organization quite well reflecting validity of the tool; for example, low scores in section ‘Information organization and storage’ was not surprise, but rather a well-known issue in the organization. Survey was considered as a good tool to describe the current, (as-is) state of information and knowledge management, serving as a basis for discussions and identification of development needs. Hence, its relevance was seen as high.

Participants were interested to see overall results of the survey (comparative data form all participating organizations) for benchmarking. When comparing results, some limitations of the method (self-assessment) were identified. For example, the organization’s scores were relatively low compared to others, even though they are known for their efforts in KM development. This may be due to high standards of respondents in the organization making them more critical than other organizations evaluated. Hence, one potential approach for using the survey could be an auditing approach where trained auditors evaluate different organizations with well-specified instructions and specifications supporting the model. In this way, benchmarking of results would be based on more consistent evaluation results.

5 Results

This study describes the design of a profiling model for information and knowledge management, which provides description about the state of information and knowledge management in organizations in order to identify development needs. Thus, the important aspect in the use of the presented model is the comparison between evaluated maturity level and employee satisfaction in the each main dimension of the model. In this purpose, for example the averages of survey responses can be used as shown in the Figure 3. The results presented in the figure are based on the data gathering during the testing of the model. This comparison enables the evaluation of the purposefulness of different development areas and prioritizing development objects. The following figure along with the table illustrates the idea.

Figure 3 Illustration of results in different perspectives of the model

Table 2 presents an example of interpreting the results including four different maturity profiles based on different combinations of maturity level and employee satisfaction. The profiling can be based on the averages of Likert-scale (1-5) results in different areas of the model. For example, results above 3 can be interpreted as high satisfaction or advanced practices and vice versa. This threshold can also be decided based on the gathered data in order to reach a meaningful amount of responses in different profiles. If the model is used in benchmarking, also the difference in the results can be used in determining the thresholds for different profiles.

For example, if organization's information and knowledge management practices and satisfaction are both scored low, as in 'Information acquisition', 'Information organization and storage' and 'Information products and services' in the Figure 3, organization can be regarded as 'Novice' related to these perspectives, and these areas should be high priority development targets.

Table 2 Example of interpreting the results of the model

High employee satisfaction and basic information and knowledge management practices "Facilitator" <p>The organization is able to take the most of the current information and knowledge management practices. The basics of information and knowledge management are covered. This area should not be prioritized in development work.</p>	High employee satisfaction and advanced information and knowledge management practices, "Advanced exploiter" <p>This is the desired situation in most cases. The information and knowledge management practices are advanced and the organization is able to exploit them fully.</p>
Low employee satisfaction and basic information and knowledge management practices, "Novice" <p>The examined area is as a whole at the rather primitive level. This area should be prioritized in the development work.</p>	Low employee satisfaction and advanced information and knowledge management practices, "Experimenter" <p>Information and knowledge management in this area is characterized by the development and experimenting of novel models and systems. However, the organization has not invested in taking the new ideas and system into use. It may also be that the developed systems are not serving the needs of employees.</p>

In this study, the profiling model was considered as a comprehensive and valid tool to determine the state of organization's information and knowledge management and identifying development needs. The primary purpose of the model is to function as a diagnostic tool implemented by self-evaluation survey. However, potential users of the model underlined the need for comparative information. If the model is used for benchmarking purposes, the use of trained auditors to conduct the evaluation in a consistent manner would increase the reliability of results.

6 Conclusions

Overall it can be concluded that there are no established academic models for maturity analysis of information and knowledge management. Although different models have been presented in the literature, surprisingly few have been tested and implemented in practice. In addition, the models do not present an overarching view to knowledge and

information management process and the choice of evaluation perspectives is not always clearly justified. There was therefore room for the new model presented in this study. More specifically, the presented model aims to fill the following gaps in the literature.

Most of the existing maturity models have the assumption that more is better, i.e. it is always desirable to obtain more sophisticated technologies and practices (Marx et al., 2012; Wettstein and Kueng, 2002). The model developed in this study creates maturity profiles which combine satisfaction of employees and the maturity of practices. By capturing satisfaction, the designed new model highlights purposeful objectives of developing information and knowledge management. It acknowledges that also lower maturity levels can suffice if employees are satisfied. In this way the model takes different contextual criteria for information and knowledge management practices into account.

This study contributes by testing the designed model. Many models have been applied as interactive audits in single cases (Bititci et al., 2012) while more extensive empirical data and testing is often lacking (Marx et al., 2012; Tung et al., 2011). Most of the existing models are generic and not segmented to specific types of industries. Implicitly they support the purposes of private companies. This study contributes by segmenting the model for the public sector. Models originating from the consultancy may be straightforward to use but such models lack theoretical foundation and are derived from an arbitrary design method (cf. Marx et al., 2012). This study aims to find the right balance between academic rigor and practical relevance.

This study identified a need for various versions and uses for the profiling model. Different versions of the model will serve two different purposes management: shorter version for frequent monitoring for trend analysis of factors supporting contemporary information and knowledge management. Longer version provides more in-depth information explaining the potential causes of changes in the results. Self-evaluation survey works as a diagnostic tool, whereas evaluations conducted by external auditors serve benchmarking purposes.

This study also provides a new kind of model for the management of knowledge workers. Earlier studies on the information and knowledge management maturity have not captured the satisfaction of knowledge workers, which eventually determines whether the information and knowledge management systems and practices are beneficial for the organization. The presented model enables that the perspective of individual knowledge workers can be taken into account in determining the objects of improvements.

Abstract

Customer value is a key element for any organization, especially to give direction to different facets of an industrial organizations. By developing Knowledge Management and knowledge-sharing practices, the value creation potential could be improved in organizations. However, in practice there are several barriers that hinder effective knowledge sharing. In this paper focus is set on the knowledge-sharing barriers typology synthesized by Riege (2001), which are then applied in an exploratory case study of an industrial organization in Finland. Based on Riege's typology, the major knowledge-sharing barriers are identified in the case organization, and their role in hindering work performance and value creation is further analysed. Finally, development actions are proposed based on the empirical findings. Our findings in this study argue that effective knowledge-sharing practices among employees is a key enabler for successful value creation in an industrial organization.

Keywords – knowledge sharing, knowledge management, work performance, value creation, industrial organization

Paper type – Academic Research Paper

1 Introduction

Studies from extant literature suggests that knowledge management (KM) is seen as a strategic and important approach but often not easy to implement in organizations (Omotayo 2015, Dalkir 2011, Bhojaraju 2005). As part of KM, a knowledge-sharing culture (Intezari et al. 2017) can only be found reasonable and beneficial if senior management demonstrates the value of a culture that supports and rewards its employees (Lee et al. 2016). Knowledge-sharing activities depend very much on motivation and on the voluntary participation of employees (Llopis and Foss 2016). In this regard, management should be skilled and sensitive to employee-sharing activities that are actively arranged/carried out within organizations (Riege 2005). In other words, KM should be the evolution of effective managerial practices that fosters an open knowledge-sharing culture that can impact better work performance in organizations. (Lee et al. 2016, Chang and Tung-Ching 2015, Moteleb and Woodman 2007, Birkinshaw 2001).

By developing KM and knowledge-sharing practices, the value creation potential could be improved in organizations (North and Kumta, 2018, Cepeda-Carrion 2017). Customer value is a key element for any organization, especially to give direction to different facets of an industrial organizations. Customer value further aids in the streamlining of strategies and goals within organizations (Blocker et al. 2011, Johnson and Weinstein 2004, Duchessi 2002). However, the understanding of value creation practices is often unclear due to the fuzzy nature of value as a concept. Whereas, knowledge sharing often cannot be implemented as a project-driven approach; instead it requires structural change starting at the policy level of the organization. When supporting knowledge sharing activities, management need to be aware of the ability to alter the culture to implement change in organizations (Corfield and Paton 2016). In fact, studies have identified several barriers can be found for employees not embracing a more sharing culture and thereby less value creation and work performance in organizations. For a deeper understanding, the research question of this study focuses on - *What are the barriers that hinder knowledge sharing to create value and work performance in an organization?*

In the next section, a review of the literature on value creation, KM practices and knowledge-sharing barriers are presented. Focus is set on the knowledge-sharing barriers typology synthesized by Riege (2005), which are then applied in an exploratory case study of an industrial organization in Finland. Based on Riege's typology, the major knowledge-sharing barriers are identified in the case organization, and their role in hindering work performance and value creation is further analysed. Finally, development actions are proposed based on the empirical findings. Our findings in this study argue that effective knowledge-sharing practices among employees is a key enabler for successful value creation in an industrial organization.

2 Brief background on value creation

Value as a term is used in many different contexts. For value definition, the customer perspective seems still to be valid (North and Kumta, 2018, Cepeda-Carrion 2017). Delivering and creating superior customer value for customers can be seen as increasing the value of the organization. There is a monetary worth to the organization in both high-value customers and individual customers which can be quantified, whereas the organization's value is quantified as the worth to its stakeholders. Nevertheless, customer value takes the perspective of the organization's customers (Sørensen and Jensen 2015). When defining customer value, customer value can be defined so that it represents the trade-off between sacrifices and benefits from the provider's relationship and product resources which the customers think and believe to be facilitating their goals (Helander and Vuori 2017). At the same time, it is quite often customer value changes because customers alter their own expectations. This aspect is a critical challenge for providers because failing to meet customer expectations may lead to dissatisfaction and terminate the customer relationship (Blocker et al. 2011).

To attain and maintain customer value, it means continuously creating experiences that exceed customer expectations (Sørensen and Jensen 2015). Considering value is often defined by the customers, Johnson and Weinstein (2004) argue that if the organization's value is outstanding then it turns buyers into lifetime customers. Companies have to create value for their customers and face the possible problems related to success and also failure such as (e.g. declining market share and customer loyalty, decreasing profits etc.) and thereby long term challenges. In any case, customer value is a key element for organizations to give direction and unite different business functions by means of strategies and common goals; recognize the importance of the focus on customer expectations and needs; and implement and develop information, personnel, business and quality systems to ensure and deliver the required customer value. For example, the study by Duchessi (2002), the approach built from the customer value perspective can be described as a pyramid with strategies and goals at the top and quality, personnel, information and business systems at the bottom.

3 Overview of knowledge management and knowledge sharing barriers

3.1 Knowledge management in organizations

According to Bhojaraju (2005), knowledge management is seen as an organizational approach that is not often easy in implementation. A number of studies (c.f. King (2009), Birkinshaw (2011), Bhojaraju (2005), Moteleb and Woodman (2007)) have defined knowledge management and its importance for organizations. The definition of knowledge has often been stated as a "justified personal belief." There are many classifications which specify various different kinds of knowledge (Hislop et al. 2018). The most relevant and important distinction is between "tacit" and "explicit" knowledge. Knowledge is often tacit in nature and has developed over a long period of time. Some of

it has merged into business activities, processes and relationships that have been created over time when a series of continuous improvements have been implemented. Whereas explicit knowledge is available in the form of sentences, words and documents, and different types of organized data like computer programs (King 2009).

Creating organizational knowledge is rather dependent on tapping the tacit and quite often highly subjective insights, hunches and intuitions of individual employees and making these insights available for use and testing by the organization. (Hislop et al. 2018) Personal commitment plays a key role in terms of the employees' sense of identity with the organization and its mission. Embodying tacit knowledge in actual technologies and products to achieve actual personal commitment will require supervisors and managers who are as comfortable with symbols and images as they are with numbers measuring work productivity and market share. Typically, knowledge management also ends up focusing on recycling existing knowledge rather than on generating new knowledge and more important is the ability to bring new knowledge into the organization. (Nonaka and Toyama 2015, Birkinshaw 2001)

The notion of knowledge management should be richer so as to create insight into 1) why to manage knowledge 2) what knowledge to manage and 3) how to manage knowledge. There is a need for multiple interpretations of knowledge and flexibility to blend and change or extend these interpretations in different organizational contexts (Moteleb et al. 2007). Knowledge management should be the evolution of good management practices (Hislop et al. 2018). KM presents a change in focus regarding the use and development of knowledge which increase the effectiveness of any organization. In this regard, extensive research has been done from different perspectives related to organization and knowledge management. However, there remains a need to combine the different perspectives on knowledge management and find a possibility to combine theory and practice that is more comprehending for organizations to use in their development towards better performance. This is why knowledge management cannot be just one project among others. It requires structural change in the policy of the organization (Llopis and Foss 2016).

Studies such as Chang and Tung-Ching (2015), Davenport and Prusak (2014), King (2009), von Krogh (1998) and Dalkir (2011) have raised different aspects of knowledge management within the organization from a process perspective. Knowledge management improves certain processes such as collaborative decision making, innovation, collective and individual learning in organizations. The outcome is often created by these organizational processes are better products, services, relationships and decisions as well as organizational behavior, which in turn lead to improved organizational performance (King 2009). Furthermore, an organization's performance depends quite a lot on how managers are able to activate individuals and teams to turn knowledge into value-creating activities. Activities can take place through five different phases: 1) initial sharing of experience, knowledge and practices among team members, 2) effective creation of concepts for new products and services based on shared knowledge, 3) justification of these concepts is rooted in the organization's strategy, focus interviews and market studies, and 4) building a prototype service offering and 5) the leveraging of concepts,

prototypes and offering throughout the organization (von Krogh 1998). Coming to the management of knowledge processes, knowledge can be refined, stored, shared, transferred, created, acquired and re-used within organizations. In a way efficient planning of KM processes can improve the processes of innovation, individual and collaborative learning and thereby decision-making within the organization (King 2009).

One of the KM processes needed to improve organizations' performance is knowledge sharing (Paulin and Suneson, 2012) and often sharing activities depend very much on motivation and on the voluntary participation of employees. Management need to be skilled and sensitive to the sharing activities that are ongoing/underway and proceeding within the organization. A knowledge-sharing culture can only be found reasonable and beneficial if management shows the benefits, supports it and rewards those who embrace it. It seems that private sector organizations use KM for internal knowledge sharing, targeting specific areas of the organization. Their KM initiatives are often concerned with managing business and administrative knowledge, whereas public sector organizations use knowledge management for both external and internal knowledge sharing through the organization and their KM initiatives are most often concerned with managing product-related knowledge (Dalkir 2011).

3.2 *Riege's barriers in knowledge sharing*

Existing literature identifies many examples of where knowledge-sharing practices have not reached their goals such as to manage the organization's skills and assets. This occurs mainly because of potential barriers to knowledge sharing. It has been agreed and acknowledged that the biggest challenges in the organization's sharing practices is maximizing and protecting the value which is derived from tacit knowledge. This tacit knowledge is held by the organization's stakeholders, in particular its customers and employees (Riege 2005). The recognition and identification of knowledge-sharing barriers has a very important role in KM strategy, whether it is part of the organizational culture or not. Failures in knowledge sharing often occur because organizations try to adjust their organizational culture to fit the goals of knowledge sharing, instead of implementing them so that the knowledge-sharing strategy would fit the organizational culture (Riege 2005). Riege's (2005) study highlights barriers at three different levels, namely organizational, individual and technological levels of knowledge sharing.

3.2.1 *Background on Riege's three levels of knowledge sharing barriers*

At the organizational level perspective, barriers quite often tend to be linked to a lack of infrastructure and resources, economic viability, accessibility of informal and formal meeting spaces, and the physical environment (Riege 2005). For successful sharing of knowledge within the organization, the right organizational conditions and environment have to exist. There are many ways to share organizational, social or individual knowledge effectively. Barriers at the organizational level can include a number of examples. This can be size of business units not small enough to enhance contact and facilitate ease in sharing knowledge, hierarchical structure in the organization that can

inhibits most of the sharing practices, deficiency of organization resources that can provide adequate sharing opportunities, lack of appropriate infrastructure which supports sharing practices, lack of transparent recognition and rewards that would motivate people to share knowledge, shortage of informal and formal spaces to generate, reflect on and share new knowledge. Finally, there can be barriers in terms of lack of managerial direction and leadership on how to communicate clearly the benefits and values of knowledge-sharing practices, sharing initiatives and its integration with KM strategy into the organization's strategic goals are unclear or missing (Riege 2005).

At the technology level, barriers occur with difficulties in integrating, building and modifying technology-based systems. Barriers also correlate with factors like unrealistic expectations of ERP/IT systems and an unwillingness to use applications because of a mismatch with requirements (Riege 2005). Knowledge sharing is also a technology issue and challenge. There is a little doubt that technology can be a facilitator to support and encourage knowledge sharing and its processes by making sharing more effective and easier. Ultimately, the key issue is to implement and choose the technology which is most suitable and provides a close fit between organizations and people. Potential barriers to sharing can happen due to lack of communication and demonstration of all the possible advantages of new systems compared to the existing one, reluctance to use IT systems due to lack of experience and familiarity with them, mismatch between integrated IT systems and processes restricts sharing practices and individual's requirements, unrealistic expectations of employees about what technology can and cannot do, lack of integration of IT processes and systems impedes the way people do things and also the absence of technical assistance and support as well as maintenance of integrated IT system's communication flows disrupt/hinder work routines (Riege 2005).

Finally, at the individual (employee) level, barriers to sharing knowledge are often factors such as the lack of trust and time, differences in national culture, lack of social networks and communication skills as well as overemphasis of position status. For more illustration, individual barriers (Riege 2005) can occur due to lack of trust in people because there may be occurring misuse of knowledge or taking unjust credit for it, taking ownership of intellectual property due to fear of not receiving accreditation and recognition from colleagues and managers, difference in levels of education, differences in gender, age differences, insufficient evaluation, feedback, capture, communication and tolerance of past mistakes that would enhance organizational and individual learning, dominance in sharing explicit over tacit knowledge such as experience and know-how that requires observation, hands-on learning, dialogue and interactive problem solving.

Motivation can be a reason for barriers at the individual level as sharing knowledge can be seen as additional work. This is due to the extra time required for communication and documentation etc. Employees may not expect reciprocal benefits from transferring their knowledge because they do not experience it or they not believe in these benefits. Even if people do expect some kind of reward for their contributions, the answer to the question "What's in it for me?" is not always clear to employees suffering from lack of motivation. The need for self-motivated creativity exists in order to foster knowledge sharing. Quite often the benefits of the contribution to a knowledge database are received

by a different stakeholder at a later point of time, and the benefits are quite often earned by colleagues of the provider, not the provider him/herself. Knowledge sharing can be beneficial only if everybody provides their knowledge unselfishly within the organization (Disterer 2001).

When going further and deeper into the individual perspective, individual-level barriers to sharing can be described as uncertainty, loss of power and revelation. Uncertainty can be seen especially as a feeling among less experienced and younger people, because they are not able to judge if their working results represent valuable knowledge. Their knowledge cannot be estimated if it is too well known or general or if the knowledge is too specific for a special situation and therefore useless for colleagues in other cases. The positioning on the scale of specific to general is by no means trivial and thus creates uncertainty (Disterer 2001). Loss of power is quite a common feature at the individual level as knowledge can be used to enforce spheres of influence and to take action; passing knowledge on to colleagues may grant some of this potential. Likewise, those who do not own this knowledge are deprived of this influence. This applies to knowledge about procedures, competitors, suppliers' methods, formulas as well as customers from the business perspective. In this sense, someone who passes on knowledge to a colleague will lose the exclusiveness of her or his influence and this might suggest some respect and job security. "Knowledge is power," where experts with rare knowledge have the monopoly of knowledge and reputation, causes knowledge hoarding rather than knowledge sharing (Disterer 2001).

4 Empirical study

The empirical research was carried out as an exploratory case study, applying qualitative research methods. The empirical data set was gathered by means of thematic interviews at a single factory unit of the industrial case organization. The interview framework was the same in all the interviews, although the interviews were very open and conversational in nature. The interview themes were as follows: background and work history, typical working week, customer value creation, information flow and data flows, knowledge management practices, challenges related to information and knowledge, change management and lastly, an open discussion on the things that work well in general and which things should be developed currently. Altogether six persons operating in various roles (sales representative, sales manager, project assistant, production manager, unit manager and key account manager) was interviewed.

Analysis of the empirical data revealed that within the case organization several changes were occurring at the organizational and personal level, all of which had an effect on the knowledge-sharing culture as well as work performance and even customer value creation potential. Despite this, at a general level the work community in the factory unit was happy and the atmosphere was good, which was further identified as one of the key factors supporting an open knowledge-sharing culture.

"The premises are mainly good, the facilities in our factory are good. The working environment is fine, very comfortable."

"High professionalism"

"Our advantage is that it is a compact factory and that they come nicely along together."

"Good spirit in a small group"

At the same time, however, due to the constant changes, the roles and job descriptions were unclear and there were difficulties in work performance and task completion.

"Unclear job descriptions, difficulties to tell colleagues what each should do"

"There is a gap between production and the office in the factory community."

It was also partly felt that all the recent changes had been made by/had come from the main office of the case organization without listening to the factory unit. Therefore, there was more dissatisfaction with the current situation than there had been earlier.

"The former factory manager was tough and clear, able to rely on things being handled. Now I have to look after him, even though it is not my job. "

Moreover, problems had been identified in the knowledge sharing both within the factory unit - due to unclear job descriptions and changed, distant managerial relationships, as well as in information system problems - and especially in the direction of the main office of the case organization.

"There is an IT system that functions at some level, but people have to check things manually too many things".

"Clearer tools should be used to manage the order-delivery process. There are gaps there between the functions."

Some shortages of resources and lack of some special skills were also identified, and it was also stated that exceptional situations caused a lot of extra adjustment due to the tough/inflexible information systems and, in some cases, the lack of proactive attitude among the workers.

"Managing Raw Material Stocks. This is especially true for information systems, such as inventory management. If you promise a customer a specific schedule, you should know how to stock up the raw material. Partly information system, sort of human resource thing. Long-term automation and inventory IT improvements could do well."

These identified challenges represented all three categories of Riege's typology: organizational, individual and technological knowledge-sharing barriers, see Table 1 for summary of the empirical results. Within the table, barriers that are present in Riege's original typology are written in *italics*.

Table 1. Empirical results based on Riege's knowledge-sharing barriers three-level typology.

INDIVIDUAL LEVEL BARRIERS	ORGANIZATIONAL LEVEL BARRIERS	TECHNOLOGICAL LEVEL BARRIERS
Poorer understanding of customer requirements in production than earlier, as contact level is missing	Communications break-down between sales, operative and development functions	Data and information is incoherent and splattered into different information systems
<i>Difference in levels of education, causing e.g. shortages in language skills</i>	Knowledge sharing problems between the unit and the corporation level	Information systems are not used comprehensively
<i>Insufficient learning loop and tolerance of past mistakes</i>	Unclear roles and job descriptions	<i>Unrealistic expectations of employees about what technology can do or can't do</i>
<i>Lack of trust (towards other units)</i>	<i>High competitiveness between other subsidiaries</i>	<i>Lack of integration of IT processes and systems</i>
<i>General lack of time</i>	<i>Deficiency of resources</i>	<i>Lack of technical support</i>

5. Discussions and Conclusion

Extensive research on different perspectives related to knowledge sharing is evident in the literature, but there remains an empirical gap with regard to understanding of knowledge sharing barriers for better work performance and value creation in industrial organizations. While many studies on knowledge-sharing barriers have been presented in the literature, description/discussion of their practical implementation is less common. This paper adds to the literature by identifying certain barriers of knowledge sharing and suggest some considerations in the context of an industrial organization. The study attempts to address the research question of what are the barriers that hinder knowledge sharing to create value and work performance in an organization. In Table 2 the identified barriers and proposed solutions to overcome the barriers are presented.

Based on the analysis of case evidence, there were knowledge sharing barriers at the individual and technological levels in the organization. There was limited understanding of customer requirements in production department. A solution such as customer visits can help to increase interaction between key customers and production people. Furthermore there were differences in levels of education due to language deficiency skills and this could be solved by providing time and support for personnel development. Lack of trust between different units in the organization is also identified as an impediment to knowledge sharing. To an extent this sharing barrier can be attributed to high competitiveness between subsidiaries. This barrier could be solved through nurture of open environment by introducing more informal meetings between the unit managers and create a development of trust in the organization

At the technical level a knowledge sharing barrier was identified which is regarding unrealistic employees' expectation of what technology can create value or not. To manage the unrealistic expectations, for example, relevant IT courses and related training programs could be offered to employees and thereby provide the understanding of how IT can support worker performance/value creation. Another knowledge sharing barrier at the organization level is the roles and job descriptions seems to be less clear and not defined

well. In a way, this unclear role definition contributed to insufficient learning loop and less tolerance of past mistakes in the organization. This could be addressed by designing clear roles and job descriptions across the organization and also create open discussions environment in the organization. Moreover established or well defined job descriptions and routing practices can create more time efficiencies in work, prioritization of tasks, learning from mistakes and overall value creation and work performance in the organization.

Table 2. Propositions to overcome the identified barriers.

INDIVIDUAL LEVEL		ORGANIZATIONAL LEVEL		TECHNOLOGICAL LEVEL	
Key identified knowledge-sharing barriers	Proposed solution to support worker performance and value creation	Key identified knowledge-sharing barriers	Proposed solution to support worker performance and value creation	Key identified knowledge-sharing barriers	Proposed solution to support worker performance and value creation
Poorer understanding of customer requirements in production than earlier, as contact level is missing	Increased interaction between key customers and production people, e.g. customer visits	Communications break-down between sales, operative and development functions	Clearer work roles, rules and practices for communication	Data and information is incoherent and splattered into different information systems	New information system acquisition and implementation
<i>Difference in levels of education, causing e.g. shortages in language skills</i>	Time and opportunities for personnel development	Knowledge sharing problems between the unit and the corporation level	More regular meetings between the unit and corporation level key people	Information systems are not used comprehensively	IT courses for the personnel
<i>Insufficient learning loop and tolerance of past mistakes</i>	Open discussion on the previous occasions. Open and justified decisions.	Unclear roles and job descriptions	Roles of the people in the unit are discussed and decided together	<i>Unrealistic expectations of employees about what technology can do or can't do</i>	IT courses for the personnel
<i>Lack of trust (towards other units)</i>	More informal meetings between the unit managers	<i>High competitiveness between other subsidiaries</i>	More informal meetings between the unit managers.	<i>Lack of integration of IT processes and systems</i>	IT courses for the personnel IT oriented person employment
<i>General lack of time</i>	Clearer job descriptions, routine practices	<i>Deficiency of resources</i>	Clearer processes, priorozation, learning from mistakes, IS development	<i>Lack of technical support</i>	IT oriented person employment

In conclusion, organizations are forced to be in the mode of continuous change and organizational agility requires efforts from management perspectives of human resources, business, knowledge and quality. This organizational mindset is the new 'normal' as organizations' operating environment is dynamic in nature. This can be seen as changing environmental dynamics in customer demands, political context and emerging/new megatrends that influence the flows of knowledge at the individual and organization levels. As for an industrial organizations being the study focus, the main objective is to create added value for its stakeholders such as customers, partners, owners and in particular employees. In practice, this means organizational decisions and processes that

can minimize barriers and reduce lead time to foster better knowledge sharing, which can create added value for the important stakeholders of the organization.

Abstract

The purpose of this paper is to explore the complexity of designing knowledge ecosystems for business education based on the theory of knowledge fields and knowledge dynamics. That means to change the paradigm of university education based on the traditional rigid curriculum into a new paradigm based on adequate knowledge ecosystems. The new paradigm reflects the needs of developing a personal learning environment in a volatile, uncertain, complex, and ambiguous (VUCA) environment. Business education should adapt its design to the complexity of the real business environment dynamics and to the need of strategic thinking. The present paper integrates results from a qualitative and a quantitative research performed in the period January-March 2019. Qualitative research is based on the critical analysis of literature dedicated to business education and on the theory of knowledge fields and knowledge dynamics. The theory assumes that knowledge can be understood as a spectrum composed of rational, emotional and spiritual knowledge fields which interact continuously. Each form of knowledge can be transformed in any other form of knowledge, as energy forms in thermodynamics. Thus, business education can integrate all of these forms of knowledge and develop a deeper understanding of the complexity of the real world. Quantitative research is based on a survey done with students enrolled in business administration program. We got 269 valid questionnaires and then we processed them by using the specialized software package SPSS. The knowledge ecosystem is conceived as a learning environment where students can benefit both of the university knowledge transfer and mind developing processes, and of internship programs in some companies which provide direct business experience for them. The design of the knowledge ecosystem considers also some other types of business activities like business clubs, entrepreneurship incubators, workshops and leadership

summer schools. Strategic thinking integrates all these forms of knowledge and creates a support for long term decision-making.

1 Introduction

Knowledge ecosystem is a metaphor built on the analogy with ecological systems and their processes. Being a metaphor, its definition is rather fuzzy (Miller, 2015; Valkokari, 2015), but the core meaning is clear. It refers to a system of systems which interact in concordance with some principles and set of values (Bray, 2007; Maracine and Scarlat, 2009). The governing principles come from the knowledge management systems and they refer to knowledge creation, acquisition, sharing, transfer, transformation and use. The ecological metaphor induces the idea that the component systems can have a positive or negative contribution to the whole dynamics of the knowledge ecosystem determined by their field of interests. The present research focuses on knowledge ecosystems designed for business education, where the component systems can be: universities or faculties having business programs, research centers or institute, companies, business incubators, financing agencies for business start-ups, students' business clubs, international students' exchange programs. Thus, the driving force of the whole knowledge ecosystem considered in the present research is business education, and the gravitational field which determine the interactions between the systems is the university system. The research question for the present research can be formulated as follows: How should the knowledge ecosystem for business education be designed such that it would satisfy much better the needs of future businessmen than the classical approach of the rational knowledge curriculum and a campus centered education based on knowledge transfer.

2 Literature review

Business education is a complex topic since the concept of *business* is defined in multiple ways. Economists define business in terms of money and profits, but business means to create value for society. As Drucker (1993, p. 79) posits, "A business is not defined by the company's name, statutes, or article of incorporation. It is defined by the want the customer satisfies when he buys a product or a service. To satisfy the customer is the mission and purpose of every business". Although business is based on economic and managerial principles it cannot be reduced to them. It integrates knowledge from multiple disciplines which can explain how to identify the needs of people and how to satisfy them by creating products and services. Business education should reflect this complexity and students should learn how to design business and how to create value for customers. They should constantly seek a "fruitful balance between reliability and

validity, between art and science, between intuition and analytics, and between exploration and exploitation” (Martin, 2009, p. 62).

Business education as performed today in business schools is based on a certain curriculum, which represents a linear composition of disciplines within a generic framework approved by some accreditations agencies. Teaching and learning are still dominated by the well-known transfer of knowledge from professors to students within the chosen disciplines (Gherardi et al., 1998). That kind of education becomes insufficient for the present students thinking that they will work in a turbulent economic environment and in a business future with many uncertainties (Bejinaru, 2018; Martin, 2009; Mintzberg, 2004; Spender, 2014). Some researchers propose to move from a static and rigid curriculum toward a dynamic and flexible one with a shortened life cycle (Albert and Beatty, 2014).

Tsang and Tsui (2017) introduce the concept of Personal Learning and Network Environment (PLE&N), by using the support of information technology. The new concept focuses on the students’ willingness to enlarge their knowledge horizon by using information platforms and developing knowledge networks. Tsui and Dragicevic (2018) consider that curriculum can be improved by engaging students, graduates and professionals in its design and integrating their vision on a fast changing business environment. Thus, they developed new approaches for curriculum design by “co-creation with the support of scenario development techniques facilitated in the personal learning and network environment (Tsui and Dragicevic, 2018, p. 850). This approach of involving students in co-creation of their curriculum stimulates their efforts in learning by creating new driving forces for knowledge exploitation and exploration (Pechham, 1995). Also, this creative approach “should cultivate student curiosity, creativeness, critical attitude, enthusiasm, and responsibility for contributing to society” (Jurše and Mulej, 2011, p. 1450). Networking implies a skill for *connectivism*, a process by which a person enters in connection with many others via internet and establishes new links (Dunaway, 2011; Vătămănescu et al., 2015, Vătămănescu et al., 2018).

Prominent business schools aim to prepare not only business workers but business leaders who can change the world. To achieve this goal, business schools should put a “greater emphasis on ethics and corporate governance” (Bajada and Trayler, 2016, p. 458). Corporate governance and corporate social responsibility require a new mindset structured around a new set of values which depart from the profit maximization principle applied without any consideration for the social and natural environment (Anninos and Chytiris, 2012; Bratianu and Bejinaru, 2017; Choudhury, 2015; Wallis and Valentinov, 2016). That idea is emphasized very well by Mitroff and Denton (1999, p. 91): “We have gone too far in separating the key elements. We need to integrate spirituality into management. No organization can survive for long without spirituality and soul”.

Business education needs a new understanding of consumers’ behaviour and their decision-making process. As Hill (2008, p. 2) posits, “Breakthrough in brain science have revealed that people are primarily emotional decision makers”. The classical split between cognition and emotion should change into a bridge, and in the new knowledge

ecosystem students should be exposed to experiential learning (Kolb and Kolb, 2005) and emotional knowledge (Bratianu and Orzea, 2013).

3 The theory of knowledge fields and knowledge dynamics

A knowledge ecosystem should approach the complexity of business environment and integrate all forms of knowledge. According to the theory of knowledge fields (Bratianu, 2015), there are three basic fields of knowledge: rational, emotional, and spiritual. Rational knowledge is the explicit knowledge which we learn by using a natural or symbolic language. It is about the mental reflection of the world in which we are living. Emotional knowledge is a wordless knowledge which results from the work done by the sensory systems and the cognitive unconscious (Damasio, 2012; LeDoux, 1998). Emotional knowledge is processed by emotional intelligence (Goleman, 1998), and System 1 of thinking (Gladwell, 2005; Kahneman, 2011). Spiritual knowledge is about cultural values and beliefs. It is about our existence and about working motivation or spirituality (Barret, 2010; Nonaka and Takeuchi, 1995). Spiritual knowledge is processed by spiritual intelligence and transformed into spiritual capital (Zohar and Marshall, 2000). Spiritual knowledge is the raw material in functioning spiritual leadership.

Knowledge dynamics can be interpreted both as a *flow* (Nissen, 2006, Nonaka et al., 2008; Schiuma, 2009), and as a *transformation* (Bratianu, 2015). For understanding the knowledge ecosystem dynamics both interpretations are useful. Knowledge flows within a company but also across its boundaries, when considering the company just a node in a network. Knowledge sharing and knowledge loss contribute directly to the flow of knowledge within the knowledge ecosystem (Bratianu et al., 2011). Knowledge flow is a metaphor coming from the Newtonian mechanics and is very much used due to its simplicity and intuitiveness. Knowledge transformation is a metaphor coming from thermodynamics and refers to the transformation of a knowledge field into another, as proved by neuroscience research. Rational knowledge can be transformed into emotional or spiritual knowledge; emotional knowledge can be transformed into rational and spiritual knowledge; and spiritual knowledge can be transformed into rational or emotional knowledge (Bratianu, 2015). This knowledge dynamics is essential in experiential learning (Kolb and Kolb, 2005), and in developing generic skills in business education (Bratianu and Vatamanescu, 2017). For instance, students in their internship program are expected to learn by doing, when emotional knowledge obtained through sensory systems is transformed into rational knowledge and integrated into the theoretical structure they got from professors' lectures. Designing a knowledge ecosystem for business education should consider this enlarged framework.

4 Methodology

The main research tool we relied on was the questionnaire to better design knowledge ecosystems for business education. In order to create this questionnaire we had to undergo several stages: the first one consisted in a thorough literature review analysis (qualitative

methodology) for establishing the theoretical framework of the research in question and it also helped in establishing potential hypotheses. Through it, we managed to better understand how knowledge dynamics acts as flow, that there are several fields of knowledge rational, emotion and spiritual and they can shift shape under specific conditions. In the second stage we drafted the questionnaire to measure the variables previously identified in the literature review. For a third stage, we tested the draft questionnaire with a smaller sample consisting in a group of experts on business education, knowledge fields and knowledge ecosystem to establish whether there are any redundancies, biases, misleading questions or the framework effect. Following, we established the final improved form of the questionnaire which consisted in 33 items. For the present article, we will only analyze the first 24 questions. Except for the demographic questions, all of them were closed questions meant to deliver answers on 5-point Likert scale: 1 (strongly disagree), 2 (disagree), 3 (neither agree nor disagree), 4 (agree), and 5 (strongly agree). The questions were randomized as to avoid the framework or priming effect and they were distributed to a non-probabilistic sample. The population we targeted was mainly made of students coming from business administration faculty at the Bucharest University of Economic Studies. We physically distributed 436 questionnaires to students, after the distribution we managed to collect 269 valid questionnaires, obtaining a response rate of 61.69%. The refined data was put to analysis by using the dedicated software SPSS 20. Furthermore we used Principal Component Analysis (also known as factorial analysis, which is a dimension reduction method). This kind of analysis results in grouping different sets random variables. Additionally, in this case the factor reveals latent correlations among variables (Tabachnick and Fidell, 2007, Vizitiu et al., 2018; Hadad, 2018), translated into an equation system.

5 Results and discussions

The structure of the statistical population under scrutiny can be characterized as follows: 126 students belonged to the second year of bachelor accounting for 46.85% of the sample, while 143 belonged to the third year of bachelor accounting for 53.15% with ages belonging to the interval 18-35-years old, the average being 20.80. The gender structure of the respondents can be depicted in the figure below:

Source: Authors' own processing

The statistic means of the first 12 variables hint towards somewhat contradictory results indicating that they have relative awareness about the type of knowledge fields confirmed by the statistical means which were mostly above average, despite the fact that the factors did not cluster as predicted in the subsequent factorial analysis. In terms of their ability of knowing the ways knowledge transfer happens the results are encouraging again revealing a mature thinking and understanding of how knowledge can shift its forms according to certain conditions and exposure to different ecosystems. The preferred learning ecosystem by the sample is composed of: on the last place they prefer learning from books (2.21), the success stories of professionals seems not to exert enough influence on their learning eco-system accounting for a mean of 2.29. They seem to be mostly motivated by Erasmus experience and other international projects which would ensure a comprehensive individual development. A still preferred instrument for the education of business students resides in the case studies with a mean of 3.48. An important element of the ecosystem that is starting to take hold of it is represented by the internet sources (3.60).

Figure 2. Knowledge ecosystem for business education

In the first part of the statistical analysis we decided to check for the consistency of the knowledge fields and awareness of the students in this respect we employed the factorial analysis reducing the 12 questions to three factors that grouped as follows. The present paper strictly analyzed the first 24 questions and the last three.

Table 2. Grouping of items into factors

<p><i>Factor 1: Learning awareness</i></p> <p>Q2. I consider that business is a dominant rational activity</p> <p>Q6. Efficient learning is based on a good motivation</p> <p>Q7. Entrepreneurship is based on learning by doing</p> <p>Q9. Learning is more efficient when there is a clear purpose in life</p> <p>Q10. I learn mostly from case studies, student projects and seminars</p>
<p><i>Factor 2: Rational field</i></p> <p>Q1. I appreciate the rationality of professors' lectures</p> <p>Q3. I always integrate new knowledge in my logical thinking system</p> <p>Q4. Appreciation of professors' critical thinking.</p> <p>Q5. I consider that business has an important emotional dimension</p>
<p><i>Factor 3: Spiritual field</i></p> <p>Q8. Working in project teams helps me in developing my emotional intelligence</p> <p>Q11. Working and learning in project teams implies sharing similar values</p> <p>Q12. Sharing knowledge is crucial for the survival of an eco-system</p>

Source: Authors' own processing

The reliability of the grouping of the factors is confirmed by the Kaiser-Meyer-Olkin test which is almost 0.8, therefore the method of factorial analysis is an efficient one to be applied on the collected sample (Table 3). The KMO test for both female and male can be consulted in the appendixes.

Table 3. KMO and Bartlett's Test

The emotional component is very important, yet dispersed throughout all the three factors: Q6-7 in factor 1; Q5 in factor 2, and Q8 in factor 3.

The first Factor is entirely devoted to *learning awareness* and builds on the rationality of the business process. Good motivation, a clear purpose in life, learning by doing and learning by means of case studies are all subsequent to learning awareness.

The second Factor, *rational field* of knowledge accounts for increased independence of the subjects which is given by their maturity of assessing the intellectual quality of the lectures, the capacity to integrate new knowledge by developing consonant and dissonant relationships with their existing structures. Moreover under this factor, subjects also have an important appetite for the critical thinking of their information conveyer, whom in our case is the professor. As surprising as it may seem, the emotional dimension of the business is highly positively correlated within this factor because most people consider that engaging in a business endeavor equally requires reason and emotion. In spite of the oversimplification of game theory pioneers, that economy is a game which can be strictly

defined by profit maximization and rationality, the current philosophy (e.g., behavioral economics) does not exclude emotional factors from the process of decision making.

The third Factor, *spiritual field*, builds on personal development via engaging in team-work and stimulating communication, with the main emphasis being placed on sharing values and knowledge.

The total variance explained per the entire model is 42.971%. At the same time we decided to conduct the factorial analysis segregated by male and female. The variance explained for male is 46.472% whereas the one for women is 42.797%. This value stems from the theoretical framing of restraining the number of factors to 3.

In each of the two particular cases (male/female), the reliability of the factorization procedure is confirmed by the Kaiser-Meyer-Olkin test with values 0.742 and 0.699 (see appendixes).

a. Rotation converged in 5 iterations.

The colors represent the variance of each clusters with respect to the range of items (initial questions 1-12). For example, Factor 2 in Table 5 is more centered on items regarding the rational knowledge (questions 1-4), compared, e.g., to factor 3 in Table 7 which is the most scattered over the whole range of items.

One can notice that Factor 3 from Male and Factor 1 from Female are almost similar: they both include Q6, Q7 and Q10, and differ only with respect to the membership of

Q2/Q9. On the other hand, it is noteworthy that Q2 and Q12 do not correlate significantly within the female factorization. This result calls for future investigation.

7 Conclusions

According to our analysis of the business ecosystems, the universities should turn their attention more to gaining access to online databases and sources for the students to be informed as it seems this is their most preferred means of acquiring knowledge and it also reveals a striking tendency of the Millennials and Z generations to orient their attention to more digitalised content.

Moreover, they exert an inclination to being pragmatic and strategic thinkers, not going for the accumulation of a large volume of information but an actual ability to learn which in turn can convert into enormous volumes of information stored. Another poignant finding is that the fields of knowledge are not clearly delineated in the minds of the interviewees, however they intertwine which could request for better teaching aligned to the necessities of the students as to further align their abilities and skills to the requirements on the labour market.

International projects play a crucial role in shaping a future employee and ensuring both self-esteem and the development of the individual and an advanced agility ability for the labour market.

With respect to knowledge dynamics, students are eager to learn by doing, to learn from their professors, projects and business meaning that these dynamics are boundaryless, confirming that the learning pattern of student has shifted.

The main limitations of the paper come from the fact that we strictly addressed the students of one faculty within the university which has actually 12 faculties, from the fact that we were not able to also conduct focus groups with different stakeholders including deans, vice-deans, rectors or curriculum developers. Further analyses can be conducted by not restricting the number of factors.

Abstract

Nowadays, Logistics has become one of the most strategic areas for organizational performance, becoming progressively more and more challenging with the birth of new regulations, innovative technologies, and new customer demands, particularly related to the spreading of Industry 4.0 and the rise of new sustainability issues. The numerous changes that have been occurring in the sector are making it a priority for educational institutions to provide students and workers with high-quality competences and skills that businesses require in order to keep pace with the market.

This paper presents some findings and perspectives from a European research project called "FRAMELOG, European Framework for 'Knowledge Triangle' in the Logistics Sector", which is focused on the knowledge dynamics of the so-called Knowledge Triangle (hereafter, KT). The KT is considered a suitable framework for defining a macro knowledge ecosystem which links educational organizations, research institutions, and for-profit entities with the common scope of creating high-quality competences. In this macro perspective, we first performed a multiple case study analysis at European level to identify some effective methods and tools used to implement dynamic knowledge-creating connections among cross-sectorial key organizations in the logistics area. Subsequently, following a literary review and focus group activities, we identified a panel of indicators that can be used to assess and guide the building of collaboration between organizations, according to the Deming Cycle.

In addition, some "Methods", "Tools and Actions" and "Guidelines" were created to help organizations working in the KT ecosystem to effectively set up those steps needed to increase collaboration within it.

From the early findings of the FRAMELOG Project, it appears that conjoint knowledge-creating dynamics, such as the sharing of good practices, the use of different guidelines and the application of stakeholder engagement techniques, can contribute to stimulating proactive relationships between organizations, in the common objective of creating high-level skills on logistic topics and for the overall logistics sector.

Reducing the distance between organizations working in the fields of education, research, and business can enable the implementation of virtuous spirals of knowledge creation in all three areas, leading to the formation of an effective knowledge ecosystem for the logistics area; by extension, this can also foster an increase in the productivity of the whole industry and greater well-being at regional, national, and European levels.

Keywords – knowledge dynamics, stakeholder engagement, knowledge triangle, logistics, supply chain management

Paper type – Practical Paper

1. Introduction

Logistics¹ and Supply Chain Management² topics have been growing in importance in both scientific literature and business practices for the increasingly strategic impact of related activities, both at a micro (single organisation) and a macro level (country). The various changes that have occurred and are occurring under multiple aspects, such as new regulations, globalization (Arvis *et al.*, 2018), new customer demands, sustainability issues (Carter & Easton, 2011), and innovative technologies, particularly the ones related to Industry 4.0 (Barreto *et al.*, 2017; Wang, Gang, *et al.*, 2016); Lamba & Singh, 2017; Macaulay *et al.*, 2015; Pfohl *et al.*, 2017), raise the need for new professionalism and both transversal and specialized competences to guide organizations through this constant transformation (Trautrimis *et al.*, 2016). A recent study (McKinnon *et al.*, 2017) highlights a significant European shortfall of competences and adequate staff profiles for logistics and underlines the need for both in-depth research and practical business-oriented solutions. In this context, public and private educational systems should react by adjusting their offer to keep it aligned with the new methods, contents, and competences required by the market and they should actively contribute to the development of this growing sector.

A theoretical approach that can be used to frame the connections and analyse the relationships among very different actors, meaning educational organizations and business entities, is the so-called Knowledge Triangle (Markkula, 2013; Unger & Polt, 2017). Within the KT, we applied the basic, well-known Nonaka theories, from the original one on dynamic knowledge creation (Nonaka, 1994) to the one on “Ba” (Nonaka & Konno, 1998; Nonaka, Konno, & Toyama, 2000).

In this framework, bilateral relationships are drawn among education, business and research organizations that are vital for “improving the impact of investments and inter-

¹ “Logistics is the process of strategically managing the procurement, movement and storage of materials, parts and finished inventory (and the related information flows) through the organization and its marketing channels in such a way that current and future profitability are maximized through the cost effective fulfillment of orders” (Christopher, 2005, p. 4).

² “Supply chain management is a set of approaches utilized to efficiently integrate suppliers, manufacturers, warehouses and stores, so that merchandise is produced and distributed in the right quantities, to the right locations, and at the right time, in order to minimize system-wide costs while satisfying service level requirements” (Simchi-Levi, Kaminsky, & Simchi-Levi, 1999, p. 1).

organizational knowledge circulation in the three activities involved” (Scipioni, Niccolini, 2018). Goal-oriented relationships among actors may enable a higher circulation of knowledge regarding competence formation – by sharing and discussing practices, instruments, ideas and future orientations – oriented to higher quality and effectiveness of the overall educational system in responding to market needs.

In this context, the European project “FRAMELOG” was funded by the European Commission from September 2016 to August 2019, to create a “European Framework for ‘Knowledge Triangle’ in the Logistics sector”, meaning a set of theoretical background and instruments designed for organizations to enhance their level of collaboration, and consequently the quality of education in the logistics area. The participating Partners, with the University of Pisa acting as Coordinator, already represent a Knowledge Triangle, with a scope that includes educational and research institutions (University of Transylvania in Brasov, University of World Economy), three specialized businesses representing associations (one at the European Level (The European Logistics Association) and two operating at the national level (Bulgarian Logistics Association and Associazione Italiana Logistica e Supply Chain Management)), as well as EU project specialists (Effebe – Finance & Banking, *Associazione per lo Sviluppo Organizzativo e delle Risorse Umane*), covering four different countries (Italy, Bulgaria, Romania, and Belgium).

Following the presentation of the different research methods and data used in the study, some preliminary findings and related discussions will be offered to share the experience of an articulated application of a theoretical framework in a real logistics context in Europe.

2. Methods

To address the presented topics, mixed qualitative and quantitative methods were used over a period of three years. To begin, a multiple case study analysis (Yin, 2009) was performed on European examples of an already applied Knowledge Triangle in the logistics area, with higher education institutions, research centres and companies actively working together in the field. Together with a literature review of European general educational systems and methods, this methodology was considered well-suited for an exploratory study of the state-of-art of the educational offer in logistics. While considering the limitations of case study research, in terms of empirical generalizability (Hammersley et al., 2000) and of transferability of specific instruments and practices investigated in different contexts, it nevertheless offered a starting point in the study of the underlying collaboration concepts and the subsequent design of an adaptable framework of criteria, indicators, and tools for the widest possible audience.

Firstly, a snowball sampling procedure was adopted. To select the sample of case studies, the FRAMELOG Project Partners provided known examples of collaborations among the three actors of the Triangle, in the logistics sector. Starting from those examples, and cross-referencing official rankings of top universities across Europe, a sample of case studies – of universities – were selected to be deeply analysed. In order to

conduct interviews with reference people of the selected cases, a template was prepared and shared with the interviewers.

Secondly, several focus group sessions were held with experts from educational, research, and business organizations, in order to theorize a framework out of the case study analysis and the available literature on the topic. It was considered essential to have a leading pattern to follow in the development of the framework and to guide the brainstorming activity; at that point, the Deming cycle (1993) was identified as the most representative one. This cycle illustrates the activity development of an improvement-oriented organization, identifying the four ideal stages of Planning, Performing, Checking, and Innovating for strategic and operative activities. In each focus group session, a document was shared among the participants to work on and, depending on the progressive results, an updated version of the same document became the basis of the following meetings. After several sessions, and a final validation among the participating partners, a conclusive version of “the FRAMELOG framework” was shared in March 2018.

Finally, to test the real effectiveness of the proposed framework among key stakeholders, both quantitative and qualitative analyses were conducted, starting from January 2019. For the quantitative analysis, a structured questionnaire with a five-point Likert scale evaluation was prepared and administered at both national and European levels; this survey was meant to assess the relevance of the presented framework and the effectiveness of the built-in tools in achieving high-quality and effective collaboration among KT actors. As regards the qualitative analysis, a European focus group session was held in Brussels on 13th March 2019, which delved into specific and highly relevant aspects of the framework in detail.

In the section that follows the main preliminary findings will be presented and discussed, although the final evaluation of the proposed framework is not yet available and the presented tools may still need to be fine-tuned accordingly.

3. Findings and discussion

In the next paragraphs, the findings presented are arranged by research method applied.

3.1 Multiple case study analysis

From the multiple case study analysis, a set of 13 examples of effective collaboration were identified across Europe¹, as summarized in the following table.

¹ From EU project FRAMELOG, *Compendium of Good Practices*, 2016-1-IT02-KA203-024565

Table 5_Selected case studies on KT application in Europe (extrapolated by the authors)

University	Country
1. Zaragoza Logistics Center (ZLC)	Spain
2. Rotterdam School of Management, Erasmus University	The Netherlands
3. The University of Huddersfield	The United Kingdom
4. Kühne Logistics University (KLU)	Germany
5. University of National and World Economy	Bulgaria
6. Montanuniversität Leoben	Austria
7. Hull University Business School	The United Kingdom
8. Jönköping University	Sweden
9. Politecnico di Milano School of Management	Italy
10. Budapest Metropolitan University	Hungary
11. University of Padova	Italy
12. University of Pisa (Polo Universitario Sistemi Logistici Livorno)	Italy
13. University of Gothenburg and Chalmers University of Technology	Sweden

The analysis of the case studies showed heterogeneity in terms of type, ownership, country of origin, and level of influence (local, national, international, or combined) of the single organizations, meaning there were different levels of influence on the integration of the Knowledge Triangle. For example, those universities with a mostly national influence present a high socio-economic impact on their respective country (e.g. ZLC: a high level of local employment), while the more international-oriented ones (e.g. KLU) activate, on average, a greater number of cross-border activities, such as participation in international projects. The principal common features of the case studies analysed can be summarized in the following points:

- a strong professional orientation toward facilitating employability, with a practical orientation of both study material and educational method;
- the development of a competency-based approach to curriculum design, and the combination of education and work experiences;
- the presence of only one strategic connection inside the Triangle, mostly between the education and business fields.

The complete description of each case study feature, along with a detailed comparative analysis, has been included in the “Compendium of Good practices”, which provides concrete examples of applicable patterns for collaboration among KT actors; it is a document that is available to and designed for organizations in the logistics area.

3.2 Focus group analysis

Following the case studies analysis, “the FRAMELOG” was set up through the focus group activity. It consists of a framework of criteria, methods, and tools identified and/or developed for educational, research, and business organizations to improve collaboration among the other actors of the KT, with the common objective of enhancing the quality of competence formation in the logistics area.

“The FRAMELOG” presents 19 indicators (for a detailed list of indicators, see Annex I); for each of them, a “Method”, a set of “Tools and possible Actions” and a “Guideline” were identified to help organizations align themselves with the identified indicators for specific collaboration-oriented activities. The above-mentioned features are organized in three sections, according to the first three Deming cycle phases: Plan, Do, and Check. The phase in which an organization works to reinvent its activity on the basis of both the “Check” stage and, in this context, the discussions within its collaboration environment, corresponding to Deming’s fourth phase (Act), is translated into a set of “Guidelines for implementing the FRAMELOG” associated with selected high-impact indicators. In fact, once the actor (an organization) considers following the Guidelines to set up its own activities, it starts moving on a positive and proactive path towards a more integrated environment in which it works with the other actors, “acting” as a collaborative player inside the Knowledge Triangle.

Table 6_Main features of "The FRAMELOG" (extrapolation by the authors)

Indicators	Phases of activity flow (PDCA)	Methods	Tools and possible actions to be used/implemented	Guidelines
------------	--------------------------------	---------	---	------------

In the study, one of the features considered most strategic for effective collaboration among educational, research, and for-profit organizations is the presence of conjoint activities between them, with a tangible result in terms of, for example, student employment, intellectual products (e.g. scientific papers, research projects), long-term partnerships, and/or dissemination events. In this logic, the “Guidelines for implementing the FRAMELOG” are intended as a guide to setting up the related collaboration activities, with the necessary adaptation to the specific context. These indications should help organizations to set up their own activities considering a combination of lessons learnt, general indications coming from other organizations’ good practices, and insights from scientific literature.

Among the tools highlighted as strategic for setting up a collaboration pattern among the KT actors, the “FRAMELOG Stakeholder Engagement Plan” merits special note. In this document, a stakeholder analysis and a summary of possible communication actions, objects, and strategies are presented as a tool to be used by organizations in attracting and managing its “key stakeholders” for collaboration. For example, the Stakeholder Engagement Plan can support the development of some activities suggested for the “Planning” phase of the collaboration, such as arranging for students to visit business facilities in order to make them aware of the real functioning of logistics procedures inside a company; this is designed to go hand-in-hand with traditional in-school learning.

Finally, after analyzing the preliminary results of the testing activity, some initial insights can be highlighted from the stakeholders’ perception of the proposed methods, actions, and tools. In particular, from the results of the Italian assessment, an overall average of 4.1 points out of 5 was reached for the tested elements. In more detail, stakeholders from both the educational and business areas seem to support the

construction of the FRAMELOG and the suggested tools; they consider those tools that are reactive and quickly applicable, i.e., with few procedural barriers for their concrete organization and development, to be most useful and effective.

In the next few months, the results from the Belgian, Bulgarian, and Romanian quantitative assessments and from the European focus group session (Brussels, March 2019) will be available and will provide a European overview of the stakeholders' perception of the framework. With the systematic evaluation of all the feedback from the FRAMELOG key stakeholders, some important indications will be highlighted and used in the final adjustment of the FRAMELOG and the developed tools to support organizations in creating high-quality logistics competences in the context of a more collaboration-oriented environment.

4. Conclusions

The orientation toward a more collaborative environment, which would enable an organization to not only reach its own stated goals, but redesign them to constantly enhance its performance thanks to its openness to new ideas, procedures, and methods to remain competitive in the market, is something that can be found in every economic sector. For logistics, it has become essential as the sector is increasingly becoming more competitive in terms of rapid technological innovations, new profiles of players coming into different areas, and fast-changing consumer needs. In this context, the formation of high-quality competences plays a strategic role in creating those essential intangible assets that support organizations in their innovation process. A possible pattern that educational, research, and business organizations can refer to when improving their collaboration for the formation of logistics-oriented competences is the Knowledge Triangle concept applied to logistics and the related "FRAMELOG" framework of methods, actions, and tools.

The embedding of the identified indicators for "FRAMELOG" implementation within the Nonaka knowledge-creation spiral concept, aligned to the Deming PDCA framework of activity, could contribute to developing a more collaborative and dynamic managerial approach for the actors inside the Knowledge Triangle. In fact, redesigning or activating collaboration-oriented strategic and operational activities as well as applying good practices and insights from scientific literature along with stimulating suggestions from experts, should help organizations to enhance knowledge creation and circulation among the KT players, as shown in the following figure.

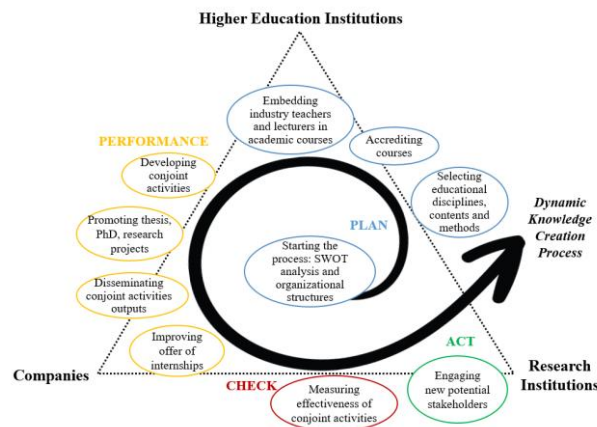

Figure 1_FRAMELOG high-impact indicators embedded in Nonaka's knowledge-creation spiral (extrapolation by the authors) within the Knowledge Triangle

Although the planning phase appears to be the most strategic one to focus on, collaboration should certainly be activated in each stage of the Deming cycle. Looking at collaboration as a constantly evolving knowledge-creation spiral, each collaboration-oriented activity builds the basis of a virtuous cycle which will progress towards high-quality relationships among educational, business, and research institutions. Only after the collaboration is enacted, can the practical design, application, and control of specific tools and conjoint processes possibly take place and lead, as specifically analysed in this study, to a higher quality of competence formation in the logistics area. Widening the application of the “FRAMELOG” outside specific contexts and single organizations, an overall and systematic enhancement of collaboration in logistics competence formation should help to shorten the distance between the three angles of the Knowledge Triangle and create an inter-organizational, hybrid Nonakian “Ba”, thus enabling the development of knowledge-sharing relationships and consequent strategic and operative processes, jointly oriented toward the enhancement of competence formation.

Figure 2_Knowledge Triangle enabling the development of Nonaka's inter-organizational and hybrid "Ba" for knowledge-creation (Authors' adaptation from Nonaka, Toyama, Konno, 2000: 14)

Like any process, this collaboration scheme would need initial proactive players to activate the process and increase the chances of success, as experienced also in other contexts and with different stakeholders (Ferraro & Beunza, 2018). So far, universities seem to be the primary activators of the knowledge-sharing process that favours KT application in Logistics. From the ongoing testing activities, the interaction among key stakeholders, the sharing of a common approach to conjoint activities, the use of quickly applicable instruments to boost collaboration, and the involvement of governance representatives are considered essential features that enable the process to be effective from a long-term perspective. Once the evaluation phase is concluded, more refined results will be available, but, for the moment, some aspects can be positively highlighted. In fact, although the applicative methods could vary from one context to another, a general attention and potential commitment of organizations within the KT to the formation of high-quality competences in Logistics has been confirmed. This is evident, in particular, in the creation of macro knowledge ecosystems in which the exchange of ideas, practices, and tools is enacted, leading its members to higher levels of performance, with wider recognition and openness to those innovations and growing opportunities deemed necessary for remaining competitive in the market.

Abstract

Industrial clusters are characterized by an intense actors interacting with the effect of sharing existing knowledge and creating new one. In this environment knowledge unevenly flows across organizational boundaries and a significant part is exchanged via informal channels.

Despite some scholars argued that only general and low-value information can be shared through this kind of channels (Breschi & Lissoni, 2001), empirical research show that specific and critical knowledge diffuses through informal networks as well (Dahl & Pedersen, 2004).

Indeed, informal ties between firms represent the fertile ground for the so-called 'information trade', according to which firms must first give useful information in order to obtain it (Rogers, 1982). Von Hippel (1987) considers informal information trade between firms as an important form of cooperative R&D, likely to occur in industries where proprietary knowledge is critical for firms' success.

Although such knowledge spillovers are recognized to be not a critical factor for firms' willingness to cluster (Krugman, 1991), they are an important form of knowledge transfer and their existence within clusters is undoubtedly linked to the one of informal networks. Scholars argue that formal ties among firms are important in explaining innovation exactly because they enable access to informal spillovers within a regional ecology (Owen-Smith & Powell, 2004, p. 9). This argument is motivated by the fact that a large portion of the knowledge exchanged across organizational borders is tacit in nature, which is informally transmitted by face-to-face interaction (Giuliani, 2010). It descends that informal inter-organizational networks represent interesting subjects of study for their pivotal role as conduits for information and knowledge diffusion.

Although several studies recognize the importance of informal networks for the dissemination of knowledge, they mostly fail in assessing the extent to which inter-organizational informal ties represent conduits of work-related knowledge.

The data belongs to an original dataset that we have built over time since the establishment of the ITC Pole of Abruzzo Region.

First results highlight that a considerable part of informal ties represents conduits of work-related knowledge.

The paper try to contribute to the literature by emphasizing the importance of informal inter-organizational networks; when studying industrial cluster as knowledge ecosystems, informal ties among cluster actors do exist and a considerable part of those are exclusively devoted to share work-related knowledge.

Keywords – Informal ties, inter-organizational network, knowledge sharing, knowledge ecosystem

Paper type – Academic Research Paper

1 Introduction

Knowledge sharing is nowadays a condition to innovate and, consequently, for the prosperity of firms. If this were not the case, firms would have sought geographic isolation and "locational patterns of innovative firms would be very different from what we observe" (Feldman, 1999, p. 19).

Geographical proximity grants firms a higher likelihood to innovate than isolated ones due to a knowledge spillover (Baptista & Swann, 1998; Beaudry & Breschi, 2003), having also a pivotal role in firm internationalization (Libaers & Meyer, 2011) and regional economic performance (Delgado, Porter, & Stern, 2014).

Despite the acknowledged importance of interorganizational networks to knowledge sharing, still little research has explored the relationship between social network properties and innovation (Fleming, King III, & Juda, 2007). As a consequence, the literature on industrial districts and clusters is characterized by an abundance of arguments on the effect of interorganizational ties on the performance of connected actors, but mainly lacks of empirical findings (Ferriani & MacMillan, 2017). Under this light, this study represents an attempt to explore the relationship between interorganizational networks and innovative performance, with a specific focus on informal networks.

Within industrial clusters¹, knowledge unevenly flows across organizational boundaries as knowledge sharing is a strongly selective process (Alberti & Pizzurno, 2015; Giuliani & Bell, 2005). Since part of this knowledge is exchanged via informal channels (Saxenian, 1994), the attempt of this study is a first exploration of informal relationships within a business network. Having the availability of longitudinal data, we perform our study on the ICT Pole of Abruzzo Region, an Italian high-tech cluster.

¹ At this stage we use the expression "industrial district" and "cluster" indistinctly to mean an agglomeration of business strongly or weakly connected in a geographical area.

In industrial cluster research, informal interorganizational networks represent interesting subjects of study, not only for their pivotal role as channel of conduits for information and knowledge diffusion, but also because of their importance in nourishing and sustaining formal interorganizational relations. For instance, the network backbone of San Diego biotechnology cluster in California emerged from ties linking managers in the early stage of the cluster formation (Casper, 2007).

We first presents the case that aroused our curiosity and then the literature review; managerial implications and direction for further research are discussed.

2. The ICT Innovation Pole of Abruzzo Region

The ICT Innovation Pole – *Polo d'Innovazione ICT* in Italian – was established in 2011 to support the formation of an innovation cluster for territorial and industrial development of Abruzzo Region. Its establishment comes as an investment in innovation and research covered by the European Regional Development Fund (ERDF), fund established under the Regional Policy framework by the European Commission with the aim to correct economic and social imbalances between the regions of the European Union. The regional administration published a Public Notice calling for the formation of innovation poles with the goal of a strategic repositioning of the economy of Abruzzo Region in the national and international markets. The call was then attended by a group of 49 companies proposing the establishment of a high-tech cluster, the ICT Innovation Pole. Cappiello and Iapadre (2016) succinctly explain the story of the ICT Innovation Pole and the dynamic underlying its establishment and development.

With regards to the aims of the present study, the ICT Innovation Pole represents an interesting case at least for three reasons. First, innovation is extremely important for firms to be competitive in high-tech industries such as microelectronics and ICT due to fast-paced technological advances. For this reason, in this industry is particularly important for firms – especially for SMEs – to collaborate with peers to ensure their seat in the next round of innovation. In such context, it appears particularly interesting to investigate the effect of informal interfirm networks on innovative performance of firms. Second, in such high-tech industries innovative performance of firms is easy measurable by using innovation inputs (e.g. R&D expenditure) and outputs (e.g. patent counts, patent citations, and new products) (Hagedoorn & Cloudt, 2003). Third, the availability of longitudinal data since the cluster establishment makes the ICT Innovation Pole a unusual unit of analysis for studying the facilitative effect of informal interfirm networks existing prior cluster formation on subsequent formal innovation interfirm linkages.

For the purposes of this first observation of informal networks we analysed two surveys performed in 2015 and 2016. Network and firm-level data have been collected each year from which relational matrices have then been coded. In each yearly survey, among other questions, firm representatives were asked to indicate from the complete list of cluster members with which one they had established informal ties during the previous year, and whether the knowledge exchanged through such ties was work-related or not.

A first data analysis highlights that a considerable part of informal ties represents conduits of work-related knowledge. More specifically, in 2014 and 2015, 85% and 63%, of the informal ties constituting the informal network acted as conduits of work-related knowledge. In the same years, 60%, and 62% of the informal network was used to carry non-work related knowledge, respectively. Finally, in the same years respectively 45% and 25%, of inter-organizational informal ties acted as a conduit for both work-related and non-work-related knowledge.

3 Literature review and hypothesis development.

Several empirical studies recognize that firms acquire large amounts of information through informal communications (Owen-Smith & Powell, 2004; Powell, Koput, & Smith-Doerr, 1996; Saxenian, 1994). Despite some scholars argued that only general and low-value information can be shared through this kind of channels (Breschi & Lissoni, 2001), empirical research show that specific and critical knowledge diffuses through informal networks as well (Dahl & Pedersen, 2004). Communications between people facilitates knowledge sharing across organizational borders (Ring & van de Ven, 1994; Saxenian, 1990), a considerable part of which occurs through informal channels. Further, social cohesion around informal relationships ease knowledge transfer between individuals (Reagans & McEvily, 2003), and this applies to interfirm informal networks as well. Indeed, informal ties between firms represent the fertile ground for ‘information trade’, according to which firms must first give useful information in order to obtain it (Rogers, 1982). Von Hippel (1987) considers informal information trade between firms as an important form of cooperative R&D likely to occur in industries where proprietary knowledge is critical for firms’ success. Although such knowledge spillovers are recognized to be not a critical factor for firms’ willingness to cluster (Krugman, 1991), they are an important form of knowledge transfer and their existence within clusters is undoubtedly linked to the one of informal networks. Scholars argue that formal ties among firms are important in explaining innovation exactly because they enable access to informal spillovers within a regional ecology (Owen-Smith & Powell, 2004). This argument is motivated by the fact that a large portion of the knowledge exchanged across organizational borders is tacit in nature, which is informally transmitted by face-to-face interaction (Giuliani, 2010).

The existence of informal interorganizational networks is physiological in industrial cluster, as informal contacts are facilitated by spatial proximity. For instance, Huggins and Johnston (2010) found that investments in social capital – used to sustain knowledge-based collaborations – where more than double in firms co-located with their knowledge partners. Spatial proximity is clearly an important determinant of knowledge sharing, which is also why industrial districts exist (Feldman, 1999). Although knowledge diffuses among organizations in all industries, the intensity and effect of knowledge streams depends upon spatial proximity (Jaffe, Trajtenberg, & Henderson, 1993; Maskell & Malmberg, 1999). Examining the ‘paper trails’ of knowledge spillovers, Jaffe et al. (1993) found patent citations to be geographically localized. Propinquity has been found

to positively influence firm innovative performance, having a contingent effect together with network position (Whittington, Owen-Smith, & Powell, 2004). However, other scholars argue that spatial proximity does not drive the establishment of knowledge linkages as much as the latter depends upon each firm's absorptive capacity (Amin & Cohendet, 2004; Giuliani & Bell, 2005). Indeed, knowledge unevenly diffuses within clusters, flowing within sub-clusters consisting of firms with similarly high absorptive capacity (Giuliani & Bell, 2005). Being co-located was not enough also in the study of a footwear district in southern Italy by Boschma and Ter Wal (2007), where not all of the cluster actors were taking part in the local knowledge network. As opposed to Giuliani and Bell (2005), however, they found that firms' absorptive capacity was not influencing their position within the local knowledge network (Boschma & Ter Wal, 2007).

In short, what emerges from the presented literature is that i) clustered firms innovate more than isolated ones, ii) innovation is geographically localized, and iii) informal networks seems to be important channels for innovation-related knowledge diffusion.

As anticipated before, informal interorganizational networks represent interesting subjects of study, not only for their pivotal role as channel of conduits for information and knowledge diffusion, but also because of their importance in nourishing and sustaining formal interorganizational relations.

Existing ties between firms encourage and nourish the formation of subsequent linkages due to the availability of information about the knowledge partner. This effect is usually referred as *facilitative* (Ahuja, 2000a), in the sense that it shows firms the collaboration opportunities worth to be seized on the basis of prior contacts with knowledge partners (Gulati, 1995; Gulati, 1999). There is also a more *substantive* effect (Ahuja, 2000a), in the sense that existing ties between firms also nourish, for instance, the commercialization of firm innovations and their adoption by partners (Gulati, 1995; Gulati, 1999). For the sake of our discourse on informal networks and their effect for interfirm linkages establishment in the cluster formation process, we clearly focus on the facilitative effect of networks.

The facilitative effect of prior social ties is closely coupled with *knowledge-based trust* (Shapiro, Sheppard, & Cheraskin, 1992), which is established between firm building upon shared norms of equity and positive experiences. It is also for this reason that alliance formation between two firms is more likely to occur if they had prior alliance ties (Gulati & Gargiulo, 1999). The willingness of a firm to establish collaborative interfirm linkages also depends upon the awareness that the collaborative counterpart might have much to lose from engaging in opportunistic behaviors (Gulati, 1998), the so called *deterrence-based trust* (Shapiro et al., 1992). Within clusters, both knowledge-based and deterrence-based trust acquire more relevance as the density of interorganizational informal network grows. It is clear that the 'knowledge base' of trust enlarges as the informal network becomes denser due to experience sharing among actors: if a firm shares its experience with a certain knowledge partner with a third firm, said experience, although indirect in nature and in the form as it has been told, enriches the 'knowledge base' of the third firm about that knowledge partner. Likewise, deterrence-based trust acquires more relevance as the informal network becomes denser, as losses coming as

results of opportunistic behavior – loss of points of contact with actors, loss of the possibility of repeated collaboration, and loss of reputation (Gulati, 1998) – are associated with significantly higher costs of isolation. This is primarily due to the fact that, knowing each other and engaging in informal networking, cluster actors share negative experiences as well (i.e. gossiping), which might significantly lessen the existing knowledge-based trust of firms towards a given actor.

Kurland and Pelled (2000) define gossiping an activity involving few people in an organization who engage in informal and evaluative talks about another organizational member who is absent at that moment. Such definition of gossiping might be extended from intraorganizational to interorganizational settings without any loss of meaning, whereby few people who belong to different cluster actors engage in informal and evaluative talks – along the interorganizational informal network – about another cluster member. In business networks, such gossiping is generally more likely to occur then the business network is dense (Rooks, Tazelaar, & Snijders, 2011), which largely support the arguments presented above.

It is for the interplay between knowledge-based and deterrence-based trust, and because of them being influenced by gossiping, that informal interfirm ties are important for innovation-related collaborations among firms. It then becomes subject of interest in industrial cluster research for the investigation of the facilitative effect on the establishment of subsequent interfirm linkages.

The paper contributes to the literature by emphasizing the importance of informal inter-organizational networks for the diffusion of work-related knowledge. When studying industrial cluster as knowledge ecosystems, informal ties among cluster actors do exist and a considerable part of those are exclusively devoted to share work-related knowledge.

Building on this body of literature, would be interesting to analyze the relationship between the position of the actors in informal networks and their innovative performance. As the position of firms in the knowledge network positively relates to their innovative performance (Boschma & Ter Wal, 2007, Ferriani & Mac Millan, 2017), it is legitimate to hypothesize that the position in the informal network moderates this relationship. More specifically, since interfirm informal relations are pivotal in sustaining and nourishing knowledge-based collaborations, which, in turn, facilitates innovation, we expect cluster actors with high centrality in informal networks to outperform the ones with low centrality.

Indeed, since interorganizational relations between members in industrial districts often come as results of informal interpersonal relations (Inkpen & Tsang, 2005), a second attempt of study could be to examine the extent to which informal ties prior to cluster formation acted as a basis for the establishment of subsequent innovation-related formal relations among cluster actors.

Abstract

Knowledge is considered one of the most important competitive resources of small and medium size enterprises (SMEs). In order to be effective, knowledge management depends in a large degree on the employees, both on those holding managerial positions, and on regular staff. Aiming to identify patterns of knowledge management (KM) approach in Romanian SMEs and their connection with company's human resource, the study applies an online survey with 108 SMEs from Romania. The study finds out that the majority of SMEs implemented KM practices derived from the problem-solving approaches of daily challenges and the knowledge handling procedures for employees. Also, the results indicate that 86,1% of the participants perceive knowledge and its management as valuable or highly valuable for their organization, highlighting a significant interest of SMEs in implementing more structured KM procedures and flows. Still, KM is a vague concept for and handled intuitively by most Romanian SMEs. These aspects hold back KM implementation, together with the lack of KM specialists and the need for additional human resources involved in KM. Overall, the study offers insights into the actual KM approaches adopted by Romanian SMEs, emphasizing the need of a better promotion among managers and practitioners of the conceptual and practical aspects related to knowledge management.

Keywords – knowledge management, small and medium-sized organizations, SMEs, human resources in SMEs, Romania.

Paper type – Academic Research Paper

1 Introduction

In the past decades, knowledge has become an important resource for organizations. Studies developed in all domains – public, business, as well as non-profit - have revealed that strategic knowledge management leads to organizational efficiency (Darroch, 2005; Mills & Smith, 2011; Valmohammadi & Ahmadi, 2015; Zack, McKeen & Singh, 2009). These positive outcomes are also registered in the case of smaller organizations (Cerchione, Esposito & Spadaro, 2015). Despite this overall benefit of knowledge management for companies, studies also reveal the need to deepen analysis to better understand the complex impact of knowledge management on various dimensions of business activities (Heisig, Suraj, Kianto, Kemboi, Perez Arrau & Fathi Easa, 2016), studies on knowledge management for small and medium sized enterprises (SMEs) being generally dispersed (Massaro et al., 2016).

Knowledge proves to be an important resource for all types of organizations (Alexandru et al., 2018; Bolisani & Bratianu, 2018; Bratianu, 2016). Controlling and using this strategic resource requires different approaches compared to tangible resources, the human factor playing an important role (Bolisani & Bratianu, 2018, p.5; Bratianu, 2018). These processes are even more complex considering the inner dynamics of knowledge, its temporal and spatial fluidity and its ability to transform itself as energy does (Bratianu & Bejinaru, 2019). These characteristics are also influenced by the human resources of an organization.

Therefore, it would be relevant that knowledge management strategies to thoroughly integrate human resources. This dimension is maybe even more important in SMEs, where employees have a significant impact on all business aspects, including determining a company to be an effective learning organization (Nolan & Garavan, 2016; Tesavrita & Suryadi, 2016).

Considering the tight relationships between the knowledge management strategies and the human resources of an organization, the present study aims to investigate patterns of knowledge management approach in Romanian SMEs and their connection with company's human resource. The study offers insights into the actual knowledge management practices in the Romanian SMEs, highlighting the need for promotion of the KM conceptual and practical aspects among Romanian managers and employees of SMEs.

2 Previous literature

2.1 Knowledge management in SMEs

When analyzing the status of knowledge management in SMEs, previous literature highlights some peculiarities. SMEs perceive the strategic value of knowledge and have improved their practices in the field of knowledge management (Cerchione, Esposito & Spadaro, 2015), but they manage knowledge in different ways compared to large organizations (Wee & Chua, 2013). Knowledge management provides SMEs a series of benefits, such as improved customer service, enhanced innovativeness, competitive advantage, access to and assimilation of external knowledge, etc. (Durst & Edvardsson, 2012; Edvardsson & Durst, 2013; Lee, Foo, Leong & Ooi, 2016; Wang & Yang, 2016). Previous research also highlights and SMEs see knowledge as a competitive resource, and their strategies aims to facilitate knowledge transfer (Alexandru et al., 2018).

Considering this positive framework, one would expect that knowledge management has become an important part of management strategies if not the core of management approaches in all types of organizations. One expects that knowledge management has become a planned strategic approach. But studies highlight two types of situations. There are organizations for which knowledge management is a deliberate strategy, while for others it develops in time, is emerging as a reaction to the organizational and environment evolution (Bolisani, Scarso & Zięba 2016; Van den Hooff & Huysman, 2009). Some organizations have an emergent knowledge management approach, while others have a deliberate/ planned approach.

An enhancer of SMEs competitiveness is the networking abilities, which are also related to the personal networking capabilities of the owner/manager (Jansen et al., 2013). Both online and offline networks, as well as personal and professional networks should be considered. In this way, the capitalization of business networks would lead to organizational development, including in processes related to the internationalization of SMEs (Vatamanescu et al, 2016; 2018). Therefore, relational capital could enhance competitiveness of SMEs.

2.2 Knowledge management approaches in the Romanian SMEs

A study developed in 2009 shows that the Romanian SME managers consider that innovation should be at the core of their activity, ensuring competitive advantage (Nicolescu, Ceptureanu & Ceptureanu, 2009). In this framework, they consider primarily new product development and incorporation of new technologies, rather than investing in human resources training – this last aspect is directly related with the size of the company (Nicolescu, Ceptureanu & Ceptureanu, 2009, pp. 958-959). Implementing knowledge management is primarily associated to enhanced innovation and improved competitive advantage by the managers of the Romanian SMEs (Ceptureanu, Ceptureanu, Zgubea, & Tudorache, 2012, pp.331-332; Ceptureanu, 2016, p.126). Knowledge is considered the main source of competitive advantage in the Romanian SMEs activating in knowledge intensive business sectors (Alexandru et al., 2018). Implementing knowledge

management is in most cases a result of the involvement of employees. The smaller the organization, the larger is the involvement of regular employees (Alexandru et al., 2018, p.1766).

In order to effectively implement knowledge management, the Romanian SMEs have to overcome some barriers, most of them related to the lack of understanding from their employees of their importance, low internal knowledge transfer or unfavourable organizational culture (Ceptureanu, Ceptureanu, Zgubea, & Tudorache, 2012; Ceptureanu, 2016). Therefore, more awareness of the importance of knowledge management among low-level employees and a strong organizational culture facilitating knowledge transfer and development would be beneficial.

Entrepreneurs value knowledge-related aspects of their employees in a high degree, especially competence, specialized knowledge and skills, as well as learning capability (Ceptureanu, 2015). This should explain the high level of training considered as means for organizational learning in young SMEs. Knowledge transfer within organization is also valued, while sharing with external parties is rather the exception (Ceptureanu, 2015). We mention that longer established Romanian SMEs, the degree of staff training is less valued (Ceptureanu, 2016). This data is somewhat in conflict with another study, showing that the larger the organization, the more training is provided; the main barrier for lack of training being the necessary financial resources (Martin, 2015, p.612). Enhanced training in SMEs through public policies and programs is considered key strategic approach to develop the knowledge economy in Romania (Hadad, 2017).

The larger the organization, the more experience, knowledge and abilities, as well as competences are valued. The only aspect evaluated higher than the previous ones by managers of SMEs is the sense of responsibility (Martin, 2015, p.610). Data suggests that the Romanian SMEs want primarily their employees to be highly reliable, and then capable of effectively caring out the tasks.

2.3 Knowledge management and the human resource

Organizations benefit from tangible and intangible resources. Knowledge is increasingly more important. Its management depends not only on the organizational capabilities and infrastructure, by the associated management strategies, but also on the employees of the organization. They are the producers, registrars, carriers, curators of knowledge. Nevertheless, it would be the role of the organization to integrate employees' knowledge into the social structure to obtain and develop organizational knowledge (Bolisani & Bratianu, 2018, p.23). A significant component of this mechanism is knowledge sharing. Considering the high importance of knowledge transfer to ensure the effectiveness of knowledge management strategies, a large part of the academic research concentrates on the processes associated to it. In most cases, non-human facilitators are considered, such as knowledge processes, knowledge innovation, technological infrastructure, or strategies (Massaro et al., 2016). Fewer studies focus on the human factor (Casimir, Lee & Loon, 2012; Chiu, Hsu & Wang, 2006; McCall et al., 2008; Teng & Song, 2011; Wang & Noe, 2010). The structured literature review of Massaro et al. (2016) identified the following human factors affecting knowledge management:

motivation, ambition, skills and absorptive capacity, decision-making capabilities, personal self-responsibility and knowledge, as well as a series of individual barriers.

The sharing behavior of employees is up to a certain degree influenced by knowledge management strategies, especially in the case of formal requests of knowledge (Teng & Song, 2011). But mostly, knowledge transfer depends on common values, shared beliefs, on the personal acceptance of sharing knowledge (McCall et al., 2008; Teng & Song, 2011), as well as on the perceived benefits (Chiu, Hsu & Wang, 2006). Also, the interaction between managers/owners and employees influences knowledge sharing, especially from the top downwards (Massaro et al., 2016).

It also depends on the dynamics of the interaction of the employees, in connection with the organizational culture (Alavi, Kayworth & Leidner, 2005; Chang & Lin, 2015; Intezari, Taskin & Pauleen, 2017). The wider professional environment might also enhance the knowledge sharing, by offering examples and social pressure (Alavi, Kayworth & Leidner, 2005). Prosociality of individuals is influenced by altruistic and egotistic factors – overall leading to an inclination to knowledge sharing at least among colleagues (Gagné, 2009; Sproull, Conley & Moon, 2013).

Another factor we mention is personal motivation (Matzler et al., 2011). Although motivation is intrinsic to an individual, human resources management, through staffing, job design, performance appraisal and compensation systems, managerial styles, and training, has a significant impact on knowledge sharing throughout the organization (Gagné, 2009).

3 Empirical assessment and results

Aiming to identify patterns of knowledge management approach in Romanian SMEs and their connection with company's human resource, the study applies an exploratory quantitative research with 108 small and medium size companies.

Consequently, an online survey was applied to collect data from a convenience sample of Romanian SMEs activating in various fields such as IT, marcom, professional consultancy and services (N = 108 participants), and SPSS statistical software was used to perform the data analysis and interpretation.

Results of the data analysis have shown that more than half (60.2%) of the 108 participant SMEs implemented different knowledge management practices as a reaction to the issues they have encountered in the daily contexts of their activity, KM practices derived from solutions to problem-solving approaches of daily challenges (51.9%) and knowledge handling procedures for employees (63%) prevailing in most of the cases.

Results indicated that 86,1% of the participants perceive knowledge and its management as valuable or highly valuable for their organization, although knowledge management proved to be a vague rather than a very familiar concept for 70.4% of the respondents.

In fact, the inferential statistics (detailed in Table 1) resulted from the analysis of variance computed on *KM_perceived_value* as factor, reveals that an increase in the

perceived value of knowledge and its management (*KM_perceived_value* factor) is significantly related with the increase in adoption of KM practices as following:

- Overall implementation of KM practices ($F = 4.673$, $p < 0.05$)
- KM practices derived from solutions to daily challenges ($F = 3.681$, $p < 0.05$)
- Knowledge handling procedures for employees ($F = 5.430$, $p < 0.05$)

Also, higher the factor *KM_perceived_value*, higher the KM awareness ($F = 2.927$, $p < 0.05$), and higher the firm's interest (/perceived need) of KM specialists ($F = 2.143$, $p < 0.05$) and additional employees involved in KM processes ($F = 2.678$, $p < 0.05$).

Table 1. ANOVA (ONEWAY by *KM_perceived_value* q1,2,4)

		Sum of Squares	df	Mean Square	F	Sig.
Overall implementation of KM	Between	20.089	10	2.009	4.673	.000
	Within	41.700	97	.430		
	Total	61.789	107			
KM practices derived from solutions to daily challenges	Between	23.128	10	2.313	3.681	.000
	Within	60.946	97	.628		
	Total	84.074	107			
Knowledge handling procedures for employees	Between	31.807	10	3.181	5.430	.000
	Within	56.823	97	.586		
	Total	88.630	107			
Need of KM specialists	Between	22.177	10	2.218	2.143	.028
	Within	100.369	97	1.035		
	Total	122.546	107			
Need of additional employees in KM processes	Between	20.825	10	2.082	2.678	.006
	Within	75.425	97	.778		
	Total	96.250	107			
KM awareness	Between	15.514	10	1.551	2.927	.003
	Within	51.403	97	.530		
	Total	66.917	107			

4 Conclusion and discussions

The study revealed that knowledge management strategies of Romanian SMEs emerge as a reaction to the encountered issues, KM practices resulting in most of the cases from problem-solving approaches of daily challenges, and knowledge handling procedures for employees. Also, the results indicate that 86,1% of the participants perceive knowledge

and its management as valuable or highly valuable for their organization, highlighting a significant interest of SMEs in implementing more structured KM procedures and flows.

Nevertheless, knowledge management is a vague concept for and handled intuitively by most Romanian SMEs. These aspects hold them back, together with the lack of KM specialists and the need for additional human resources involved in KM implementation. In fact, our study confirms the findings of Desouza and Awazu (2006), which emphasize the peculiarities of KM approach in SMEs, especially the dominance of informality and socialization in the knowledge creating cycle, the existence of common knowledge as a common frame of reference, and the people centered KM – need of KM specialist and need of additional employees in KM processes.

Exploring the Romanian context, the present study uncovers the main KM practices adopted by SMEs and the role KM plays in their process of transition from capital-based industrial economy to knowledge-based economy. The context and the findings of our study are similar to Serbia's case discussed by Uzelac et al (2018). Serbia's case revealed opposite behaviors of the SMEs from developed countries, in which knowledge is shared because it is power, comparing to SMEs from transitional countries, in which knowledge is hoarded because it is power (Uzelac et al., 2018). This could explain the differences revealed by our study in the adoption of KM practices in terms of KM perceived value and KM awareness. Because similarly to Serbia, Romania has a difficult, less structured and less organized environment, where KM practices are necessary to respond to the daily challenges, making the study of KM in SMEs relevant for the understanding of the big picture.

Last, but not least, the present study highlights the need for dissemination of the conceptual and practical aspects related to knowledge management among Romanian managers and communities of practice. On this point, we opine that academia might offer its support through presentations at business events and KM training sessions.

Abstract

The general objective of this research is to identify and argue which are the main strategies that a university can apply in order to develop an appropriate entrepreneurial ecosystem mainly throughout managing the knowledge processes, knowledge resources and knowledge actors. Firstly, the content of the qualitative analysis serves the purpose of designing the framework about the role a university can play for contributing to local economic and social growth. Thus we are mapping and arguing the essential components and processes for serving the role of a university in developing an entrepreneurial ecosystem. In this sense we are approaching concepts like: strategic knowledge processes, the components of the entrepreneurial ecosystem, the role the university can play in developing the mechanism of an entrepreneurial ecosystem. Quantitative research is based on a survey using questionnaires filled in by students enrolled in business administration area programs and special programs offered to all those interested in becoming entrepreneurs. There were registered a number of 202 valid questionnaires and then we processed them by using the specialized software package SPSS v.25. The quantitative analysis offers the possibility of identifying the main factors which influence the students entrepreneurial behaviour. By processing the data throughout Principal Component Analysis (PCA) we identified a set of 6 factors which are the most powerful in predicting the students success as future entrepreneurs. In the discussion section we will argue the significance of each factor. Combining these results with the university's resources (infrastructure, endowments, technology, human capital, intellectual capital, and knowledge) we concluded to a couple of strategies that universities might implement in order to develop an entrepreneurial ecosystem, starting with the perfecting of their main actors, which are the students.

Keywords – knowledge strategy, entrepreneurial ecosystem, entrepreneurial university, entrepreneurship, business strategies.

Paper type – Academic Research Paper

1 The Mission of the Entrepreneurial University

As a vector of nowadays society, education contributes to the development of social and economic domains which in turn contribute to raise the life-level of the individual. At this moment, universities are constraint to switch from knowledge adaptation processes to knowledge generative processes, and to further become entrepreneurial universities. From institutional perspective, there will be created a basic impact of acknowledging the actual state of universities' evolution towards the pattern of an entrepreneurial university which should be viewed as a strategic road, nowadays (Bejinaru, 2018; Volkmann et al., 2012).

It has been a while since entrepreneurial aspirations have reached the academic mainstream. The academic involvement in technology transfer, firm formation and regional development represent a step closer to the academic ideal which is the entrepreneurial university. "The entrepreneurial trend was also boosted by the success of the iconic "technopreneurs". Technology entrepreneurs such as Steve Jobs of Apple, Bill Gates of Microsoft, Jeff Bezos of Amazon, or Larry Page and Sergey Brin of Google have become the "poster children" of the entrepreneurship movement world-wide" (Mazzarol, 2014). As universities get closer to the entrepreneurial nucleus, the greater becomes the tension between the old missions -of research and teaching, and the new mission - of entrepreneurship (Block et al., 2014; Dima et al., 2017; Prelipcean & Bejinaru, 2016; 2018; Maroufkhani et al., 2018; Nabi et al., 2018; Sultan et al., 2016; Wells, 2017).

Presently, universities world-wide are the most powerful force for shaping the future generations of businessman, managers and entrepreneurs throughout the knowledge transfer and learning processes. Since 1947, when Harvard Business School has started the first course of entrepreneurship, this educational trend has been continuously gaining interest at a global scale and has been also considered that entrepreneurship will become "the major academic discipline for business education in the 21st century" (Bae, 2014; Bratianu et al., 2011; Mason & Brown, 2014; Sternberg, 2014; Volkmann, 2004).

In this sense, we can observe that educational programs on entrepreneurship exist world-wide but certainly are different from one university to another (Janssen, 2016). They basically divide into either mostly theoretically programs which focus on developing research competencies or mostly practical programs which target the developing of abilities like business planning, interpersonal skills, negotiation skills, creative thinking and others (Bejinaru, 2018). These facts explain why the facilitators which drive the learning are either academic teachers, working in higher education institutions, or practitioners, as businessman, managers or real entrepreneurs (Bejinaru & Prelipcean, 2017; Bejinaru, 2017; Fayolle & Redford, 2014; Sultan et al., 2016; Vatamanescu et al, 2017).

Certainly, at this point in time, we can say that entrepreneurial education programs have become more and more popular by each day. However, paradoxically to this trend, the question arises as to what is the main mission of the universities throughout these educational programs in the field of entrepreneurship, namely: to support the specialization of the students as future entrepreneurs, to increase the number of companies set up after the graduation or to facilitate the acquisition of adequate

knowledge, skills and behavior in order to successfully cope with the global business environment? (Prelipcean & Bejinaru, 2018)

2 The Entrepreneurial Ecosystem

What we want to achieve through this research is to highlight the most propitious strategies that a university can apply in order to create an entrepreneurial ecosystem in the environment in which it operates. At this stage of our qualitative research, we want to map out and substantiate the potential of universities to develop an entrepreneurial ecosystem through the internal and external knowledge processes, knowledge resources and knowledge actors that they can manage. In this sense, we consider key concepts as the strategic processes of knowledge dynamics, the components of entrepreneurial ecosystems, and last but not least the role that the university can play in developing a framework for an entrepreneurial ecosystem in a region with a fairly economic low profile, where opportunities and potential abound (Gustafsson et.al., 2015; Hapenciuc et al., 2016).

To start with, an entrepreneurial ecosystem is a group of interdependent and interlinked elements that working together generate the dynamics of the entrepreneurial environment. The components of such an ecosystems are represented by individuals, groups, organizations, and institutions that have an influence on how these actors work and interconnect; in entrepreneurial ecosystems, these can be laws and policies or cultural norms (Maia & Claro, 2013; Mason & Brown, 2014; Stam, 2015). In this sense, we emphasize that an entrepreneurial ecosystem consists of a set of tangible and intangible resources and a multitude of actors characterized by an interdependence relationship that creates important synergies (Carvalho et al., 2010).

Daniel Isenberg (2011; 2014) is the creator of the Entrepreneurship Ecosystem Model (Figure 1) which, at start, consisted in 6 basic components, and to which step by step have been added several new components by passionate researchers of the domain (Hamilton, 2011; Maroufkhani et al., 2018; Suresh & Ramraj, 2012).

The Entrepreneurship Ecosystem Model relies on the dynamic and unhindered interaction between the six macro components, which according to their common mission, will generate the optimal conditions for entrepreneurs to collaborate and grow independently. Considering the six dimensions proposed by Isenberg, which are: policy, finance, culture, markets, supports and human capital, we appreciate that for our research is more appropriate to structure them as 3 dynamic areas, such as: the entrepreneurial framework (surrounding environment, the education, business environment and investment climate); the interacting actors, and the strategies regarding entrepreneurial support and culture. Related to the three elements, we shall provide further discussions about enhancing the working together of the involved actors within the entrepreneurial ecosystem.

*Figure 1. Entrepreneurial ecosystem 6 components model
(Isenberg, 2014)*

The current outlook on ecosystems is moving away from the context of the industrial organization economy, generally associated with Michael Porter from Harvard Business School, who takes the lead in gaining competitive advantage and profits while protecting new entrants and substitutes in a well-defined industry. In accordance with this traditional approach, the industries are comprised of competitors, suppliers and customers. From a strategic point of view, this perspective is limited because it does not pay enough attention to factors such as organizations that produce complementary products, the infrastructure on which the organization and the various institutions depend, individuals and interest groups that affect the organization as a whole. We believe that an ecosystem encompasses a wider and more complex environment in which organizations operate. In such an ecosystem we include the components of Porter's economic model and we propose to add new ones as potential and important players outside the competitive environment, namely social, political, or cultural forces (Bloom & Dees, 2008).

Entrepreneurial ecosystems are fundamentally based on interaction systems between several co-specialized, but hierarchically independent actors, many of whom are unknown to each other. At this point, co-specialization or multiple specialization means that different stakeholders play different roles - research institutions, start-ups, established businesses, and so on. In such a context, complementary skills and services are created and certainly depend on others to achieve their goals, which means that strategic management is paramount (Bratianu & Vatamanescu, 2017; Cantaragiu & Hadad, 2017; Stam & Spigel, 2016).

The basic feature of these entrepreneurial ecosystems lies precisely in the hierarchical independence described in the above rows as a release from the formal command lines so that each player can optimize its performance. The paradox and at the same time the

challenge that occurs in this context is mutual dependence which, on the one hand, limits you to what other actors in the ecosystem do, but on the other hand requires dynamic and permanent cooperation between the actors involved (Acs et al., 2017).

A different structure of the entrepreneurial ecosystem, presented in Figure 2, is suggestive for how is working the dynamics of the components inside. This entrepreneurial model relies primarily on new entrepreneurs who want to successfully exploit their abilities, aspirations and attitudes in this field. Entrepreneurial spirit is driven by the dynamics of the trial and error process. This means that real entrepreneurs will undertake certain risks when they start a business in order to check if the opportunity identified will be a good idea to make money or not. Even in the case of a failure, for a passionate entrepreneur, it is not the end but an opportunity to test a new idea. We believe that, this is how entrepreneurship dynamics works (Acs et al., 2017; Adejimiola & Olufunmilayo, 2009).

Figure 2. The structure of the entrepreneurial ecosystem

3 Research Design and Data Analysis

3.1 Research design

The main research objective, of this research, is to explore through which strategies universities can develop their entrepreneurial ecosystem. In this scope, we undertook also a quantitative analysis upon the main actors within this framework, namely the students.

The students play multiple functions and are the major contributors to the success of this type of entrepreneurial ecosystem.

We developed the quantitative research throughout applying a questionnaire in order to investigate the main factors that predict the students success in the entrepreneurial ecosystem after graduation. The questionnaire was designed to reveal the students characteristics across a range of 6 dimensions like (1) personality traits, (2) achievement motivation, (3) attitude, (4) framework conditions, (5) skills and knowledge, (6) work experience in the entrepreneurship field; being adapted after a validated instrument of ECENT international project (ECENT, 2006).

Personal traits are necessary to investigate because they reflect the quality of interaction with others. The items in this group test the students ability of adaptation to changes, the reaction to changes, the behaviour towards others and the self-perspective while carrying out tasks. *Achievement motivation* section emphasize the students ways of working and their perception about their future accomplishment. The *attitude* section contains items which reveal the students' approach of business situations. The items about the *framework conditions* examine the students and their families approaches towards self-employment and knowledge about running a business. The dimension about *skills and knowledge* is actually revealing the key issues like basic business knowledge, financial planning, motivation methods, team-working abilities and skills for decision making. The sixth dimension regards the issues of *work experience in the entrepreneurship* field which is also relevant for the students trajectory as entrepreneurs (ECENT, 2006; Mahendra et al., 2017; Vatamanescu et al., 2017; Wells, 2017).

The data obtained from quantitative analysis will provide the testing of the following hypotheses:

H1: Students consider 'personal traits' to be a priority for entrepreneurial success

H2: Students consider 'achievement motivation' to be a priority for entrepreneurial success

H3: Students consider 'attitude' to be a priority for entrepreneurial success

H4: Students consider 'framework conditions' to be a priority for entrepreneurial success

H5: Students consider 'skills and knowledge' to be a priority for entrepreneurial success

H6: Students consider 'work experience' to be a priority for entrepreneurial success

After the hypotheses validation we will be able to better understand the factors revealed, according to their hierarchy and thus to estimate their influence on the students entrepreneurial behaviour. We consider these results as being useful for improving the learning experience, both through theory and practice, that universities deliver to their students.

3.2 Data Analysis

The next step for the data analysis was complying with the statistical methodology and thus we first assessed the accuracy of the method and employed the Bartlett and Kaiser-Meyer-Olkin (KMO) tests (Table 1). According to the values obtain to these tests

we have the validation for applying the principal component analysis method onto the collected data. The value of KMO is ,845 -which indicates a very good adequacy of the selected method. A value below 0,6 of the KMO test would have questioned the adequacy of the method. Both the Bartlett test and the KMO test show an excellent accuracy for using the principal component analysis for the present research.

Table 1. KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.	.845
Approx. Chi-Square	1624.124
Bartlett's Test of Sphericity	df
	346
	Sig.
	.000

Further with the Principal Components Analysis, we selected the rotation option which is more advantageous because it maximizes the variance of the factors components and leads to smaller loadings of variables for each factor. The basic principle of this method is to extract the smallest number of components that represent as much as possible from the total information contained in the original data. The Principal Components Analysis helps us to interpret a smaller amount of data due to the fact that it leads to grouping together the variables with similar statistical evolution. We have to specify that using the Principal Components Analysis eliminates data redundancy and makes it much easier to read from a statistical point of view (Arkkelin, 2014). The final output makes the interpretation of the factors more pertinent. Following this protocol we obtained in the first rotation 6 factors explaining 69.925% of the responses enclosed in the original database.

In the case of Principal Components Analysis, a factor, represents a latent variable which should be named and referenced in order to be representative for the information embedded. The load structure of a factor may provide suggestions in this regard. Loading values greater than 0.6 are considered important, those below 0.4 are considered less significant. The higher load variables represent the mix of the initial variables that determine the factor, so become the most relevant in proposing the name of the factor. Conforming to this general condition we were allowed to further process a second rotation with an established number of factors in order to converge to the initial hypothesis of our research. Applying the presented rules we shall propose the factors interpretation considering primarily the components with the highest loadings. In Table 2 we present the reliability tests and Mean values for each factor, which we further discuss.

Table 2. Reliability Statistics of Factors

	Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	Mean
Factor 1	,786	,788	4,35
Factor 2	,775	,784	4,30
Factor 3	,761	,769	4,22

	Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	Mean
Factor 4	,758	,763	4,01
Factor 5	,746	,754	3,87
Factor 6	,722	,726	3,34

We consider that the hierarchy of the factors obtained as a result of the statistical processing and analysis represents the validation of the previously stated hypothesis:

- ✓ *H1: Students consider 'personal traits' to be a priority for entrepreneurial success; has been validated by Factor 4;*
- ✓ *H2: Students consider 'achievement motivation' to be a priority for entrepreneurial success; has been validated by Factor 3;*
- ✓ *H3: Students consider 'attitude' to be a priority for entrepreneurial success has been validated by Factor 5;*
- ✓ *H4: Students consider 'framework conditions' to be a priority for entrepreneurial success; has been validated by Factor 6;*
- ✓ *H5: Students consider 'skills and knowledge' to be a priority for entrepreneurial success; has been validated by Factor 1;*
- ✓ *H6: Students consider 'work experience' to be a priority for entrepreneurial success; has been validated by Factor 2;*

Considering the *Mean* values presented in Table 2, we can conclude on the hierarchy of the factors according to students perceptions which were registered throughout the questionnaires. Thus, the randomly distributed items within the questionnaire, have grouped in 6 factors, retrieved by the Principal Component Analysis, in the following hierarchical order.

Factor 1, with the highest Mean value=4,35 represents the '*skills and knowledge*' dimension. This fact confirms that the responding students acknowledge the importance of this category of education and are motivated in developing their '*skills and knowledge*'. This high value of the Mean could also suggest the fact that students fairly appreciate the strategic importance of education for their future career as entrepreneurs. This fact is commendable for the students and should be of critical interest for the university leadership.

Factor 2, registering the Mean=4,30 represents the students' '*work experience*' in the field of entrepreneurship. This factor is the surprise of research, because it comes second after education and might appear as a paradox. The explanation might have two directions; first, meaning that students have experienced the real business life, and acknowledged the advantages; second, students got tired of learning and are eager to start their working phase. Both motivations are forecasting positive effects for students.

Factor 3, having a Mean=4,22 posts on the third place the dimension of '*achievement motivation*' for the students future entrepreneurial success. This result can be associated to the perspective that these students are studying for their future, for becoming entrepreneurs. Being at the middle of the ranking, shows us that the power of

'achievement motivation' might have a great influence for succeeding as an entrepreneur. Thus, even if it is rather a self-developing dimension, universities should work on improving the motivational drivers for students.

Factor 4, that registered a Mean value of 4,01 reflects the importance of students' *'personal traits'* when speaking about the individual success as an entrepreneur. It is interesting to notice this dimension placed the fourth. Through these lenses, we appreciate that respondents balanced the *'personal traits'* with education and practice and considered them less important. Motivations may vary from lack of self-confidence, modesty, or rather a more pragmatic way of thinking which appreciates more specialized education and field experience than innate behavior.

Factor 5, *'attitude'* registered a Mean of 3,87 that is revealing a low perception about its influence upon the real success of the entrepreneur. It is a rather controversial result, as it is widely acknowledged that the "spirit" of the entrepreneur is a strong and restless force. The philosophy of the entrepreneurial spirit is the trial and error dynamics which is endless. We believe that having the appropriate *'attitude'* empowers the entrepreneur to never give up. For this case, maybe the young age and the context of the respondents provided this *'attitude'* limitation.

Factor 6, reflecting the *'framework conditions'* registered a Mean of 3,34 and ranked the last. It is obvious that the *'framework conditions'* are not a primordial issue for students entrepreneurial success. Respondents didn't award too much importance to their families approaches towards self-employment and knowledge about running a business.

Once more, according to the processed data, this is the hierarchy offered by students about the determinants of success as future entrepreneurs. The knowledge revealed from its interpretation must become basic pieces for the formulation of the university's educational and development strategy (Bejinaru, 2017; Bratianu & Bejinaru, 2017). The results provided by Principal Components Analysis have shown us the students' perceptions about their entrepreneurial potential. The final conclusion is that students perceive that their success will come rather from the university throughout education, learning and practicing skills than other determinants, like personal traits, family context, background experience, or attitude. The limits of the research consist in the narrow sample and context, which could be extended in a future research.

4 Conclusions

Throughout this research we focused on revealing the impact of entrepreneurship education on students' entrepreneurial intention. The results showed that entrepreneurship education will provide the basis of entrepreneurship notions, forming attitude, behavior, and mind set of entrepreneurs. According to the PCA results, entrepreneurship education is the main way to create business thinking and enhances self-efficacy of the university and students for growing the entrepreneurial ecosystem. Entrepreneurship education helps to train our university graduates so that they will cope with their future challenges and especially the unemployment condition of the country. During the last two decades, has

been recorded a substantial growth of entrepreneurship educational programs in most developed countries.

What we succeeded to identify is that the students vision upon the realities of the entrepreneurial ecosystem must be the cornerstone for the university strategies. Furthermore, the university has the 'strains'/the tools of modeling during the study cycles, in a considerable manner the behavior of the future entrepreneurs. Universities should do their best for increasing the entrepreneurial potential of its students in a dynamic ecosystem.

Through this work we brought to attention the dynamic interrelations between the university and the entrepreneurial ecosystem. Our aim was to highlight the university's mission of creating and developing the components of the entrepreneurial ecosystem by mainly shaping students' thinking and behaviors. We believe that through the action of generations of graduates, the university can be a dynamic exponential force and can contribute significantly to the creation of economic and social value (Bratianu & Bejinaru, 2019). In line with the ideas discussed in the paper, we maintain that the university has a central mission in terms of long-term strategy for the development of the entrepreneurial ecosystem.

Abstract

The lack of appropriate knowledge management practices for networks has consistently been found to be the most critical failure factor of inter-organisational collaboration. Identifying the typical barriers in network-level knowledge sharing is essential for developing expedient knowledge management practices for networks. This paper contributes to the issue by examining what kind of knowledge management practices to overcome network level knowledge sharing barriers are presented in literature. The study applies literature review that is carried out with a scholarly literature-exploration tool powered by artificial intelligence. The results of the literature review reveal that the number of articles that especially address knowledge management practices to overcome network level knowledge barriers is surprisingly limited. Many of the articles brought up knowledge sharing as the key activity in networks' success, but left the question of how to reduce the knowledge barriers, and thus promote knowledge sharing in practice, unanswered. The paper concludes that there is a lack of articles that report research, developing or designing functional knowledge management practices that enable effective knowledge sharing on a network level. This underlines the existence of a research gap and the need for especially empirical research on the issue.

Keywords – Knowledge management practices, Knowledge sharing, Network, Knowledge barrier.

Paper type – Academic Research Paper

1 Introduction

Connecting and collaborating over organisational boundaries is an increasingly common way to pursue business benefits and synergy gains. Instead of standing on one's one against all others, organisations have more and more adopted networking with other

organisations as a strategy to improve their performance and competitive position. Through inter-organisational networking, organisations reach for additional knowledge resources in order to gain monetary benefits or to create new competence based on the knowledge shared in the network (Magnusson and Nilsson, 2003). This calls for effective knowledge sharing within the network, whereas disruptions in knowledge sharing reduce the performance of the network and reduce the expected benefits of the collaboration (Ke and Wei, 2007).

A factor disturbing the transmission of knowledge from source to recipient is called knowledge barrier (Riege, 2005; Szulanski, 2003). The presence of knowledge barriers diminish the likelihood of network members benefiting from the collaboration as they inhibit understanding and interpreting new information (Paulin and Suneson, 2012). With a view to assist the assessing and improving the existing practices regarding knowledge sharing and the identifying the possible bottle-necks Riege (2005) presents a categorization of knowledge barriers. Riege's (2005) categorization divides knowledge barriers into individual (e.g. personal attributes, experience and competence), organisational (e.g. cultural issues, lack of leadership) and technological (e.g. unrealistic expectations, lack of technical support). Riege (2005) points out that strategies and practices to overcome the knowledge barriers vary greatly depending on the organisation's attributes. The situation can be even more complex in the network context, as it elicits specific factors influencing the effectiveness of inter-organisational knowledge sharing.

Vuori et al. (2018) supplement Riege's (2005) general categorization focusing on the network level by identifying two more knowledge barrier categories that hinder effective knowledge sharing particularly in inter-organisational network context. These knowledge barriers are classified as network-specific and knowledge-specific. Network-specific knowledge barriers include network's cognitive proximity, geographical distance between the network members, lack of intermediary, and trust and strength of relationships (Vuori et al., 2018). For example, cognitive proximity (organisations having similar bodies of knowledge) makes it easier to absorb a network partner's knowledge, but as it may already be known to the receiver, the value of the knowledge shared may not be high (Wuyts et al., 2005; Nooteboom, 2006). In addition, Trust and strength of network relationships have an effect to the existence of knowledge barriers (Hislop, 2005; Solitander and Tidström, 2010): frequent interaction and reciprocity in knowledge sharing between the network members promotes trust and consequently decreases knowledge barriers.

Knowledge-specific knowledge barriers consist of the complexity, tacitness, stickiness and ambiguity of knowledge, and knowledge protection (Vuori et al., 2018). As an example of these, cultural differences elicited from, for example, occupational, national, organisational, or societal origin, may lead to diverse interpretations of knowledge making it complex for the network members to understand (Abou-Zeid, 2005; Korbi and Chouki, 2017). Network context also causes a boundary paradox (Quintas et al., 1997) for the member organisations, as while seeking external knowledge from the network they face the risk of exposing their own vital knowledge to others. This

emphasizes knowledge protection especially in cooperative networks, where the members are simultaneously collaborators and competitors (Corallo et al., 2012; Khamseh and Jolly, 2014; Salvatat et al., 2013; Solitander and Tidström, 2010). As a result, an overprotective attitude becomes a barrier for sharing even non-critical information within the network. Vuori et al. (2018) state that since knowledge sharing activities on an inter-organisational network level tend to be more complex than those on intra-organisational level these new knowledge barriers categories need attention.

A knowledge barrier can be either the existence of an explicit barrier or the absence of a critical success factor of knowledge sharing (Schwartz, 2007). The latter implies that if knowledge sharing is not supported efficiently, the probability of the presence of knowledge barriers increases. Therefore, fostering knowledge sharing in networks by applying suitable knowledge management practices enhances the network's chances to reach its goals. Vuori et al. (2018) continue by stating that identifying the typical barriers in network-level knowledge sharing is essential for developing expedient knowledge management practices for networks. However, a lack of appropriate knowledge management practices for networks has consistently been found to be the most critical failure factor (Ke and Wei, 2007; Trkman and Desouza, 2012).

This paper aims to increase the understanding regarding this research gap by examining those knowledge management practices aimed to remove knowledge barriers that hinder effective knowledge sharing in the network level. The research question is formulated as "What kind of knowledge management practices to overcome network level knowledge sharing barriers are presented in literature?" The study applies literature review that is carried out with scholarly literature-exploration tool which is powered by artificial intelligence (AI).

2 Literature review

2.1 Methodology and data gathering

Literature review is a time-consuming task for scholars, as the amount of journals and articles increases massively every year. In order to produce reliable results scholars need to invest a lot of their time just in finding the potentially relevant articles from the mass, let alone screening and reading them. Therefore, it is no wonder AI-powered search engines focused on searching and linking together scientific articles, such as Iris.ai (<http://iris.ai>) Meta (<http://meta.com>), and Semantic Scholar (<http://www.semanticscholar.org>), have been gaining researchers' interest in recent years. Resting heavily on visual representation they aim to provide scholars a multifaceted overview of relevant literature instead of just acting as citation indices like conventional database search tools (Extance, 2018; Fricke, 2018). Utilizing AI enables these tools to examine the full-text intelligently instead of looking at the mere keywords and titles, and therefore they find hidden connections, relationships and overlapping between papers (Fricke, 2018). They aim to save the users' time by quickly going through masses of open access research papers, grouping them in a form that provides a relevant and precise

overview of the topic, and also make full-text of the results easily accessible (Sentence, 2017). Some of these tools are free at least for basic queries, but some demand rather high cost for premium access in order to use more sophisticated filters and refining tools (Extance, 2018). The aptness and precision of these tools is for each user to determine, as, like any other search engine, they leave the interpretation and final analysis of the results to the user.

In this literature review we used the free version of Iris.ai. We provided its explore function the research question (“What kind of knowledge management practices to overcome network level knowledge sharing barriers are presented in literature?”) accompanied with 457 word text describing the research problem including keywords. Iris.ai extracted the most important words from the text, screened 5 million open access papers (including journal articles, conference articles, book chapters, theses) searching for contextual synonyms, and classified each relevant paper under different topics. This resulted in 387 papers grouped by their main concepts and subconcepts, visually grouped as a map, where larger shapes present stronger concepts with more subtopics. The map of this search is represented in Figure 1.

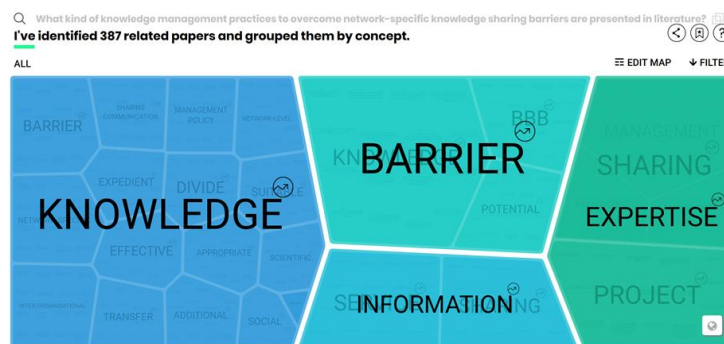

Figure 1. The map generated by Iris.ai, visually representing the paper's subjects and scope.

Each shape (e.g. “Knowledge” in Fig. 1) in the map presents the main concept of the papers grouped in this section. The second layer of shapes (e.g. “Transfer” in Fig. 1) are its subconcepts and possible further subtopics. The bottom layer is formed by relevant paper titles in each subconcept. By clicking the title of the paper the abstract, the metadata and the paper's overall relevance score calculated by Iris.ai can be reviewed.

Artificial intelligence can only do so much, and therefore also this search needed to be refined by human effort. We went through each main concept, subconcept and subtopic and checked for any duplicate papers. For example, all the articles in subconcept “Barrier” in the main concept “Knowledge” were duplicates of the subconcept “Knowledge” in the main concept “Barrier”, i.e. these subconcepts were identical and their articles were only counted in once. As a result the number of articles was reduced to 314. Then, again one main concept (e.g. “Expertise”) and subconcept (e.g. “Sharing”) at a time, we reviewed the papers by their title and abstract and assessed which of them

actually passed our search criteria i.e. could potentially provide answers to our research question. The Yield of our search is presented in Table 1.

Table 1. Number of articles (*duplicate categories, taken into account in the final n)

Concept	Subconcept	Topic	1 st screening	Final yield
BARRIER 41	BBB (blood brain barrier) 15			
	Knowledge 10*		1	
	Potential 15			
EXPERTISE 45	Project 15			
	Sharing 30	Management 13	1	
		Management planning 3		
		Managing 14	1	
INFORMATION 24	Service 15			
	Sharing 9		1	
KNOWLEDGE 204 (+10 duplicate articles in "Barriers")	Additional 12			
	Appropriate 13			
	Barrier 10*

	Inter-organisational 14		9	9
	Management policy 12			
	Network-level 16		7	3
	Network-specific 14		4	2
	Scientific 11			
	Sharing communication 14			
	Social 14			
	Suitable 16			
	Transfer 13			
n=314			n=29	n=17

This first round of screening resulted in 29 articles. On the second round all of these articles were read and re-grouped according to their topics. In this phase we eliminated 12 articles not passing the criteria to answer to our research question, which meant that the article did not discuss knowledge sharing or in more general terms knowledge management at the level of inter-organisational networks. Thus, in total 12 articles were excluded in the final screening either as it did not discuss organisational network or it didn't focus on knowledge sharing and/or knowledge management. For example, some of the excluded articles only focused on technical networks or they discussed only intra-organisational knowledge management. After exclusion, we ended up with 17 final articles that were taken to more profound review. These results are presented in the next section of this paper.

2.2 Results

By following the aforementioned data gathering process the literature review resulted in altogether 17 articles meeting the search criteria. Even though it can be argued that the use of AI in the literature review may have left out of the initial scope some relevant

articles and thus the final number of articles could be a couple of more articles, it still can be argued, that the total number of articles that especially address inter-organisational level knowledge sharing is surprisingly limited. Furthermore, even out of these 17 articles there were only few (in total 7 of the 17 final articles) that focused on identifying and developing practices that enhance inter-organisational knowledge sharing. Most of the seventeen articles that passed through the final screening phase focused only on identifying knowledge sharing as a key activity in networks' success, but they lacked the actual discussion on what are the functional knowledge management practices that can make the effective knowledge sharing happen in networks. Thus, there certainly exists a research gap. In next, we will concentrate on discussing those seven articles that at least some way brought up the potential practices to support inter-organisational knowledge sharing.

Conklin et al. (2013) focused on the role of individuals and social aspects in enhancing knowledge sharing in networks when they pointed out the important role of knowledge broker (KB). They argued that KB's help communities of practice (COPs) to evolve and they help people with similar interests or challenges to engage and exchange knowledge. In their two articles Leung et al. (2013, 2011) on the other hand pointed out more "technical" approach to enhance knowledge sharing in network when they argued that common "language" needs to be acquired within the network through suitable ontology development. With this approach they emphasized the use of mapping approaches, levels of automation and mediation methods to matching techniques. Bellini et al. (2016) proposed rather traditional ways to enhance knowledge sharing in networks by stating that "Collaboration, open communication, and trust are some partnering elements that imply effective knowledge transfer and, consequently, lead to successful outcome." However, they did not open up these in more detailed way.

Kess et al. (2007) was in fact the only article that really developed practices to enhance knowledge sharing in networks. However, they had studied knowledge sharing in the special case of outsourcing network relationships. Nevertheless, they argued that best practices for knowledge sharing were different kinds of meetings, accurate documentation and systems. They also emphasized the need for daily social interaction between key contact persons and the use of traditional communication channels like phone and e-mail.

The last two articles that in some extent discussed practices, were Capaldo (2014) and Lake and Erwee (2005). Capaldo's (2014) study brought up four viewpoints to knowledge sharing between network organizations. The first viewpoint was information sharing in terms of context specific knowledge, i.e. environmental information. Information sharing was mostly done between network's key actors and in a very informal way. Second viewpoint concentrated on knowledge transfer, and it was mostly related to expert-specific know-how that aimed at solving a certain problem at hand. Third viewpoint was in-house knowledge production, that focused more on intra-organizational aspects, and fourth viewpoint was knowledge co-production. This fourth viewpoint was the most interesting in the article, as it really took the interaction between the network actors into focus. It was also concluded in the article that effective knowledge sharing in the network needs personal relationships, functional macro culture, trust and reciprocity.

Lake and Erwee's (2005) research on knowledge exchange in a regional network focused on using the classic SECI-model of Nonaka and Takeuchi (1995) as a tool to understand more deeply network level knowledge sharing. They studied how tacit knowledge was made explicit at regional network level through fourteen embedded cases. In the article they formulated network level knowledge management as following: "Knowledge management in regard to networks involves cooperating across organisational boundaries to systematically find, select, organise, distil, present and share authorised information that meets the strategic and operational learning intent of all parties to a cooperation. The assumption in this definition is that all parties have in place strategic policies to protect unauthorised transfer of confidential information and those parties to the cooperation do not source unauthorised information, but do willingly share authorised information." As we can see from this definition, they emphasized not only the knowledge sharing aspect, but also the other side of the coin, knowledge protection. They used in their study the classic Nonaka and Takeuchi (1995) SECI-model, and brought up especially the difficulty in socialization phase of the model, as socialization needs e.g. trust between the interacting people and a shared "language", referring to shared schemas.

3 Discussion

Using AI-powered tool in the literature review most likely affected the limited relevance and the small amount of the articles passing the criteria in this study. However, using traditional databases and their search tools would have required a more rigid planning of the scope and criteria, as well as limiting the search to only small number of target journals and/or databases, as majority of the work would have been done by hand. The decision to use AI-powered Iris.ai opened up a possibility to design a more elaborate research scope and leave the most laborious part of search to the tool. In all, we conclude that even though the tool enabled us to quickly grasp a an overview on the topic, the contents of the results were not as accurate or relevant as we would have hoped for. However, in order to judge the actual aptness of the AI-powered tool used, a comparative study should be made using the traditional literature review search tools. Namely, it might not provide any more relevant articles to the subject, proving that the limited amount of relevant articles found by the AI-powered tool is not the actual issue, but the lack of research conducted regarding the topic.

What comes to the results of the literature review, the total number of articles that especially address knowledge management practices to overcome network level knowledge barriers was surprisingly limited. Some of the 29 articles passing the first round were irrelevant to the topic. Only 10 of the 17 articles surpassing to the final round discussed knowledge sharing in the network context, but their discussion of the matter was left on a very general and abstract level. Seven articles dealt with inter-organisational knowledge sharing to some extent, but even they did not take the discussion to a very precise level. Many of the articles brought up knowledge sharing as the key activity in networks' success, but left the question of how to reduce the knowledge barriers and thus promote knowledge sharing in practice unanswered. Based on our study we argue that

there is a lack of articles that report research, developing or designing functional knowledge management practices that enable effective knowledge sharing on a network level. This underlines the existence of a research gap and the need for especially empirical research on the issue.

Abstract

The “knowledge ecosystem” is a fascinating metaphor, which allows us to effectively depict the exchange of information and ideas between the knots of a more or less defined network of entities having similar aims and operating in the same environmental context. The ecosystem metaphor has been variously argued to be fitting with the interplay that

happens between different academic domains, which reciprocally share conceptual frameworks, empirical tools, and theoretical insights to push forward our knowledge about timely scientific issues. However, there is the risk that – far from bringing toward the establishment of a knowledge ecosystem – the exchange of information and ideas between different scientific disciplines triggers a process of knowledge contamination, which may produce unexpected drawbacks. In fact, knowledge contamination implies a sort of alteration of scientific domains which are more likely to draw research tools and approaches from other disciplines. Adopting an exploratory slant, this paper tries to investigate the interplay between management and two scientific domains which show an increasing influence on management studies, namely philosophy and neuroscience. A descriptive bibliometric approach was designed to shed light on the exchange of knowledge between management and these two disciplines. On the whole, the analysis concerned 199 scientific articles, 152 about the management-philosophy interplay and 47 about the neuroscience-management interplay. In this preliminary step of the research, the attention was focussed on the references made and the citations get by these items. Sticking to the exploratory nature of this research, we did not have research hypothesis guiding our excursion in the fields of knowledge ecosystem and knowledge contamination. Rather, we developed two assumptions, which steered our study. Specifically, it was thought that if the number of referenced articles belonging to the philosophy and neuroscience fields was equal or lower than the number of citing articles belonging to these two areas, then a knowledge ecosystem could be supposed to exist; alternatively, if the number of referenced articles belonging to the fields of philosophy and neuroscience was higher than the number of citing articles ascribable to these two areas, a knowledge contamination was expected to occur. The research findings supported the latter assumption, suggesting that management studies may be at risk of contamination from other disciplines. Further conceptual and empirical developments are required to fully disentangle the “knowledge contamination” issue in management studies and to identify the missing steps to the establishment of a knowledge ecosystem between management and related scientific disciplines.

Keywords – Knowledge ecosystem, Interdisciplinary research, Scientific Knowledge; Management; Contamination

Paper type – Academic Research Paper

1 Introduction

The “ecosystem” metaphor is gaining a growing prevalence in the management literature (Lusch, Vargo, & Gustafsson, 2016). In general terms, this concept involves an interpretation of organizations as knots of a large and interdependent network of entities (Taillard, Peters, Pels, & Mele, 2016), which share complementary resources and participate in value co-creation activities (Letaifa & Reynoso, 2015). It is worth noting that an ecosystem may be also composed of a network of networks (Aarikka-Stenroos & Ritala, 2017), which – either directly or indirectly – interact in their respective processes of value generation and dissemination (Järvensivu & Möller, 2009).

The ecosystem idea is especially fitting to depict how the members of different organizations operating in the field of higher education and academic research exchange and share their respective knowledge, paving the way for processes of “cross-fertilization” (Bartolo, Wicks, & Ott, 2002, p. 31) of their intellectual and cultural capital (Miller, Mcadam, Moffett, Alexander, & Puthusserry, 2016). However, in the last few years, knowledge ecosystems in the higher education setting have been characterized by a more or less significant homogeneity in terms of cultural and scientific affiliation of individual members (Bozeman & Corley, 2004). Current interdisciplinary networks, on the opposite, find their distinguishing competitive factors in the variety of members’ scientific domains (Vătămănescu, Andrei, Dumitriu, & Leovaridis, 2016).

Even though scholars and practitioners are paying a growing attention to the ecosystem perspective in order to investigate how knowledge networks are established between people who belong to heterogeneous scientific domains, still little is known about the risks that are brought by the propensity of members affiliated with a specific scientific area to prevail over others (Bordons, Morillo, & Gómez, 2004). Such a propensity may bring to conflicting – rather than collaborative – behaviors (Macfarlane, 2017). In this specific circumstance, far from paving the way for knowledge sharing and co-creation, the ecosystem approach may determine knowledge contamination, which is expected to degenerate into co-destruction of value (Cunningham, Menter, & O’Kan, 2018).

Drawing on these introductory notes, the paper tries to shed light on a specific instance of knowledge exchange between members of the academia affiliated with different scientific domains. Going more into detail, the attention will be focussed on the indirect transmission of knowledge which is typified by the dynamics of citations and cross-citations of articles published either in conventional channels of scientific publications – such as books, peer-reviewed journals, and conference proceedings – or in alternative channels, here included grey literature, by authors belonging to various scientific fields. Adopting an ecosystem standpoint and sticking to a descriptive bibliometric approach, we will investigate the interaction between scholars coming from different epistemological and ontological perspectives. In particular, the attention will be focused on the exchange of knowledge between scholars belonging to the “management” field with colleagues operating in the areas of “philosophy” and “neuroscience”. The decision to analyse these two fields was motivated by their conceptual proximity with management studies (see, among the others, Case, 2007; Mollona, 2009; Lindebaum, 2016; McDonald, 2018).

The paper is organized as follows. Section 2 briefly describes the research design and methodology: it delves into the research strategy which was arranged and used to collect the contributions that were included in this research; moreover, the approach which was devised to analyse available data is presented. Section 3 includes the main study findings: it is articulated in two subsections, one of which is dedicated to the exchange between management and philosophy, while the other concerns the management-neuroscience interaction. Section 4 critically discusses the research findings, acknowledging the limitations which affected this research. Lastly, Section 5 shed light on the main research

conceptual and practical implications, illuminating several avenues for further development.

2 Research design and methods

A systematic approach has been designed to collect the scientific contributions useful for the purpose of this research. In light of its comprehensiveness and extension (Aghaei Chadegani, et al., 2013), Elsevier's "Scopus®" has been identified as the primary source to search, select, and screen the relevant items to be included in this study. At the moment, *Scopus®* is one of the largest citation databases available to the scientific community. It indexes about 1,5 billions of citations, which are provided by more than 5,000 international and national publishers established in various areas of the World.

The research design was articulated in two steps. On the one hand, a specific query was devoted to the management-philosophy interaction. A generic query was run in the field "Title" of the main research interface of "Scopus®". Specifically, the word "philosoph*" was queried, without any limitation concerning publication year, type of publication, type of source, language, and authors' affiliation; however, in line with the aims of this study, a restriction was put on the scientific domain of the retrieved items: only contributions belonging to the sub-field "Business, Management and Accounting" were included in the research. On the other hand, we replicated the same approach to collect items concerning the management-neuroscience exchange. In this case, the word "neurosci*" was queried, introducing the same limitation criteria used for the previous query. In sum, this research design allowed us to elicit all contributions published by management scholars with a more or less direct reference either to "philosophy" or to "neuroscience". On the whole, we retrieved 1,410 items for the "management-philosophy" couple and 209 items for the "management-neuroscience" couple, for a total number of 1,619 records potentially relevant for the purpose of this research.

The authors agreed a set of selection criteria which inspired the preliminary screening of the collected records. First, since we were interested in the mutual exchange of knowledge between the disciplines contemplated in this study, we excluded all the items which did not report any citation by other scientific contributions. This criterion led to remove from the analysis about 4 in 10 items (38.9%) concerning the "management-philosophy" dyad and slightly less than a third (31.1%) of the records concerning the "management-neuroscience" interchange.

Second, the retained items were carefully screened in their title, abstract, and keywords by the authors. Three inclusion criteria were defined in order to guide the identification of relevant contributions to be included in this study: a) the items which improperly used the terms related to "philosophy" and "neuroscience", but did not include an analysis about the interdependences of management studies with these two disciplines were excluded as "out of topic"; b) the items which – even though embracing either the philosophy or the neuroscience perspective – did not focussed on management topics, but concerned wider economic themes, such as consumer behavior, regulatory and policy affairs, and macro-institutional issues – were removed as "out of scope"; and c) the items

which merely included a conceptual and/or theoretical digression on the use of methodologies and research approaches drawn by management scholars from other disciplines were discarded as “not relevant”.

The application of these criteria led to the inclusion of 152 contributions about the “management-philosophy” couple and 47 records concerning the “management-neuroscience” couple. The references made by retrieved papers have been classified – for each unit of analysis – in two groups: on the one hand, references to articles published by journals which were affiliated with the “management” subfield; on the other hand, references to articles published in journals which were listed either in the “philosophy” or in the “neuroscience” subfields. In addition, a cross-reference analysis was performed on the papers citing the records included in the analysis. Also in this case, the items were classified in two groups, according to their distinguishing scientific domain.

Although, in light of the exploratory nature of this research, we were unable to define clear research hypothesis guiding the steps of our study, we stuck to several *ex ante* assumptions, which triggered our research activities. We argued these assumptions from the insights suggested by the prevailing scientific literature (see, among others: Walsh, Weber, & Margolis, 2003; Gu, 2004; Schildt, Zahra, & Sillanpää, 2006; Nerur, Rasheed, & Natarajan, 2008). First, it was assumed that the higher the number of references to articles published in areas other than management, the greater the degree of knowledge exchange between different fields. Second, as far as the cross-citations’ analysis was concerned, we assumed that: *a*) if the number of referenced papers belonging to the philosophy and neuroscience fields was equal or lower than the number of referencing paper belonging to these two areas, then a knowledge ecosystem composed of management scholars and academics from either philosophy or neuroscience could be maintained to exist; on the opposite, *b*) if the number of referenced papers belonging to the fields of philosophy and neuroscience was higher than the number of referencing papers affiliated with these two areas, then a knowledge contamination was expected to occur.

3 Findings

3.1 The management-philosophy interplay

The vast majority of records concerning the management-philosophy couple which were included in this study consisted of articles published in peer reviewed journals (96.1%). In addition to them, 2 books (1.3%), 3 books’ chapters (1.9%), and 1 conference proceeding (0.7%) were taken into consideration. As expected, all the records involved in this analysis referenced at least 1 manuscript which belonged to the management field; besides, more than 9 in 10 items (92.1%) included at least 1 reference to articles ascribable to the “philosophy” subject area. Going more into detail, the average number of references to management studies was 36.6 ($\sigma=22.3$; min=1; max=108); otherwise, philosophy-based articles accounted – on the average – for 10.6 references ($\sigma=11.6$;

min=0; max=82). From this standpoint, it could be maintained that most of the records investigated in this study drew on philosophical insights to make their arguments.

The average number of citations for each record was 26.5 ($\sigma=43.1$), ranging from a minimum of 1 to a maximum of 286. Interestingly, citations in journals, books, or conferences whose main subject area was either directly or indirectly related to philosophy were much more infrequent as compared with citations get by management-rooted studies: on the one hand, the average number of citations from philosophical manuscripts was 0.28 ($\sigma=0.66$), ranging from a minimum of 0 to a maximum of 5; on the other hand, the average number of citations get by articles ascribable to the management discipline was 24 ($\sigma=38.8$), ranging from a minimum of 0 to a maximum of 284 references. In addition, it is worth noting that only 31 items (20.4%) were cited at least once in a source belonging to the philosophical area; alternatively, 98% of the analysed records were cited at least once in management-based sources.

These preliminary findings pointed out that, while the investigated records were likely to be more or less influenced by conceptual and practical arguments developed in the philosophical realm, they were not equitably effective in soliciting interest from philosophy scholars. In other words, far from leading to the establishment of a knowledge ecosystem, the interplay between the disciplines of philosophy and management seemed to result in a sort of contamination of management theories and tools with ideas and concepts derived from philosophical studies. The cross-tabulations reported below in Table 1 help in making this point. We classified available items in three groups: 1) items with a prevalence (66% or more) of references to philosophical sources; 2) items with a prevalence (66% or more) of references to management sources; 3) items with an evenly number of references to management and philosophical sources. We found that items with no citations from philosophical avenues largely prevailed in these three groups. In particular, more than one third of items with a prevalence of references to philosophical sources (71.4%) had no citations by philosophy-based journals; moreover, more than 4 in 5 items with an evenly distribution of management and philosophical references (80.5%) showed no citations by philosophical avenues.

Table 1. Cross-tabulation between groups of items and no. of citations in philosophical avenues

	<i>Citations by articles published in philosophical avenues</i>		
	0	1 or more	Total
Articles with prevalence of philosophy-based references	5	2	7
Articles with prevalence of management-based references	83	21	104
Articles with an even number of management- and philosophy-based references	33	8	41
Total	121	31	152

Source: Authors' elaboration

It is worth noting that a large part of the records which received at least one citation from articles published in philosophical journals and books were hosted in the *Journal of Business Ethics* (22.5%). Moreover, citations from philosophical studies were common among articles published in journals which were not solely focuses on management issues and showed an interdisciplinary slant, such as *Accounting, Organization and Society*, *Academy of Management Learning and Education*, and *Business Ethics Quarterly*. This result seems to suggest that philosophy scholars are more attracted from management studies with an interdisciplinary slant than from articles primarily focussed on management issues.

3.2 The management-neuroscience interplay

Slightly less than 9 in 10 items focussing on the management-neuroscience interchange which were contemplated in this research were published in peer-reviewed journals (87.3%). Besides, we retrieved 4 conference proceedings (8.5%), 1 book (2.1%) and 1 book's chapter (2.1%). All the records had at least 1 reference to articles published in avenues related to neuroscience; the same was true as far as references to studies published in the management field were concerned, with the sole exception of 1 article, which did not show any reference to management-based articles. In particular, the investigated items had, on the average, 33.1 references to neuroscientific sources ($\sigma=42.2$; $\text{min}=1$; $\text{max}=282$); alternatively, the average number of references to articles rooted in management was 21.2 ($\sigma=14.5$; $\text{min}=0$; $\text{max}=80$). Therefore, while in the management-philosophy exchange references to management studies prevailed over references to philosophy-based sources, in the management-neuroscience couple references to theories and tools rooted in neuroscience were more common than references to management studies.

The number of citations get by the analysed records ranged from a minimum of 1 to a maximum of 91 ($\mu=15.6$; $\sigma=21.2$). It is interesting to note that citations from management sources largely prevailed over citations from contributions hosted in avenues ascribable to the neuroscientific domain. On the one hand, the average number of citations which came from management-rooted studies was 11.9 ($\sigma=15.8$), ranging from a minimum of 0 citations to a maximum of 67 citations. On the other hand, the neuroscience discipline accounted – on the average – for 1.9 citations ($\sigma=2.8$), with the most cited manuscript scoring 13 citations and the less cited manuscript reporting no citations from neuroscientific sources.

Echoing the insights obtained from the examination of the management-philosophy interchange, we found that management scholars were likely to be influenced by conceptual and practical arguments elaborated by academics affiliated with neuroscientific disciplines; otherwise, neuroscience-based research turned out to be poorly receptive to insights and contributions proposed in the management field. Once again, a sort of knowledge contamination propagating from neuroscience to management seemed to appear; in fact, only spotted signs of knowledge exchange and co-creation between these two scientific domains were noticed.

The cross-tabulations reported in Table 2 support these considerations. Replicating the same approach used for the management-philosophy couple, we classified available items concerning the management-neuroscience interplay in three groups: 1) items with a prevalence (66% or more) of references to neuroscience sources; 2) items with a prevalence (66% or more) of references to management sources; 3) items with an evenly number of references to management and neuroscience sources. Surprisingly, items with no citations from neuroscientific sources were more common both in the group of articles with a prevalence of neuroscience-based references (56%) and in the groups of articles with a prevalence of management-based references (76%). Alternatively, items which scored at least 1 citation from papers rooted in the neuroscience realm prevailed among the group of articles with an even number of references to management and neuroscience sources (57%). From this point of view, it could be maintained that citations from studies based in the neuroscience domain were solicited by the mix of management theories and approaches with neuroscientific concepts and tools.

Table 2. Cross-tabulation between groups of items and no. of citations in neuroscientific avenues

	<i>Citations by articles published in neuroscientific avenues</i>		
	0	1 or more	Total
Articles with prevalence of neuroscience-based references	5	4	9
Articles with prevalence of management-based references	2	1	3
Articles with an even number of management- and neuroscience-based references	15	20	35
Total	22	25	47

Source: Authors' elaboration

Lastly, yet importantly, it is worth noting that a significant part of the articles which scored at least 1 citation from neuroscientific sources were published in scientific avenues which promoted critical thinking, the design of creative research strategies, and the adoption of non-traditional research methods, such as the *Journal of Management Inquiry* and *Academy of Management Perspectives*. On the opposite, papers published in traditional management sources were found to be less likely to report citations from articles rooted in the neuroscience discipline.

4 Discussion

The research findings should be contextualized to the main limitations which affected this study. First, we only focused on articles indexed in *Scopus*[®]; even though this decision restricted the breadth of our research, it did not significantly affect the relevance of our research, since *Scopus*[®] allowed us a comprehensive coverage of the current

scientific literature. Second, the descriptive approach taken to collect data and to interpret available evidence constrained the depth of our study; nevertheless, it was consistent with the exploratory purposes which inspired our research. Third, and lastly, the focus on the interplays between management and philosophy and between management and neuroscience was not exhaustive; however, it permitted us to obtain some preliminary insights to envision future conceptual and practical developments.

The research findings suggested that there is a relevant interconnection between both philosophy and management and neuroscience and management. On the one hand, we found that journals affiliated with the management area were likely to pay attention to philosophical issues, which were usually exploited as an alternative – and critical – perspective to enhance our understanding of timely management topics, such as leadership, inter-organizational relationship, sustainability, organizational resilience, and decision making (see, among others, Hassard, Kelemen, & Cox, 2007; Cunliffe, 2009; and Klikauer, 2011). However, it seemed that management journals were more open and inclusive as compared with philosophical-based avenues, which were less prone to make reference to conceptual and practical developments proposed by management sources. On the other hand, management studies were receptive toward tools and approaches coined in the neuroscience domain, which were used to delve into the main behavioural issues that currently challenge management knowledge, such as organizational learning, organizational loyalty, employees' empowerment, and organizational commitment (see, *inter alia*: Anrold, 2018; McDonald, 2018; and Jack, Rochford, Friedman, Passarelli, & Boyatzis, 2019). Nonetheless, only spotted evidence was retrieved about the propensity of neuroscience scholars to derive insights from management studies in order to nurture further conceptual and/or practical developments in their research field.

These results invite us to argue that a process of knowledge contamination is currently characterizing the interplay between management and other disciplines, such as philosophy and neuroscience. This is not consistent with the adoption of an ecosystem metaphor to unravel the exchange of knowledge and ideas between different scientific disciplines (Fraser, 2018). Rather, it suggests that relatively younger and softer disciplines – such as management (Drucker, 1974; Goldman, 2016) – are more likely to be influenced and shaped by scientific domains which show a more established tradition – such as philosophy – and a more solid and reliable empirical approach – such as neuroscience. Sticking to a Darwinist perspective, it seems that management studies are experiencing a third step of their evolution, which brings from positivism and constructivism to a mixed, co-evolutionary approach, that is deeply affected by contamination of traditional management theories and frameworks with insights generated in conventionally distant scientific domains (Khorasani & Almasifard, 2017).

5 Conclusions

It has been variously maintained that, while knowledge ecosystems may be crucial to improve the quality and the innovativeness of individual agents' activities, knowledge contamination may have relevant negative drawbacks on the viability of specific knots of

the networks. In fact, knowledge contamination implies a gradual fragmentation of the identity of the members of the ecosystem which are more likely to be influenced by other knots. This sets the conditions for the decay of their distinguishable contribution to the long-term sustainability of the ecosystem it-self. From this point of view, there is the risk that the process of knowledge contamination experienced by management studies may – in the long run – impair their ability to factually concur to the generation of distinctive and field-specific scientific knowledge. However, further developments are required to shed light on this issue. First of all, an expansion of this study is required, in order to enhance the reliability of the research findings and to illuminate the various facets of the interplay between management, philosophy, and neuroscience. Second, a deeper study involving a content analysis of the items included in this research is thought to pave the way for the collection of better insights about the implication of knowledge contamination produced by other scientific domains on management. Lastly, yet importantly, a larger number of disciplines should be contemplated in the research strategy and design, in an attempt to shed light on the generalizability of the results.

Abstract

Crowdfunding has recently emerged as a buzzword in the cultural and creative sector, mainly indicated as an alternative to the decrease of public funding (Bonet and Donato, 2011; Bertacchini et al. 2011). However, this issue is still not investigated in specific fields such as the cultural heritage sector that is yet reluctant to implementing crowdfunding campaign. This paper aims at filling this research gap by focusing on exploring the perception of crowdfunding in cultural heritage institutions by means of an empirical investigation of a relevant sample of organizations in France. The results of the research shed light on the uses and values of crowdfunding in this specific context, paving the way for future comparative research in a broader geographical areas.

Keywords – Cultural Heritage, Crowdfunding, fundraising differentiation

Paper type – Academic Research Paper

1. Introduction

Recently the debate on the necessity of alternative funding for the cultural heritage sector (Bonet and Donato, 2011; Bertacchini et al., 2011; Donato, 2013; Greffe, 2010), has been focusing on crowdfunding as a promising "alternative source of financing" (Chaboud et al., 2018; Yang et al., 2016; Stiver et al. 2015). This last approach has been indicated as particularly significant for the cultural heritage sector (Guesmi et al., 2016; Baujard, 2017). Although several specific crowdfunding platforms were launched for this sector,

cultural heritage organizations seems still reluctant in choosing this fundraising tool if compared to other cultural and creative sectors such as cinema or performing arts. Our research aims at answering this topic, exploring in particular the following main research question:

- Is crowdfunding a necessary financing tool facing the withdrawal of public authorities and fundraising traditional channels and facing financing requirements of a cultural institution in the heritage sector?
- What functions does crowdfunding represent for cultural institutions in the cultural heritage sector?

In order to answer these questions, the investigation analysed a representative sample of five cultural heritage organizations in France: the Centre des monuments nationaux, the Musée des Arts Décoratifs, the Réunion des Musées nationaux – Grand Palais, the Musée du Louvre and the Musée national Picasso in Paris.

After this introductory section, the theoretical basis of the research are presented in section two. Section three explains the research design and methodology, while section four presents and discuss the research results. The last sections draws some concluding remarks, discussing also the contribution of the results to the scientific and professional debates and proposing actions to overcome current limitations of the investigation.

2. Cultural heritage and funding: theoretical perspectives

Over the last decade, the cultural heritage sector has faced important financial challenges; this is due to different factors, mainly linked to the changes in traditional forms of funding.

As highlighted by Bonet and Donato (2011), the economic and financial crisis investing western economies starting from 2008, has had a significant impact also on the cultural heritage sector. Over the previous decades, economic support to the cultural and creative field had expanded, giving opportunities of significant investment in the preservation and enhancement of cultural assets. Policies supporting culture were particularly significant in some European countries, such as Italy (Trupiano, 2005), France (Timbart, 2005; Manda, Nicolescu, & Mortelmans, 2017) or Germany through the development of a *Kulturstaat*, where government strictly support the development and preservation of cultural heritage and cultural organizations (Scheytt, 2015). This abundance of funding was severely questioned when the general economic situation started to enter in the crisis: in a moment of scares funding, culture no longer was a stringent priority. This decrease of public funding to culture (Eurostat, 2011, 2015) led cultural organization (especially in the cultural heritage sector) to think of alternative forms of financing, to help them survive in times of economic downturn. A first option, could be identified in the creation of more frequent cooperation with the private sector (O'Brien, 2011; Borin, 2017). The decrease of traditional public forms of funding for the field could trigger a reflection on the need to reform the governance systems and management models of the cultural sector in order to make its different subjects more financially sustainable (Bonet and Donato, 2011), to increase public-private and multi-

stakeholder partnerships (Borin, 2017). In this framework, significant reflection was carried out on the need to conceive the cultural sector as a network of interdependencies and collaboration: in order to make it sustainable, the implementation of cultural ecosystem approaches has been advocated (Borin and Donato, 2015), based on a new vision of the field related to the ecology of culture approach (Holden, 2015).

Another alternative was based on the idea that cultural organizations need to differentiate the forms of financing (Borin, Donato and Sinapi, 2018) to address the inner fragility that characterizes the sector (Greffé, 2010). This approach underlined the need to create connections with other sources of funding, not only banks and traditional sponsors and individual donors but also with the citizens and communities, both real and “virtual”. Indeed, private donations have been decreasing in this period (Bertacchini et al., 2011; Donato, 2013) and they could no longer be considered a viable option to compensate the decrease of public funding. Exploring the potential of an involvement of citizens through small contributions has increasingly been considered a practical alternative. In this context, crowdfunding has emerged as a buzzword and has been indicated as a promising “alternative source of financing” (Chaboud et al., 2018; Yang et al., 2016), especially for those projects or sectors that encounter problems in accessing to traditional forms of capital. Crowdfunding could potentially be a viable way to deal with government budget cuts (Stiver et al. 2015), particularly for the cultural heritage sector (Guesmi et al., 2016; Baujard, 2017): the proliferation of crowdfunding platforms designed with the cultural and creative sector (e.g. Commeon) or even more specifically on the heritage sector (e.g. Dartagnans) seem to confirm this potential. However, cultural heritage institutions are sometimes reluctant to implement crowdfunding initiatives, especially if compared to other cultural and creative sectors such as cinema and performing arts.

3. Research Methodologies

In order to investigate the above mentioned research questions, the authors decided to adopt an inductive approach, because of its open-ended and exploratory nature that best fitted the investigation.

Qualitative methodology was selected given its suitability for shedding light on how the topics of the research were manifested in the research domain (Denzin et al., 2006) and on the basis of consideration of qualitative research as the most appropriate research method for investigating in-depth a phenomenon and its dynamics (Yin, 2014). The criteria of representativeness was at the basis of the selection of the research sample (Patton, 2002): authors decided to focus on cultural heritage institutions in France and in the Parisian area, thus including in the research sample two among the most important national heritage institution (Centre des Monuments Nationaux; the Reunion des Musee nationaux – Grand Palais), whose central branch is located in Paris, plus three main Parisian museums. The resulting sample includes five cultural heritage organizations: the Centre des monuments nationaux, the Musée des Arts Décoratifs, the Reunion des Musées nationaux – Grand Palais, the Musée du Louvre and the Musée National Picasso. These organizations are all located in Paris, and are world-recognized organizations in the

cultural heritage sector. In order to further meet the criteria of representativeness, the sample included both institutions that have already launched a crowdfunding campaign and ones that are planning but have not already launched a crowdfunding activity.

For each of the above-mentioned institutions, semi-structured research interviews were carried out, mainly with managerial or fundraising staff, in order to further investigate the research topics. The research protocol was amended when required during the interviews. The interviews were recorded, transcribed and manually coded. The chosen coding method was axial coding (Boeije, 2010; Charmaz, 2006; Glaser, 1978; Glaser & Strauss, 1967; Strauss, 1987; Strauss & Corbin, 1998), identifying three main axial codes related to the research questions and their related subcategories and verbatim. The results were finally confronted with the theoretical debate (developed in the preliminary analysis of the literature on the research topic).

The results of the research are presented in the following section, first providing more detailed information about the institutions of the research sample and then presenting and commenting the axial coding results.

4. Results of the empirical research: crowdfunding to compensate the decrease of public funding?

The empirical research consisted in a preliminary phase of selection and analysis of the cultural institutions and a second phase in which semi-structured research interviews were carried out with a selected sample of managers of the involved institutions. This later analysis, led to conclusions regarding the contributions to academic debate and practice.

4.1 Presentation: overview of cultural organizations in relation to fundraising strategies and crowdfunding

4.1.1 Centre des monuments nationaux (CMN)

The Centre des monuments nationaux (CMN) is a public cultural institution belonging to the Ministry of Cultural Affairs. Its main missions are to conserve, to preserve, to restore and enhance several national monuments located in different parts of France. The CMN is self-financed for the 82%, (Source: Annual Report, 2017). Over the last years, the CMN has experienced a significant decrease of public subsidies from the Ministry of Cultural (3.8 million euros between 2016 and 2017). At the same time, the CMN had an increase of expenses (+18,4M € in 2017), that they aim to partially cover through fundraising (more specifically, 600 000 euros for the functioning budget and 150 000 euros for the investments budget, used principally for restorations) employing a total of 3 staff members who are full-time on fundraising. While the central branch target mainly big sponsors and less private individuals, local administrators of peripheral branches (different cultural heritage sites located in France) focus on local public funds as well as on individual donors, especially for specific projects. The CMN has developed a specific

CF campaigns mainly through the platform My Major Company (collecting 40 000 euros in 2017) but major donations do not pass through the platform (340 000 euros in 2017). Four famous monuments were selected with different projects, budgets, and targets: the Pantheon, the Cité de Carcassonne, the Mont-Saint-Michel and the Domaine national de Saint-Cloud. In the chart below, the results of this operation demonstrate a real success in terms of financing objectives, people awareness to needs of the restoration of French heritage, as well as the media impact.

Table 1 - Results of the operation of CMN - My Major Company
(Source: Annual report, 2017)

Monuments	Number of patrons	Average donation	Donations total	Financing objective	Project financing
Panthéon	1 183	57,96 €	68 565 €	5 000 €	1 371 %
Mont-Saint-Michel	380	62,51 €	23 755 €	5 000 €	475 %
Carcassonne	391	52,61 €	20 569 €	20 000 €	103 %
Saint-Cloud	91	51,09 €	10 330 €	10 000 €	103 %
Total	2 045	60,25 €	123 219 €		

Following this positive result, MCN created its own CF platform, called “Ma Pierre A l’Édifice” (MPAE) with the objective of not only reducing costs, but also «to present several projects at the same time in such a way that our donors can have the choice and can turn their donations towards the most relevant project to them, from which they feel the nearest ». The main financial objectives of crowdfunding campaigns are usually determined to correspond to approximately 10% of the total budget.

4.1.2 Musée des Arts Décoratifs (MAD)

The Musée des Arts Décoratifs is classified as “association law of 1901”, and belongs to a non-profit association including the Musée des Arts Décoratifs, the Musée Nissim de Camond, the Library of the Arts Décoratifs, the Ateliers du Carrousel, and the Ecole Camondo. It incorporate therefore museums, pedagogic organisations and a library related to decorative arts, design, fashion, textiles, advertising and graphic design. Its mission is to share and to pass down knowledge in the above mentioned fields, while at the same time preserving, restoring and increasing its collections. Public subsidies consist in almost half of 30 million euros in the MAD budget 2017, while the following most important source of funds is sponsorship (5,6 million € in 2017, 19% of the total budget or the organization). Indeed, some projects need to be entirely financed by patronage to be produced. The organization employs three full-time staff with the objective to raise 6 million euros. They have strict links with the association of Friends of the MAD, middle and major French and foreign donors, and the International Committee. Though the MAD has never developed a crowdfunding campaign they have developed several participative fundraising activities, also creating a web page called “jedonneenligne.org”, inside MAD

website that allowed them to finance two acquisitions (collecting 10 000 euros in only three weeks).

4.1.3 Réunion des musées nationaux – Grand Palais (Rmn-GP)

The Réunion des musées nationaux – Grand Palais (Rmn-GP) is a public establishment with industrial and commercial functions under the supervision of Ministry of Cultural Affairs. In 2011, the RMN and the GP merged to create a broader international cultural organization specialized in museums. Similarly to the CMN, the RMN-GP collects and redistributes revenues from ticket entrance and shops of its museums. It manages places such as the Grand Palais, organises temporary exhibitions in these museums and manages museum shops. In short, the Rmn-GP performs both cultural and commercial tasks. With reference to its budget, the Rmn-GP is self-funded for approximately 80% (Source: Annual Report 2017). Public funding are nonetheless important and the organization has suffered a decrease of public subsidies (they currently have approximately 3,4 million euros). Donations and sponsorship income constitutes around 4,3 million euros with 63 patrons, sponsors and partners, although the objective of the patronage department of the Rmn-GP is around 5 to 6 million euros. To fundraising department employs eight persons in full-time, focusing mainly on financing temporary exhibitions and specific cultural projects. Sponsorship and donations are sometimes used also for operating costs.

Rmn-GP's fundraising department has so far not launched a CF campaign but they are considering launching one in 2019. Each of their associated museums could launch CF campaign independently. However, during the research the participants have clearly pointed out that the most efficient and important fundraising strategy is still the corporate patronage, hence CF campaigns could probably just be a collateral source of funding.

4.1.4 Musée du Louvre

The Musée du Louvre is a public museum that over the years has increasingly focused on the mission to become a welcoming and accessible museum. It is self-financed for approximately 70%, (Source: annual report in 2017). Over the last two years, the Louvre has witnessed a decrease of public subsidies till 4 million euros. On the contrary, the patronage incomes are up to 19 million euros: it has increased (+2,8M €) thanks to acquisitions and also in relation to the successful CF campaigns « Tous mécènes! ». The fundraising department (with a large team of fifteen people) has implemented a fundraising strategy focusing mainly on corporate patronage and individual donations ». The museum has an internal CF platform « Tous mécènes! » allowing publics to donate for specific projects of the museum. Louvre's strategies aim at developing ties between donors and the cultural institution through a privileged relation, sometimes established by means of the engagement in crowdfunding: «it was especially touching to see that above the donations collection, these campaigns have allowed to create a new link between the Louvre and its public. 50% to 70% of contributors are loyal and will donate for the next campaign, whereas some of them will finally integrate the Patrons Circle with major donors of the museum». In 2010, the creation of Louvre's own platform called "Tous

mécènes!" was based on the urgency to create and manage crowdfunding projects internally and driven by the objective of making participative financing sustainable in the long run. Since then, the Louvre has successfully implemented several crowdfunding campaigns (see table 8), such as the 8th campaign on the acquisition of *le Livre d'heures* of Francois Ist, a success in terms of collection of funds, number of donors, media and press coverage as well as in terms of innovation in the communication campaign.

Table 2 - report on the campaigns launched on the platform "Tous Mecenes!" since 2010
(Source: TM website)

Year	Type	Achieved objective	Set objective	Success rate	Nb of donors
2010	Acquisition of <i>Les Trois Grâces</i>	1 260 000 €	1 000 000 €	126%	7200
2011	Restoration of two masterpieces of Egyptian architecture	500 000 €	500 000 €	100%	1900
2012	Acquisition of two statuettes	800 000 €	800 000 €	100%	4500
2013	Restoration of <i>la Victoire de Samothrace</i>	1 000 000 €	1 000 000 €	100%	6700
2014	Acquisition of <i>Table de Teschen</i>	800 000 €	1 000 000 €	80%	4500
2015	Acquisition of <i>L'Amour essayant une de ses flèches</i> of Jacques Saly	680 000 €	600 000 €	113%	4300
2016	Reconstitution of funeral chapel of Akhetétep	500 000 €	500 000 €	100%	3300
2017	Acquisition of <i>Livre d'heures</i> of François I ^{er}	1 400 000 €	1 000 000 €	140%	8500
2018	Restoration of arc du Carrousel	330 000 €*	1 000 000 €	/	2041*

4.1.5 Musée national Picasso-Paris

Opened since 1985 thanks to the generous contribution of his heirs, the Musée Picasso is a national museum centered on a collections of artworks by the artist Pablo Picasso with the mission "to present the work of Picasso, to preserve and conserve his collection, and to contribute to the influence of the artist". The museum relays on a self-financed up to 70% of the total budget. Compared with other cultural institutions, the museum has incurred in minor decreases of public subsidies. However the institution has a decrease in sponsorship and donations. The fundraising department, composed only by two people, pursue the goal of collecting around 500 000 euros per year, that has proved to be very challenging for such a small team. There are no association of Friends of the Museum, especially due to a lack of human and time resources. For the same reason, the museum has still not considered a crowdfunding campaign. In addition, the available human resources have no specific competences on that. Moreover, CF projects usually raise not significant amounts of money that are not certainly covering the investment in time and energy of the staff. However, the managers were available to launch a CF campaign on other objectives, such as to make CF on an exceptional project beyond usual activities of the museum to stress the necessity of public's contributions. According to the interviewee «MP cannot function by thinking that all resources must come from an appealing to the contribution, to the generosity [...] it is not safe to let people think that the museum cannot manage its missions without a public contribution and [...] it is not true».

4.2 Crowdfunding: a viable alternative to traditional financing?

The preliminary analysis of the cultural heritage organizations confirmed that crowdfunding has emerged in the framework of the reflection of alternative financing tools for cultural heritage organizations. In the following phase of the research, the analysis focused on exploring this topic further, trying to understand if crowdfunding a necessary financing tool to deal with the withdrawal of public authorities and fundraising traditional channels, and what are the perceived functions of crowdfunding in cultural heritage institutions. These topics were addressed through semi-structured interviews with a selected sample of managers and fundraisers from the above mentioned institutions. The analysis of the results, carried out through manual axial coding, highlighted three main results that are presented in the following paragraphs.

A first result refers to the fact that crowdfunding is perceived neither as a necessary nor as an accessible financial tool. In particular, the categories indicate that although there was a change in almost all the sample institutions related to the decrease of public funding and increase of the expenses, crowdfunding is not considered as a viable alternative.

The interviewees argued that usually cultural heritage projects (especially those related to preservation or restoration) require important budgets that cannot be raised through crowdfunding. With the significant exception of the Louvre museum, the majority of crowdfunding campaigns raise amounts of funding that are insufficient, therefore not effective if compared with the efforts required to carry out a fundraising campaign. Furthermore, there are several barriers and drawbacks when implementing this type of fundraising: notably, the lack of resources, visibility of the institutions, competences as well as a clear identification of crowdfundable projects (see table 3). This results confirms the literature on the inefficiency of crowdfunding compared to other types of fundraising activities such as big individual donations and sponsorships.

Table 3 - Research results 1: CF as non-necessary and non-accessible financing tool
(Source: own elaboration)

Category	Sub-category	Nr. of Verbatims	Nr. Of Sources
Non-necessary and non-accessible financing tool	Scheduled and already financed crowdfunding projects	1	1
	Barriers to entry for crowdfunding market access:		
	- lack of resources (<i>cf Table 10 R2 – Investment in the campaign</i>)	-	-
	- lack of visibility	1	1
	- identification of CF projects	15	5
A complementary financing tool (then an alternative financing tool)	- lack of competences (communication & marketing, website & CRM, legal)	7	2
	Insufficient collected amounts	5	3
	Huge budgets for projects in cultural heritage sector (CF projects are part of them)	5	3
	Not the most efficient and profitable lever of resources	6	3

The second research result highlights how crowdfunding is often perceived as a useful communication tool. During the interviews it emerged that the key factors to ensure a successful crowdfunding campaign are related to a clear definition of the communication strategy, including a clear statement of the mission, value and identity of the project and the organization, and a clear identification of the networks of contacts and donors. Starting from this point of view the interviewees argued that crowdfunding is important for promoting a positive image of the organization, for increasing the commitment of the community so as to legitimate this fundraising practice amongst the cultural heritage communities and institutions (see table 4).

Table 4 - Research Result 2: Crowdfunding as communication tool
(Source: own elaboration)

Category	Sub-category	Nr. of Verbatims	Nr. Of Sources
1. Increasing notoriety & visibility			
	1. Target new publics (potential visitors and donors)	5	2
	2. Target potential patrons	3	1
2. Positive image			
	1. Dynamic cultural institutions	2	2
	2. Modern cultural institutions oriented towards innovation	2	2
	3. Expertise of cultural institutions on (popular) patronage	1	1
	4. Competitive cultural institutions positioned on a growing market and in the cultural environment	2	1
3. Legitimate the practice of participative financing by cultural institutions			
	1. Participation of the crowd to the CF campaign and demand from donors	4	2
	2. Participation of patrons and partners	5	2
	3. Importance of medias	3	2
	4. Influence of history about cultural institutions and their strategies (precursors)	5	3
	5. Obstacles due to the evolution of Culture in France (importance of public subsidies, distinction public – private funds, late professionalisation of Culture, dominance of historic patronage, perception of an elitist culture, self-censorship by cultural institutions)	7	1
4. Develop commitment of communities			
	1. Awareness of project & development of an affective link between donors and cultural institutions	4	2
	2. Building of a privileged relation between donors and cultural institutions	2	2
	3. Creating ambassadors and early contributors to increase the success rate in the early days of CF campaign	4	2

Finally, a third research result points out that crowdfunding is perceived also as a useful community-engagement tool, thus overcoming just communication of the specific project for which the crowdfunding campaign is carried out. For creating a successful

campaign, crowdfunders need to mobilize their entire community, both internally and externally to the cultural heritage institution. Internally, the crowdfunding team should be able to involve the staff of the organization in the crowdfunding activity increasing their sense of belonging and mobilizing them in the key stages and element of the project, so that they can become a lever to reach the existing communities of donors. Once the internal actions are completed, the crowdfunding activities could be used to further reinforce the current donors' sense of engagement through project's co-construction mechanisms. Crowdfunding could finally become a means to reach out to the broader "crowd", creating new communities around the projects and raising awareness about cultural heritage preservation and enhancement, thus also "educating the crowd" (see table 5).

Table 5 - Research result 3: Crowdfunding as a community-engagement tool
(Source: own elaboration)

Category	Sub-category	Nr. of Verbatims	Nr. Of Sources
1. Belonging to a community of donors or patrons			
	1. Shared values with cultural or geographic links to the CF project or the cultural institutions.	15	4
	2. Social connections and membership (get social capital)	5	3
	3. Necessary cohesive identity facing the social context	3	1
2. Appropriation by the crowd			
	1. Awareness on cultural heritage	12	4
	2. Commitment in CF projects and cultural institutions' activities (and feeling of being concerned for communities)	11	5
3. Co-construction between patrons and cultural institutions			
	1. Participation in CF campaigns	5	2
	2. Involvement of patrons in activities and maybe in the decision-making process of cultural institutions (PPPs)	5	1
4. Education of the crowd			
	1. Popularisation of patronage and awareness on donations to become new patrons	8	2
	2. Civic engagement and citizenship	6	4
	3. Responsibility towards projects and cultural institutions to become actors of cultural politics, cultural life and society	5	2

5. Conclusions

The objectives of this research were to explore the use of crowdfunding in the cultural heritage sector, investigating if it is perceived by cultural heritage organizations as a viable alternative to traditional forms of fundraising and what are the other uses and values that are associated to it.

The literature review highlighted indeed that over the last decade there was a significant decrease of public funding. This reduction of public budgets for culture affected in particular cultural heritage institutions that traditionally relied more on this source of financing due to the high costs and low return on investment typical of the cultural heritage sector. In this context, crowdfunding increasingly entered the financial discourse, especially after successful campaigns carried out by emblematic cultural heritage institutions such as the Louvre museum.

The research results however highlighted that using crowdfunding is not always appropriate nor convenient. In line with the literature on the broader cultural sector (Guesmi et al., 2016; Baujard, 2017; Viotto da Cruz et al., 2017), crowdfunding is implemented in the framework of broader fundraising strategies, targeting big donors and sponsors as well. Among this strategies, crowdfunding proves to be the less efficient due to its high human resources costs and low profitability; these characteristics are particularly significant for cultural heritage organizations. Therefore it is a corollary source of funding, not at all capable of substituting public funding nor over types of donations and sponsorships.

The analysis of the second research results instead shed light on the perception of the real value of crowdfunding for cultural heritage institutions. In line with literature finding, the results indicate that crowdfunding is an important communication tool, having an impact on the image of the organization and project changing the traditional “stale” perception of cultural heritage and linking it more with digital innovation and communication strategy. As argued by one of the interviewees, crowdfunding activities should be considered «as a real communication campaign and not as a fundraising campaign», «popularising an establishment» to the general public in a more disruptive way than classic institutional communication». Interviewees also underlined that crowdfunding is a communication tool that can develop non-financial outcomes (Chaboud et al., 2018), becoming a notoriety tool (Guesmi et al. 2016; Mollick, 2014).

The third result brings about more interesting research contribution: it indicates that crowdfunding is not just communication tool regarding the project and activities of the cultural organization but it is rather used as a community engagement tool, referring both to the internal and external community. While our literature review revealed that crowdfunding could gather a community around a project, the research results highlight that for the cultural heritage organizations of our sample it could work as a way to raise awareness about not just the project but the whole organization and more broadly to the importance of cultural heritage to society. Both internal and external teams can gather around a crowdfunding project to increase the perception of the relevance of local cultural heritage in the crowd.

These research results contribute both to the academic debate and to practice.

From the point of view of the academic debate, they highlight that cultural heritage crowdfunding has peculiar characteristics compared to other sectors of the cultural and creative field. While crowdfunding campaigns could be a significant financial tool for cultural and creative industries in general, measuring up to public funding amounts, in the cultural heritage sector they often remain marginal in the budget. Moreover, in contrast

with the literature on general crowdfunding for the cultural and creative sector, crowdfunding is perceived not only as a communication tool, but rather as a community-engagement tool around the whole cultural heritage field.

From the point of view of the practice, the results could dimension the expectations of using crowdfunding to substitute public funding and shed light on the importance of using it with other purposes, more related to the aims of cultural heritage institutions as mediators in the preservation and enhancement of a common identity.

The main limitation of the research are related to its limited geographical scale: the results could be therefore potentially tested in other areas, for example in other European countries where cultural heritage constitutes a significant component of the cultural and creative ecosystem.

Abstract

In the face of the dramatic shrinking of public and private funding, the cultural and creative sector is increasingly relying on crowdfunding around the world. This is especially true for the crowdfunding models of project-based donations and rewards (RC/DC), rather than longer-term equity and lending models. Yet international cultural and creative crowdfunding (CCCF) remains a fragmented and below-potential market, where a high number of diverse platforms operate at national or international level in a highly specialized manner, sometimes also with matching public funding. The reasons for the untapped potential of CCCF include a lack of transparency and capacity (of operators' financial practices) and of trust, coupled with quite differently binding (or favouring) national fiscal regulatory frameworks. This paper focuses on regulation by critically comparing and discussing the main features of the two major frameworks for CCCF activity, namely the USA and the EU. We begin by analysing the RC/DC development in both regions. This analysis emphasizes the legal and regulatory situations in both areas, and their possible impacts on CCCF operators. This review of the regulatory circumstances illustrates the current situation for national (and regional) policy surrounding RC/DC in contrast to other pre-sale or charitable fundraising revenues. In the final section, we outline the major areas over which regulatory action might be expected, including taxation and matching (subsidies), consumer and investor protection, and information provision. In most of these areas, public policy specific to CCCF is relatively under-developed. For each of these areas, we discuss critical design features for policy and, correspondingly, identify how efficiency and equity might be affected by policy. We conclude by recommending key policy priorities and suggesting directions for future research in this emerging arena.

Keywords: Cultural and creative industries; Reward-based and donation-based crowdfunding; Comparative regulation policy.

1 Introduction

Face to the global shrinking of public and private funding in the cultural and creative sector, in the last years crowdfunding has emerged as a valid alternative or complementary mode of funding the arts and culture. In addition to reasons for public support of institutions advancing public-goods aspects of research and development, strong rationales for subsidizing the cultural and creative sector frequently find support in theory and in practice (Throsby 1994). Whether it is Baumol and Bowen's (1965) cost disease arguments or public-goods aspects of many cultural resources, powerful normative arguments support subsidizing the cultural and creative sector – and crowdfunded ventures are no exception.

Crowdfunding in the cultural and creative sector (CCCF) is mainly oriented toward the financing of projects, rather than structural finance. CCCF usually takes the form of donation (DC) or reward crowdfunding (RC), where only in the latter case the backer expects a reward, either symbolic or in kind (e.g. limited editions, tours, networking sessions and prototypes), more rarely monetary. Developed initially and especially in the USA, but also in the UK and continental Europe, CCCF represents a market in significant expansion and evolution. CCCF is becoming increasingly important to finance cultural and creative projects and ventures, untapping entrepreneurial potential (Lazzaro 2017). Furthermore, it favors community involvement, market research and audience development, the sharing of information and promotion, besides the development of professional skills (De Voldere and Zeqo 2017). Yet, it is not free of barriers and risks.

If we look at the market of the CCCF, it looks quite fragmented in terms of platforms' business models, geographical distribution/concentration, relevance of CC sectors covered, available information, implied skills to operate and access this market, and, in particular, regulation, with distinct features of RC/DC compared to investment, or equity- and lending based, crowdfunding. In such a rapidly evolving marketplace, becomes then crucial to look at the two main areas interested by CCCF, namely the US and Europe, and to critically analyze and compare their respective regulatory frameworks. In this sense, the major contribution of this paper is to highlight current regulation aspects of CCCF from an economic perspective and through a comparative way of its two major markets, in order to offer policy recommendations to main stakeholders.

Our approach begins with an analysis of some fundamental features of RC/DC and the associated benefits and barriers (Section 2). After this conceptual description of the emerging RC/DC phenomenon, we turn to an assessment of the regulatory frameworks that may enhance CCCF benefits and limit CCCF barriers and risks in both the United States (Section 3) and the European Union (Section 4). The review of the literature and industry reports for the US and then for the EU highlight different priorities and approaches to regulating crowdfunding around the world. We provide a critical comparison of these regulatory frameworks in Section 5. This comparative lens leads to some policy recommendations as well as suggestions for future research in this field.

2 Benefits and barriers to CCCF expansion

The rapid emergence of RC/DC, especially for cultural and creative projects and ventures, points to many benefits and barriers. At its core, crowdfunding's key distinctive innovation owes to its dramatically lower transaction costs for fundraising associated with its online platform and associated technologies. The growth in crowdfunding as a preferred fundraising technology comes as some creators are better able to reach their market. The lower transaction costs can affect the intensive margins by lowering fundraising costs among existing contributors, which helps the viability of previously marginal projects as well as giving creators better 'market research' data from crowdfunding campaigns' performances. As lower transaction costs have expanded the size of the crowd, more interested contributors can be identified and previously unviable ('niche') projects can receive a "green light".

The advantages of the crowdfunding platform and approach have been touted at length elsewhere. Broader geographic distribution of financing for entrepreneurial projects often leads the list of crowdfunding's benefits (Sorenson et al. 2016). How crowdfunding platforms fit with a "world is flat" perspective on the global economy continues to receive scholarly attention (e.g. Agrawal et al. 2015, Giudici et al. 2018), with a preliminary conclusion that new venture financing is far less geographically concentrated under crowdfunding (Yu et al. 2017).

Crowdfunding research routinely shows that projects with better information describing their venture are more likely to succeed in their fundraising goals (Mollick 2014, Courtney et al. 2017). Lastly, allowing creators to collect better market research data through a crowdfunding campaign can yield great value to creators, including enhancing their odds of later receiving more traditional venture capital (Butticé and Noonan 2016, Xu 2017). In general, projects that receive a higher amount of pledged money through crowdfunding attract more subsequent interest from investors (particularly in the world of technology), although "this positive effect emerges (and becomes more intense) only when it is complemented by the presence of patents granted for the new product idea (Roma et al. 2017).

Advocates often point to crowdfunding's ability to "democratize funding" (Mollick and Robb 2016) and "levelling the playing field" (De Buysere et al. 2012). Spillovers from RC/DC to other more traditional forms of financing new ventures and IP protection remain important areas for future research. Bringing creators more directly in contact with their audience or crowd may offer benefits other than just improved market research.

Despite the rapid rise of RC/DC, it faces significant barriers and poses some serious risks. The most immediate issue, mentioned above, concerns information asymmetry and the lack of transparency. Although information asymmetry in fundraising is not exclusive to crowdfunding, merely shifting the marketplace to an online forum hardly resolves the matter. Although the growth of crowdfunding platforms suggests that either this concern is overstated or that there is a great deal of 'lemons' (Akerlof 1970) waiting for the crowdfunding opportunity, the fundamental challenge of better enabling transparency remains. Perhaps a bigger concern for crowdfunding is the moral hazard problem (Strausz

2017), or the possibility that creators fail to adequately deliver to their backers. Once funded, in most (all?) crowdfunding platforms, projects may face suboptimal pressure to deliver on their promises. Though reputational effects may be severe, one-off creators who simply scam the market before disappearing into anonymity pose a threat. Subtler, and potentially more threatening, are the biases that crowdfunding might support. Although it might promise to ‘democratize’ funding, its theoretical promise might be replaced by a reality of discrimination (Rhue and Clark 2016, Youkin and Kuppaswamy 2017) and other biases (Greenberg and Mollick 2017, Johnson et al. forthcoming).

Agrawal et al. (2014) find that crowdfunding is not geographically constrained and tends to support ‘market-for-superstar’-style distributions with fundraising highly skewed to a few creators. Crowdfunding capital may substitute for other traditional sources of financing, although this research continues to evolve (see, e.g., Roma et al., 2017; Yu et al., 2017). In addition, Agrawal et al. (2014) also observe a prominent role of friends and family in early stages of fundraising.

Ultimately, lacking a regulatory system in place at the outset, the crowdfunding approach enjoyed some rapid growth without (legal) barriers and associated compliance fixed costs (Calcagno and Sobel 2014). But unregulated growth can pose some risks, especially if participants in the crowdfunding marketplace are victims of fraud, predation, or bias, or if the inherent risk on the platform deters optimal investments. The absence of clear standards and stable regulation in these markets can dissuade creators and backers from participating, and it can lead to distortions. This may be especially true in Europe, at globally, where variation in national regulatory frameworks limit growth of what is essentially a global marketplace. The lack of harmonization between national systems stands as a major barrier. Compounding this lack of harmonization in regulatory systems are important differences in fiscal regimes, financial incentives, payment systems, intellectual property rights, data protection, professional standards, languages, and more. Crossing borders or switching among crowdfunding platforms can require significant adjustment costs. Market fragmentation in RC/DC crowdfunding, especially in a post-Brexit world, remains a serious barrier to its continued expansion.

3 CCCF regulatory framework in the USA

The fiscal regulatory framework governing donation- and reward-based cultural and creative crowdfunding ventures within the United States is still emerging. Though more limited than the European legal and regulatory framework(s) for maintenance of crowdfunding, the existing laws and regulatory climate in the United States provide opportunities and challenges for regulators and those engaging in CCCF. Prior reviews of crowdfunding regulation in the US explicitly focus solely on laws such as the JOBS Act of 2013 that only apply to equity-based crowdfunding. In short, the JOBS Act exempted crowdfunding from federal securities laws to allow small businesses to raise capital from a variety of sources that included using crowdfunding to sell securities to the general public (Securities and Exchange Commission 2018). Although, the law does not apply to RC/DC, it has inspired a number of state-specific exemptions to increase local investment

in small business both related to and separate from the arts.

US federal and state laws do touch on crowdfunding in a limited way. Federal law governing crowdfunding is contained within the Code of Federal Regulations. This federal code provides guidelines and requirements for issuers, intermediaries and funding portals of financial securities.¹ State laws regarding crowdfunding, on the other hand, generally aim to encourage local investment. Thus, they tend to include more provisions related to reward-based crowdfunding. States vary in policy areas such as the maximum income that can be received from equity-based crowdfunding ventures and the necessary ratio of investors pledging money from within the state itself. Explicit references to RC/DC by state agencies are rare. Relevant state codes apply exclusively to equity-based crowdfunding ventures. State-level regulation of CCCF only applies to ventures resulting in small businesses using equity-based crowdfunding; and RC/DC campaigns garner no special regulation.

Taxation of RC/DC remains an unclear and evolving situation in the United States. Government regulation and taxation of the crowdfunding platforms themselves depends on the company. For example, Kickstarter is a public-benefit corporation (which mixes tenets of profit maximization with concern for public benefit), while alternatives such as GoFundMe are for-profit companies. Although the tax treatment of these companies is straightforward, how to tax the crowdfunding ventures themselves – the creators, vendors, and investors – remains more complex. Generally, income accrued by artists and content creators on crowdfunding platforms is treated as taxable income by federal law (Metrejean and McKay 2015). Though seemingly straightforward, some questions remain over what sorts of expenses are deductible and how (if at all) the Gift Exclusion under Section 102(a) of the federal tax code can be utilized in relation to crowdfunding ventures. The former issue depends on whether the venture is deemed a business or a hobby (Metrejean and McKay 2015). In general, income accrued from crowdfunding ventures is treated as taxable income gained as the result of a business transaction at the federal level and, presumably, at the state level as well. When declaring income from crowdfunding ventures, no clear consensus exists for the timing of reporting. There is no guidance given at the federal level.

Other regulatory concerns about crowdfunding platforms focus on issues of intellectual property (IP), patent law, and intentional acts of fraud perpetrated via crowdfunding platforms. Roberts and Nowotarski (2013) observe that the nature of “crowdfunding compounds the general difficulties faced with any product launch in a crowded IP landscape with unprecedented exposure of projects at the very earliest stages.”

Fraud in reward-based crowdfunding captures considerable public attention in the United States. This includes acts of fraud (intentional or otherwise) and failing to deliver the rewards or perks promised by the crowdfunding project. According to one study (Mollick 2015), only around 9% of projects fail to deliver promised rewards, with the majority of those failures being from smaller projects and no noticeable links between failure rates and demographics such as education, gender and family status. Limited

¹ 17 C.F.R. § 227.100-503.

options exist for jilted investors to ensure reception of deliverables or a refund of their donation. Crowdfunding platforms generally refuse to refund money directly to investors when projects fail. Though frustrated backers of larger fundraising efforts occasionally undertake legal action. The lack of case law may be due to the high legal costs relative to the small donation amounts typically made to artists and vendors (Moore 2015). Regulatory frameworks for rewards-based crowdfunding in the US do not oversee the platforms themselves, but they do include general regulatory mechanisms for fraud (intentional or otherwise), such as consumer protections offered by the FTC and state attorneys general.

To conclude, the regulatory framework governing crowdfunding platforms in the United States is much looser for reward-based ventures than the stricter SEC laws governing equity-based investment in crowdfunded securities. The CFR contains no regulations strictly related to reward-based crowdfunding, and laws passed at the state level also fail to provide notable structure or guidelines for vendors and artists hoping to fundraise by using reward-based incentives. Some scholarly literature does address relevant issues such as gift exemption, IP theft, and fraud. But, by far, the regulation and its scholarly analysis are more plentiful for crowdfunding artists and platforms within the European Union.

4 CCCF regulatory framework in the EU

In Europe, the Cultural and Creative Sector (CCS) is defined by the EU regulation.¹ It is thus not surprising that the CCCF as such has been increasingly part of the policy agendas of the European Union as well as of its member countries. Policies are mainly aimed at (indirectly) improving the CCCF regulatory framework, besides its awareness and hence its adoption by users (De Voldere and Zeqo 2017).

Overall, crowdfunding regulation is mainly competence of member states, a number of which have developed specific legislations in the last couple of years. A harmonisation at the EU level is in fact not the rule, and so far there is no European crowdfunding legislation or ad hoc EU authority in charge of crowdfunding regulation, leading to a EU fragmented market (Patti and Polyák 2017). A major consequence of that is the hindering of cross-border crowdfunding (ECN 2017). As for RC/DC in particular, the EU is even less likely interested to play a harmonization role in its regulation (ECN 2017), as in RC/DC financial return, securities and financial markets stability are not involved. Regulation of RC/DC is quite unrestrictive or unspecific, and regulation requirements simply imply standard trade or business licensing (Patti and Polyák 2017). Contrary to IC, RC/DC is also excluded from the recent Proposal for a Regulation of the European Parliament and of the Council on European Crowdfunding Service Providers (ECSP) for Business,² because it does not deal with financial products and related information

¹ Regulation (EU) No 1295/2013 of the European Parliament and of the Council of 11th December 2013 establishing the Creative Europe Programme (2014 to 2020) and repealing Decisions No 1718/2006/EC, No 1855/2006/EC and No 1041/2009/EC.

² COM/2018/0113 final - 2018/048 (COD).

asymmetries.

At a more global level, the regulation of crowdfunding in general falls within the scope of the International Organization of Securities Commissions (IOSCO), like in particular the limitation of cross-border activities, due to different regulatory systems (De Voldere and Zeqo 2017). Yet in the last years the European Union, together with its member states, has become interested in the growing overall crowdfunding market and its potential, including them in a series of economic, financial and innovation policies.¹ Among them, the public consultation on the mid-term review of the Capital Market Union of 2017 by the European Commission,² which urges the strengthening and integration of EU capital markets and EU-wide supervision to favor the development of SMEs and hence job creation (ECN 2017), considers the role of Financial Technology (“FinTech”), including crowdfunding, as increasing efficiency and competition.

The EU approach toward RD/DC and more specifically CCCF regulation remains rather soft, by means of workshops and public consultations, communications, a Stakeholders Forum, reviews, reports and commissioned studies. In fact, besides fostering ‘hard’ regulation and fiscal incentives, policy makers can fulfill ‘softer’ roles toward CCCF, such as facilitators of the sharing of information, for instance on best practices, key performance indicators and market analysis, matchfunders, funders or owners of platforms, funders of research on crowdfunding and awareness campaigns, etc. (De Voldere and Zeqo 2017).

National regulatory frameworks differ in whether they treat specifically about crowdfunding or not (Patti and Polyák 2017) and the degree through which they facilitate or, on the contrary, restrain crowdfunding (De Voldere and Zeqo 2017). United Kingdom represent(ed) in the EU the most facilitating country, where more than 80% of European alternative finance is concentrated, followed by France, Germany, the Netherlands and Finland. Furthermore, the UK shows the highest average amount of money raised per campaign (Cambridge University 2016). Main features of UK’s most supportive policy include a progressive regulation and tax reliefs (CrowdfundingHub 2016).

RC/DC is diversely developed in the EU member states (ECN 2017).³ For instance, Belgium was among the pioneers and nowadays counts many platforms and a flourishing activity, contrary to Austria, Cyprus, Latvia and Lithuania, the latter even lacking any RC/DC platform. In Ireland RC/DC is quite developed and is the most diffused crowdfunding model, although the market is relatively small, and it is operated by local and Irish versions of international crowdfunding providers.

Since RC/DC does not generally imply financial investments and returns, similarly to the EU, national legislations are usually less concerned about it. National regulation measures for RC/DC are rather more limited and less impacted by the EU regulation with respect to IC for the reasons mentioned above (ECN 2017). These measures may be general, like mandatory licensing of (usually nationally) platforms, or concerning

¹ Such as the European Commission for Innovation Union, Capital Markets Union, the Green paper on long-term financing of the European economy and the Entrepreneurship 2020 Action Plan.

² COM(2017) 292 final.

³ However, available data on crowdfunding in the various countries may not be always complete.

payment service. In a number of EU countries crowdfunding may be also subject to other related national laws and regulations on anti-money laundering and anti-terrorism financing, consumer protection, privacy/personal data protection, advertising/marketing, intellectual property, fundraising and humanitarian agencies. Similarly, despite the absence of a EU crowdfunding harmonization, recently developing national crowdfunding regulations are often impacted by other, related EU regulations, such as those on data protection and consumer protection. As for the protection of backers, in Europe this falls under consumer protection regulation and in particular under Directive 1999/44/EC on the sale of consumer goods and their conforming, Directive 2011/83/EU on consumer rights and withdrawal on distance sales, and Directive 93/13/EC on unfair terms in consumer contracts (Gutiérrez and Sáez 2018).

Yet various exceptions to missing or reduced specific regulation of RC/DC exist in EU countries (ECN 2017). For instance, in the Czech Republic DC is subject to public collection requirements and scrutiny by the regional authority,¹ possibly refraining platforms from DC.

Despite the absence of crowdfunding harmonization in the EU, there are regulation similarities and/or cross-border activities between neighboring countries and in common language areas. Larger national crowdfunding markets are also the most interested by international (in/outbound) activity.

To conclude, RC/DC is the prominent crowdfunding model in a number of European countries. Noticeably, it is not regulated at the EU level and is rather the object of a variety of recent and developing national regulations, although these regulations tend to be general rather than specific about RC/DC. The practice of RC/DC is also quite varied across countries, as the associated business models of the operating platforms. The lack of regulation harmonization at the EU level favors a fragmentation of the crowdfunding market, leaving the sizes of national markets relatively small, and limiting crowdfunding crossing borders. Furthermore, a lack of a clear and comprehensive regulation favors uncertainty, hinders consumers' confidence, and hence the upscaling of the market. Therefore the majority of EU countries, especially the most experienced ones, are in favor of a regulation of crowdfunding and its EU harmonization, at the same time avoiding too heavy, non-transparent and onerous regulation. On the other hand, a minority of relatively less experienced countries (e.g. Malta, Slovakia, etc.) are in favor of a more liberal framework to facilitate the market expansion.

5 A critical comparison and policy recommendations

The review of regulatory frameworks in the US and EU is summarized in Table 1. Across several dimensions, the similarities and differences in regulatory approaches are apparent. Overall, considerable similarities exist, especially for this emerging technological platform and the body of regulatory law and practice still being developed. In contrast, the US and the EU display very different degrees of harmonization in

¹ No specific regulation instead exists for platforms.

regulatory frameworks within the continents. In the US, the lack of active state-level regulations (and the limitations on US state governments regulating interstate commerce, which CCCF often represents) leaves the federal government to establish CCCF-specific regulations. The result is a highly harmonized, and largely unregulated, single market for CCCF in the US. By contrast, the lack of a strong harmonizing effort at the EU level has allowed for diverging regulatory approaches by member European states.

Table 1: Comparison between US and EU regulatory frameworks for CCCF

Dimension	United States	European Union
Regulation of equity-based crowdfunding	JOBS Act (2013) to allow and regulate	Proposed EU regulation for ECSP
Regulation of RC/DC overall	Little or no special attention – just like any sale or donation	Little, but some member states regulate more stringently
Role of federal/EU-level regulation	Primary, yet largely silent	Soft, largely consultations
Role of state/national-level regulation	As taxing authority, offers some guidance	Primary, some fragmented markets and regulation
Taxation of creators	As income, generally ambiguous	Mixed, sometimes as sales
IP protection	No special policy	No special policy
Fraud protection	Like any other transaction; platforms self-regulate	Like any other transaction
Changes over time	Remains largely unregulated	Continues to evolve, especially at state level

5.1 Self-regulation

Crowdfunding for the investment world has drawn the attention of regulators, but the RC/DC operations remain “below the radar,” certainly in the US and across many EU member states. Gutiérrez and Sáez (2018) highlight the innovativeness of RC compared to investment-based crowdfunding. They show how the regulation of RC, which has developed in a legal vacuum, should not be assimilated into the rather regulated investment-based crowdfunding framework. In light of the limited scope of federal and state laws designed to regulate RC/DC, the crowdfunding platforms engage in some self-regulation.

5.2 Harmonization

Disparate regulatory frameworks create extra uncertainty and cost for creators engaging in crowdfunders. Moreover, by fragmenting the markets, the potential for crowdfunding to tap into larger marketplaces – larger crowds – is diminished. The ‘scale economies’ of crowdfunding are lost without harmonization across jurisdictions. Removing misunderstandings about crowdfunding platforms can help reduce frictions surrounding breached contracts when projects unintentionally fail to deliver (Ganatra 2015).

5.3 Intellectual property rights and fraud

Concerns about IP protection and fraud remain in the reward-based crowdfunding context. In both the US and the EU, more general laws to protect IP and protect against fraud continue to function and apply to crowdfunding; no special regulation exists. Whether that approach, coupled with self-regulation, will continue to be sufficient remains to be seen. Further, whether there are efficiency gains from alternative regulatory approaches is an open question. In the US, platforms and third-party information providers undertake considerable effort at self-regulation with respect to fraud. Issues about IP protection however, are another matter. Instituting better protections exist to attract innovators to share their ideas may enable further expansion of CCCF. Some scholars see existing patent protections for crowdfunding projects as inadequate for protection of artists.

5.4 Recommendations

Firstly, harmonizing the RC/DC crowdfunding regulatory regimes among the states holds the greatest promise to remove barriers for continued beneficial crowdfunding expansion. This especially applies to the EU, where different states' approaches limit the market size and pose additional complications, but it also can apply to the US.

Secondly, as new regulation comes into play for these emerging marketplaces, balance should be struck to encourage entrepreneurship. Especially for the creative and cultural projects, the unstructured and open nature of crowdfunding holds considerable promise. From a cultural perspective, diversity levels of procedural formalism across countries could also produce different effects of crowdfunding regulation on entrepreneurs (Stephen et al. 2009). Restricting entry of creators to crowdfunding platforms, perhaps by raising the bar for disclosure and other entry costs, may reduce instances of creator failure, but such screening would also limit entry to crowdfunding. Again, striking a balance between the openness and accessibility of these platforms for non-traditional artists and creators requires (implicitly) defining and accepting some risk tolerance for the marketplace as a whole.

More proactively, public officials could consider ways to leverage the strengths of crowdfunding platforms to improve their own policymaking and funding decisions. For instance, the power of crowdfunding platforms reach larger and more targeted population and elicit their preferences for various ventures can be used to inform public projects and goals. Matching funding programs can more directly link public funds to the will of the public (i.e., the crowd). Such an approach can complement other funding allocation rules to both allow public demand to help influence where public funds go and also potentially "crowd in" additional private support. Crowdfunding can promote the CCS and amplify public investment warrants additional attention.

Miao (2015) recommends several reforms to balance the need to protect IP while encouraging innovation in crowdfunding platforms. Allowing creators' crowdfunding campaigns as nonprejudicial disclosures as long as patent applications are subsequently filed promptly and clarifying experimental use exemptions for crowdfunding, for

instance, may be welcome improvements that encourage innovation without risking theft. Ganatra (2016) provides recommendations on future transparency and regulation for the emerging market of RC/DC.

6 Conclusions

Crowdfunding represents an important alternative, or complement, to the financing modes and sources of the cultural and creative sector. Furthermore, crowdfunding is relevant for its informative, promotional, co-creative and democratizing features. Rewards and donations, with their distinctive features, are the prominent models in CCCF. We have assessed the benefits and barriers of CCCF and RD/DC through the lenses of regulatory frameworks, the institutional instruments allowing, or supporting, crowdfunding to achieve its potentials and overcome its barriers. We have critically considered and compared the regulatory frameworks of the two main marketplaces, namely the US and the EU, in terms of involved authorities and respective roles, regulation intensity and specificity and degree of harmonization, together with other aspects of taxation, IPR and fraud.

CCCF presents a series of benefits and barriers, and crowdfunding's ability to achieve its potentials and overcome its barriers depends directly on how it is regulated. At the same time, over-regulation and excessive costs ought to be avoided. Limited regulation by public authorities may allow for self-regulation of operators, and hence contribute to openness, creativity, and accessibility in the CCCF marketplace. As for IPR, the practice of CCCF calls for more specific transparent regulation. A lack of harmonization within the EU and internationally may pose considerable challenges to CCCF and its expansion. In fact, while a non harmonized market may deter new entrants because of perspective profits face to bureaucracy costs, investments and market size, sufficiently liberalized single small markets may favor big international (or global) entrants, with consequent expansion of the market although with possible drawbacks, first of all in terms of diversity.

Recommendations point to a harmonization of RD/DC and CCCF, starting from the EU, and to a supportive, rather than oppressive, regulation, for instance enhancing transparency, stressing measures in favor of entrepreneurs, tolerating some levels of risk, and fostering more forms of public-private partnership.

Because of the distinct features and functioning of RC/DC with respect to other crowdfunding models, future research should deserve more separate and focused efforts, also based on available data. The study CCCF in particular allows to better disentangle the innovation component typical of creativity, and new collective creative patterns. Spillovers from RC/DC to other more traditional forms of financing new ventures and IP protection remain important areas for future research.

Abstract

Trade fairs, conferences and congresses serve to exchange expertise and knowledge. Often the existing potential cannot be used despite high concentration of knowledge carriers or is subject to barriers in the communication. This paper presents a proven design of an open workshop, which offers the possibility to involve the participants of such events for an interdisciplinary exchange, up to the targeted scientific, social or economic problem solving.

The design of the workshop will involve participants being led by a "step-by-step guide ("Workshop Tourguide"). By setting the framework and the specific request for individual ideas, the first step is to create an "Idea Market" that will be made visible to everyone. In a development loop, the ideas are verified and developed within the knowledge ecosystem in order to continue their work in groups. Through the process of making all ideas visible and accessible at all times, ideas are effectively enhanced in their quality. In the final step, the ideas in teams are worked out with the help of the "Proposal Design Canvas" and recorded for further development.

As it has been shown, by applying this design, empirical barriers to knowledge exchange and communication can be resolved in order to work cooperatively on solution proposals. The workshop design can be applied to dynamic and fluctuating events such as trade fairs, conferences and congresses in order to interrogate bundled knowledge, bring it together in a targeted manner and further develop it through grinding processes. The "Workshop Tourguide" serves as an adaptable template that can be used for all creative solution finding.

Keywords – cooperative innovation thinking, circulating knowledge, workshop-design, open innovation, knowledge transfer.

Paper type – Practical Paper.

1 Introduction: Knowledge driven ecosystems

During fluctuating events like trade fairs, international expert conferences or congresses, a huge amount of knowledge is compactly assembled in one place in a non-intersecting time. Most of the present knowledge provider cannot be interrogated or used due to parameters like time and unawareness of existing expertise. Further barriers like foreign languages or different terminologies are factors that prevent the participants from communicating and exchanging their ideas effectively. To request, document and expand the potential knowledge of such dynamic and temporary knowledge ecosystems, an equally dynamic and validated workshop design for cooperative innovation thinking was developed.

2 Framework: INTEGER-workshop

In framework of INTEGER (Intelligent Technologies for secure and Resilient cities and societies), a joint German-Japanese research project funded by the German BMBF (Federal Ministry of Education and Research), the Laboratory of Knowledge Architecture had to submit six Horizon proposals within 2019 and 2020. Another condition and goal of the project was the networking of international research institutions through personal contacts, which should lead to long-term knowledge links (Porter, 1998).

Thematically, the proposals focused on disaster resilience and management for European cities and societies. To supplement the consortium with partners with expertise and experiences in this specific field of science, the project included first responders and researchers from Japanese authorities and universities such as Waseda University, Osaka University and Toyohashi University of Technology. In order to benefit from a mutual exchange of knowledge and to develop initial project ideas for the proposals, a workshop-session was held in Tokyo. A variety of researchers from across Japan were invited to attend the workshop, but the participants were unable to attend the workshop during the same period. For this reasons, the event had to be extended, allowing all participants to attend the workshop at any time later date. Under these conditions, which equate to a trade fair or scientific conference, a workshop was designed to create as much knowledge transfer- and growth as possible.

3 Challenges of knowledge transfer in knowledge ecosystems

3.1 Elements of a knowledge ecosystem

The technical term "ecosystem" comes from the ecology and is explained with the "teaching of the household". Initially, the definition was limited to the study of organisms and their interactions in the environment. In the 20th century, the definition was extended to a global system of organisms and the inanimate environment as well as the climate. In current usage, the word "ecosystem" is used synonymous when individual elements in a closed space or system co-exist in symbiosis with each other and benefit from each other.

The term "knowledge ecosystem" is an approach in knowledge management with the aim of having a valid decision-making basis through the existing pool of knowledge. It is also assumed that new innovations emerge from a system of knowledge. The "knowledge ecosystem" consist, different to the business-, or innovation ecosystem, of actors from research institutes, innovators and technology entrepreneurs serve as knowledge nodes (Valkokari, 2015). Further Valkokari outlined, the relationship and connectivity of their elements (actors) is decentralized and earns synergies through knowledge exchange.

Comparable with the natural scientific consideration of the ecosystem, it is assumed that constituents of different species or genera together produce new ones. What is referred to a hybrid in the field of biology (such as the crossing of two plant breeds) can be translated for knowledge management as the "technical interface" that results from multidisciplinary within a closed system. The workshop can be seen as closed system, while the participants are the elements of the system. To make it ecological in terms of knowledge management, the workshop needs formats to make knowledge exchange possible to create innovative ideas in a collaborative way between the participants.

3.2 Practical challenges of knowledge exchange

If knowledge exchange is understood as a communication process (Schmiedgen, 2015), it takes place between the sender and the receiver (Shannon & Weaver, 1963). The transfer of knowledge occurs when the receiver decodes, interprets and cognitively processes the transmitted information (Garavelli et. al, 2002). In order to expose barriers of knowledge transfer that arise in practice, we conduct a series of qualitative telephone interviews. The three interview partners were industry representatives who transfer and distribute information across several companies for example within a supply chain. In order to cover a broad range of sectors, companies from different industries and with different scale were surveyed: a) electronic engineering: 12.000 employees, annual sales of 2,5 milliard euros (2017), b) handcraft interior construction: 250 employees, annual sales of 50 million euros (2016), c) software-development and consulting: 100 employees, annual sales of one-digit millions (2018). The following barriers were named or confirmed during the interviews a), b) and c). Only the barriers that can be transferred to trade fairs, conferences and workshops are listed:

Barriers of knowledge transfer	A)	B)	C)
• linguistic barriers: communication in foreign language with limited language skills. Usually in English as non-native language.	yes	yes	yes
• terminology: gap between technical languages, e.g. the differences between the terminology of an architect and an industrial designer. In some case the same terminology stands for different subjects.	yes	yes	yes
• subject distance: barriers due to lack of expertise in other areas, particularly in interdisciplinary projects (Chua, 2004).	yes	yes	yes
• insider language: use of internal language of a field of work, a department or an institution.		yes	yes
• withhold of knowledge: a participant holds back with information, because he fears that someone else take over the pronounced idea or withdraw his knowledge in order to misappropriate it elsewhere.	yes	yes	yes
• succession: lack of structure and coordination, while several participants has to communicate with each other (at the same time).			yes
• responsibilities: unclear responsibilities, who is allowed to decide or who can decide over whom.			yes
• Addresses barrier: knowledge exchange and agreements to / with wrong contact person or without the right participant being present.			yes

4 Double Diamond Design Model

The Double Diamond is a design process model developed by the British Design Council, showing four phases of developing a creative idea focusing on solving a problem. The double diamond shape results from the four phases: 1) discover, 2) define, 3) develop and 4) deliver (see *figure 1*). Starting point is a scientific, technological, entrepreneurial or social problem that needs to be solved. From there, the first diamond opens with the phase of *discovery*. In this first phase, research will be carried out on existing standards, fields of research and results, etc. This creates a wide range of possibilities and options that may contribute to problem solving. In the phase of *definition*, the collected information is filtered according to corresponding criteria and reviewed for relevance. The field of possibilities diminishes, but becomes more goal-oriented. After the problem definition, the second diamond opens again with the phase of *development*. This time, focus is on the concept development of the problem by considering different types of approaches. The second diamond is closed in the phase of *delivery*. Here, the different approaches through validation and testing lead to a successful implementation. This leads to the solution of the initial problem (Stickdorn & Schneider, 2010).

Figure 1: representation of the Double Diamond method by the British Design Council.

5 Use case of Double Diamond in framework of INTEGER

The use case in framework of INTEGER was the workshop for new knowledge for proposal development in Tokyo, a set target, that Quin et al. clarifies as the main outcome of a knowledge ecosystem (Quin et al., 1998). The ideas for proposal approaches would come from a supra-regional, interdisciplinary consortium. Therefore, the model of the Double Diamond has been extended to the bottom-up approach of co-creation, which helps to make the system of knowledge carriers as such more resilient (Anderson, 1999; Clippinger, 2004). Through the use of co-creation, the knowledge ecosystem experiences a characteristic which, according to Valkokari, belongs to the innovation ecosystem (Valkokari, 2015).

The set problem was to create a project idea suitable for the selected calls, which corresponded to the interests and expert opinions of the respective partners from the interdisciplinary participants who were present at different times. The workshop design was therefore based on the Double Diamond model (see figure 2), with intermediate steps being introduced, especially in the third phase, where the workshop is belonging to.

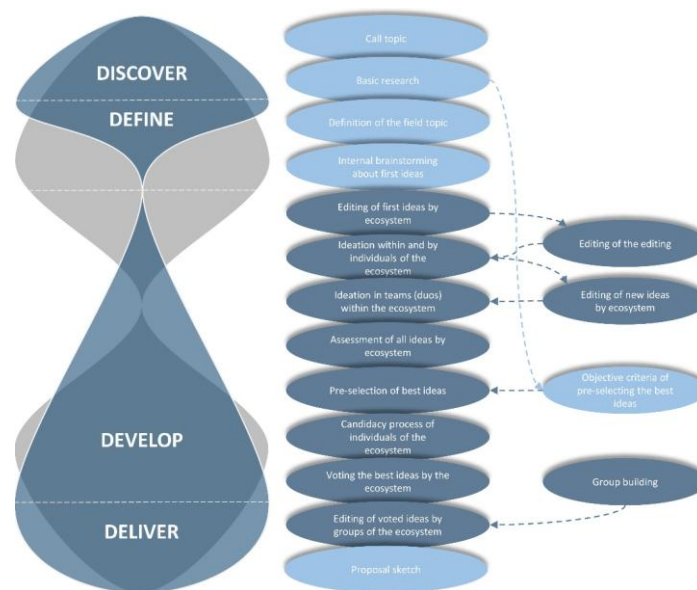

Figure 2: workshop design in comparison to the double diamond method

5.1 Phase 1- Discover

In preparation of the workshop, we scanned the call to identify the topic area and sub-topics. Then we created a keyword-cloud with all relevant keywords clustered to general terms such as “disaster management”, “resilience” and “preparedness”. Based on this, a basic search is carried out for each terminology as well as related topics and references of existing approaches, concepts, tools, products or services. The basic research also

established objective criteria that should serve as a basis for decision-making in the third phase.

5.2 Phase 2 - Define

After spreading out the field of opportunities, we filtered them by defining each topic, sub-topic and term of the state-of-the-art-research. Then we adjusted the definitions with the internal and external expertise of our partners, that will participate in the workshop.

To initiate a creative innovation thinking process, the participants need to pass the three spaces of “inspiration, ideation, implementation” (Brown, 2008). Starting with inspiration, we generated first idea outlines in an internally brainstorming session and formulating these ideas to half-page. These were displayed on posters, called “Project Sketches”.

To guarantee a uniform process for all participants on all workshop days, a “Workshop Tourguide” was designed and handed out to all as a booklet served as a step-by-step guide without the need for a workshop host (see *figure 3*). The first half (upper part) consists of a collection of all the necessary information, guidelines and pointers to the overall project: the INTEGER project, the European tenders and their main topics. The second half (below) names and describes the respective actions of the individual steps and illustrates them.

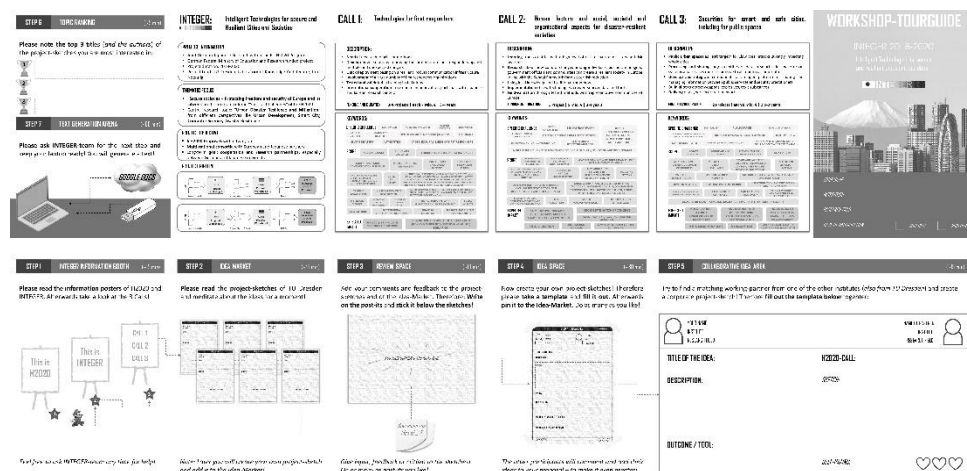

Figure 3: “Workshop Tourguide” as step-by-step-instruction.

In order to invite the right regional Japanese partners and to attend the workshop, we followed Kostoff's three criteria to select the right co-creators of an innovation that the potential partners had to fulfill: 1) multiple recommendations, 2) significant publications in the field and 3) literature citations (Kostoff, 2003).

5.3 Phase 3 - Develop

The third phase took place exclusively during the workshop in Japan and consists of seven steps. Prepared posters explained the workshop participants the set framework of innovation thinking textually and graphically at the “Information Booth”. At the “Idea Market”, the previously internally developed idea outlines were also made visible and accessible to all on posters. Referring to the phrase “learning by doing” (Rosenberg, 1976), Carayannis et al. points to the effect that continuous acquisition of knowledge has a cumulative impact on future innovation (Carayannis, 2003). Therefore, the shape of the Double Diamond gets extended by polishing through external expert loops at this point.

In the following, the carrier of knowledge of different disciplines, meaning the workshop participants, are referred to collectively as the “ecosystem”.

Step 1) At the “Review Space” the ecosystem gets instructed to give written feedback, comments and critics to the prepared idea outlines of the Idea Market basing on their expert knowledge. Therefore, they add their remarks via Post-it to the existing posters. This method should be made use of the honey-pot effect (Ott & Koch, 2012), after which a larger amount of participants organically accumulates where most interest arises. The quantity and quality of the ideation process as part of the innovation thinking (Brown, 2008) give conclusion of the quality of the idea as a whole. Because the comments are visible to all, they can be commented on by other experts in another loop.

Step 2) At the “Idea Space” the individuals of the ecosystem fill out a template with own ideas for innovations within the set framework and add it to the Idea-Market. The idea of the expert now circulates in the self-build knowledge ecosystem and expand the diversity of ideas. New participants of the event (workshop) will give feedback on this expert-idea, so that the idea gets validated in a short period of time and through an interdisciplinary jury.

Step 3) At the “Cooperative Idea Area” the individuals of the ecosystem get instructed to team up with one of the other experts to co-create a cooperative idea outline. Together they sketch their raw idea in the prepared placeholder in their Workshop Tourguide. If the idea is promising to both partners, they fill out a new template at the Idea Space (step 2) and add another draft to the Idea-Market. This step serves to bring together different disciplines of the ecosystem. Each individual of the ecosystem notes the idea drafts he and his personal field of research is corresponding the most into his Workshop Tourguide. After the event he can contact the authors of the drafts he is interested in for a prospective cooperation.

Step 4) Every individual of the ecosystem receives the same number of markers to mark the idea / ideas of the Idea Market that he finds the most interesting and promising. As a result, the ecosystem as a whole determines which ideas should be pursued further.

Step 5) The best ideas of the Idea Market get pre-selected by the workshop hosts. For this, the assessments of the ecosystem are counted. In addition, according to objective criteria previously defined in the phase of discovery of the Double Diamond, it is decided which ideas should be pursued. The objective criteria may arise, for example, from the questions: does the idea fit the call, is the idea realistically feasible, is there a suitable European partner for the idea?

Step 6) After the pre-selection there were still too many ideas left, as they all could have pursued. Therefore, everyone should audition in front of the ecosystem whose idea was selected. The idea provider had to answer the questions of the ecosystem, for instance: What is new about this idea? What makes this idea different from existing approaches? How should the idea be implemented, what resources and resources are needed?

Step 7) After the candidacy process of the individuals, the ecosystem was asked who wants to contribute to the individual project approaches. The projects with the most votes will be selected for the next step. At the same time processing expert groups are formed.

5.4 Phase 4 - Deliver

In the forth phase, the built expert groups of the ecosystem come together to continue to work on the project outlines. For this purpose, a digital template was developed, which should summarize and deepen the ideas to deliver solutions to the set framework in form of proposal sketches.

The digital template is based on the Business Model Canvas by Osterwalder and takes up the structure to describe a business idea and its implementation. This model is designed so that everyone can understand it with the help of segmentation and illustrations (Osterwalder and Pigneur 2010). To capture and deliver the solution to the set problem, the required content queries were segmented and presented as a customized version of the Business Model Canvas (BMC). The resulting "Proposal Design Canvas", in contrast to its model, contains all the scientific aspects of a proposal, which must be queried in the call and presented in the appropriate formality.

6 Evaluation

The workshop design was used and tested within the time from January 15 to 20, 2019, in framework of INTEGER. After the implementation, conclusions could be drawn as to which barriers in communication or the exchange of knowledge with the design a) were remedied, b) mitigated and c) could not be improved. With reference to paragraph 3.2 (“practical challenges of knowledge exchange”), the list of known barriers and the effect of the workshop is showed below:

Barriers of knowledge transfer	remedied	mitigated	not improved
• linguistic barriers			
• terminology			
• subject distance			
• insider language			
• withhold of knowledge			
• succession			
• responsibilities			
• Addresses barrier			

The linguistic barriers (between English, German, Japanese) could be mitigated by the use of graphic elements to explain the project idea at the Ides Market. The templates for the development of an independent idea also prompted the participants to pin down the idea graphically. In principle, the existing linguistic barrier could not be eliminated, especially if facts of a specific discipline had to be explained.

The gap between the technical languages (architecture, social science, computer science) was inevitably closed by the participants in the workshop, because they formulated their ideas comprehensibly for all. Terminologies were also immediately questioned by other participants when used in an interim presentation. However, when developing their own project projects, specialist terminology was used especially in computer sciences, which subsequently had to be supplemented with an explanation.

The subject distance between disciplines persisted, as it could not be made up by the participants in the short course of the workshop.

Insider language, so using internal terms, was not present. This can be traced back to the fact that concepts were explained to the crowd as a whole or were visible to all participants on the posters. This has led to the renunciation of such language.

Objectively, no statement can be made as to whether knowledge was contained to the other participants. In general, it could be observed that the exchange of expertise was a general interest among all participants. Research institutes, universities and representatives of companies spoke openly about their own project experiences and gave hints to existing and comparable ideas on their part. Ideas were communicated transparently, especially in individual discussions with the participants.

The greatest added value of the workshop design is the simultaneous communication of a multitude of ideas. Participants were able to use the posters to find out about existing project ideas at any time, read their contents and read what others have left behind about

the idea as a feedback. The simultaneous communication of several participants was made possible by the permanent accessibility and visibility of all project ideas in one place.

The potential barrier to the question of responsibilities has been mitigated by the participants themselves. As each participant entered the workshop with an individual agenda, everyone knew what responsibility he wanted to take on in the proposals to be developed: the leading role of a project, a core role or as a supporting unit. By eliminating a hierarchy (the hosts have taken only one moderating role) there was little bias among the participants to express their opinion. Waseda University students, who also attended, were included in the workshop process and there was no barrier to the question of responsibility.

The barrier to the correct addressing of an issue has been almost completely eliminated by the workshop design. Through an initial mutual introduction of all participants the existing competences were known to everyone. However, the introductory round could not be repeated as often as possible during the workshop as soon as a new participant joined. The right addressing for a best possible exchange of knowledge nevertheless was possible. Each poster, as well as the Idea Sheets of the participants, was given a name so that the ideas could be traced back to the author. In the same way it was possible to track which participants left feedback at the Review Space. The real mediation of the matching participants took place through the hosts, who had a permanent overview through the visible connections (name on poster and nameplates for all participants).

7 Practical implementation

As a result of the workshop design, the Workshop Tourguide emerged. This guideline contains all the information you need to know about the project and the workshop process in a step-by-step lead. The Workshop Tourguide together with the poster presentation template and the Proposal Design Canvas provide the necessary means to carry out further workshops to generate ideas for writing a research project in a goal-oriented manner. In addition, the method can be applied wherever knowledge carriers come together in a condensed manner to map existing knowledge, to exchange ideas and to find technical interfaces in order to initiate an interdisciplinary project approach. The workshop design is expanded predestined to intergrade in fluctuating events such as trade fairs, international expert conferences, congresses or similar events with massive partake in independence of the problem that is to be solved in a scientific, theoretical or creative way.

8 Conclusions

The proposed workshop design for an expanding knowledge transfer allows a direct and indirect exchange of knowledge between experts from different disciplines within an unstable knowledge ecosystem. The basis in the form of the Workshop Tourguide gives

an understandable instruction for the participants of such a workshop, however, as it has been shown, moderation of the individual steps by hosts is required.

It has also been shown that new entrants must first be briefed and not be integrated directly into the current workshop process. Here we see pent-up demand. The conduction under real conditions has revealed that the direct exchange through community work in the form of the “Cooperative Idea Area” worked well and new ideas were generated. The indirect exchange of the “Review Space” also has added value for the project ideas. It should be emphasized that the quality of the proposals increases with each additional review loop and has been expanded by meaningful additions. For small numbers of participants, it should be taken into account that a separate loop should be added after the “Idea Space” in order to specifically encourage the grind of the new ideas.

A danger of the open and transparent design of the workshop is that participants can be biased if they comment on ideas what is visible for everyone. The anonymizing of the comments would circumvent this danger, but would have the disadvantage that the respective knowledge cannot be traced back and matched with suitable participants.

Abstract

The extant literature has often concluded that small and medium-sized enterprises (SMEs) are confronted with the lack of various resources (ranging from the tangible to the intangibles ones), a fact which determines them to act proactively and acquire the needed assets via different forms of collaboration with their counterparts. In this vein, the creation or affiliation to strategic networks have emerged as a fruitful path towards knowledge sharing as a reaction to fierce competition and with a view to enhance their competitiveness and renewal capacities, more specifically, their innovative performance. Starting from these premises, the current endeavour aims to advance some theoretical propositions depicting managers' multifaceted communication and interaction relationships with their prospective or extant partners in an endeavour to share relevant knowledge. By addressing varied forms and channels for knowledge sharing, the paper intends to assemble a coherent and comprehensive puzzle, theoretically positing the influence of a multifold relational design on SMEs innovative performance. Thus, it paves the way for a better understanding of the state of the field and avails new empirical research directions.

Keywords – Knowledge Sharing, Strategic networks, Small and medium-sized enterprises (SMEs), Relational design.

Paper type – Academic Research Paper

1 Introduction

The scrutiny of the innovative performance research has consistently brought to the fore that inter-firm boundary-spanning knowledge comes forward as a pivotal factor of innovation, especially in the case of small and medium-sized enterprises (SMEs) (Zeng et al., 2010; Franco and Haase, 2015; Vătămănescu et al., 2016a; Gomezel and Rangus, 2018). SMEs have exponentially opened up their borders via a diversity of collaboration (knowledge) networks, starting from the formal / formalized aggregations (i.e. strategic alliances, joint ventures, licensing, etc.) to informal / nonformalized ones, mainly based on deliberate managerial decisions and cemented by strong managerial relationships (Spekman et al., 2000; de Man and Duysters, 2005; Culpan, 2009; Andrade Rojas et al., 2018). The managerial decisions to move away from individualized business to a network-based approach substantially stem from the sheer awareness of their firms' state-of-the-art in terms of available resources, functional capabilities, knowledge on the market conditions, etc. (Soto-Acosta et al., 2016) and result in strategic endeavours for ensuring a common ground for knowledge sharing (both tangible and intangible) with potential allies (Franco and Haase, 2015; Păduraru et al., 2016; Vătămănescu et al., 2016b, 2017a,b). Here, the partners' joint and similar objectives stand for the driving force for SMEs becoming part of strategic networks with a view to increase their innovative performance within the industry of reference.

Filling knowledge gaps and acquiring new wells of knowledge are the most common denominator for engaging in strategic networks with upstream and downstream collaborators in the sector (Thorgren et al., 2009; Vătămănescu et al., 2017a). Such undertakings have been credited with success as a consequence of the establishment and development of strong inter-firm relationships among the key organizational actors (i.e., entrepreneurs, managers, CEOs, etc.), all the more so as the network springs as a relational platform for members willing to harness strategic renewal and innovation via learning and knowledge acquisitions (de Man and Duysters, 2005; Andrade Rojas et al., 2018; Vătămănescu et al., 2018; Vătămănescu and Pinzaru, 2018).

In this vein, managers' multifold relational designs (i.e., knowledge sharing via multifaceted interactions and forms of communication at the managerial level) have directly influenced the roots and routes of knowledge sharing with their counterparts given that the process has been recognised as a determinant of competitiveness and, at the same time, as one of the main challenges faced in networks (Păduraru et al., 2016; Vătămănescu et al., 2016a,b). As a set of fine-grained and mainly unique practices and methods, the sharing mechanism from a relational perspective imprints an intricate nature to the interactions and relationships among network members. Moreover, the relational design of knowledge translation within strategic SMEs networks poses even more

challenges as the cooperative form is mostly dynamic in that partners' collaboration relies on the exchange of certain resources, ideas, knowledge, while preserving their interdependence in additional areas. Managers in the network are the ones to decide what, where, when and how they are open to share, giving way to different levels of openness and commitment with a view to achieving the innovative performance targeted by their units.

Pursuant to Curado, Muñoz-Pascual & Galende (2018), the extant body of literature on whether and how firms can leverage relational capital and knowledge sharing for innovation is equivocal whereas the underlying processes responsible for mobilizing relational capital are yet to be deemed conclusive. That being the case and building on the previous depicted considerations, the present endeavour aims to advance novel propositions covering the relational antecedents of innovative performance within the context of strategic SMEs networks. The emphasis is laid on the relational design of knowledge sharing among network members (i.e., managers as firm's key players with direct access to various sources of firm knowledge).

The overall approach considers the deliberate bottom-up formation of strategic SMEs networks as a driver for boundary-spanning knowledge flows (Fukugawa, 2006; Thorgren et al., 2009). The envisaged communication and knowledge exchanges are either offline (in person), or online (ICT-based), either direct, or via an intermediary, and mostly founded on specific (business-centric / competitive) knowledge. All these knowledge sharing facets are expected to exert different effects on members' innovative performance which is understood – consistent with Thorgren et al., 2009 – by means of improving the competitive position, reducing costs, improving products or services, developing new products, and improving R&D effectiveness.

Furthermore, in order to dig deeper into the scope of SMEs strategic networks, we proceed by delineating between two different types of aggregations in line with Franco and Haase (2015). The authors advanced two groups of criteria to account for the choice of alliance associates: 1) criteria connected to the activity and business abilities, and 2) criteria correlated with the personality of the partner. Even though the current literature on the innovative performance has yet to consider such a particularization of strategic networks, embracing a specific approach may spring as a theoretical step forward a more intricate research model.

By corroborating these aspects, the remainder of the paper focuses on advancing some theoretical propositions describing the relationships among the twofold SMEs strategic networks, various types of knowledge sharing and the innovative performance. In this sense, it hews the path for further empirical studies aiming at assessing conceptual and structural models in specific sectors.

2 Theoretical propositions

The contemporary business world has become increasingly heterogeneous, competitive and globalised. In this front, the phenomenon of network creation is extensively viewed as critical to support and maintain a company's performance and

prosperity in the field of reference. Particularly within the settings of small and medium-sized enterprises (SMEs), business networks (with a particular emphasis on alliances) could be specifically valuable in that they favour the attainment of competitive advantages and strategic objectives.

A study conducted by Rivera-Santos, Rufin and Wassmer (2017) stated that one of the main drivers why small companies engage in strategic networks is to enhance their competitive status when going up against opponent firms. They concurred that companies frequently frame and employ their alliance portfolios as devices to adapt within the competitive context in order to outline the style of the competition. The alliance portfolios of the companies can also be moulded by competition and therefore portray the effect of a multifaceted process in which strategically acting enterprises develop alliance assignments during the time by embarking into both offensive and defensive alliances shaped mainly by the managers within a rational strategy process (Wincent and Westerberg, 2005). Commonly, firms are coerced to reshape the structure of their alliance portfolios so that they can enhance their competitive status face to their opponents in a business area or just to settle their competitive edge (Elmuti and Kathawala, 2001).

Another investigation developed by Kmiecik and Michna (2018) underlined that when business rivalry in a market is serious, a company should struggle to acquire, transform, and harvest knowledge when it comes to the actions initiated by the competitors. By cultivating a wider spectrum of knowledge abilities via strategic networks, SMEs can gain and integrate market knowledge more effectively and efficiently (Vătămănescu et al., 2017a.b). On the contrary, when competitive fervour is reduced, companies may be hesitant to expand knowledge management practices by apprehending such an endowment as unessential and inefficient.

Based on the findings of these studies, we advance the following main propositions with its two derivatives (in line with Franco and Haase's, 2015 twofold criteria):

P1. A high level of competition in the field has a positive influence of the formation of SMEs strategic networks.

P1A. A high level of competition in the field has a positive influence of the formation of SMEs strategic networks based on criteria related to the activity and business abilities.

P1B. A high level of competition in the field has a positive influence of the formation of SMEs strategic networks based on criteria associated with the personality of the partner.

To numerous organizations, a fruitful collaboration within networks and a suitable framing of interorganisational contacts is a subject of survival (Vuori, Helander and Mäenpää, 2018). Within the economic context of the 21st century, the cases of networks that have been established solely for the purpose of sharing knowledge is continuously increasing. Ioanid et al. (2017) reinforce the view that strategic networks offer the chance for dialogue to distinct groups with important capacity of knowledge sharing that in other contexts would be reluctant to relate. In line with Iturrioz, Aragon and Narvaiza (2015) initiating business contacts and ties amid network members decreases the expenses invested in joint efforts, easing dialogue and knowledge transfer.

Abou-Zeid (2005) addressed the channels for social knowledge transfer in both online and offline environments: such as personnel transfer, electronic mail, groupware, telephone, video conferencing, face-to-face meetings, training seminars and courses, specialist knowledge transfer groups, communities-of-practice or communities of interest. In this front, a research carried out by Appel-Meulenbroek, Weggeman, and Torkkeli (2018) points out that one-on-one knowledge sharing cultivates collaboration and reinforces the strategic network. Here, SMEs managers are primarily accountable for the degree in which knowledge is distributed and exchanged among actors and for the level of energy channelled to gain and ascertain knowledge in order to boost communication within the strategic network.

Raposo, Ferreira and Fernandes (2014) affirmed that face-to-face/ in person interactions and geographic proximity with business partners are valuable factors which propel better access to information, certain specific knowledge exchanges and further they enforce innovative performance. When the study refers for example to the biotechnology sector companies, the authors support the idea that, in many situations where firms from this sector are assembled into clusters, they are able to generate more innovative performance in comparison with the context when they are geographically dispersed (Raposo et al., 2014).

Consequently, founded on the extant literature implying the existence of connections between strategic networks, knowledge sharing channels and innovative performance, the following propositions are formulated:

P2. SMEs strategic networks have a positive influence on SMEs innovative performance via the mediating effect of offline (in-person) knowledge sharing among members.

P2A. SMEs strategic networks based on criteria related to the activity and business abilities have a positive influence on SMEs innovative performance via the mediating effect of offline (in-person) knowledge sharing among members.

P2B. SMEs strategic networks based on criteria associated with the personality of the partner have a positive influence on SMEs innovative performance via the mediating effect of offline (in-person) knowledge sharing among members.

Vuori et al. (2018) underlined that knowledge networks can be restricted or accessible, can differ in geographical diffusion and dimension, thus partners are expected to communicate one-on-one or through ICT. Their study also envisioned that some of the most important elements when assessing the process of knowledge sharing within a strategic network refer to geographical range which accounts, to some extent, for the usage of ICT. An investigation performed by Popa, Soto-Acosta and Martinez-Conesa (2017) denoted that within the precise situation of SMEs, targeted online influx and outflux of knowledge are even more pertinent to deliver sustainable advantage and innovative performance in face of competition as this type of organizations are confronted with harsher means pressure.

In another perspective, a survey of 150 Finnish technology-intensive firms showed that ICT-based knowledge sharing has a positive effect on innovative performance, but

presents in the same time high levels of accidental and intentional knowledge leakage (Ritala et al., 2015).

Given these aspects, we presume that:

P3. SMEs strategic networks have a positive influence on SMEs innovative performance via the mediating effect of online (ICT-based) knowledge sharing among members.

P3A. SMEs strategic networks based on criteria related to the activity and business abilities have a positive influence on online (ICT-based) knowledge sharing among members.

P3B. SMEs strategic networks based on criteria associated with the personality of the partner have a positive influence on online (ICT-based) knowledge sharing among members.

According to the extant literature, the trust in business partners has been widely researched in the sphere of SMEs and uncovered to be prominent, probably the most significant influencer of alliance achievement within this business area (Thorgren et al., 2009). Concurrently, the assumption of a high level of commitment is liable to catalyse the associates' actions in the spirit of a genuine partnership (Valkokari et al., 2012).

Keszei (2018) argue that strategic network empowerment can increase knowledge sharing in a direct way. The effort to sustain the predisposition of SMEs managers from strategic networks to share directly what they know is essential to the continuous creation of superior new product development performance. The study also accentuates that firms should build up organisational cultures where managers' knowledge-sharing willingness (using direct approaches) with their counterparts within the scope of a strategic network is of paramount importance.

Further, according to Sulistiyani and Harwiki (2015), the affiliation of a SME to a strategic network is positively related to the fact that the managers get more encouraged to contribute their knowledge about their own businesses to members, groups and companies within the respective network. This co-relation where companies share their own practices and methods could increase the creation of new ideas and the development of new opportunities that could propel the advancement of innovation capabilities and innovative performance.

Studies have proved that inter-organizational collaboration within a network of partners can be an important driver for innovation performance. For instance, the inquiry led by Andrade Rojas et al. (2018) has recommended that when proficient business collaborations furnish more eclectic assemblages of information and skills, it is more plausible that the expected gains of innovation can be completed at basic costs. They continue by affirming that a central aspect within a business alliance supports the organization in its access to multifarious competences and resources, as a result of its open links with various business allies. Direct knowledge sharing empowers a business to a more favourable comprehension of market necessities and to product creation, thus entertaining the interests of the stakeholders (Castela et al., 2018). Castela et al. (2018) underlined that companies in a central position in the intra-sector or cross-sector network sharing information about their own businesses are more inclined to be innovative.

Given these considerations, we advance the following propositions:

P4. SMEs strategic networks have a positive influence on SMEs innovative performance via the mediation of direct knowledge sharing among members.

P4A. SMEs strategic networks based on criteria related to the activity and business abilities have a positive influence on SMEs innovative performance via the mediation of direct knowledge sharing among members.

P4B. SMEs strategic networks based on criteria associated with the personality of the partner have a positive influence on SMEs innovative performance via the mediation of direct knowledge sharing among members.

Natalicchio et al. (2018) enforced these aforementioned findings in that, due to the lack of strategic resources and long-range development plans, SMEs managers rely on their abilities and the chemistry with potential partners to a great extent in their endeavour to strengthen knowledge sharing processes, thus counting less on a mediator's role. Nevertheless, as trust and commitment between prospective partners emerge as long-term processes which are expected to influence the development of a strategic network (Păduraru et al., 2016; Vătămănescu et al., 2016b) with a positive influence on direct knowledge sharing, resorting to an intermediary tasked to share knowledge among the members of the respective strategic network may arise as a suitable innovative solution in certain contexts.

The mental closeness and intensity of the partnership are often founded on direct interaction between parties (Vuori et al., 2018), yet there are cases where an intermediary can advance confidence and assign network resources in a favourable way for all the involved sides. Which is more, sometimes, the absence of an intermediary can develop into a fundamental knowledge obstacle in the network frame of reference (Myllärniemi et al., 2013).

Therefore, in the light of the abovementioned arguments, we formulate the following propositions:

P5. SMEs strategic networks have a positive influence on SMEs innovative performance via the mediating effect of the usage of an intermediary (a certain partner from the network) to share knowledge among members.

P5A. SMEs strategic networks based on criteria related to the activity and business abilities have a positive influence on SMEs innovative performance via the mediating effect of the usage of an intermediary (a certain partner from the network) to share knowledge among members.

P5B. SMEs strategic networks based on criteria associated with the personality of the partner have a positive influence on SMEs innovative performance via the mediating effect of the usage of an intermediary (a certain partner from the network) to share knowledge among members.

A study conducted by Curado, Munoz-Pascual and Galende (2018) showed that, within a more and more complex business environment, knowledge sharing within the inter-organizational realms plays a consistent part in the growth of organizational learning skills. Knowledge is an essential component which maintains an effective and efficient decision-making process and consequently knowledge sharing could support the

generation of competitive advantage and innovation via multifold information exchange (Vătămănescu and Pinzaru, 2018).

Hernandez-Espallardo et al. (2018) contended that companies within the same sector are more inclined to provide business-centric knowledge regarding the product series, technology, operating systems, business models, and management patterns in order to benefit from common knowledge and gain competitive advantage.

Given these considerations, the following propositions can be put forward:

P6. SMEs strategic networks have a positive influence on SMEs innovative performance via the mediating effect of sharing competitive (business-centric) knowledge among members.

P6A. SMEs strategic networks based on criteria related to the activity and business abilities have a positive influence on SMEs innovative performance via the mediating effect of sharing competitive (business-centric) knowledge among members.

P6B. SMEs strategic networks based on criteria associated with the personality of the partner have a positive influence on SMEs innovative performance via the mediating effect of sharing competitive (business-centric) knowledge among members.

3 Discussion and further research avenues

The formulation of the aforementioned theoretical propositions was meant to pave the way for integrative empirical endeavours liable to address intricate conceptual and structural models covering the case of SMEs strategic networks.

In this front, the paper adds to the extant literature on the topic in several ways. Firstly, it proposes a comprehensive framework for the relational design of knowledge sharing among network members. To the best of our knowledge, this is among the first undertakings simultaneously discussing offline (in person) and online (ICT-based), direct and intermediate, and business-centric / competitive knowledge exchanges.

Secondly, the study differentiates between two types of strategic networks - i.e., based on criteria connected to the activity and business abilities, respectively on criteria correlated with the personality of the partner. Such a disentanglement in the context of knowledge sharing flows and innovative performance is unprecedented and opens up new avenues for further research.

Thirdly, all the theoretical propositions assume the mediating effect of multifaceted knowledge sharing in the relationship between strategic networks and SMEs innovative performance, setting the premises for a further thorough investigation of the underlying and probably interlinked relational processes.

Even though the current endeavour is prone to become a step forward towards the comprehension of SMEs innovative performance within the context of a fierce competition, the main limit resides in its merely theoretical nature, thus calling for future in-depth analyses.

Abstract

The purpose of our study is to examine the impact of reverse knowledge transfer from foreign subsidiaries to parent companies on the latter's R&D performance, based on a questionnaire survey of Japanese companies.

Based on intensive review of existing studies on global R&D and reverse knowledge transfer, we try to advance the current literature by examining issues that have been unaddressed: what are the type of knowledge and mechanism of knowledge transfer from subsidiaries to parents? In particular, we focus on the transfer of "tacit knowledge" as well as "unintended" transfer and investigate their impacts on the parents' R&D activities and related performance.

To pursue the purpose, we conducted a questionnaire survey of more than 3,000 Japanese MNCs with overseas subsidiaries. The result showed the following points. First, concerning the type of knowledge, the transfer of tacit technological knowledge as well as market-related knowledge has a significant positive impact on the parents' R&D performance. Second, regarding the pattern of reverse knowledge transfer, unintended knowledge transfer has a positive effect on the parents' R&D performance to a certain point before turning negative. In other words, there is an inverse U-shaped relationship between unintended reverse knowledge transfer and R&D performance of the parent companies.

Keywords – foreign subsidiary, unintended knowledge creation and transfer, reverse knowledge transfer, tacit knowledge, R&D Performance

Paper type – Academic Research Paper

1 Introduction

The purpose of our study is to examine the impact of knowledge transfer from foreign subsidiaries to parent companies on the latter's R&D performance, based on a questionnaire survey of Japanese companies.

Prior studies on global R&D management traditionally assumed that knowledge and capabilities within multinational corporations (MNCs) would flow in one direction, along the hierarchical structures, from parents down to subsidiaries. After the 2000s, however, many scholars and practitioners have shown increasing interest in an active role of foreign subsidiaries in the process of knowledge creation and transfer within MNCs (e.g. Hakanson and Nobel, 2000; Frost, 2001; Zhou and Frost, 2003).

Knowledge transfer from subsidiaries to parents is often referred to as “reverse” transfer. While existing studies have deepened our understanding about the conditions under which the reverse knowledge transfer takes place and boosts the parents' R&D performance (e.g. Piscitello and Rabbiosi, 2004; 2006; Ambos, et al., 2006; Schotter and Bontis, 2009; Rabbiosi, 2011; Rabbiosi and Santangelo, 2013; Driffield, et al., 2016), there is a dearth of study on the types of knowledge transferred from subsidiaries to parents and the patterns of the transfer. In our study, we will pay attention to these missing aspects to demonstrate the importance of the transfer of tacit knowledge and “unintended” pattern of knowledge transfer from subsidiaries to parent companies.

The contents of this paper are as follows. In next section 2, we review existing studies on global management, especially on the reverse knowledge transfer in global R&D operation. In section 3, we explain research method and show research results. In section 4, we discuss about the results to derive some implications. The final section 5 is conclusion.

2 Literature Review

2.1 Meta-national perspective and the concept of reverse knowledge transfer

The study builds its theoretical foundation upon the “meta-national” perspective of global management (Doz and Santos, 1997; Doz, Santos and Williamson, 2001) that advocates the possibility of knowledge and value creation all around the world including developing countries. It also underscores the significance of sharing and utilizing such knowledge and value globally for firms to achieve a competitive edge over its rivals.

Based on the perspective, various streams of studies on globalization management have been developed, ranging from identifying the factors and effects of intra-MNC knowledge flows (Harzing and Noorderhaven, 2006) to the kind of agency relationships between parents and subsidiaries (Mudambi and Navarra, 2004). Among those studies, one of the most prevalent issues is knowledge transfer from subsidiaries to parent companies (e.g. Hakanson and Nobel, 2000; Frost, 2001; Zhou and Frost, 2003; Ambos, et al., 2006; Piscitello and Rabbiosi, 2006; Schotter and Bontis, 2009; Rabbiosi, 2011; Rabbiosi and Santangelo, 2013). It is often referred to as “reverse” knowledge transfer, in

contrast to the “forward” knowledge transfer in which knowledge flows from parents to their subsidiaries.

On the topic of the reverse knowledge transfer, its impact on the parent company’s R&D activities and the conditions under which it creates significant impact have been examined from various perspectives. For instance, Piscitello and Rabbiosi (2004) established that foreign R&D activities of Italian MNCs had a positive impact on the innovative performance of their parent companies. Hakanson and Nobel (2000) analysed technology transfer from foreign subsidiaries of Swedish MNCs back to their home operations and found supporting evidence for reverse technology transfer under the condition that subsidiaries had a global mandate to develop specific know-how. Ambos et al. (2006) also explored the conditions under which reverse knowledge transfer can affect the R&D capability of parent companies. Their empirical survey results indicated that the competitive strength of the host countries of subsidiaries, the strategic role of subsidiaries and the absorptive capacity of parent companies matter.

More recently, Rabbiosi (2011) examined the impact of the coordination mechanism, such as subsidiary autonomy and communication pattern, between subsidiary and parent company on reverse knowledge transfer. Their findings showed that the combination of high autonomy and personal communication as well as low autonomy and electronic-based communication positively affect the extent of reverse knowledge transfer. While Rabbiosi and Santangelo (2013) clarified that subsidiary age is an important determinant of parent company benefits from reverse knowledge transfer, Driffield, Love and Yang (2016) found the subsidiary location and parent-subsidiary distance as significant factors.

2.2 The type of knowledge and the pattern of knowledge transfer

A review of the existing literatures on global R&D management shows increasing importance of reverse knowledge transfer as a factor that could facilitate R&D activities of the parent company in home country. While they have deepened our understanding about the conditions under which reverse knowledge transfer takes place and boost the parents’ R&D performance, there is a dearth of research on the type of knowledge and mechanism of transfer from subsidiaries to parents. According to the knowledge-based theory, firms exist because they offer conditions for more efficient management of knowledge structures and processes than market transactions (Grant, 1996). One central characteristic of organizational knowledge is its “tacitness”, that is, the degree to which it can be codified or articulated. Assumed to be sticky, tacit knowledge is deemed as a potential source of advantage (von Hippel, 1994) because, unlike explicit knowledge, it is inimitable and appropriable (Spender and Grant, 1996). Firms therefore are superior to markets in their ability to organise processes and structures to integrate both tacit and explicit knowledge across different epistemic communities (Hakanson, 2010). Applying the knowledge-based perspective, we postulate in this study that knowledge that is created in foreign subsidiaries and transferred to their parents could come in different forms, such as technological or market information. Technological knowledge includes product and process knowledge, and could be tacit or explicit.

Considering that foreign subsidiaries are often faced with a different environment from that of the parent company at home, it is assumed that the subsidiary can create and transfer unique knowledge as an epistemic community that is not expected in advance. In this sense, knowledge transfer from foreign subsidiaries is not always conducted in an intended fashion, but rather knowledge can be transferred in an unintended manner.

In this paper, we build on the intersection of “meta-national” and “knowledge-based” perspectives to examine the dynamics of knowledge creation in foreign subsidiaries and the effect of their unintended knowledge transfer on the R&D activities and performance of the parent companies.

3 Research

3.1 Research Method

To investigate the impact of reverse knowledge transfer on the parents’ R&D performance, a questionnaire survey was conducted by the National Institute of Science and Technology Policy, a research arm of the Ministry of Education, Science and Technology in Japan. The questionnaires were delivered to 3,029 overseas subsidiaries of Japanese MNCs and returned from 672 subsidiaries.

Using the data collected from the survey, we performed two multiple regression analyses. First is about the impact of the types of knowledge and second is about the impact of the patterns of knowledge transfer on R&D performance of parent companies. In both analyses, we set country and industry which subsidiaries belong to, size (the amount of R&D expenditure) of subsidiaries, their role in global R&D operations and autonomy of R&D activities as control variables.

2.2 Results

Our regression analysis yield several interesting results, as presented in Table 1 and 2.

Table 1. Relationship between the type of knowledge transferred and the contribution to parent company's R&D performance

	Contribution to parent company		
	1	2	3
Transfer of explicit K			0.170 (1.846)
Transfer of tacit K			0.230* (2.049)
Transfer of product-related K			0.008 (0.078)
Transfer of process-related K			-0.021 (-0.245)
Transfer of market and customer K			0.232** (3.293)
R&D performance of local subsidiary		0.210** (3.258)	0.163** (2.908)
R&D expenditure	0.041 (0.245)	0.049 (0.297)	0.014 (0.096)

R&D intensiveness	0.053 (0.315)	0.056 (0.344)	-0.020 (0.144)
Major R&D activity	-0.308 (-4.753)	-0.260** (-3.989)	-0.100 (-1.668)
Degree of autonomy	-0.181 (-2.825)	-0.213** (-3.357)	-0.169** (-3.085)
Country dummy	-0.040 (-0.618)	-0.021 (-0.330)	-0.085 (-1.522)
Industry dummy	-0.145 (-2.262)	-.130* (-2.057)	-.119* (-2.087)
Observations	224	224	221
R2	0.137	0.178	0.413
Adjusted R2	0.114	0.151	0.379

Note: **: p<0.01, *: p<0.05

First, the impact of knowledge transfer from foreign subsidiary to parent company is different depending on the type of knowledge. The result shows that the transfer of tacit technological knowledge as well as market-related knowledge have significant positive impacts on the parents' R&D activities ($p<0.05$ and $p<0.01$, respectively), while explicit knowledge transfer itself does not demonstrate such significant effect (see Table 1). This finding is important for R&D managers as they should consider how to convey sticky knowledge difficult to be coded and articulated.

Table 2. The impact of unintended knowledge transfer on the contribution to the parent company's R&D Performance

	Contribution to parent company		
	1	2	3
Unintended knowledge transfer			-0.003 (-0.029)
Squared term of unintended knowledge transfer			-0.275* (-2.479)
R&D performance of local subsidiary		0.210** (3.258)	0.210** (3.043)
R&D expenditure	0.041 (0.245)	0.049 (0.297)	0.051 (0.288)
R&D intensiveness	0.053 (0.315)	0.056 (0.344)	0.054 (0.306)
Major R&D activity	-0.308** (-4.753)	-0.260** (-3.989)	-0.250** (-3.615)
Degree of autonomy	-0.181** (-2.825)	-0.213** (-3.357)	-0.121 (-1.773)
Country dummy	-0.040 (-0.618)	-0.021 (-0.330)	-0.048 (-0.707)
Industry dummy	-0.145* (-2.262)	-.130* (-2.057)	-0.077 (-1.150)
Observations	224	224	192
R2	0.137	0.178	0.217
Adjusted R2	0.114	0.151	0.179

Note: **: p<0.01, *: p<0.05

Second, concerning the pattern of knowledge transfer, the unintended reverse knowledge transfer itself has no significant impact on parent company's R&D performance. However, the squared term of the unintended knowledge transfer from foreign subsidiary to parent has a significant negative impact on the parent's R&D activities ($p < 0.05$) (see Table 2). In other words, there is an inverse U-shaped relationship between unintended reverse knowledge transfer and R&D activities of the parent companies. This implies that the degree of unintended knowledge transfer from subsidiaries renders a significant positive impact on the parent's R&D activities up to a certain point, beyond which it becomes negative.

4 Discussions

The results of this study have demonstrated that the reverse knowledge transfer from foreign subsidiary can actually be beneficial to their parent company's R&D activities, but the effect seems to be different depending on the type of knowledge transferred from subsidiary. The transfer of tacit knowledge as well as market-related one is found to have a higher impact on the subsidiary's contribution to the parent than that of explicit knowledge. These findings are an important contribution to the current literature which lacks investigation into the type of knowledge in the reverse knowledge transfer.

Also, our research results have implied the possibility and challenge of "unintended" knowledge transfer from foreign subsidiary to parent: it can facilitate R&D activities of parent company, but too much transfer has an adverse effect. These are also expected to advance the knowledge on reverse knowledge transfer in the field of global R&D management. Future research may therefore build upon these results to investigate the underlying factors and ascertain any moderating or mediating effect they may have on the relationship between unintended knowledge transfer and R&D performance of MNCs.

From a management perspective, our results suggest that global R&D managers should understand the fact that foreign subsidiaries can generate a variety of knowledge including technological and market, product and process, and tacit and explicit knowledge. Such knowledge should be regarded as critical resources that can enhance organizational capabilities of MNCs in the global context. To create and capture the value from such knowledge, the managers should make inventory of knowledge periodically for future use and transfer within a whole company, put in place appropriate knowledge management, establish ICT systems and, more importantly, a human interaction mechanism for facilitating the transfer of tacit knowledge created in foreign subsidiaries.

One of the most important implications for business managers is about the impact of unintended knowledge transfer. Considering that too less and too much transfer of unintended knowledge can harm R&D activities of parent company, R&D manager shall evaluate carefully which knowledge shall be transferred from foreign subsidiary to parent company.

For policy-makers, our results may promote a shift in mind set about relevance and issues of R&D globalization. Traditionally, the developed economies such as Western countries have concerned that R&D offshoring could lead to "hollowing out" of their

competitiveness (OECD, 1999; Driffield et al., 2016). Our findings imply, however, that R&D globalization does not necessarily erode the competitive advantage of the R&D capabilities in the home countries. Instead, with the appropriate management of knowledge resources and the relevant complementary assets, firms that engage in global R&D activities could bring higher productivity and growth benefits to their home economies.

5 Conclusions

Building on the theoretical ideas of “meta-national” and “knowledge-based” perspectives, we investigated the impact of knowledge transfer from foreign subsidiaries to parent company on the latter’s R&D activities. Our study adds value to existing studies on reverse knowledge transfer by focusing on issues erstwhile un-addressed: the types of knowledge and the patterns of knowledge transfer from subsidiaries to parent company.

Reverse knowledge transfer from foreign subsidiary can be beneficial to their parent company’s R&D activities, but the effect is different depending on the type of knowledge. Our study revealed that the transfer of tacit technological knowledge as well as market-related knowledge have significant positive impacts on the parents’ R&D activities. Also, the degree of unintended knowledge transfer from subsidiaries renders a positive impact on the parent’s R&D activities up to a certain point, beyond which it becomes negative.

To the best of our knowledge, this is the first study to explore the impact of such unintended knowledge transfer using empirical data, contributing to an area that is important but insufficiently studied in the current literature.

Abstract

In the shift toward Servitization, the adoption of a Product Service System is a key element in ensuring competitiveness of firms. Nevertheless, an increasing attention must be put on Product Service Systems design, especially on the design of product and service components, together with the effective design of their interaction as a system.

The aim of this study is deepening the interrelationships between the adoption of Open Innovation practices and product-service design. The research involves a stratified sample of 9 companies adopting different categories and degrees of Product Service Systems. The research protocol was built in order to investigate the adoption of Open Innovation practices distinguished in inbound, outbound and coupled practices, with the aim of understanding if there are particular (set of) practices adopted within contexts characterized by different degrees of product-service design relevance. Analysis of results allowed to formulate three different theoretical propositions, linking the relevance and characteristics of Open Innovation practices to certain context of Product Service System adoption.

Keywords – Product Service System Design, Servitization, PSS Tactics, Case study.

Paper type – Academic Research Paper

1 Introduction

Business strategies focused on Product Service System (PSS) directly imply a redesign of the company's value proposition. In this context, PSS design of product-service relationship is a key topic; indeed, PSS can reach its potential only if designed and implemented by a series of firms constituting a focused network (Mont, 2002).

Understanding successful (and unsuccessful) elements in product-service innovation when designing a PSS is a key aspect for research on the topic as the main interest of academia and practitioners is no longer centred on the product sold and its characteristics, but rather on providing solutions (Geng et al., 2010; Song and Sakao, 2016). In their literature review, Reim et al. (2015) found that “scholars tend to discuss PSS business models and implications for implementation using five distinct sets of tactics” (p. 6). These tactical areas involve choices at an operational level for firms, following the decision of adopting a specific business model, and they refer to: *contracts, marketing, network, product and service design, sustainability*. Therefore, the choice of a particular business model will influence the set of available tactics and their importance, according to the context. Among the tactical areas identified, Product/service design plays a relevant role for what concerns Functionality and Customization.

Open Innovation (OI) is “the use of purposive inflows and outflows of knowledge to accelerate internal innovation and to expand the markets for external use of innovation, respectively” (Chesbrough et al., 2006). Another important strategy to ensure an effective design of PSS is adopting Open Innovation practices: in fact, the adoption of a perspective focused on OI, involving also the network related to PSSs' providers, allows to reach a wider all-encompassing perspective of the new value proposition.

The research paradigm of OI attracted through years a considerable number of contributions, even from different research fields (Gassman, 2006), involving other topics and dimensions of research such as strategy and leadership. Because of this growth, the topic caused a proliferation of theoretical studies and literature reviews (Elmquist et al., 2009; Huinzig, 2011; Kovacs et al., 2015): however, despite rising numbers of contributions, little has been done to investigate effective implementation of OI in companies (Huinzig, 2011).

Although the adoption of OI practices is a wide phenomenon in many different companies and contexts (Huinzig, 2011), scholars agree upon the existence of difficulties related to their systematic and shared implementation in the organizational context, mainly because of cultural barriers and resistance to change. (Gassman, 2006; Giannopoulou et al., 2011; Chesbrough and Brunswick, 2014).

When considering the adoption of OI practices for a meaningful exploitation of knowledge flows (inside and outside firms' boundaries), managers must take on new decisions related to time, modes, partners, and aims of cooperation (Huinzig, 2011).

2 Research aim and methodology

This work investigates the practices implemented by firms adopting PSS-related Business Models with a focus on collaborative innovation processes. The main research question is:

RQ. How do firms implement OI practices for product-service design?

The aim is conducting a holistic and contextualized investigation on the practical implementation of OI in PSS contexts, so the research is a multiple case study (Yin, 1984; Eisenhardt, 1989) that involved 9 firms and their PSS design processes and practices. Companies are dimensionally different, operates in diverse industries and can be classified in different categories and types of PSS, i.e. Product-Oriented, Use-Oriented and Result-Oriented (Tukker, 2004). These characteristics allowed us to deepen the analysis and to perform a better comparison.

We collected data through semi-structured interviews with a manager (or an equivalent role) in each of the involved companies. After a first set of questions focused on the description/classification of PSS offering (Reim et al., 2015), the interview aimed at understanding the implementation process of the considered PSS cases. First of all, we checked with interviewees for the presence or absence of OI practices according to a list derived from previous works in related literature (Van de Vraende et al., 2009; Battistella et al., 2017); then, we asked interviewees to measure the relevance of tactics connected to product-service design assigning a score (ranging from 1 to 5).

Finally, moving from both literature streams on OI and PSS, we derived a framework for the analysis of PSS design and innovation, matching it with OI practices, as emerging from the interviews.

Selection criteria brought to a stratified sample of firms, whose main characteristics are summarized in Table 1.

Table 1 Sample of selected PSSs

<i>Firm</i>	<i>Country</i>	<i>Industry</i>	<i>Net sales</i>	<i>Size</i>	<i>Contact</i>
PO_1	Netherland	Communications	NA	SME	Financial Manager
PO_2	Sweden	Household appliances	€ 12.92 bln	MNC	R&D Manager
PO_3	Japan	Material handling	€ 1.8 bln	MNC	Manager of After-sale services
UO_1	U.S.	Advertisement	€ 742 mln	MNC	Director of Bik sharing division
UO_2	Italy	Mobility	NA	SME	Fleet Manager
UO_3	Italy	Coworking spaces	NA	SME	Vice Director
RO_1	U.S.	Textile	€ 215 mln	MNC	Vice President of Product and Innovation Department
RO_2	Swiss	Engineering	€ 1.9 bln	MNC	IoT Manager
RO_3	U.S.	ICT	€ 5 bln	MNC	Business Development Manager

Firms in the sample are quite well differentiated according to net sales (from few millions to more than 10 billions), dimensions (3 SME and 6 MNC), industry and country.

3 Theoretical framework of analysis

3.1 OI Practices

Practices of OI have been the main object of analysis for this research. As reported above, they are related to how companies implement OI process: they include all activities and approaches (how these activities are conducted) that companies define, adopt, and deploy, to implement OI (Chesbrough and Crowther, 2006; van de Vrande et al., 2009) into innovation projects/efforts. Consequently, firms adopting more practices proved to be more open in the innovation process (Burcharth et al., 2014): nevertheless, implementation of OI practices and the “degree of openness” varies according to various factors, like specific contexts and strategies pursued by organizations.

According to literature (Battistella et al., 2017), different concepts have been developed to describe how companies put in practice OI: organisational modes (Bianchi et al., 2011), activities (Chesbrough and Brunswicker, 2014; Wynarczyk et al., 2013), methods (de Backer, 2008), and actions (Greco et al., 2015). According to Battistella et al. (2017), practices have been categorised according to three core process models of OI (Chesbrough and Crowther, 2006; West et al., 2014): “(1) outside-in process or Inbound Open Innovation, e.g. crowdsourcing, which allows to source and acquire expertise from the crowd; (2) inside-out process or Outbound Open Innovation, e.g. venturing that aims to create new ventures to sell company’s ideas and resources in the marketplace; and (3) coupled process or coupled Open Innovation, which combines knowledge inflows and outflows between actors such as in building R&D collaborations for joint innovation and exploitation.” (Battistella et al., 2017, p. 7) Table 2 summarizes all the practices retrieved from literature.

Table 2 Open Innovation practices derived from literature

<i>Practice</i>	<i>Definition</i>
<i>Inbound OI</i>	
Contracting with external R&D service / activity providers	Outsourcing / Purchasing R&D services / activities, both technical and scientific, from specialised providers
Crowdsourcing	The act of outsourcing a task in the problem solving process to an undefined crowd, in the form of an open call (Afuah and Tucci 2012), with the aim of obtaining new o reviewed ideas, services or content

External networking	It includes all activities used to acquire and maintain connections with external sources of new knowledge, both individuals and organisations, through both formal contractual collaborations and more general and informal activities
IP in-licensing / inward licensing of IP	Acquiring licenses and then access to external intellectual property rights (e.g., trademarks, patents, copyrights, etc.) via formal licensing agreements
Mass Customisation	“Production of products which have been customised by the customer, at production costs similar to those of mass-produced products”
Mergers and acquisitions	Operations that aim to absorb knowledge and external technology with faster establishment in new markets, while reducing costs and increasing the possibility of releases
Publicly funded R&D consortia	Participation in R&D consortia with other public or private organisations in which R&D activities are fully or partly funded by governmental organisations
Scouting / Searching for / Collecting information from external sources	In this practice are included for example searching internet for new trends or technology, reading technical magazines, collecting information from other organisations
Specialised services from OI intermediaries	Contracting services of intermediary organisations specialised in open innovation to act as intermediaries between a “searcher” – an organisation with an open innovation problem – and “solvers”
Innovation awards and competitions	Invitation to participate in an innovation context where submitting innovative ideas
University research grants	Funding of external research projects by researchers and scientists in universities to access external knowledge
User innovation	Following the theory by von Hippel (1986, 1988) the majority of new products and services are co-developed, or at least refined, by the end user
<i>Outbound OI</i>	
Commercialising / selling technologies	Sale of a market-ready novel product idea to a third party that facilitates the transfer of certain technology / knowledge through a network of contacts
Corporate venture capital or incubators	Offering supportive environments for entrepreneurs in order to develop potentially profitable ideas and to identify novel paths to exploiting technology
Donations to commons or non-profits	Donations to commons or non-profits (e.g., open-source communities) or making patents available for free, in order to support external R&D
IP out-licensing and patent selling / outward licensing of IP	Selling licenses for internal intellectual property rights (e.g., trademarks, patents, copyrights, etc.) to external organisations via formal licensing agreements or via single payment
Minority equity investments	Equity investments, e.g. in university spin-offs or in venture capital investment funds, to develop new projects (or companies) based on ideas originating within the company
Participation in public standardisation	Participation in standardisation activities via formal standardisation agencies (e.g., ISO) or informal standardisation consortia (e.g., OASIS)
Supplying R&D services / activities	Providing / Supplying R&D services / activities, both technical and scientific. It also includes making companies’ own innovations available to others (also for free) and actively participating in other's innovation projects
Venturing (Spin-offs and Spin-outs)	Starting up new ventures founded by company’s employees outside organisational boundaries, drawing on internal knowledge and allowing the exploration of new business to commercialise innovations not used internally, while minimising the negative impacts of entering in for the parent company

Coupled OI

Dyadic / joint co-creation / co-development	Involvement / Integration of one or multiple external innovation creators in a phase of the innovation process (i.e. generation, evaluation, development and/or testing of innovative ideas, products or services)
Joint ventures	Investing in independent joint ventures jointly with external partners, where risks and rewards are negotiated and shared formally
R&D collaborations and strategic / technology alliances / consortia	Cooperation (without equity involvement) between non-competing companies with the aim of pursuing a common innovative objective

3.2 PSS Tactics

In their literature review Reim *et al.* (2015) found that “scholars tend to discuss PSS business models and implications for implementation using five distinct sets of tactics.” (p. 6) These tactical areas involve choices at an operational level for firms, following the decision of adopting a specific business model. Following, the choice of a particular business model will influence the set of available tactics and their importance, according to the context.

Five tactical areas summarize all the key aspects of PSS business models: *contracts*, *marketing*, *network*, *product and service design*, and *sustainability*. For the purposes of our study, we selected only the tactics from the area of *product and service design*.

Table 3 summarizes the two selected tactics and their characteristics for the three different categories of PSS.

Table 3 Product and service design tactics derived from literature

		<i>Product Service System</i>		
		<i>Product-Oriented</i>	<i>Use-Oriented</i>	<i>Result-Oriented</i>
<i>Product and service design</i>	Functionality	<ul style="list-style-type: none"> • Easy to maintain • Easy to reuse • Improved reliability 	<ul style="list-style-type: none"> • Easy to maintain • Increased durability • Easy upgrading and remanufacturing • Reliable service provision 	<ul style="list-style-type: none"> • Significantly large opportunities • High flexibility
	Customisation	<ul style="list-style-type: none"> • Very limited 	<ul style="list-style-type: none"> • Some customization for large customers 	<ul style="list-style-type: none"> • High degree of customization

Source: Reim *et al.*, 2015.

Following, to each tactic was assigned a score from 1 to 4 representing its relevance in the cases considered.

4 Results of the analysis and discussion

The sample of 9 cases has been analysed in accordance with the framework presented in the previous section. Table 4 below summarizes results emerged from the analysis of cases, with OI practices retrieved together with relevant tactics for product and service design.

Table 4 Results of the analysis

		<i>Product-Oriented</i>			<i>Use-Oriented</i>			<i>Result-Oriented</i>

	Functionality	3	1	1	3	3	4	2	3
	Customization	4	1	1	1	1	2	2	3

What immediately emerges is that there is a weak adoption of outbound practices, which is mainly due to the importance of Intellectual Property (IP) in PSSs: indeed, this is what ensures a competitive advantage for firms focusing on a mixed offering of products and services.

Maintaining control (as far as possible) over IP is a key aspect for firms to secure their position over competitors: this is the case for example of car-sharing BM, where the technology implemented (linked to cars' functionality and ease of rent for customers) plays an important role for the success of the overall offering.

The only cases of firms commercialising technology are PO_2 and PO_3, but this is connected to the specific choice of companies of outsourcing all maintenance services to external partners: we can therefore state that in this case outbound practices give a non-negligible contribution to the adoption of the considered PSSs, but since there is no great relevance of *Functionality* and *Customization*, no inference can be made upon the adoption of these OI practices. Furthermore, the only other practices founded in those cases are connected to the provision of external activities and external networking, and are related again to the need of providing maintenance services.

The great majority of cases adopt coupled practices of OI, and both practices named "Joint co-creation/co-development" and "R&D collaborations and strategic alliances" are always recurring in pair. Only in PO_2, PO_3 and RO_3 these practices are not implemented, because in those cases PSS offering is almost entirely based on technologies internally developed, and firms operate in stable markets. Furthermore, these cases are showing the lowest degrees of importance for tactics related to Product and Service design.

Inbound practices are those mostly adopted, with Use-Oriented category presenting the highest number of practices involved. The "External networking" practice has been adopted by all companies involved in this study, and this allows to state that networking surely plays a key role in PSS adoption, even if with different extents. Considering that the Use-Oriented category is the one with the highest relevance of tactics linked to Product and Service design, we can therefore state that:

Proposition_1: the adoption of Open Innovation practices is particularly relevant in Product and Service design for Use-Oriented PSSs.

In Product-Oriented cases only the first company (PO_1) adopts a variety of practices, and is the only case implementing “Mass customization” and “User innovation”: the firm offers a new modular and fair smartphone, with a high degree of innovation, as demonstrated also by the highest scores in “Extent of innovation”, “Functionality” and “Customization” tactics. By comparing this evidence to the other two PO cases (with the lowest scores in the above tactics), we can see how the innovation potential of the offering and its “disruptive nature” highly influence the adoption of “invasive” OI practices, like for instance “Mass customization” and “User innovation”.

A similar result can be observed also for UO_3 case, where the firm’s offering is focused toward the provision of coworking spaces and is linked to the adoption of “User innovation” practice: this case presents the second-highest score for the tactics cited above, confirming what stated in the case of PO category, and allowing for a generalization of the results.

Since the cases presented above present the highest scores attributed to the tactics for Product and Service design, it is possible to make an inference on the relationship between the innovativeness of the offering and the adoption of OI practices, according to the following:

Proposition_2: the degree of innovativeness of the offering is a key determinant for the adoption of Open Innovation practices, and is closely linked to a higher degree of customer involvement in the design process.

UO_1 and UO_2 are the only cases where “R&D consortia” practice was retrieved: this is linked to the difficulties that a single firm faces when developing sharing-based BM, i.e. bike sharing (UO_1) and car sharing (UO_2). Some particular business models require a wide variety of competences and contributions to be effectively implemented, and it is crucial for firms understanding under which modes and conditions there can be a win-win cooperation with partners, in order to deliver the best offering and being competitive in markets that present a high degree of uncertainty and risk. This statement is supported also by the adoption of “Inward licensing of IP”, giving another evidence of how crucial is cooperation with partners in some PSS cases. According to this finding, we can derive a third proposition:

Proposition_3: cooperation with commercial partners through Open Innovation practices is a key requirement for the successfully delivering offerings based on the “sharing” formula.

Result-Oriented cases do not present particular trends nor specific and different practices: all three adopted both “Contracting with external R&D/activities providers” and “External networking”, proving that (as already stated) cooperating with peers and suppliers is a key element when providing solutions to customers instead of “stand-alone” products. RO_2 case is one of the few cases inwardly licensing IP: this is a case of an IoT solution in B2B market, an offering characterised by high innovative content, as proved by tactics related to this aspect.

5 Conclusions

Data gathered allowed us to conduct comparisons between the involved cases, and the performed analysis brought to the identification of interesting findings, which shed light of interrelationships between PSS adoption and OI practices implementation.

An interesting result emerging from the analyses performed is that there is no adoption (except few examples) of outbound OI practices in PSS-related BM, with the exclusive adoption of inbound and coupled practices, mainly concerning network and alliances constitution.

Another important result emerged is about a correlation (according to cases) between the innovative potential of PSS, depending on specific offering's characteristics, and a tendency toward openness and adoption of OI practices. Indeed, cases like PO_1 (modular smartphone) and UO_3 (coworking spaces), found out to be the more concerned toward OI and chances it offers, for example by involving customers and adopting mass customization solutions.

Furthermore, also cooperation with partners proved to be a key element when developing sharing-based offerings (e.g. bike-sharing and car-sharing).

Linking the two concepts of OI and PSS is important because it helps in understanding how PSS adoption and implementation can benefit from the employment of OI practises, according to different organizational forms and offerings.

Many studies focused on different aspects of OI, offering useful insights and proposing frameworks to support decision making: this work sets out a contribution for managerial and research implications by giving more detailed insights on how to deploy which open innovation practice. This research opens up a series of new and useful research directions for scholars, and a series of considerations for practitioners, linked to an effective exploitation of OI practices in the specific context of PSS.

Abstract

Knowledge translation activated by knowledge-intensive organizations is supported by several factors among which intangibles assets. This paper aims at analysing knowledge translation and organisational performance in the football industry, discovering both the role of professional football players' skills transfer and determinants helping to achieve positive performance at organizational level.

The research question is answered through a quantitative method using both the multiple regression analysis and the network analysis. This research investigates the performance of the professional football players before and after the transfer process from a club (source organization) to another club (recipient organization) in order to analyse the intra-organizations dynamics.

We try to understand which factors are helping knowledge and specialist knowledge to be transferred and to contribute to the successful run of organisations in the football industry.

We show the need for the coexistence of variables' combinations to achieve the transferability of professional football players' capabilities and performance.

The results of this paper are for academic community, practitioners and policy makers as theoretical and practical advances.

Keywords: knowledge translation, drivers, performance, intangibles, football industry.

1 Introduction

Knowledge transfer processes and knowledge-intensive organizations are investigated under several perspectives (Argote et al., 2000; Lombardi, 2019; Secundo et al., 2019). In this scenario, the knowledge flows activated by several actors become a key issue analysing the interplay internal-external organizations context, recognizing phases and forms of knowledge translation (Graham et al., 2006; Seaton, 2002). Knowledge translation activated by knowledge-intensive organizations is supported by several factors (Krylova et al., 2016; Lönnqvist, Laihonen, 2017) among which intangibles assets (Wiig, 1997). In the football industry, intangibles assets also recognized as intellectual capital (IC) and it assume several forms: players, brands, taking part in specific competitions, information and communication technology (Trequattrini et al., 2017), along with improvements to business processes affecting performance and competitiveness. Thus, the impact of knowledge translation and the identification of factors fostering knowledge transferring supports the successful run of contemporary organisations in all economic sectors.

In this direction, our research investigates the relationship between knowledge owned by human resources belonging to source organizations and its translation processes towards recipient organizations. Thus, this paper aims at analysing knowledge translation and organisational performance (Lombardi, 2019; Trequattrini et al., 2018) in the football industry, discovering both the role of professional football players' skills transfer and determinants helping to achieve positive performance at organizational level. This research is directed to discover factors of intra-organizations (professional football clubs) dynamics in the knowledge translation processes. Thus, we investigate how professional football players incorporate specialist knowledge during a staying period in a club (source organizations) and consequently how it is translated into the new club (recipient organizations) when professional football players are transferred.

The research question is answered through a quantitative method (Anderson et al., 2012; Bell et al., 2018) using both the multiple regression analysis and the network analysis (Carrington et al., 2005). Particularly, data are collected from professional websites and analysed through two phases. In the first phase, we identify our sample. In the second phase, we identify the professional football club performance before and after the players' transfer using the framework by Nakauchi et al. (2017). We understand which factors are helping knowledge and specialist knowledge to be translated and to contribute to the successful run of knowledge-intensive organisations in the football industry. Results of our analysis serves all economic sectors and are directed to academic and practical communities as well as to policy makers as theoretical and practical advances.

The remainder of the paper is organised as follows: Sections 2 and 3 examines literature. Section 4 presents the research methodology. Section 5 presents primary evidence, discussion and conclusions.

2 Knowledge Transfer and Knowledge Translation

Scholars investigate knowledge transfer intra and inter organizations (Argote, Guo, 2016; Chen et al., 2014; Gil, Carrillo, 2016; Jones, Mahon, 2018; Lombardi, 2019; Secundo et al., 2019) owing to its impact on organizational performance and business processes. Argote and Ingram (2000) stated that “Knowledge transfer in organizations is the process through which one unit (e.g., group, department, or division) is affected by the experience of another.”. Thus, knowledge transformation assumes several forms fostering replication and adaptation (Williams, 2007), becoming knowledge translation (Simeone et al. 2017).

Although knowledge is transferred among actors in several ways among which social practices (von Krogh, 2012), tacit vs explicit (Nonaka, Takeuchi, 1995), the knowledge flows is intended as the interplay internal-external organizations context, recognizing knowledge translation (Graham et al., 2006; Seaton, 2002). Simeone et al. (2017) asserted that knowledge translation “involves processing new knowledge, interpreting it according to the needs and interests of a specific organization and transforming it into forms that are more suitable for the specific organizational context of application”. Albino et al. (1998) argued that the knowledge transfer’s objective among individuals or organizations allow them to acquire new knowledge.

Additionally, Lombardi (2019) argued “The current knowledge economy highlights the relevance of understanding if knowledge is transferable as well as which are variables influencing organizational performance in all types of companies including start-ups companies requiring new forms of financial funds (Lombardi et al., 2016). Thus, KT into the organization and business processes is relevant to achieve high performance, innovation processes and competitive advantages.”. Thus, the understanding of factors or variables influencing KT is a key issue. For example, Milagres and Burcharth (2019) analyse KT in inter-organizational partnership, proposing main factors influencing KT among which macro-environmental (e.g. industrial policy, intellectual property regime), inter-organizational (e.g. synergy-seeking motives), organizational (e.g. capabilities, intangible resources, behavioural aspects and internal processes) and individual levels (e.g. motivation, emotions, learning behaviour). Thus, KT is investigated also in the measurement perspective among which the KT Curve exists (De Luca, Cano Rubio, 2019).

3 The role of human resources in knowledge-intensive organizations

In the knowledge economy (Powell, Snellman, 2004; Sullivan, 2000), the business management is increasingly concerned with intangible resources as fundamental assets increasing the total value of organisations in the long-term (Lombardi et al., 2016; Teece, Pisano, 1998). Knowledge is an intangible asset and it represents a resource capable of generating new knowledge (Stewart, Ruckdeschel, 1998). Thus, the process of knowledge creation and knowledge transfer inter and intra organisations have been covered by several studies (Ajith Kumar et al., 2009; Alipour et al., 2011; Guechtouli et al., 2012).

Knowledge transfer is a complex topic concerned with the organisation, creation, capture and distribution of knowledge, ensuring that it is available for future users (Lee, 2010).

In this direction, many scholars (Jacob, 2014; Lundvall, Rodrigues, 2002) examine knowledge and the strategic role of human capital (HC). HC represents a relevant determinant of corporate competitive advantage (Becker, 1964; Lev, Schwartz, 1971; Lombardi, Dumay, 2017; Nonaka, 1994) and it involves the set of abilities, capacities and knowledge owned by human resources within the organisation. Thus, the most successful companies manage human resources efficiently, providing incentives to invest in the skills' development.

Knowledge-intensive organizations base their activities on the interaction of intangible components (Aureli et al., 2019; Nikitina, Lapina, 2019). Thus, human resource management becomes a business strategy because competitive advantage is built on the ability and talent of a company's most productive staff (Becker, 1964). According to Becker (1964), a clear distinction between two types of human capital exists: general skills and firm-specific skills. Human resource general skills refer to abilities and expertise applied in very differentiated contexts, as they are highly flexible and adaptable. Human capital skills (firm-specific) refer to specific distinctive skills having an exclusive value related to the environment in which they were generated.

Thus, human resources are investigated in the light of their skills becoming knowledge workers (Blair and Kochan, 2002; Drucker, 1998; Tapscott, 1996; Blackler, 1995; Williamson, 1979). Groysberg (2012) states that HC (general type) can easily be transferred from one setting to another, while firm-specific human capital will only ever be productive in the environment in which it was formed. However, knowledge workers' skills used in to organizations allows identifying great talent workers called "stars workers" (Marshall, 1920; Rosen, 1983; Simonton, 1999). Thus, stars workers performance is transferable from one organisation to another (Groysberg, 2012).

Human resources are also recognized as "a source of competitive advantage in that it is competitively unique and makes a contribution to value and or cost. But whereas all core competencies are sources of competitive advantage, not all competitive advantages are core competencies" (Hamel, 1994, p.18). Companies, in order to safeguard a stable and lasting competitive advantage must counter the growing dynamism that characterizes the social, economic and political context. Therefore, the need to develop dynamic capabilities (Teece, 2007) or the ability to integrate, build and reconfigure internal and external resources and skills in response to rapid environmental changes is found.

Highly specific resources within the organisations cannot be transferred because they lose part of their value if used in a different context from the one in which they were created and accumulated (Dierickx, Cool, 1989). Therefore, if workers' skills can be easily transferred from one organisation to another organization, they are not a source of competitive advantage, since the consequence would be that individuals could leave their organisation at any moment and so deprive it of its acquired competitive advantage. With the emergence of the *War for Talent* (Florida, 2006; Groysberg, 2012), companies no longer make do with "second league players" and are busy attracting talented people with incentives such as paying them very high salaries. Modern organisations invest

considerable effort and resources into the process of recruiting, developing and retaining the most talented people, those with key skills, to contribute most in achieving high levels of performance (Tarique, Schuler, 2010).

4 Methodology

We use a quantitative methodology (Anderson et al., 2012) based on the multiple regression analysis and the network analysis (Carrington et al., 2005) to answer our research question as follow:

RQ1: What are factors of knowledge translation contributing to the successful performance of knowledge-intensive organisations?.

We define the football industry as the sector in which we conduct the analysis. Particularly, data are collected from the professional websites. Using the multiple regression analysis, the first phase of this research is directed to compose our sample selecting the football players that were moved in a new club in three seasons. In the second phase, the professional football club performance is identified before and after the player's transfer, to analyse performance's similarities and differences between inter-groups (professional football clubs). Additionally, this research investigates the performance of the professional football player before and after the transfer from a club to another club in order to analyse the intra-group dynamics.

Lastly, we use the framework by Nakauchi et al. (2017) to identify factors influencing the transferability of professional football players' capabilities and performance. This framework was chosen because it specifically focuses on the understanding of knowledge flows. The authors uses "five key aspects of KT within an organization: the knowledge itself, the knowledge recipient, the knowledge source, the relationship between the recipient and the source, and the structure of the network." (Nakauchi et al., 2017).

3.1 Research context, sample, data collection and analysis

The football industry is an entertainment sectors (Beech, Chadwick, 2004; Söderman, Dolles, 2013). In Italy, the football industry represents the main sport with 32 millions euros of fans and 4 millions euros of sport players (Report Calcio, 2018). Italian professional football contributes around 7% to the GDP and it is directed to produce goods and services for society. Thus, professional football clubs are assimilated to cultural enterprises and they are knowledge-intensive organizations (Aureli et al., 2019; Trequattrini et al., 2017) supported by the intangibles interactions.

To compose our sample we selected the population of professional football clubs participating to the "Big Five" Leagues (Report Calcio, 2018) in the European scenario, choosing all strikers transferred during one season. We selected strikers participating to at least 50% of European Leagues' matches, retrieving the market value of two seasons. Additionally, we assumed related data for each striker useful to conduct the analysis. Thus, our sample is composed of around 3-4% of professional football players from selected clubs in the European scenario.

In this way, we applied the multiple regression analysis and the network analysis to our sample to investigate the knowledge translation phenomenon. Using the multiple regression method, we investigated the transferring process of professional football players through: i) Output Variable. We defined this variable as the difference between professional football players' performance before and after their transferring; ii) Input Variable. We defined this variable through the variables by Nakauchi et al. (2017) framework. Additionally, we're going to use the network analysis applied to data of our sample in the third phase of our research.

5 Primary evidence, discussion and conclusions

Using the Nakauchi et al. (2017) framework, this paper is based on the quantitative approach to understand factors affecting the transferability of professional football players' capabilities and performance. Particularly, we answer the question: "*RQ1: What are factors of knowledge translation contributing to the successful performance of knowledge-intensive organisations?*".

Through primary evidence of our quantitative analysis, we firstly assume that there are not positive correlations data. Thus, the KT of professional football players is not confirmed. Such results mainly depend from the context in which players are working. In fact, professional football companies are systems producing goods and services for society. Their resources have to be combined efficiently to achieve fixed objectives.

Thus, professional football clubs are entertainment companies identified also as knowledge-intensive organizations (Aureli et al., 2019; Trequattrini *et al.*, 2017) based on the intangible assets interaction (players, brands, taking part in specific competitions, information and communication technology). Professional football clubs have a high roles specialization and they need of high flexibility and auto-coordination in the several phases of matches.

Thus, organizational model of professional football clubs is similar to small and medium enterprises (SMEs) ones in which several requirements exists. Particularly, they need qualified human resources (Becker, 1964; Lev, Schwartz, 1971; Lombardi, Dumay, 2017; Nonaka, 1994), advanced and specific competences, human resources able to cover several rules in the light of small dimensions and the activity's interdependence. Hence, interaction among intangibles resources in the professional football clubs justifies the influence of activities and results of a player on the team performance. In this perspective, team performance and player performance depend from the ability of the team members (all players) to assume well-organized and coordinated working behaviours.

The results of the analysis provide both theoretical and practical contributions to the existing literature (Argote, Guo, 2016; Chen et al., 2014; Gil, Carrillo, 2016; Jones, Mahon, 2018; Lombardi, 2019; Nakauki et al., 2017; Simeone et al. 2017). Interestingly, our results can be used academic community, practitioners and policy makers as practical advances supporting the knowledge translation theories. The limitations of our paper derive from the analysis of only the striker figure among the football players' roles.

Future research is directed to complete the analysis and to investigate and compare more football seasons and different champions all over the world.

Abstract

Recent technological advancements have induced significant changes in the whole society, and thus in workplaces and lifestyles. A drastic reduction in physical activity has been documented by recent scientific investigations, with consequences on human postural attitudes. It is a fact that, in any given moment of the life, human body has a "posture" can be static (resting) or dynamic (walking). Moreover, when people assume poor postures during the day, their body become more susceptible to injuries (Aartun, 2014). Recent epidemiological data stated that back pain starts early in life and that prevalence rates increased rapidly during adolescence, reaching adult levels around the age of 18 (Jeffries, 2013). Furthermore, several authors considered long retained erroneous positions as a possible cause of postural diseases which do contribute, in their opinion, to the development of pathological forms (Shalavina, 2013).

With this evidence, prevention should have a central role in order to avoid damage and pain in day-to-day life (Cardon, 2004; Calvo-Munoz, 2012), but it is poorly practiced in the majority of countries, even in the Western world. This paper analyses through a holistic approach the effects of knowledge translation (Simeone et al, 2017) adopting new technologies in healthcare system and in particular exploring how the interaction among health complex system's stakeholders in open innovation processes can influence the co-creation value in health lifestyle process. A pilot project has been carried on with the

involvement of 432 people in Apulia Region, including the management of residence for elderly people, physicals, elderly patients and their families and medical professionals. The study analysed previous database on the use of technologies in health care organizations and it brings to light the fact that chronic populations is growing, so the necessity to ward diagnosis of chronic diseases became an important aspect to reduce the costs in the Healthcare assistance.

Keywords – Knowledge transfer, open innovation, design, knowledge translation

Paper type – Academic Research Paper

1 Introduction

The evolution of Information Technologies (IT) opens new scenarios in the healthcare systems: novel technology, such as inertial sensors, smartphone, low-cost video/depth camera, pressure sensors and motion ambient sensors, offer an innovative approach that can efficiently capture, analyse and share movement data and may provide an easy-to-implement fall risk assessment (Mancini et al, 2010; Mukhopadhyay et al, 2015; Kumari et al, 2017). In the last years, a wide range of sensor technologies have been used in fall risk assessment in older adults (Sun et al, 2018), but technology transfer is often a complex process that requires cooperation between organizations and within the various departments of a receiving organization.

In this paper we analyse how new technologies have been implemented strategically to promote knowledge transfer (Seaton, 2002) through a participatory approach, interpreting needs of health organizations and stakeholders and, therefore, contributing to empowerment social change. In this scenario the health care organizations, open, adaptive and collaborative systems, are capable of developing deep partnerships with patients, their families and the community benefits from offered services, improving thus the effectiveness and efficiency of medical care. To achieve this, it is necessary to implement a holistic approach in which patients are active co-creators of knowledge transfer and where they can acquire knowledge from another one (Albino et al, 1998).

A pilot project has been carried on with the involvement of 432 people in Apulia Region, including the management of residence for elderly people, physicals, elderly patients and their families and medical professionals. The study analysed previous database on the use of technologies in health care organizations and it brings to light the fact that chronic populations is growing, so the necessity to ward diagnosis of chronic diseases became an important aspect to reduce the costs in the Healthcare assistance. The empirical investigation focuses on the fact that late life cognitive impairment and physical impairment are leading causes of disability, falls, institutionalization, and death among the elderly (Marengoni et al, 2009). These cognitive and physical impairments in late life are inter-related through shared pathophysiological mechanisms and could probably be manifestations of a single complex phenotype, even if a chronic condition, by itself, is not the only deficit that increases frailty (Panza et al, 2015).

During ageing, falls are the most common cause of injury in the elderly and they are a common, serious, growing public health problem (Kannus et al, 2005). The high incidence, long-term effects, and costs of falls will affect our healthcare system: over the next 20 years, the number of falls and the associated costs are projected to increase substantially (Florence et al, 2018). Consequently, in this research we implement an organizational and technological model that aimed to create the behaviours and perceptions of elder individuals in to health and safety in, developing a new distinctive way of thinking, approaching and solving problems (Buchanan, 2004) among all the stakeholders.

2 Background

During the last years, social innovation ideas have increasingly been considered as a key factor in the Europe Strategy 2020 which does emerge by bench-marking in countries that have faced up this problems with the goal to identify the best practices in the field of health education at school and to evolve them in relation to our interdisciplinary approach. When dealing with studies on health in the educational field, the institutions cannot keep the subjects involved apart and they should be considered as what they actually are: the bonds of a network aiming to semantically and socially strengthen the ties.

As stated by the World Health Organization (WHO), individuals have the right to claim back their own health and they must not delegate responsibility by blindly trust medical advice, because physicians need patients who are fully aware and prepared to tackle the therapies advised. In order to obtain this result, the subjects involved need to understand each other and each one's needs. Full reciprocal understanding can be possible starting from a common language, easily comprehensible by all the subjects involved. For this reason, the research group has decided to adopt a socially innovative strategy (see Fig. 1).

At the core of the concept of social innovation lies the active involvement of citizens into public service delivery. This involvement is often referred to as “co-creation” (Voorberg, 2014). Social innovation and co-creation are “magic concepts” (Pollitt and Hupe, 2011; p. 642), which during the last years have been embraced as new modernization or reform strategies for the public sector. Social innovation implies processes of exploration and implementation of new ideas about how a society deals, as political community, with a number of vital challenges; like the growing ageing of the population, the budgetary crises, the quality of our educational system, or the regeneration of socially and economically deprived cities and regions (Mulgan, 2009).

3 Methods

3.1 Research Approach

The questionnaire was created for exploratory purposes and based on common, non-specialised language. The aim was to measure if the participants are familiar with notions related to correct posture and if they pay attention to the spinal column in everyday contexts (while sitting, standing and working).

3.2 Sample

Forty hundred and thirty-two people in Apulia Region, including the management of residence for elderly people, physicals, elderly patients and their families and medical professionals, have been enrolled for the purpose of the present study.

3.3 Data Analysis

We considered as dichotomous variables the possible answers, assuming good postural behaviours as value 1 and incorrect behaviours as value 0. The higher the score the better was the knowledge on correct postural behaviours. The data on postural behaviours during work and daily activities were reported as mean and standard deviation and they expressed the percentage of mistakes. The educational level and the technology use as categorical variables were reported as percentage. We tested the relationship among the continuous variables and the categorical variables with crosstabs. We finally performed a non parametric test, in particular the Kruskal-Wallis H test, in order to determine if there was statistically significant difference between the level of education (none, high school and university) on the score. All statistical analyses were completed using IBM SPSS version 23 (with the level for statistical significance set at $\alpha = 0.05$).

4 Results

In Table 1 we reported the mean and standard deviation for the variables workBehav, dailyBehav and adultScore which respectively represent the postural behaviours during work and daily activities and the overall score obtained for the questionnaire. The histograms of the three variables showed the distribution of frequency response. The Kolmogorov-Smirnov Test checked for the normal distribution: since all the variables were statistically significant, we rejected the null hypothesis and the variables were not normally distributed.

Table 1 Frequency distribution for continuos variables workBehav, daily Beahav and adultScore

	N	Minimum	Maximum	Mean	Standard Deviation
workBehav	432	,00	1,00	,2617	,27692
dailyBehav	432	,08	,83	,3796	,14152
adultScore	432	2	13	9,08	1,969
Valid Cases (listwise)	432				

Figure 1 Frequency distribution histogram of Descriptive Variables for continuos variables workBehav, daily Beahav and adultScore

The two categorical variables (techUse and eduLevel) were reported in Table 2 and 3 respectively as percentage.

Table 1 TechUse variable as percentage

	Frequency	Percentage	Valid Percentage	Cumulative Percentage
Valid No	94	21,8	21,8	21,8
Yes	338	78,2	78,2	100,0
Totale	432	100,0	100,0	

Table 2 EduLevel variable as percentage

	Frequency	Percentage	Valid Percentage	Cumulative Percentage
Valid None	54	12,5	12,5	12,5
High School	296	68,5	68,5	81,0
University	82	19,0	19,0	100,0
Totale	432	100,0	100,0	

The relationship among the categorical variables and the continuous ones was analysed in terms of crosstabs with chi-squared test.

The results showed that there was a significant association among the educational level (independent variable) and the knowledge on correct postural behaviours at work, daily and overall (dependent variables: workBehav, dailyBehav, adultScore). In addition,

we found a relationship between the use of technology and daily postural behaviours (Figure 2) and between the use of technology and the total score, as showed in Figure 3.

Figure 2 Box plots of dailyBehav and adultScore according to techUse

Finally, the results for the Kruskal Wallis H Test showed that there was a statistically significant difference among the level of education on correct postural behaviours (as reported in Table 4 and 5).

In particular, we observed that high educational level corresponded to higher knowledge and attention, as depicted in Figure 3.

Table 4 Kruskal Wallis H Test

	eduLevel	N	Mean Ranks
workBehav	None	54	224,06
	High School	296	223,10
	University	82	187,70

5 Discussion

The current society is characterised by a great variety of ICT tools, which are rapidly spreading, and they are used for disseminating information and building social ties (Castells, 2004). However, in line with the features of the present age, the consequences of this phenomenon are two-fold (Bauman, 2011): on the one hand, individuals have numerous tools enabling them to acquire a huge amount of just-in-time information and to reach a great number of contacts; on the other hand, the huge amount of information available to them and the efficiency of transmission usually determine a loss in the quality of contents and also affect the uptake of contents themselves, as effective learning requires accurate reasoning, which in turn may be time-consuming.

The speed characterising the network and consumption society plays a crucial role in the selection process, with people tending to select information according to personal mood rather than logical and critical thinking. Similarly, the strengthening of ICT enables users to add contacts to their networks in a faster and more efficient way than ever before: smart phones, iPad, iPod, tablets, computers, internet, instant messaging applications, social network websites, etc., all integrate users into large and thick networks. These tools, though, are spreading up to a point that they tend to prevail direct personal ties, determining a preference for indirect communication.

The speed of information and social exchanges significantly reduces the chances to examine contents and relationships which would be possible, instead, through regular and direct contacts between subjects. As a result, individuals are more informed but at the same time very confused, given the lack of control over the genuineness of information, as well as the lack of spaces for social discussion on the validity of information.

6 The relationship between knowledge and innovation

The Triple Helix of development and innovation shows the correlation between the helices dynamics of “university–industry–government relations” that drives knowledge and innovation in the global knowledge economy and society (Etzkowitz and Loet, 2000). We suggest that advanced knowledge-based economy and advanced democracy have increasingly similar features, in the sense of combining and integrating different knowledge modes and different political modes. The relationship between knowledge and

innovation from our viewpoint it makes sense, not to treat knowledge and innovation as interchangeable concepts.

In this context is born a new paradigm the Quadruple Helix of the development and innovation where the correlation between “media-based and culture-based public” as well as to “civil society”. Knowledge and innovation policies and strategies must acknowledge the important role of the “public” for a successful achieving of goals and objectives. On the one hand, public reality is being constructed and communicated by the media and media system. On the other hand, the public is also influenced by culture and values. Knowledge and innovation policy should be inclined to reflect the dynamics of “media-based democracy,” to draft policy strategies. Particularly when we assume that traditional economic policy gradually (partially) converts into innovation policy, leveraging knowledge for economic performance and thus linking the political system with the economy, then innovation policy should communicate its objectives and rationales, to the public, to seek legitimization (legitimacy) and justification (Colapinto and Colin, 2012).

The PoSE project objective in his evolution reinforce the increase of the people diagnosed with postural disease and improve a new model to provide a support system able to guide the physician decisions, if reached, allows from the social point of view:

1. to increase quality of life of patients and to reduce the much more serious occurrence of diseases related.
2. to contribute to the affordability of health care systems in reducing the costs of complications due to undiagnosed postural disease
3. to reduce the number of accidents, workplace, etc. postural disease and its related direct and indirect social costs.

According to Europe 2020 strategies for growth and job, this study became a novel approach to co-create value in health care system. The methodological approach adopted must be multidimensional and interdisciplinary, with the involvement of medical, epidemiological, engineering, sociological and economic expertise, addressing the complexity of the patient from all viewpoints, not reducing it, yet analyzing, understanding, rearranging and managing it in an organic manner.

This experience follows the HORIZON 2020 strategy - quadruple helix development and innovation, in which the citizen (end-user in our case) plays a crucial role. The study stimulates social innovation by transferring research results from the closed industrial laboratory towards real life contexts where citizens and users become co-developers.

In this scenario we can evaluate the socio-economic perspective. Traditionally economic evaluations involve the identifying, measuring and valuing both the inputs (costs) and outcomes (benefits) of alternative interventions (Pommier, 2010). The inputs and the outcomes included in this study depend on both the questions being addressed and the perspective of the study. For example, in our study, the education sector in a health promotion intervention (PoSE) may be compared to other uses, such as the teachers time for prevention, or the use of alternative equipment in terms of value for life-style. The main steps that will be developed through the project for a balanced socio-economic evaluation will be:

- Life-style of students and families in the school life (input);

- Digital divide of students and families (input);
- Level of education (input).

The focus of these results will be relevant in term of professional training, assessment of new technologies and adaptation of operational procedures for a health promotion intervention, like Postural Education at School.

The objective of this pilot work is thus to disseminate our findings and experiences on how school system should rethink their innovative processes under the requirement of value co-creation. As Hannon emphasized, the needed innovation must arise from the joint work of skilled and creative practitioners, co-creating with their learners, and actively engaging parents and caregivers in order to meet the challenges we face in reshaping schools for the future (Hannon, 2009). Thanks to our program, we enhanced the involvement of citizens in the management of their healthcare process for a new frame of value creation (Fig. 6). We were able to involve school management, physical education teachers, students and their families and medical professionals in an holistic model that aimed to create the behaviors and perceptions of individuals in to health and safety in schools and to conceive the school as a workplace tailored to the needs of the students and teachers.

The preliminary results of this study showed a new competitive space for industrial and social growth. However, in order to compete effectively, managers need to invest in knowledge industry for the new infrastructure capabilities, as well as new functional and governance capabilities that are centered on co-creation through high-quality customer-company interactions and personalized co-creation experiences (Prahalad and Ramaswamy, 2004).

6 Conclusion

The interviews showed the importance of dialogue. If you deal with education, regardless of the target, it is necessary that not only doctors, but the whole social environment of the patient and what is involved with a culture of accountability, communication and attention to itself and to the other.

The challenge we proposed here is certainly difficult, mainly because the sources of health information are too many and in most of the cases in conflict with each other, creating confusion both in medical and educative professionals. However, studies of sociology highlight the fact that the construction of a system of communication exchanges between social actors can create the basis for a common language and positive feedback for effective cooperation.

Abstract

Open innovation is a relevant approach to support the development of established companies as well as startups in the contemporary economy. Entrepreneurs are increasingly using this approach to develop new products, services and processes fostering the rule that collective intelligence wins against the single innovator. Interestingly, public bodies are increasingly supporting the development of open innovation tools to assist companies. Many regions are supporting the development of accelerators to support the development of startups. Thus, open innovation is used both by private firms and public bodies.

In the Region Friuli Venezia Giulia, in the northeast of Italy, the local Government has developed a program to support start-uppers creating specific tools dedicated to helping new entrepreneurs to fine tune their business ideas. The program's name is Imprenderò, and it offers various free educational as well as consulting services to promote the entrepreneurial culture, teach the basics of management, organization, accounting, and business planning, and help start-uppers to define their strategy, and build their investment plan and budget.

This paper employs a mixed method approach, to analyze both quantitative as well as qualitative data coming out from the program. Data are collected during the years 2011-

2012. The study employs a multiple case study approach, using the Culture-Ambience-Organization-Strategy (CAOS) model by Paoloni (2011), to deepen variables that affect the opportunity brought by open innovation approaches, trying to understand also the differences between male and female entrepreneurs.

Interestingly enough, the effectiveness of the program appears to be strongly related to some variables. More precisely: culture and competitive ambiance, as well the organization and strategy decided by the start-uppers influence the effectiveness and efficiency of open innovation tools.

The study is novel and useful for several reasons. First, it allows first to detect variables that influence the likelihood of venture opening, with particular reference to the knowledge transfer to and from start-ups, also considering the gender issue. These results can build within existing literature review on entrepreneurship, as well as knowledge management. Additionally, the case study methodology can gather insights about how entrepreneurs have embraced difficulties in providing managerial suggestions. The overall results might be useful for policymakers to develop concrete actions to support entrepreneurship. Finally, the sample may be considered relevant since the program granted free access to everybody, and therefore covered the all population of the single area analyzed.

Keywords – CAOS model, Strategy, Knowledge Transfer, Open innovation, Start ups

Paper type – Academic Research Paper

1 Introduction

Open innovation is a vital approach to support the development of established companies as well as start-ups in the contemporary economy. Entrepreneurs are increasingly using this approach to develop new products, services and processes fostering the rule that collective intelligence wins against the single innovator (Secundo *et al.*, 2019). According to the literature, the Public Sector should play an active role in supporting and promoting private entrepreneurship, which is considered essential to reach economic growth (Dal Mas, Massaro, *et al.*, 2019; Intarakumnerd and Goto, 2018; Spiegler and Halberstadt, 2018). Interestingly, public bodies are increasingly supporting the development of open innovation tools to help companies as well as the creation of new business ventures. Examples include hackathons among entrepreneurs, public entities and NGO to support tourist development (Marangon *et al.*, 2018); the creation of accelerators to support the development of start-ups (Bagnoli *et al.*, 2018); the organization of dedicated financed entrepreneurship and mentoring programs (Cincera *et al.*, 2018; Price and McMullan, 2012) for instance in Malaysia (Mustapha and Subramaniam, 2016), North America and Europe (Braidford *et al.*, 2013; Dal Mas, Paoloni, *et al.*, 2019; Matulova *et al.*, 2018; Varela-Candamio *et al.*, 2018). Thus, open innovation is used both by private firms and public bodies. Starting from this premise, this study aims to analyse the knowledge transfer to and from companies and start-ups in open innovation initiatives developed by public entities, with a special reference on companies created and run by women.

2 Literature review and research question

The role of both public as well as private sector is considered relevant in supporting the creation of start-ups (Massaro *et al.*, 2018). Entrepreneurship is claimed to be a vital element to stimulate growth and development of any country, and women entrepreneurs play a significant role in the economic development. More in details, according to the literature they can help to stabilize the economy particularly during the periods of economic crisis or recession (Musaazi *et al.*, 2015; Mustapha and Subramaniam, 2016; Ramadani *et al.*, 2015; Roy and Lahiri-Roy R., 2010; Sowmya *et al.*, 2010), as they are often seen as “engine change” (Cohen and Huffman, 2007). Entrepreneurship and its required hard as well as soft skills have been included in several academic curricula (Lans *et al.*, 2014; Massaro *et al.*, 2014), this means that several countries across all continents have emphasized and promoted entrepreneurship to support their economies (Mustapha and Subramaniam, 2016).

Open innovation approaches have been used to foster the stimulation of new business ideas, the networking among potential entrepreneurs, startupper, existing organizations, and public entities, thus helping the creation of new business ventures, especially in complex environments (Bagnoli *et al.*, 2019; Marangon *et al.*, 2018).

In open innovation approaches, knowledge transfer from and to startupper, existing companies, universities and research centers, ... has been considered as a vital element to ensure the success of the open innovation initiative (Secundo *et al.*, 2017, 2019).

Considering the relevance of open innovation in fostering the creation of new business ventures, and the importance of the knowledge transfer process, our research question is:

RQ: *how does the knowledge transfer to and from companies and start-ups work in open innovation initiatives developed by public entities, with a special reference on companies created and run by women?*

To do so, we gather both qualitative and quantitative data from a programme run in the Region Friuli Venezia Giulia, Italy, financed by the local government and the European Social Fund in 2011-2012, to foster the creation of new business ventures.

3 Research context

We gathered data for our study in the Region Friuli Venezia Giulia of Italy, in the years 2011-2012. Those years were critical for existing companies as well as for new business ventures, with a particular emphasis for companies run by women. In 2010, the public registry enrolled 133 thousand new companies with employees, with 1.700 fewer units than in 2009. Most of the new ventures were classified as individual firms, with 71% driven by male entrepreneurs, and only the remaining 29% by women. Female ventures were mainly about commercial activities (almost 40% of the total) and other services (over 33%) (ISTAT, 2012). In Friuli Venezia Giulia, the situation was in line with the national picture. The number of start-ups decreased radically in the period 2007-2011, with the only exception of 2010 (Unioncamere Friuli Venezia Giulia, 2012), with

28% run by women. Fields with significant female involvement were personal care services (50%), hospitality and food (45%) and agriculture (33%).

4 Methodology

Our research uses a mixed method approach. More precisely we carry on our analysis using an explanatory sequential method, that start with a quantitative study and then conduct qualitative research to deeper explain the quantitative results (Creswell, 2014).

4.1 Quantitative data collection

The first step relates to the quantitative analysis. We analysed structured data collected from a program called “Imprenderò.” The project offered to potential start-uppers free workshops, courses, mentoring, as well as consultancies, to define their business ideas and develop their business plans. The program aimed also to keep connected entrepreneurs-to-be together with various entities: existing companies, public bodies, universities and incubators. The project is considered relevant since it was developed in Italy during the crisis by a public organization (the Region Friuli Venezia Giulia) to foster entrepreneurial activities, as recommended by the literature to promote entrepreneurship and keep various stakeholders connected.

We analysed 418 fully developed business plans, and we followed up the participants with a phone interview to get detailed information about the participant and the eventual opening of the initiative.

We gathered data about the opening of the initiative, the previous working condition of the potential entrepreneur (in terms of employment condition and experience in the same sector) and the complexity of the initiative (measured by the forecast investments and the number of required employees).

4.2 Qualitative data collection

After gathering the quantitative data, we analysed some case studies (Yin, 2009) using a revised version of the CAOS model of micro entrepreneurship by Paoloni (Dal Mas, Paoloni, *et al.*, 2019; Demartini and Paoloni, 2013; Paoloni, 2011; Paoloni and Demartini, 2012; Paoloni and Dumay, 2015), to understand the knowledge transfer to and from the various dimensions of the model: the factor C (about the characteristics of the entrepreneur), the factor A (about the ambience where the company operates), the factor O (the organizational and managerial aspects), and the factor S (the strategy conceived by the organization).

We decided to use the framework of the CAOS model because it allows to map the characteristics of the entrepreneur, of the managerial organization, as well of the external competitive environment.

The following figure shows the CAOS rectangle in its revised version.

Figure 1. The CAOS Rectangle

Personal characteristics of the entrepreneur (C)	The ambience/environment in which the micro-enterprise operates (A)
Organizational and managerial aspects (O)	Strategy (S)

5 Results and Discussion

5.1 Quantitative data

The results of the Imprenderò program show that 61% of the people involved started their businesses. 196 business plans were developed by women (46%), and only 73 of them opened the venture (37%). This means that there is a significant difference between men and women. 44% of the participant had previous experience in the same sector/industry of the new venture. 56% of the persons in the sample was employed at the time of the questionnaire, while 32% was unemployed by less than one year and 12% was unemployed for more than one year.

Moreover, the results show how women have much more difficulties in starting new ventures if their employment condition finds an extended period of inactivity. Interesting, not having a previous working experience in the same sector is not a limit both for female and male entrepreneurs. Women are much more sensitive to the complexity of the initiative compared to male entrepreneurs, considering both the total investment as well as the number of employees to start up the venture.

5.2 Qualitative data

The interviews with several participants using the CAOS model to map the initiatives allowed to use to analyse the factors that can influence the opening of a new firm, focusing on the knowledge transfer in the program, seen as an open innovation initiative.

5.2.1 The personal characteristics of the entrepreneur

The interviews showed that collective classes and project works helped the potential entrepreneurs not only to analyse their business ideas and to avoid crucial mistakes, but they were precious chances to get to know each other and benefit from someone else's experience.

Luciana, who opened her own bar, said *"The part of the classes I enjoyed more was the coffee break – The teachers and mentors of the program were just great, but the best part was exchanging ideas with the other participants. We all had different ideas, background, level of education and experiences, but we all were there to become entrepreneurs. Exchanging point of views helped me to see things from a different perspective, adding values and ideas to my initial thoughts."*

In some cases, people who got to know each other during the classes for the first time later became business partners.

For instance, Sara, educator, stated: *"My business idea was about opening a restaurant involving disabled people as workers. Dealing with kids and adults with*

disabilities is my job, so I know exactly how to deal with them, how to motivate them. I love to cook but managing a restaurant is another story. I was lucky enough to meet Giulia, a professional chef. She liked the idea at once, and now we have found a location to let our dream become true! Merging my and Giulia's knowledge and experience will be the key."

5.2.2 The ambience/environment in which the micro-enterprise operates

The knowledge coming from the competitive environment appeared to be relevant to enhance the efficacy of the program. Participants who got in touch with other companies, universities, and public entities had a better performance in class and in opening their venture.

Renzo, a pharmacist working for a local hospital stated: *"My business idea was born seeing that we wasted too many expensive drugs due to their packaging. Once open, most liquid drugs (to be injected) must be used at once, and if the patient needs just half of it, the other half is thrown away. I talked to my chief and with the director of our University spin-off, and we discussed the business idea together. They are very much supportive and provide me with data and trials. Their knowledge is precious to me, and to my journey as a new born entrepreneur!"*

Arianna works as a consultant for several art galleries, but she wanted to open a small factory in her grandmother's town to produce the local "grissini" (breadsticks), following her grannie's recipe. She stated: *"My Granma's grissini were among the best memories of my childhood. I loved the idea of producing them in limited quantities and selling them in small deli shops. However, my only starting point was the recipe. The local university, faculty of agriculture and food, was so much supportive. They provided me with data and with ideas about the production processes. I am so happy I decided to involve them; they know everything about the market. And the upcoming Expo [Expo Milano 2015, n.d.r.] and the interest towards the "slow food" way of life is surely a plus to support my start-up."*

5.2.3 The organizational and managerial aspects (O)

The organizational and managerial aspects were also positively influenced by the knowledge transfer coming out from the program.

Anita, who opened a workshop where she sold products from local producers and artisans [to read the full story of Anita see Dal Mas et al, 2019] declared: *"What I learned during the classes and seminar was so important to me to develop my idea. I have no employees; however, I needed feedbacks and tips on how to structure my processes (what and how to buy, which contracts to be used, how to deal with clients, how to advertise my shop's initiative, ...). I will forever thank the teachers and mentors for all the knowledge they transfer to me: thanks!"*

Same as Andrea, who opened his restaurant. He said: *"As a professional cook, I know exactly how to work. The kitchen has no secrets to me! But as an entrepreneur, I need to run all the company – from the financial side to the marketing side. I will have full responsibility of my initiative! The mentorship of Marco and Francesca helped me to*

define how to deal with all the processes that, as an employee, were unknown to me. Now I feel more confident, and I am learning by doing.”

5.2.4 The strategy

The strategy was surely influenced by the knowledge acquired during the program.

Barbara, who later opened an e-commerce about beauty and cosmetic products, stated: *“The program allowed me to learn from a Professor of a famous business school about the most recent marketing tools. I even didn’t know they existed, and how they could influence my sales! After discussing with him, I started to implement his tips and guess what, I could immediately see my visitors and conversion rate increase.”*

Roberta said: *“Among my group, I was the one with the clear business idea. I wanted to open a pizzeria in my dad’s former pastry shop. The teacher decided that during the project works, my mates who were still unsure about their possible start-ups would work with me. Well, this was the best gift ever! Discussing with them allowed me to think in a different way. There are too many pizzerias in my town, I had to differentiate my venture from the existing ones, and the brainstorming with them (whom I saw as potential and future clients of mine) allowed me to define a strategy. I am happy to say that I was able to open my restaurant afterwards, and things seem to go well. My former Imprenderò mates are the most welcome clients!”*

6 Conclusions

Our results show how the effectiveness of the open innovation program to enhance entrepreneurship appears to be strongly related to some variables. More precisely: culture and competitive ambiance, as well the organization and strategy decided by the start-uppers influence both the effectiveness and efficiency of open innovation tools. Start-uppers benefited from the program and its knowledge transfer in several ways. Unfortunately, the program also highlights the condition of female entrepreneurs, who experience more difficulties than men in opening their venture, especially if it requires massive investments and employees to coordinate, and if the female entrepreneur has been out from the labour market for an extended period of time.

The study allows to first detect variables that influence the likelihood of venture opening, with special reference to the knowledge transfer to and from start-ups. Additionally, the case study methodology can gather insights about how entrepreneurs have embraced difficulties providing managerial suggestions. The overall results might be useful to policymakers to develop concrete actions to support entrepreneurship. Finally, the sample may be considered relevant since the program granted free access to everybody, and therefore covered the all population of the single area analysed. Additionally, the select cases meet the definition of polar types (Yin, 2014) supporting the knowledge development within the research field.

Abstract

As purveyors of knowledge-based services to the manufacturing sector, industrial service enterprises must deploy the information technology (IT) resources that, in combination with other non-IT resources and competencies, enable their capacity for organizational learning (OL), and for explorative learning in particular. In this context, we take a configurational approach to investigate the digital ecosystem of explorative learning in these firms to explain their competitive performance. The 'digital ecosystem' notion refers to the interplay between the three following configurational elements: 1) IT capabilities for exploration (IT infrastructure and e-business), 2) strategic capabilities for explorative learning, and 3) organizational size. The aim here is to identify the different causal configurations that account for the nonlinear complex interplay of these three elements as they jointly enable explorative learning and thus affect competitive performance. Survey data obtained from 92 industrial service enterprises were analysed with the fuzzy set qualitative comparative analysis (fsQCA) method in order to answer the following research question: What are the different digital ecosystem configurations for explorative learning that are associated to high levels of competitive performance? As it allows for equifinality, the fsQCA analysis identified six causal configurations that

characterize the sampled firms' digital ecosystem of explorative learning, two being equally associated with high innovation performance, and four being equally associated with high productivity.

Keywords – Explorative learning, IT capabilities, Strategic capabilities, Competitive performance, fsQCA.

Paper type – Academic Research Paper

1 Introduction

In a digital world that has shifted from a product-based to a knowledge-based global economy, one of the most important issues for strategic management and information systems (IS) researchers lies in identifying the effects of the firm's information technology (IT) resources that, in combination with other non-IT resources, enable its capacity for *organizational learning* (OL) (Andreu and Ciborra, 1996; Kane and Alavi, 2007). As purveyors of knowledge-based, high value-added services to the manufacturing sector (Bryson, Keeble and Wood, 1997), industrial service enterprises must answer a dual management challenge, namely the digitalization and globalization of their business environment by implementing a digital transformation strategy (Setia, Venkatesh and Joglekar, 2013). The strategic management of IT by these firms is thus meant to enable their learning processes and support their learning mechanisms (Raymond, Bergeron, Croteau and St-Pierre, 2015), and in so doing, to maintain or improve their competitive performance in terms of innovation and productivity (Aboal and Tacsir, 2018).

Strategic management and IS researchers have studied OL processes under two forms, namely exploration and exploitation (March, 1991; Kane and Alavi, 2007). *Explorative learning* essentially refers to the firm's acquisition of new knowledge or replacement of existing knowledge in its organizational memory, whereas *exploitative learning* refers to the firm's reuse, diffusion and refinement of its existing knowledge (Li and Huang, 2013). We focus on the first form in this study, since it is most conducive to achieving high levels of competitive performance in the highly turbulent environment in which most industrial service firms operate (Teece, Peterhaf and Leih, 2016).

From a capability-based view (CBV) of the firm's digital transformation (Easterby-Smith and Prieto, 2008), we focus here on what we term the *digital ecosystem of explorative learning*, that is, on the firm's IT capabilities for exploration, on its strategic capabilities for explorative learning, and on the extent to which and manner by which these capabilities, in combination, enable firms to attain high levels of competitive performance. In characterizing, contextualizing and valuing this digital ecosystem, we take a 'configurational' approach that is grounded in contingency theory instead of the traditional universalistic or 'best practices' approach (Doty, Glick and Huber, 1993). Furthermore, by identifying the 'capability configurations' of industrial service enterprises (Miller, Eisenstat and Foote, 2002), we allow for complex and nonlinear relationships as well as for 'equifinality', i.e. for the possibility for these firms to achieve high levels of competitive performance through different explorative learning paths and

from different starting positions in terms of their IT and non-IT resources (Gresov and Drazin, 1997).

As applied here, the configurational approach is based on the premise that there are specific combinations of the firm's IT and non-IT capabilities that enable its explorative learning processes and, in turn, positively influence its competitive performance (Fiss, 2011). Therefore, the research question to be answered by this study is the following: *In the context of industrial service enterprises, what are the different digital ecosystem configurations for explorative learning that are associated to high levels of competitive performance?* In answering this question through an empirical study of 92 Canadian firms operating in the industrial services sector, we hope to provide a deeper understanding of the nature and effects of the complex interplay between the firm's IT and explorative learning capabilities in this context.

2 Theoretical and empirical background

In integrating concepts and insights obtained from the configurational approach, from the CBV and from the strategic IT management literature, we wish to contribute to OL theory and to the closely-related 'absorptive capacity' theory (Sun and Anderson, 2010). We also wish to contribute to OL practice as it is enabled by IT strategic management in an industrial service context. In order to do so, we initially propose that competitive performance depends on specific configurations of the three elements – in this case, IT capabilities for exploration, strategic capabilities for explorative learning, and firm size as the contextual contingency – that, together, compose the firm's digital ecosystem of explorative learning. We define a configuration as a specific combination of elements that together generate the outcome of interest – in this case, competitive performance. This proposition leads us to empirically validate a research model that is based on the configurational approach, as presented in Figure 1, and as further explained below.

2.1 IT capabilities for exploration

IT capabilities are defined herein as the organization's ability to 'mobilize and deploy IT-based resources in combination or co-present with other resources and capabilities' (Bharadwaj, 2000, p. 171). More specifically, these capabilities include the IT assets of the firm such as the computing technologies and applications platform that constitute its 'IT infrastructure' (Ajamieh, Benitez, Braojos and Gelhard, 2016). Organizational IT capabilities also include the IT competencies that allow a firm to enable its business processes as well as its knowledge management through its use of IT (Joshi, Chi, Datta and Han, 2010), that is, through its 'e-business' capabilities (Zhu, 2004). Now, certain IT infrastructure and e-business capabilities may be categorized as being either mainly explorative or exploitative through the notion of 'IT ambidexterity' (Lee, Sambamurthy, Lim and Wei, 2015), in line with Levinthal and March's (1993) conceptualization of how firms pursue either exploration or exploitation. Herein, we focus on explorative IT infrastructure and e-business capabilities as the IT capabilities for exploration of interest.

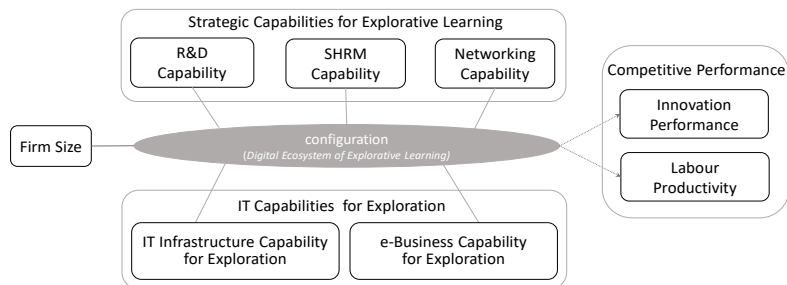

Figure 1: Research model on the digital ecosystem of explorative learning

2.2 Strategic capabilities for explorative learning

Defined as ensembles of accumulated knowledge and competencies that enable the firm to deploy its assets and coordinate its activities (Desarbo, Di Benedetto, Song and Sinha, 2005), strategic capabilities are deemed to shape critical organizational outcomes such as innovation performance (e.g. Di Benedetto, DeSarbo and Song, 2008) and productivity (e.g. Hutton and Eldridge, 2019). Recalling that explorative learning is viewed as a ‘dynamic’ capability, the firm’s strategic capabilities may be envisioned as organizational capabilities that hierarchically underlie its dynamic capabilities (Grant, 1996). Three strategic capabilities, namely research and development (R&D) (Martínez-Senra, Quintás, Sartal and Vázquez, 2015), strategic human resource management (SHRM) (L’Écuyer and Raymond, 2017) and networking capabilities (Husain, Dayan, and Di Benedetto, 2016) have been identified in the literature as having close ties to OL.

In the industrial services sector, the R&D capability refers to the firm’s ability to acquire, assimilate, transform and exploit new knowledge, in conjunction with its human and intellectual capital and knowledge management competencies, in order to develop new services (service R&D) or improve the process by which existing services are rendered to manufacturing firms (process R&D) (Koschatsky and Stahlecker, 2010). Now, this capability may also be considered as a proxy for the ‘learning’ dimension of the firm’s absorptive capacity (Lucena and Roper, 2016). In empirical research, the R&D capability has been observed to both enable and determine explorative learning (Bresman, 2013; Martínez-Senra et al., 2015).

The SHRM capability is defined as the firm’s capacity to develop, motivate and empower human resources in order to meet strategic goals in a dynamic, turbulent and sometimes hostile environment (L’Écuyer and Raymond, 2017). The SHRM capability has been found to interact with the OL in determining the performance of the HR function (Camps, Oltra, Aldás-Manzano, Buenaventura-Vera and Torres-Carballo, 2016). Further,

certain SHRM practices such as talent management, positively impact OL (Oltra and Vivas-López, 2013).

The networking capability is specific to the firm and indicates its ability to manage relationships with suppliers and other business partners (Human, and Naudé, 2009). The networking capability has been found to positively moderate the impact of explorative learning on competitive performance (Chung, Yang and Huang, 2015) and conversely, the OL capability has been found to positively mediate the impact of the networking capability on competitiveness (Husain et al., 2016).

2.3 *Competitive performance: innovation performance and labour productivity*

Viewed as a dynamic capability, OL has been studied in the strategic management literature with regard to its direct and indirect effects on performance (Easterby-Smith and Prieto, 2008). In particular, prior research has thus confirmed the positive impact of OL on the firm's innovation performance (Onağ, Tepeci and Başalp, 2014) and on labour productivity (Peters, Riley, Siedschlag, Vahter and McQuinn, 2018). As a result, we will focus on innovation performance and labour productivity as the competitive performance outcomes of interest.

2.4 *Organizational context of explorative learning: firm size*

In the services sector, firm size may be thought of as a proxy for certain aspects of the firm's organizational context, given the fact that smaller firms are generally found to be less-endowed than larger firms in terms of available resources and competencies (de Brentani, 1995; Nunes et al., 2010). Firm size thus constitutes a potentially important contingency for industrial service firms in developing their IT capabilities for exploration and their strategic capabilities for explorative learning (Chikweche and Bressan, 2018).

3 Methods

3.1 *Sample*

This study's data were culled from a benchmarking database that contains information on 92 industrial service enterprises located in Quebec, Canada. These enterprises offer knowledge-based high value-added services to the manufacturing industry, and in areas such as IT, human resources, R&D and logistics. The database was created by having the firms' top executives and IT manager answer a twenty-page questionnaire to gather wide-ranging data on the competitive performance and business practices of their firm. In exchange for providing this data, the firms obtained a comparative diagnosis of their strategic situation and competitive position. As the sampled firms' size varied from 4 to 146 employees with a mean of 31, they are SMEs (small and medium-sized enterprises).

3.2 Measures

The sampled firms' IT and strategic capabilities were assessed with surrogate measures taken from the extant IS and strategic management literatures. IT capabilities for exploration were assessed through the organization's IT infrastructure and e-business capabilities. These two capabilities were measured with summative indexes calculated from the number of IT-based and Web-based systems and applications such as rapid prototyping and e-business intelligence that are used by the firm mainly for explorative purposes (Raymond et al., 2015). The R&D capability was assessed through a commonly-used surrogate measure, namely the R&D budget per employee (Raymond and St-Pierre, 2010). The SHRM capability was measured by assessing the average level of development of ten high-performance HRM practices (Fabi, Lacoursière, Raymond and St-Pierre, 2010). The networking capability was measured by the number of the firm's partnerships with other organizations in domains such as marketing, R&D and service delivery (Raymond and St-Pierre, 2013). Innovation performance was assessed by the proportion of sales ascribed to new or modified services, a commonly used measure (Raymond and St-Pierre, 2010). Finally labour productivity was assessed with the financial measure frequently used by researchers and practitioners, i.e. the firm's gross profit per employee (Bryan, 2007).

4 Results

The research questions were answered by using fuzzy set qualitative comparative analysis (fsQCA), an appropriate method for small samples (Ragin, 2008). This method uses Boolean algebra to identify different configurations of elements or causal conditions that are associate to the same preferred outcome. The principal contribution of fsQCA lies in its ability to evaluate the relation between a configuration and an outcome. Analysis of our configurational framework was preceded by a direct fuzzy set 'calibration' of the research variables, as it is recommended when indexes and Likert-type scales are used for variable measurement (Liu, Mezei, Kostakos and Li, 2017). The descriptive statistics and calibration thresholds of the research variables are presented in Table 1.

Table 1: Descriptive statistics and calibration of the research variables (n = 92)

Configurational element	Fuzzy Set Calibration			mean	s.d.	min – max
	fully in	cross-over	fully out			
Firm Size ^a	40	25	10	31	27	4 – 146
R&D Capability ^b	3000	500	0	4525	12352	0 – 69747
SHRM Capability ^c	0.40	-0.05	-0.40	0.04	0.45	-0.81 – 1.43
Networking Capability ^d	5	2	0	2.5	2.7	0 – 12
e-Business Cap. for Explor. ^e	4	1	0	2.1	1.9	0 – 6
IT Infrastr. Cap. for Explor. ^f	4	1	0	2.7	1.5	0 – 4
Innovation Performance ^g	0.30	0.05	0.00	0.18	0.30	0.00 – 1.00
Labour Productivity ^h	0.67	0.33	0.10	0.41	0.44	-1.07 – 2.31

^a number of employees
^b R&D budget / number of employees
^c mean level of development of 10 high-performance HRM practices (standardized variables)
^d number of formal collaborations with customers, suppliers, consultants, universities and research centres
^e number of explorative activities that are realized by the firm through e-business applications and the Web
^f number of technologies and systems that are used by the firm for explorative purposes
^g sales of new or modified services / total sales
^h gross profit / number of employees (x 100 000 CAN \$)
<i>Nota.</i> Calibration thresholds: fully in = top quartile, crossover = median, fully out = bottom quartile.

The fsQCA method allows one to analyse the configurational elements that, together, are ‘sufficient’ to produce the chosen outcomes (Ragin, 2008). This method was thus applied to two sets of configurations: one for high innovation performance and another one for high labour productivity. In demonstrating equifinality and as presented in Table 2, the results of the fsQCA analysis identify six causal configurations, i.e. two sets of configurational elements (or causal conditions) equally associated to high levels of innovation performance (HI1 and HI2) and four sets equally associated to high levels of productivity (HP1, HP2, HP3 and HP4). The overall solution coverage indicates the proportion of cases that are covered by all reported configurations, whereas the overall solution consistency assesses the degree to which capability configurations are subsets of the outcome. In this study, the consistency cut-off point was set at 0.75, following Ragin’s (2008) recommendations.

Table 2: Configurations for high innovation performance and labour productivity

Configuration Configurational element	High Innovation Performance		High Labour Productivity			
	HI1	HI2	HP1	HP2	HP3	HP4
<i>Firm Size</i>	⊗		⊗	●	●	
<i>R&D Capability</i>	●	●				●
<i>SHRM Capability</i>	●	●	●	●	●	●
<i>Networking Capability</i>			●	●	⊗	⊗
<i>e-Business Cap. for Exploration</i>		●	●	●	⊗	⊗
<i>IT Infrastructure Cap. for Explor.</i>	●	●	⊗	●	●	●
Conditions tested						
Consistency	.780	.834	.835	.822	.779	.736
Raw coverage	.255	.314	.152	.215	.179	.120
Unique coverage	.034	.093	.050	.102	.084	.025
Overall solution consistency	.779		.800			
Overall solution coverage	.348		.402			

Legend. ● : presence of a core condition ● : presence of a peripheral condition
⊗ : absence of a core condition ⊗ : absence of a peripheral condition
blank: immaterial condition (“don’t care”)

The high-innovation performance configurations, HI1 and HI2, highlight the primary importance of strong R&D and SHRM capabilities ('core' conditions) and the secondary importance of a strong IT infrastructure for exploration capability ('peripheral' condition). Also, HI1 applies to small-sized enterprises whereas HI2 adds a strong explorative e-business capability as a core condition and is irrespective of firm size ('immaterial' condition). This would mean that neither of the two competing explanations of the size effect on innovation performance (Amara, Landry, and Doloreux, 2009), namely the positive effect of large size as an indicator of available resources, or the positive effect of small size as an indicator of firm flexibility, is at work here.

The first two high-productivity configurations, HP1 and HP2, highlight the primary importance of having strong SHRM, networking and e-business capabilities. Furthermore, HP1 is characterized by the lack of strong IT infrastructure capability in small-sized enterprises, whereas HP2 adds a strong IT infrastructure capability as a peripheral condition in medium-sized enterprises. The last two high productivity configurations, HP3 and HP4 are characterized by the presence of a strong SHRM capability and the absence of networking and e-business capabilities as core conditions as well as by the presence of a strong IT infrastructure capability as a peripheral condition. Also, HP3 applies to medium-sized enterprises, whereas HP4 requires a strong R&D capability as a core condition and is irrespective of firm size.

5 Discussion

In answering the research question, a fsQCA analysis allowed us to unveil different digital ecosystem configurations, that is, six causal 'recipes' of strategic capabilities for explorative learning, IT capabilities for exploration, and firm size that equally attain high levels of innovation performance and labour productivity. In line with the configurational approach, contingency theory and the CBV, these equifinal configurations manifest a 'gestalts' type of alignment or 'fit' between the firms' IT capabilities for exploration and strategic capabilities for explorative learning (Raymond and St-Pierre, 2013). Hence, instead of establishing linear relations between each of the digital ecosystem elements and the performance outcomes as the traditional variance approach does, the three sets of configurational elements of the digital ecosystem are analyzed in combination as they jointly affect the competitive outcomes (Fiss, 2011).

With regard to digital ecosystem configurations unveiled, one first notes that the SHRM capability is present in all configurations of both high innovation performance and high labour productivity, and may thus be deemed as a 'necessary' condition. This means that explorative learning benefits the firm in terms of its competitive performance to the extent that employees are strongly motivated and empowered to undertake exploration activities. Another strategic capability that appears to be necessary to achieve high innovation performance is the R&D capability. However, this capability does not appear to be necessary for high labour productivity. This points to the industrial service firms' difficulty in being both highly innovative and highly productive simultaneously, as these two outcomes are shown here to be achieved through very different capability

configurations. One might also surmise that productivity, as opposed to innovation, would benefit more from exploitative rather than explorative learning, and in particular from IT capabilities for exploitation such as enterprise resource planning (ERP) systems and e-commerce applications (Fabi et al., 2010).

With respect to the IT for exploration capabilities, a strong IT infrastructure is a peripheral rather than a core condition in the attainment of high innovation performance and high labour productivity, that is, it must be present but it is not ‘determinant’. A strong e-business capability for exploration is also present in one of the two high innovation performance configurations and in two of four high labour productivity configurations. In the high productivity case, the e-business capability appears to work in tandem with the networking capability, that is, when one is present the other is present (HP1 and HP2) and, conversely, when one is absent the other is absent (HP3 and HP4). This would be an indication that a ‘mismatch’ between these two capabilities for explorative learning (i.e. a strong networking capability with a weak e-business capability or vice-versa) would be detrimental to achieving high levels of productivity. This again points to the fact that by presuming IT capabilities to directly enable the firm’s learning processes and to linearly effect its performance independently of other non-IT capabilities, one is bound to have a more limited understanding of the true role and impact of these capabilities (Woodside, 2013).

In addition to its contribution to OL theory, our study also contributes to OL practice. That is, our findings may provide managers of industrial service SMEs (and those who assist them) with different digital ecosystem configurations that may be emulated with the aim of enabling their explorative learning processes and improving their competitive performance. Given the IT and non-IT resources at their disposal, these firms may envisage the capability configuration that best fits their specific business environment and organizational context.

Abstract

The exponential growth of data existing on the web and generated by organizations and individuals, computer systems and digital devices, is opening new scenarios and opportunities for their exploitation, and new technological and managerial challenges are arising about the collection, transformation, storage, processing, usage, and visualization of such huge amount of data. The Big Data paradigm has therefore emerged as a socio-technical system that allows for offering innovative services in many data-intensive applications and domains. Within the Big Data field, the Big Social Data concept emerged as a relatively new phenomenon with multiple meanings and applications. According to the literature, the Big Social Data paradigm still lacks of a clear and shared definition. Thus, through a Systematic Literature Review, this paper aims at fulfilling this gap by providing a conceptualization of the Big Social Data paradigm that includes a possible definition, the distinguishing characteristics and properties, and some applications in real-life settings. Furthermore, by leveraging an existing taxonomy of data types, this paper proposes an extension that is specific for the Big Social Data domain, by introducing a new category of data type, namely “Digital Context Data”, which includes data related to the patterns of digital context dynamics. Finally, specifically for this new category of data type, two example applications in data-intensive domains (i.e. smart tourism and e-health) have been provided to demonstrate

how the Big Social Data paradigm can describe, both explicitly and implicitly, the patterns of digital context dynamics.

1 Introduction

The exponential growth of data existing on the web, generated by organizations and individuals, computer systems and digital devices, opens new scenarios and opportunities for their exploitation, and creates new technological and managerial challenges related to their management and processing (Sivarajah et al., 2017). The Big Data paradigm has therefore emerged in recent years as a socio-technical system for acquiring, storing, managing and analysing data in flexible and efficient way, in the ultimate goal to offer innovative services in data-intensive applications and domains such as healthcare, banking, tourism, education, public administration, and intelligent manufacturing (Elia et al., 2018a).

From a data perspective, as much of social interaction is nowadays mediated by information technology and takes place in online social media, the emergence of extensive amount of user-generated contents has spread more widely and quickly, thus providing organizations with opportunities to obtain information and extract knowledge to generate value for individuals, companies, and territories (Elia et al., 2018b).

In this scenario, Big Social Data (BSD) that has been defined as “any high-volume, high-velocity, high-variety and/or highly semantic data generated from technology-mediated social interactions and actions in digital realm, and which can be collected and analysed to model social interactions and behaviour” (Olshannikova et al., 2017), has become an emergent research topic. BSD can be considered a particular category of Big Data argued to represent about 90% of all Big Data (Gandomi et al., 2015), and refers to large volumes of data generated by users and describing social behaviour and interactions in digital environments.

Theory background and studies related to BSD show that this paradigm has multiple meanings and still lacks of a clear and shared definition (Ward & Barker, 2013; Halavais, 2015). This paper aims at fulfilling this gap by providing a twofold contribution: i) a conceptualization of the Big Social Data paradigm by defining the key characteristics and properties; ii) a taxonomy of Big Social Data types by extending some previous researches on the topic.

The research methodology used for this study is the Systematic Literature Review (SLR), which is a rigorous and transparent form of literature review that includes the identification, the synthesis and the assessment of all available evidences, quantitative and qualitative, in the aim to generate a robust and empirically-derived answer to a focused research question. SLR encourages researchers to engage more critically with the quality

of evidence (Mallet et al., 2012), and represents a guide for the research process that ensures transparency of the review, breadth of studies included, objectivity, and reduction of implicit researcher bias (Gough and Elbourne, 2002).

The main finding of this paper consists in a conceptualization and definition of BSD paradigm that can help researchers to build proper methods for a purposeful processing and analysis of this specific typology of data. This contributes to face the emerging challenges related to the growth of human-generated data, which calls for novel tools, frameworks and methodological approaches as well as multidisciplinary expertise to exploit the potential value embedded in these sources of data (Olshannikova et al., 2017). A further contribution is related to the proposition of a taxonomy of Big Social Data types, with example applications in data-intensive domains (i.e. smart tourism and e-health).

This paper is structured as follows: sections 2 presents the literature background, section 3 illustrates the research methodology and the main steps of the Systematic Literature Review, whereas section 4 presents the main results achieved. Afterwards, section 5 introduces a taxonomy of BSD types and describes a possible application in two data-intensive domains (smart tourism and e-health). Finally, section 6 discusses the results achieved and highlights some limitations of the study, which can open new paths for further research.

2 Related Literature

Big Social Data was a concept developed by Lev Manovich (2011) and it gained great interest in research on digital culture and society. One of the earlier examples of BSD applications is presented by Procter et al. (2013), which illustrates how Twitter has influenced the movement during the 2011 London riots. Since then, besides the growing interests of researchers and practitioners on this topic, the concept of BSD has been defined and interpreted in many ways for various purposes, generating a large research debate on BSD definition and its main conceptual aspects. The analysis of the literature shows that the BSD have been considered as:

- the science that studies the relationships between physical data of the real world and data on social media (Ishikawa, 2015), or as a social science that through quantitative analysis methods studies the connections between information flows and human behavior (Pentland, 2014);
- the result of approaches based on social computing (Guellil, 2015; Nguyen, 2015; Tang, 2014), or as a result of what derives from the communicative practices (mediated by technology) of our daily life (Coté, 2014);
- a purpose-driven research approach for a society-oriented view, which leverages the shift of Big Data towards media, communication, cultural and computational social science to explore the digital humanities domain (Burgess & Bruns, 2012) and find new ways for enhancing the governance and organizational improvements (Housley, 2014).

- a methodology based on the combination of three elements (Bello-Orgaz et al., 2016) such as Big Data (as a processing paradigm), Social Media (as the main source of data), and Data Analysis (as a method to acquire new knowledge for users or companies).

To confirm this latter approach, Golbeck (2014) referred to the BSD paradigm to extract insights from social media data and online social interactions of people for descriptive and predictive purposes, with the ultimate goal to influence human decision-making in various application domains. Other researchers focused mainly on the application and utilization of data analytics techniques (Cambria et al., 2013; Bravo Marquez et al., 2014), reserving little attention to understand the real meaning and nature of BSD.

Thus, different interpretations and terms with which researchers refer to the “social” aspect of Big Data have emerged. The most common terms are “Social Big Data” (SBD) and “Big Social Data” (BSD), which are often used interchangeably and in any case are not clearly and uniquely defined. Among the definitions present in the literature, very few highlight BSD properties, methods of generation and possible uses. That one given by Olshannikova et al. (2017) describes the BSDs as “any high-volume, high-velocity, high-variety and/or highly semantic data that is generated from technology-mediated social interactions and actions in digital realm, and which can be collected and analyzed to model social interactions and behavior”. Nevertheless, the same authors state that the multidisciplinary and multi-dimensional nature of BSD challenges to the development of a better conceptualization and definition of the concept.

Another research issue related to BSD is the lack of a comprehensive list of data types that can be crucial for identifying research opportunities and practical means towards data-driven research (Olshannikova et al., 2017). Research contributions on this topic focus mainly on creating taxonomy of data types in the context of online social networks (OSN). Beye et al. (2012) identified nine data types by focusing on the goals of different OSN, whereas Schneier (2010) focused solely on the task of establishing a taxonomy without suggesting a structured methodology and without mentioning any details and foundation about the data types. Årnes et al. (2011) extended the latter work with short definitions and a list of examples for each category, without providing any details and explanations about the particular data types. Richthammer et al. (2014) followed a user-centric approach to propose a fine-grained taxonomy in which the individual data types are arranged hierarchically. Finally, Olshannikova et al. (2017) extended and re-organized latter research with a focus on Big Social Data and proposed a taxonomy with three category of data types describing respectively the self-representation in digital environment, the communication and knowledge creation/distribution through technology, and the patterns of digital social relationships.

From the above literature, two research gaps emerge: the first one relates to the absence of a clear and formal definition of Big Social Data, also in terms of key properties and key features; the second one is related to the development of a taxonomy of BSD data types and to the analysis of how the BSD paradigm can be applied in different data intensive domains.

In order to address these gaps, section 4 in the present work proposes a definition of BSD derived from a Systematic Literature Review, while section 5 presents a taxonomy that extends the spectrum of BSD data types.

3 Research Methodology

The research methodology adopted to carry out this study is based on a Systematic Literature Review (hereafter SLR). SLR is a rigorous and transparent form of literature review, which involves the identification, the synthesis and the assessment of all available evidences, quantitative and qualitative, in the aim to generate a robust and empirically-derived answer to a focused research question. SLR represents also a guide for researchers during the research process, and ensures transparency of the review, breadth of studies included, objectivity, and reduction of implicit researcher bias (Mallet et al., 2012; Gough & Elbourne, 2002). Besides, SLR encourages researchers to engage more critically with the quality of evidence (Mallet et al., 2012).

3.1 SLR process and its application

The process of SLR has been developed by following four key steps: search, selection, analysis, and synthesis (Keele, 2007; Centobelli et al., 2017; Günther et al., 2017). The search has been performed by considering two scientific databases (i.e. Scopus and Web of Science), and a query has been designed and executed to extract the research papers containing “big social data” OR “social big data” OR “big social media data” in the title, keywords or abstract. In table 1, extraction criteria are summarized as well as the results of the first step of the methodology.

Table 3. Extraction criteria for the search step

EXTRACTION CRITERIA	RESULTS
Keyword used	"big social data", "social big data", "big social media data"
Fields of the research	Title, Keywords, or Abstract
Data Range	Until 2018
Language	English
Document Type	Conference Papers, Articles, Book Chapters
Results from Scopus	218
Results from Web of Science	146
Duplicates	139
Total number of items	225

As for the selection step, a set of exclusion criteria (listed in table 2) has been applied to contain the research focus and reduce the number of candidate papers to be further analysed.

Table 4. Exclusion criteria for the selection step

ESCLUSION CRITERIA	N. OF ITEMS EXCLUDED
1. Items whose full text was not available	22
2. Format not compliant with the document type (Conference Papers, Articles, Book Chapters)	4
Total number of items remained	199

The remaining 199 resources have been examined in the third step of the SLR methodology, i.e. the analysis, through a qualitative study focused on the aims of the research presented, which included two tasks:

1. a term frequency analysis on abstracts to identify the key research topics in the BSD domain;
2. a qualitative study to extract any definition (proposed or referenced) on BSD in order to be mapped on the aforementioned research topics.

The first task (i.e. the term frequency analysis) generated 70 terms overall. Authors have considered mutual relationships between terms in order to group them and consequently have identified four key topics in the current BSD research literature, which are illustrated in Figure 1: Sources (i.e. places where BSD can be found), Properties (i.e. attributes and characteristics denoting the BSD), Technologies (i.e. methods and tools for BSD processing in order to generate value), and Value (i.e. effects and impacts of BSD in the applicative domains).

Figure 4. The four key research BSD topics and related most frequent terms

The second task (i.e. the extraction of BSD definitions and their mapping on the four research topics) generated 107 definitions overall, respectively extracted from 107 research items. Each definition has been properly extracted from the research item and analysed in order to map it along one or more research topics.

As for the last step of the SLR (i.e. the Synthesis), the authors and two experts operating in the Big Data domain have been involved in three meetings for a collective discussion. Before to join each meeting, all the participants had the time to analyse individually the research items, as well as to take some notes and comments to be shared

during the plenary sessions. The expected goal at the end of the third meeting was to harmonise all the contributions and provide a synthesis for reaching a consensual and formal definition of Big Social Data.

4 Towards a definition of Big Social Data

Most of the analysed research papers define BSD along the perspective of data sources, specifying that they represent “Big Data from social media sources”. Some of them provide a more detailed analysis, as the paper of Ishikawa et al. (2018) that defines BSD as a “collection of big data composed of real world data, open data and social data”. Other researchers define BSD as “multiple distributed sources but with a strong focus on social media” (Reuter et al., 2017), or as “social media applications or platforms that range from social networks, micro blogs, discussion forums, wikis to podcast networks, picture and video sharing platforms, ratings and reviews communities, social bookmarking sites, and avatar based virtual reality spaces” (Akter et al., 2016).

As for the properties characterizing the BSD, a remarkable group of definitions highlights the characteristics of Big Social Data in terms of data attribute, and emphasizes the well-known Big Data 3V model (Volume, Variety, Velocity). From this perspective, Bello-Organ et al. (2016) define Big Social Data as data characterised by “different formats and contents, their very large size, and the online or streamed generation of information”. Few other researchers as El Alaoui et al. (2018) add to the aforementioned model two other V-based properties (i.e. Value and Variability), while Olshannikova et al. (2017) underline the semantic richness of BSD.

Another group of definitions emphasizes the technological issues behind Big Social Data collection, management and processing. Bednár (2017) talks about “various data analytics methods and Big Data processing technologies”, while Peng et al. (2016) highlight the need of non-traditional techniques, tools, and methods to handle Big Social Data. Finally, Mukkamala et al. (2014) stress on the necessity to have proper methods, techniques and tools coming from computational social science.

In relation to the different forms of value that Big Social Data can generate, there is a noteworthy number of research papers in which BSD are referred as the means to offer new insights to understand deeper user’s social behaviour and interactions (i.e. Vepsäläinen et al., 2017). Besides, other researchers highlight value in terms of impacts on advancement on society, generation of relevant knowledge for users and companies, prediction of real-life outcomes, and generation of new opportunities to study city dynamics and urban social behaviour. More in particular, El Alaoui et al. (2018) refer to “the massive set of opinions that could be processed to determine people tendencies in the digital realm”, while Del Vecchio et al. (2018) discuss the possibility to improve “the effectiveness of the decision-making process, as well as in terms of sustainability”. Furthermore, few other researchers state that BSD value consists in providing “meaningful facts and actionable insights that go beyond traditional social science research methods” (Mukkamala et al., 2014) or in creating “unprecedented opportunities to study city dynamics and urban social behaviour” (Silva et al., 2013).

Thus, by considering the outputs of the synthesis step of the SLR, the core concepts of Big Social Data are represented by:

- the attributes of data in terms properties and characteristics (i.e. Volume, Variety, Velocity);
- the social media services and platforms as main data sources;
- the usage of proper technologies and non-traditional techniques, tools and methods to collect, manage and analyse such typology of data;
- the insights coming from the processing and analysis of data for creating social value, as well as for generating positive impact for companies and society.

Based on these considerations and evidences, the formal definition of Big Social Data proposed in this article is:

“Big Social Data is that subset of Big Data generated from people’s actions and interactions within social media services and platforms, properly collected and analysed to provide crucial insights into human behaviour, people’s preferences and relationships, social interactions and transformations, and real-life outcomes prediction”.

This definition is compatible with several groups of definitions analysed during the SLR process, and tries to harmonize different research efforts and applicative perspectives from which BSD has been studied in the last years. Furthermore, this definition stresses on BSD as human-generated data that is the key to make BSD concept clearer and distinctive within the general field of Big Data. Indeed, in accordance with Olshannikova et al. (2017), differently from machine-generated data that could be analysed through mere Big Data Analytics tools and applications, human-generated content requires more intelligent solutions to provide insight on people’s relationships, opinions and behaviours.

5 A taxonomy of BSD data types

As discussed in previous sections, besides the need for a clear and consensual definition of BSD, another research issue is related to the lack of a comprehensive list of BSD data types. As mentioned, Olshannikova et al. (2017), by enhancing previous research contributions, proposed a non-extensive taxonomy of BSD data types made by the following categories:

- Digital self-representation data, which refer to identity depiction and communicative body in digital environment;
- Technology-mediated communication data, which refer to data generated in bidirectional communication, as well as to knowledge creation and knowledge distribution through the usage of digital technologies;
- Digital relationships data, which refer to data that reveal patterns of digitally enabled social relationships.

Starting from the definition of Big Social Data proposed in the previous section, our purpose is to include data types that are functional to build and analyse a context from which disclosing valuable knowledge from BSD sources, in the form of human

behaviour, people's preferences and relationships, social interactions and transformations, real-life outcomes prediction.

In such a perspective, a new category of data type named "Digital Context Data" has been added to the classification proposed by Olshannikova et al. (2017). It grounds on the concept of "context", which refers to "any information that can be used to characterize the situation of an entity (a person, a place, or an object) that is considered relevant to the interaction between a user and an application, including the user and applications themselves" (Dey et al., 2000). According to this definition, the "context" is characterized by all those informational dimensions that are important to understand the dynamic interactions between users and applications, which constantly change and cannot be limited only to the knowledge of the location of the user itself. The informational dimensions that delimitate the boundaries of the context derive from the knowledge needs related to the BSD value function, which represents the "why" and "how" BSD contributes to generate value in the form of human behaviour, people's preferences and relationships, social interactions and transformations, real-life outcomes prediction. Once defined, the context can evolve based on the knowledge and insights discovered during the analysis; similarly, the original knowledge needs shaping the initial context can evolve and contribute to reshape the BSD value function.

Table 3 summarizes the core categories of the BSD domain, and describes the contribution that this paper aims at provide by referring to this specific issue.

Table 5. Taxonomy for BSD data types

CATEGORY AND DEFINITION	TYPES OF DATA
Digital self-representation data (Olshannikova et al., 2017) Data related to identity depiction and communicative body in digital environment	<i>Profile data:</i> <ul style="list-style-type: none"> - Login data (name/nickname/e-mail address and password); - Mandatory data (services and application required data like, for example, full name, citizenship, and birthday); - Extended data (profile pictures, education, tags of interests). <i>Self-published content</i> (e.g. personal documents, pictures, videos, interests): <ul style="list-style-type: none"> - Disclosed data (to the public); - Entrusted data (content sharing within trusted digital community). <i>Data published by the community</i> (e.g. pictures, narrations, videos, posts) and related to content shared by other users, which contribute to the digital identity creation.
Technology-mediated communication data (Olshannikova et al., 2017) Data related to two-way communication, knowledge creation and distribution through technology	<i>Private communication data</i> like instant 1-to-1 messaging and content sharing. <i>Public communication data</i> like 1-to-many messaging, commenting, information contribution, editing of existing entries. <i>Collaborative communication data</i> like many-to-many participatory content sharing, chats, video-conferences.
Digital relationship data (Olshannikova et al., 2017) Data that reveal digital social	<i>Explicit data:</i> Friendship data-Followee/Follower data; <i>Implicit data:</i> Data that is revealed through technology-mediated communication data (e.g. tweets could be analysed to infer connections)

relationships patterns	between people)
Digital context data Data that reveal the dynamic patterns in the digital environment that constitute the users' context.	Data produced automatically and derived from user's interactions within the digital environment, which continuous change according to the people's actions and interactions with other people and systems operating in the social media. This data can be <i>explicit or implicit (inferred)</i> and characterize the user's digital context in terms of: <ul style="list-style-type: none"> - Digital relationship data (Olshannikova et al., 2017); - Location related data (e.g. data from mobile/wearable devices); - Time related data (e.g. data on scheduled actions); - Interests, preferences, mood, and opinions.

Thus, Digital Context Data describe the users' context that may change over time, in terms of digital relationship data, location and time, interests, preferences, mood, and opinions. These data, which are often referred to as *digital exhaust* or *digital breadcrumbs*, are typically generated by devices, digital services or environments in which a user operates. Inferences can be made about individual and/or collective behaviour allowing an increasingly observation of actions and interactions of individuals in real time as well as over time (Watts, 2016).

Definitely, four BSD data types as multi-modal and heterogeneous types of data have been identified:

- Digital relationship data, as defined by Olshannikova et al. (2017) that reveals digital social relationships patterns, and refer to data about friendships/followers, business relationships, and networks analysis (Benhiba et al., 2017) along both the structural view (e.g. network topology, roles of nodes, communities and subgroups) and the dynamic view (e.g. time changes of the network's topology in terms of nodes and relationships);
- Location data from mobile or wearable devices expressing context-aware information, and related to geographical position (e.g. GPS), proximity-based connections (e.g. Bluetooth) or resources (e.g. applications);
- Time-related data referring to particular activities or scheduled actions (i.e. environment access, content generation, etc.);
- Individual's interests, preferences, mood, and opinions, expressed in textual or multimedia format (i.e. texts, tags, hashtags) and used to communicate specific individual or group behaviours, social interactions, and tendencies for a wide range of social-related insights.

Although data from these sources would characterize specific context dynamics conditions, it is still difficult to access and combine multiple data sources. Watts (2016) envisions an ad-hoc virtual environment as a facility that combines multiple streams of data, creating richer and more realistic portraits of individual behaviour and identity, while retaining the benefits of massive scale, called "social supercollider" that would bring new chances for realistic and consistent research outcomes.

5.1 Example of Digital Context data type in data-intensive domains

To understand better the relevance and the implications of identifying the Digital Context data category and its related data types, the description of two scenarios of BSD are described, by referring to two data intensive applications such as smart tourism and e-health.

Smart Tourism relies on extensive adoption of emerging technologies, such as social media and mobile technologies, smart devices and sensors to collect and exploit the huge amount of data for creating new value propositions (Gretzel et al., 2015; Sigala et al., 2012). Big Data applications in smart tourism are already mature, and different types of Big Data were successfully used in tourism research. User-generated contents in tourism (Li et al., 2018) are a “low cost” and easy access source of data, and they are mainly composed by online textual data (used for product reviews and blogs released on social media) and online photo data (posted on photo sharing websites or social networks). Online textual data can explicitly be generated by users to express their satisfaction and dissatisfaction towards tourism product or to share perspectives and experiences, thus providing valuable and unambiguous information for potential tourists. Besides, the same type of data conveys implicitly feelings, sentiment and mood of tourists, which can be measured to estimate tourist satisfaction in relation to other factors (i.e. guest experience) or to provide insightful implications for hospitality industry and marketing attractions (Guo et al., 2017). Online photo data uploaded by tourists contain useful information about users, locations and time; it is a rich source of Big Social Data for analysing tourist behaviour and popular tourism destinations, i.e. where to travel (Zhou et al., 2015), travel routes, i.e. how to travel (Kurashima et al., 2013), and tourism duration, i.e. how long travelling (Lee et al., 2014). On the other hand, device data as GPS and Bluetooth data provide massive high-quality data in tourism domain. Both of them can explicitly express tourist behaviour in terms of spatial, temporal and spatial-temporal behaviour. GPS data can be further analysed to propose efficient itineraries based on multiple GPS trajectories (Yoon et al., 2010), predict tourist next destinations (Zheng et al., 2017), or understand resident attitudes towards tourism (Ayscue et al., 2016).

For what concerns the scenario on e-health, benefits of Big Data application can be identified in the prevention of diseases, identification of modifiable risk factors for disease, and design of interventions for health behaviour change (Barret et al., 2013). According to Swam (2013), Big Data streams can be summarized in three categories, namely: (a) traditional medical data (e.g. EMRs, personal and family health history, medication history, lab reports, pathology results); (b) “Omics” data, which refer to large-scale datasets in the biological and molecular fields (e.g. genomics); (c) data from social media, which consist of signs and behaviours on how individuals or groups use the Internet, social media, mobile applications, sensor devices, wearable computing devices, or other technological and non-technological tools to better inform and enhance their health. The latter category refers extensively to what is known as Big Social Data and they can be mapped to the Digital Context category presented in our taxonomy. As described in Hansen et al. (2014), location-based information (derived from Global Positioning Systems, Geographic Information Systems, and other open source mapping

and visualization projects) explicitly generated by users are collected to provide information on the environmental and social determinants of health (Walker et al., 2017); disease outbreaks near a specific location was inferred from implicit location information (Jurgens, 2013). Also, user-generated content (UGC) within blogs and social networking services plays an important role in healthcare domain. Health-related UGC are used to assess disease spread in real-time or people sentiments and moods (Bhatia et al., 2019) or to facilitate discourse on non-emergency healthcare (Cassa et al., 2023); monitoring UGC can help to control the spread of infectious diseases via crowd surveillance (Bansal et al., 2016). Finally, Social Community Data can be collected or inferred from personal health data and advices shared amongst patients and consumers (Wicks et al., 2010).

6 Discussion and Conclusions

This paper focuses on providing a better conceptualization and a consensual definition of Big Social Data paradigm in order to help researchers to build proper methods for a purposeful processing and analysis of this specific type of data. This contributes to face the emerging challenges related to the growth of human-generated data, which calls for novel tools, frameworks and methodological approaches as well as multidisciplinary expertise to exploit the potential value embedded in these data sources. In order to reach this purpose a Systematic Literature Review has been conducted describing all the different phases that compose the research activity. The proposed definition represents a peculiar contribution in the current research debate in terms of BSD sources, attributes, technologies and social value as well as of BSD definition as human-generated data that differentiate BSD within the general field of Big Data.

A further contribution is related to the extension of a Big Social Data type taxonomy proposed by Olshannikova et al. (2017). A new category of data type has been introduced, namely “Digital Context Data” defined as data that reveal patterns of digital context dynamics. Example applications in data-intensive domains, such as smart tourism and e-health, have been provided in order to demonstrate how Big Social Data are already used to describe explicitly and implicitly patterns of digital context dynamics.

The implications of this result are valuable for both researchers and practitioners. The former are interested in developing further the distinguishing issues related to the BSD paradigm, as well as in a deeper analysis of data intensive domains to validate the definition provided in this paper. The latter can receive insights to purposefully design applications and services based on BSD to generate value for citizen, individuals, companies and territories, keeping in mind that BSD accessibility and privacy issues are still a central challenge as they may obstructs the utilization of BSD and the related exploration opportunities.

Further research is needed in two distinct directions: on one side, it could be useful to validate the definition proposed in relation of existing applicative researches. On the other side, it is still necessary to develop further the taxonomy of BSD data type with applications in more data-intensive domains.

Abstract

Companies are required to be compliant to differing kinds of legal and regulatory obligations due to their differing business models and the extremely diverse products and services they offer. Today the question “what is RegTech” is still not properly addressed. This paper is discussing definitions in the literature that represent the meaning for academics, practitioners and Authorities to deliver the conceptual definition to be used in research and scientific literature. The mission of our research is to have a map of regulatory technology with relationships to the FinTech innovation for:

(i) financial stability;

(ii) prudential regulation, so protection of the customers;

We will conduct a systematic literature review in Scopus and ISI Web of Science, SSRN, Google Scholar and Microsoft Academic as well as advanced research of the contents provided consultancy firm involved in RegTech and Authorities. The keywords are “RegTech” AND “is” OR “aimed to” using an inductive coding counting the word indicated as a direct object aside from the verb inside each contribution.

This paper gives a definition of the regtech concept from consultants, academics and authorities expressing Regtech’s perimeter and compare results between academics, practitioners and authorities.

In our study we address the following questions:

(1) *What is RegTech?*
(2) *How is RegTech definition in the literature?*
(3) *Which topics and uses are discussed in the context of RegTech by actors involved?*
The theme is very new and the existing academic literature is today narrow in this field.

Keywords –Regtech, Finance, Innovation, Fintech, Digital Technologies

Paper type – Academic Research Paper

1 Introduction

Since the Global Financial Crisis the financial services industry has faced a growing amount of regulatory change, as both international and domestic legislators for improving the functioning of the industry and reduce systemic risk.

Regulators have moved towards a risk-based approach where access to data is key to prudential supervision. For financial institutions, all of this regulatory activity has meant cost increases, in terms of capital (e.g. Basel III), operations (e.g. human resources), or penalties.

On the last point alone, since 2008, banks penalties in the western world have been calculated in over \$242 billion (DW Arner 2016).

Arguably, academics, industry and regulators share an interest in reducing fraud. A range of stakeholders are interested in increasing transparency and creating monitoring processes.

An increasing number of FinTechs applying technology to the regulatory process appeared into the market. These firms have a mission: to take the cost out of regulatory processes, giving adequate monitoring of transaction and deliver valuable real-time risk information.

The interest about Fintech and in particular the newborn RegTech is very strong from regulators. FCA¹, the UK's financial market Authority, presented a new way for the regulation's approach, its "regulatory sandbox"².

The research motivation is to focus the perimeter of RegTech that is not clear despite the consensus on the major impact that regulatory technology, RegTech, will have on the financial services industry. Moreover, no common definition of RegTech has yet been derived between academics, practitioners and authorities. Today the question "what is RegTech" is still not properly addressed.

No complete descriptions have been made so far to extract a consensual meaning and a definition of RegTech. But the methodology and definitions used must be precise and uniform.

¹ Financial conduct authority

²Sandbox is defined as space where financial services companies are encouraged in cohorts to test new products without regulatory consequences including RegTech solution. Another objective is to understand the trend of regulation from the academics.

The objective of this study is to offer a definition of definitions proposed by main actors in academic, consultancy and authority world, in order to discover what is inside the word “RegTech” through coding of definitions. The definition is useful to monitor and to map so determine a perimeter of RegTech for improving regulation and the comply to regulatory matters.

Detailing our research questions are:

- (1) What is RegTech?
- (2) How is RegTech definition in the literature?
- (3) Which topics and uses are discussed in the context of RegTech by actors involved?

Our results include three components: a conceptual definition of RegTech that reflects its perception by literature, the main actors involved in the development of the definition of RegTech (namely organizations, concepts and locations) and the differences between the different authors selected clusters.

In the end, this leads us to the conclusion of the study, but also we propose and stimulate with ideas for future research.

For academics, specifically the mission of our research could be to have an organic map of RegTech regulations with relationships to the FinTech technological innovation.

”RegTech” goals include:

- (i) financial stability;
