FOREWORD

Knowledge in Digital Age

Welcome to the 15th edition of IFKAD. This 2020's edition is signed by a disruptive event which has affected not only our annual academic event by it is profoundly touching and influencing the life of organisations and communities worldwide. Indeed, the coronavirus pandemic is introducing a new level of uncertainty and posing difficult and even unprecedented challenges for the sustainability of organisations and communities comparable only to the once generated by war.

Because of the coronavirus pandemic, we have decided to run IFKAD as a blended event with some sessions to be managed onsite and other online. For organisational reasons and taking into account the Matera is so far a coronavirus free city, we have opted to move the onsite event in Matera from the 9th to the 11th September 2020.

This year's IFKAD is supported by the University of Basilicata, the University of Rome Tre and the Chinese Culture University. The purpose of IFKAD 2020 is to understand the role of knowledge in the digital age to support organisational value creation dynamics and shape a sustainable future. Today's Digital Age is providing immediate access to data and information at a broader and more comprehensive quantity, and the acceleration of digital transformation is offering new paradigms for creating and managing knowledge.

The 15th edition of IFKAD wishes to extend our theories, findings and business discourses about the role and the dynamics of knowledge in the time of digital transformation and to what extent new technologies in combination with new strategic knowledge management approaches are innovating business models and supporting growth. The understanding of the role and methods of managing knowledge in the digital age takes even more relevance in today's scenario of facing the coronavirus pandemic. Technologies are proving to be the way to support knowledge sharing and the knowledge-based platform to guarantee the quasi-normal operation of organisations.

The coronavirus outbreak is first and foremost a human tragedy which is impacting on the people's lives across the world. But it is also having significant implications on the global economy and the enterprises' survival. The working mechanisms of socio-cultural and economic-production ecosystems are under threatening of disruption, and organisational systems are challenged to understand how they can face the consequences of the epidemic's spreading and impact. Organisations at the macro and micro level must learn how to meet and contain the adverse outcomes of the coronavirus outbreak. The business models and traditional working mechanisms are at stake.

Around the world meanwhile, the governments are putting in place actions both to contain the spreading of pandemic across territories and to manage the economic crisis, organisations must develop strategies and implement management initiatives to respond to the waves of disruption that the epidemic is generating. The understanding of the

strategy, projects and tools to manage the knowledge to get through the coronavirus crises is essential for survival and sustainability of any private, public and social organisation. The capacity of creating, employing and deploying knowledge is critical to protect the business and to guarantee that organisations can continuously contribute to the value creation dynamics of stakeholders' wealth creation. Knowledge management is essential to drive organisations through the crisis. It can help to implement change management, to optimise operations, and most importantly, to support organisational learning mechanisms that can turn into innovations strengthening organisational systems of responding to a complex socio-economic landscape. Knowledge management can contribute in different ways to face the coronavirus crisis. The management and assessment of knowledge assets can drive the workplace protection ensuring employees safety and engagement to find new solutions. A knowledge-based view of the employment and deployment of new technologies can support smart working, the security of employees' expertise from dispersion, the creation of knowledge communities for innovation, the strengthening of social capital to face the psychological and sociological human tragedies. Knowledge management strategies play a central role in developing supply chains resilience and reorganise operations. The assessment and protection of intellectual capital are critical to reducing the risks of a financial downturn. Finally, knowledge-based strategies can help to maintain relationships with customers and key stakeholders.

The mission of IFKAD is the development of research and scientific conversations aimed at contributing to theory-building as well as to the managerial practice about the role of knowledge as an organisational value-driven source. Our view is that organisations are primarily in the business of knowledge and from their capacity of managing knowledge depends on their future business sustainability and value creation capacity.

I want to extend my thank to all those colleagues and friends that every year work to make IFKAD a successful scientific event as well as a great social gathering where to meet old friends and make new once. Despite the particular moment we are living, I am sure that IFKAD2020 will continue to inspire a fruitful conversation capable of nurturing our curiosity and scientific expertise. And to provide insights that can help organisations to navigate during the difficult time and complex socio-economic landscape generated by the coronavirus crisis.

Abstract

The major purpose of this paper is to determine the opportunities and challenges relating to successful innovation management in SMEs in German and Slovakia. The research includes SME case studies so that recommendations can be made to SMEs for enhancing innovation management in the firm. In this research secondary data is gathered predominantly from empirical studies on SMEs; since these data sources are permanent the research can be repeated easily and therefore the reliability of the findings is enhanced. In order to answer the research problem, numerical and textual data is gathered but it is analysed in different ways. There are not participants in this study, since secondary data is the only source, hence the major ethical consideration is to ensure that the original author´s intentions are expressed when interpreting the data. This research identified key innovation management success factors for SMES as: innovation management models needed to be adapted to different organisational contexts; culture had a high impact on innovation management focus; social acceptance was a major factor for original new product market success so that customer needs and competitor activities were important information sources; cross cultural and cross functional teamworking. The failure factors identified were skills shortage in the labour market; lack of skills in the company; market uncertainty, imitation by competitors; lack of R&D planning and management. The study made three new findings, which add to the current knowledge: innovation circles were an effective innovation management approach to generating and developing ideas and getting innovation to market quickly; government agencies that encourage firms to collaborate effectively enhance the level and success of innovation; SMEs and large companies have distinctly different rankings of barriers to innovation and small and micro firms are more effective in original product innovation and speed to market than medium sized companies.
The limitations of this study are the lack of primary research that was possible. Therefore, recommendations for further include repeating this research but using primary sources of information, a small group of SMEs. The findings would be compared with these secondary outcomes. The surprising finding that micro and small companies were more successful than medium sized companies at new product/service innovation and generating high proportions of

their turnover from it, justifies further research into this concept. The validity of the study findings is strong as demonstrated by the convergence of findings with those of the established concepts comprising the Literature Review.

Keywords – Innovation, Organizational Change, SME, Barriers.

Paper type – Practical Paper

1 Introduction

Businesses thrive in a dynamic environment and in the contemporary global marketplace, organisations aim to survive by gaining competitive edge to increase their market share. As competition becomes increasingly difficult, companies need to find new ways of differentiating themselves, the traditional ways of doing business are becoming less attractive, because technology is constantly changing, and companies cannot rely on their current positions. Whilst large companies become more rigid, smaller organisations gain market share because of their ability to innovate and adapt to new technologies, new market situations and customer needs (Reichwald and Piller, 2009, p.1). The introduction of new technologies with appropriate strategies may also generate sustainable competitive advantage, this is not merely a consequence of adapting to change but also the ability to innovate. Large companies tend to react more slowly to changes in the market owing to their size and relatively bureaucratic structure, but they possess the resources to increase innovation. In terms of innovation, companies of all sizes experience advantages and disadvantages and traditionally innovation has been driven by a company's Research and Development (R&D) department but many companies have recognised its limitations and implemented interventions that would expand their knowledge sources. Therefore, closed innovation represented by internal R&D is becoming obsolete and organisational preference is for an open innovation framework.

The prerequisites for future success include the creation of the optimum environment for innovation so that competitiveness is continuously strengthened but often the challenges are the coordination of innovation specialists and removing organisational obstacles, such as silos, traditional sector mind-sets, and bureaucratic processes. In contrast to large organisations, Small and Medium sized Enterprises (SMEs) rarely have an innovation strategy or an innovation management system for systematically planning and implementing innovative practices, partly because management is usually focused on operational activities that are necessary for survival, so that strategic considerations are relatively neglected. Innovation research to date has focused primarily on large enterprises, rather than SMEs and therefore the purpose of this paper is to gain insight into the characteristics of innovation management including the challenges encountered.

2 Methodology Used

The essential of this paper is to determine the opportunities and challenges relating to successful innovation management in SMEs in German and Slovakia. The research includes SME case studies so that recommendations can be made to SMEs for enhancing innovation management in the firm.

The resolution of this research problem requires a philosophy that enables integration of objective facts and subjective opinions, because cause and effect links between innovation management methodology and new innovation product or service success is usually measured by economic means. This economic measurement is based on numerical factors, for instance number of successful innovations and associated revenue streams. However, the selection of the appropriate innovation methodology is subjective, and relies on the company owner's preferences and cultural norms, as identified in the Literature Review bellow. Therefore, the research philosophy selected is a pluralist or pragmatic approach (Onwuegbuzie and Leech, 2005, p. 382-385). The objective and the subjective stances to research comprise three interlinking philosophies: epistemology, ontology and axiology.

Therefore, the perspective of the pluralist philosophy is choice, the researcher adopts the stance most suitable for the specific research (Onwuegbuzie and Leech, 2005, p. 382-385). Since objective and subjective stances must be combined, the research design must reflect this, so for this study the major design elements are the explanatory and the exploratory approaches.

The purpose of explanatory design is to identify cause and effect links between key variables, in this case innovation management and commercial success, whereas the exploratory approach seeks to gain deeper insight into new phenomena or those that are not fully understood, as is the case with innovation management in SMEs.

In this paper a case study is the selected research strategy because it focuses on a small number of SME companies, in which real life issues are experienced and its purpose is to use multiple sources to gain deep understanding of innovation management within them. The case study is ideal for this research because it answers questions of what, when, how and why so that different perspectives on the issues can be expressed. Hence the case study forms the unit of analysis for the research (Saunders et al., 2008, p. 145-147).

The data gathering, and analysis is conducted using mixed methods, because the method is well established with the pluralist philosophy and allows the objective or positivist approach to be employed concurrently with the subjective stance (Onwuegbuzie and Leech, 2005, p. 385); it also provides a more holistic understanding of the issues so that the answer to the research problem demonstrates more than one perspective (Creswell and Creswell, 2017, p.1).

In this research secondary data is gathered predominantly from empirical studies on SMEs and published data on the case company; since these data sources are permanent the research can be repeated easily and therefore the reliability of the findings is enhanced (Ritchie and Lewis, 2010, p.270). In order to answer the research problem, numerical and

textual data is gathered but it is analysed in different ways. The numerical data is subjected to statistical analysis, which means that statistical constants indicate the significance of the findings, in other words is there a proven relationship between the two variable or not. The textual data is scrutinised to find recurring themes, expressed in the publications in certain words and phrases. Each of the themes is interpreted by the research with the purpose of expressing the meaning that the author associated with the words in the text.

The appropriate methodology is employed to enhance the reliability and validity of the findings. In terms of reliability the researcher provides full details of all research sources so that another researcher can access all of the data sources, whereas the validity of the findings is demonstrated by the degree of convergence they have with previous studies, for instance (Ritchie and Lewis, 2010, p.273-277). There are not participants in this study, since secondary data is the only source, hence the major ethical consideration is to ensure that the original author´s intentions are expressed when interpreting the data (Ritchie and Lewis, 2010, p.278).

3 Literature Review

Innovation is required for sustainable business but is a complex process that is often accompanied by organisational change, but change management usually fails (Beer and Nohria, 2000, p. 1-8), because the challenges of implementing change are as problematic as accomplishing successful innovation (GIZ©2012). Therefore, identifying a robust strategic change management system is vital.

Organisational change management is difficult to define (Stewart and Kringas, 2003, p. 1), since the term managing change has two distinct inferences: making changes in response to impacts over which the organisation has little control; invoking change in a planned and systematic manner (Stewart and Kringas, 2003, p.2). Contemporary organisations are confronted with diverse challenges resulting from globalisation and technological advances, which have necessitated new forms of operation and control (Kotter, 1996, p. 18).

A broader definition of organisational change suggests that globalisation is "an increasing consciousness of the organisation of finance, investment, production, distribution and marketing in ways that pertain to or embrace the world; a phenomenon that has both reinforced and been reinforced by the wider, more longstanding but continuing noting that history of technological developments that have reduced the significance of geographic space" (Sheil, 2001, p. 11). Globalisation has invoked diverse business risks for enterprise organisations (Kotter, 1996, p. 18), so that they must implement improvements to maintain competitive stance and to survive; in other words, change processes are vital to the retention of competitive advantage. These processes vary according to the organisation's characteristics, and may include elements of structure, vision and culture, financial aspects, organisational locations and control, transformational relationships, and technological developments. Therefore, organisational

change management can be primarily described as the implementation of efficient, effective methods to foster modifications throughout the organisation, whilst simultaneously encouraging all employees to accept the change, which is the most challenging aspect. Sustaining change is very challenging, as most companies comprise multiple work cultures which make change management increasingly difficult (Porras and Robertson, 1992, p. 719-822); sustainable change requires changes in organisational behaviours, values and rituals.

The importance of change management and the high failure factor, are reflected in the academic interest in the phenomenon, for instance Mintzberg and Westley (1992, p.41), subdivided it into four cycles, which describe the content and levels of change, means and processes, episodes and phases, and sequences and patterns of change. In comparison, Alvesson and Sveningsson (2016, p. 17) assume that the most important factors are its dimensions, sources, content and the political aspect. Therefore, it is apparent that both economic and social factors change an organisation, so that management planning is vital and that change cannot be effected by spontaneous experiments conducted by subordinate managers and employees (Alvesson and Sveningsson, 2016, p. 18).

Change may be instigated in various ways, from the need to resolve internal issues to engaging technological advances and strategic change must be shaped in terms of its scope, resource use, synergy and competitive advantage (Naghibi and Baban, 2011, p. 542). This means that strategic change is the change of the goals and vision of an organisation by focusing on achieving greater success; changes implemented do not always succeed (Naghibi and Baban, 2011, p. 542). The reasons for failure include poor implementation that is often characterised by poor communicate of change to the employees, and most importantly resistance to change because the organisational culture is so deeply embedded, according to Naghibi and Baban (2011, p. 542).

Change is associated with new policies, behaviours, patterns, methodologies, products or new market ideas and the management of change involves the design and construction of new patterns, or the re-conceptualisation of old ones, so as to enable more productive activities (Kanter, 1992, p.279). Change may also include the transformation of structures, procedures, regulations and rules, technology, education, and development (Lycke, 2003, p.206), affecting all parts of an organisation (Kanter, 1992, p. 11). However, organisations are mostly affected by environmental changes, which require an adjustment of inner processes to influence employees reshape their values and behaviours so that they coincide with selected strategic direction (Lawrence et al., 2006, p. 66). Zimmerman (1995, p. 15) argues that the workforce is the main facilitator of change, because they are involved into the processes of change and Swedberg and Douglas (2005, p.51) propose that gradual implementation limits resistance to change. Therefore, change can be understood as an ongoing process that occurs in public and private organisations and enables organisations to compete and develop innovative products or skills more effectively and generate higher profits and/or other desired goals (Doppler and Lauterburg, 2014, p.67). However, if change is not effectively managed there will be not

change, and the organisation is unlikely to survive in the longer term goals (Doppler and Lauterburg, 2014, p.122).

The main external barriers to changing to and innovation culture are regulation, bureaucracy, social acceptance, accessing employees with the requisite skills and knowledge, the external environment including sourcing the funding. The inhibitory effect of regulatory frameworks and bureaucratic procedures are exemplified by strict occupational safety, environmental and consumer protection regulations, which consume resources that could be applied to innovation (IW CONSULT©2015, p.443-451). The bureaucracy and regulation relating to new technologies deters SMEs from innovating to produced them (IW CONSULT©2015, p.56).

The barrier that relates to social acceptance often poorly understood (Currall et al., 2006, p. 153-155), it is very often linked to regulatory requirements, but the early adopter stage of the product life cycle is characterised by small numbers of consumer purchasers, who know about the product and are willing to take the risk that it will accomplish the claims made for it. This success of this stage is vital to more general acceptance as more information emerges.

Skills shortages are major barrier to innovation, especially professional skills especially in science and technology but also the soft skills required for collaborative working and information exchange and intercultural competence (Hunter, 2010, p. 88). The location of SMEs may also present a barrier to accessing graduate and postgraduate students, who tend to prefer major cities in which larger established firms are located. Large companies also have more resources to recruit staff on a global basis, although they may be somewhat hindered by immigration restrictions (IW CONSULT©2015, p.74).

A major barrier to innovation for SMEs is attracting adequate funding for new projects, owing to lack of collateral to act as security for a loan or absence of company credit rating (IW CONSULT©2015, p.80). The projects that tend to be favoured by funding organisations such a venture capitalist are high tech innovations rather than application related research. Access to suitable funding sources with terms and conditions that are manageable by SMEs is one of the major enablers or restrictors of developing an innovation culture and instigating the associated change management initiatives.

4 Findings and Discussion

Four analysed and researched studies on innovation management revealed a range of diverse but significant findings, which show distinct convergence with the major concepts and theories relating to innovation and organisational change. In studies, the impact of culture on the management of innovation, specifically, which aspects are considered to be important and the national reputation for innovation converge with idea the capacity of leaders to create an innovative culture in the organisation is of paramount importance (Furr and Dyer, 2014, p. 82-88). They also highlight the difficulty that firms appear to have in altering their innovative attempts from that associated with national culture, generating the necessary organisational change, to appeal to a more global market for

instance, traditionally the Irish SMEs have little innovative culture and fail to significantly contribute to the nation's high cultural standing in EU ratings (Kotter, 2015, p. 132), and less than 30% German SMEs participate. The French appear to concentrate on internal R&D and neglect external information available from customers, whereas the UK and Portuguese firms are more open to external contributions, with Portuguese being particularly externally focused. Hence, new patterns, behaviours and methodologies appear to change very slowly and learning is likely to be inhibited (Kanter, 1992, p. 279). The Korean study demonstrated that in terms of open innovation 50% or less of large firms and SMEs considered interaction with the external environment important. Therefore, the relatively low commitment to the social learning process that drives change may inhibit SMEs from optimising the initiation of innovation and of competitive advantage it represents (Kotter, 2015, p. 132), (Lawrence, 2006, p. 66).

Innovation management was considered to comprise scanning the external environment to identify change (Moore, 2004, p. 88), changes in organisational behaviour to optimise innovation (Vahs and Brem, 2013, p. 27), but customer demands, customer relationships and detailed analysis of competitor products were cited as more important in the first cross cultural study. In the German SME study nine factors were identified, which added teamwork, HRM tools and collaboration with external contacts. An interesting innovation management activity that was only mentioned in this study was specific innovation development practices, for instance the creation of innovation circles, changing the specialist composition of project teams regularly and interventions to enable employees to share information to develop the innovation strategy. These activities reflect at the very least a type of innovation process is concerned (Vahs and Brem, 2013, p. 225) and in some cases a managed approach to change that mirrors the first four stages of Kotter's (2013, p.23) eight stage change model, however, in terms of actual innovation management the concept of innovation circles did not appear in any of the established innovation management literature in the Literature Review for this study and can be considered a new finding. It may also be particularly suitable for SMEs owing to the flexibility of their organisational structure. In the Irish study formal management procedures were not found to generate superior outcomes that when no formal innovation management took place, the higher outcomes shown by the data for innovation management could not be statistically linked to innovation management.

In the Korean case, eight categories of specific innovation management were identified: training, marketing, employment of external knowledge, introducing external R&D, organisational change, product and process innovation support and internal R&D focus. This conception of innovation management implies focus on strategic and operational issues as were mentioned in the German study in which appropriate strategy was considered to be a substitute for it, converging with Franken and Franken (2011, p. 225).

In the Irish SME case a different type of innovation evaluation process was employed and concentrated on managing three distinct innovation stages, rather than focus on finer

detail such as resources; attention to internal and external idea generation, development of the concept and then distribution of products into the relevant market (Davenport, 1992, p. 1). Hence this approach was also highly concerned with marketing innovation (Levitt, 1962, p. 102) and organisational innovation (Moore, 2004, p. 88). The focus of this model is very similar to that of Hartschen et al. (2009, p. 11).

However open innovation was considered in all four studies, and perceived be relatively unimportant in the early study which spanned three countries, especially in France, where the implication was that closed innovation was preferred (Dyer and Singh, 1998, p. 676). The date of this study may have some relevance to the overall conclusion made by the researchers, since globalisation has generated more focus and diverse approaches as external environmental changes have increasingly impacted on firms (Kotter, 1996, p. 18). The findings of the study of German SMEs the German study suggested that whilst combination of internal and external sources for innovation often provided a superior outcome, that this could be equally well achieved by a closed approach if the firm developed a suitable strategy, which has some alignment with the RBV concept of the firm (Dyer & Singh, 1998, p. 576). The study also suggested the major open innovation choices was outside-in (Gassman and Enkel, 2004, p. 15), as did the Irish SME study, which mentioned no knowledge sourcing activities except use of external knowledge.

As with the Irish SME prime activity and competence, the Korean firms tended to focus most, and most effectively on original new innovations, using the invention, develop and commercialise process. They also concentrated on both outside-in and inside-out, coupled open innovation (Gassman and Enkel, 2004, p. 13), and with a wider range of contacts, since universities and research centres were also a preferred source, especially for long term projects and the lower risk of exploitation of their ideas by an external partner. This represents a different context for innovation that found in the other three studies, much broader external knowledge sourcing and possibly a consequence of governmental agency supports to extend networking in these firms; a factor not mentioned in the established literature and therefore a second new finding from this study.

Hence, the findings from these studies align with the established theory, that identical innovation processes and approaches are to be expected owing to each firm's specific set of circumstances (Damanapour et al., 2009, p. 650).

Innovation success factors varied from a need to use open innovation on a continuous basis if the firm opted for open innovation, otherwise success was less certain, to highly detailed innovation management as in the Korean case but also developing detailed strategy as a substitute for formal management, an idea that has similarities to the German eight element innovation management model. Social acceptance factors were emphasised by the Korean case, specifically the marketing activity and training required to ensure that the original invention met market needs; the Korean SME focus on customers, competitors in the same market and affiliates aligns with this strategy and with the

established literature's emphasis on social acceptance as a success factor (IW CONSULT©2012, p. 443-451). The Irish case also suggested that managed innovation resulted in more original product and service innovations and faster market introduction and penetration; these findings tend to align with the Korean research. The importance of working closely with key customers was also mentioned in the cross cultural study, this align with altering behaviours and organisational change to leverage productivity (Kotter, 2012, p. 24-25). Cross cultural teamworking was found to a success factor in all four studies (Kotter, 2015, p. 132), but the Irish study also mentioned appointing a team manager, defining key metrics to measure progress, and specifying an R&D budget (Vahs & Brem, 2013, p. 27).

The barriers to SME innovation had substantial emphasis in the Korean study, which rated them by impact finding that shortage of skills in the labour market and internally were the two highest barriers, followed by market uncertainty, new product or service imitation by competitors and limited R&D planning and management. In the other studies the main barriers highlighted were lack of access to financing networks; many of these align with established studies (IW CONSULT©2015, s. 28-34). A third new finding emerged from the Korean study, which established a list of ratings of barrier to innovation for SMEs and large companies, and whilst the Irish study noted that formal innovation management appeared to be more important in the large company context than for SMEs. Whilst the highest barriers to innovation for SMEs related to skills shortages, market structure was rated first for large companies; large companies ranked labour market skills shortages 3 and internal skills shortages 11.

A surprising finding from the Irish context was that large firms tended to be more innovative than SMEs, which is partly contradicted by the findings of that study, which show that the micro and small SMES have more capacity for getting original products to market and speedily, as well as generating higher proportions of their total revenue from them than medium sized companies. In the Literature large firms are considered to have lower innovation capacity than small firms, so that the findings of this study do not align with accepted theory that large firms are less innovation ready owing to lack of organisational flexibility (IW CONSULT©2015, s. 23). However, the Korean study also suggested large firms had advantages for innovation, specifically their access to advanced technologies that SMEs did not.

The outcomes of the case study conducted in Slovakia are different from the above. The company culture is highly traditional, it is hierarchical, risk averse as demonstrated by tight budgeting and the lack of change in the behaviours of the Slovak based employees in recent years; a short term orientation that represents a barrier to change, exemplified by retention of old technology that represents its cultural norms (IW CONSULT©2015, p. 34); it has many attributes of large company culture that impedes organisational learning (Leavy, 2005, p. 4). Whilst the company information implies that change to an innovative culture has already taken place, in fact some of the systems and processes have changed, whilst the culture has not, as Kotter (2012, p. 37-142),

emphasises, the first stages represent a shift in some behaviours but that does not indicate that cultural values have altered. The organisation is between steps 5 and 6 of the eight-stage plan, as suggested by celebrating successes and system alterations, but Slovak employees retain a public sector attitude. In addition, the Managing Directors are not leading the culture change as they retain inappropriate structures in Slovakia and high risk attitude that is not appropriate to an innovation culture (Kotter, 2012, p. 37-124).

The current arrangement that resemble an innovation management attempt to change to an innovation culture include creating the environment for substantial exchange of information and perspectives.

The company is striving to accomplish two types of innovation, incremental which is more typical of large companies and original innovation that is more often successful in SMEs (Govindarajan et al., 2010, p.76). It is also employing considerable external knowledge from its clients when on their premises, which it merges with its current knowledge in order to improve its offering to them, so that both inside out and outside-in open innovation, coupling is a key innovation management approach (Gassman and Enkel, 2004, p.13).

Amongst the barriers to change not already specified, is the shortage of skills in Slovak which is implied by high staff turnover.

The total company is not strictly an SME as it has more than 250 employees, but the Bratislava location comes within the definition of a micro or a small enterprise. It currently has the latest technology, a small flexible team and has been provided with training support all of which are innovation management techniques to create an innovation culture. However, serious barriers to innovation are the restricted budgets.

UVI can be described as a paradox at this stage, whilst its business model offered to clients promotes open innovation, its internal organisation generally represents a culture that is hindering innovation.

5 Conclusions

The aim of this paper was to develop a broad understanding of innovation management linked to related management literature. In the theoretical framework the related concepts were appraised as relevant to answering the research problem, specifically innovation, innovation management, open innovation and organisational change in the context of developing an organisational innovation culture.

The research problem was to identify the opportunities and challenges for successful innovation management in SMEs. This objective was accomplished in two ways, firstly be selecting a small sample of empirical studies, which evaluated innovation management, innovation culture and organisational change from diverse cultural perspectives and using different innovation management evaluation models, these were presented, analysed and discussed and the key success and failure factors identified as well as specific innovation management techniques and the differences between large, medium and small organisations. A new case study was then introduced, a German

organisation, which had recently internationalised by creating a new company in Bratislava, Slovakia. Its organisational structure, main activities innovation approaches were identified and its strengths and weaknesses as an innovative company were evaluated. The findings showed that this company, retained a traditional hierarchical culture despite espousing that it practices open innovation and helped its clients to do so. The findings from the four cases were then applied to the German company as potential opportunities and threats.

This research identified key innovation management success factors for SMES as: innovation management models needed to be adapted to different organisational contexts; culture had a high impact on innovation management focus; social acceptance was a major factor for original new product market success so that customer needs and competitor activities were important information sources; cross cultural and cross functional teamworking. The failure factors identified were: skills shortage in the labour market; lack of skills in the company; market uncertainty, imitation by competitors; lack of R&D planning and management.

The study made three new findings, which add to the current knowledge: innovation circles were an effective innovation management approach to generating and developing ideas and getting innovation to market quickly; government agencies that encourage firms to collaborate effectively enhance the level and success of innovation; SMEs and large companies have distinctly different rankings of barriers to innovation and small and micro firms are more effective in original product innovation and speed to market than medium sized companies.

The limitations of this study are the lack of primary research that was possible. Therefore, recommendations for further include repeating this research but using primary sources of information, a small group of SMEs. The findings would be compared with these secondary outcomes. The surprising finding that micro and small companies were more successful than medium sized companies at new product/service innovation and generating high proportions of their turnover from it, justifies further research into this concept.

The validity of the study findings is strong as demonstrated by the convergence of findings with those of the established concepts comprising the Literature Review.

Abstract

The digital age has been witnessing important changes derived from ICTs development in every economic sector (Soava, 2015). Consequently, if they want to survive and develop in the digital age, the different economic sectors will need to integrate ICTs into their everyday activities. The tourism sector currently arises as a key driver of economic growth and job creation. The influence of ICTs on the tourism sector has been twofold. On the one hand, changing how organisations operate in the tourist market; and, on the other hand, developing a new way for customers to interact with these tourism enterprises. The future of the tourism sector is going to require 'digital skills'.

In view of the above, this work has as its aim to identify the gap existing between the current and future needs regarding digital skills, as well as the training needs for the 2030 horizon in Spanish tourism organisations belonging to five subsectors (Accommodation; Food & Beverage; Destination Management; Visitor Attractions; and Travel Agents & Tour Operators).

The development of this work is framed within the European project called *Next Tourism Generation* (NTG). It can be described as a multidisciplinary association that involves 14 partners from 8 countries. The NTG Alliance seeks to develop a Blueprint Strategy for digital and sustainability (green and social) skills within the tourism and hospitality sector.

A mixed research methodology, which combined qualitative and quantitative approaches, served as the basis for this research work. Qualitative research took place between April 2018 and March 2019 and went through three stages: *desk research*, *focus groups* and *interviews*. Quantitative research developed from January to June 2019 by means of an online administered survey (*Qualtrics*). 139 Spanish tourism organisations participated.

Both research methodologies provided interesting results not only about the current and future status of digital skills in the Spanish subsectors analysed but also about the training needs associated with them. Those findings constitute the starting point to develop a Europe-wide blueprint strategy able to provide employees, employers, entrepreneurs, teachers, trainers and students with a set of core digital skills represented in a skills matrix.

Keywords – NTG Alliance, Digital skills, Tourism, Training

Paper type – Practical Paper

1 Introduction

The appearance of the Internet, together with the development of Information and Communication Technologies (ICTs), have revolutionised today's economic context, giving rise to the emergence of the digital economy. The digital age has been witnessing important changes derived from ICTs development in every economic sector (Soava, 2015). Consequently, if they want to survive and develop in the digital age, the different economic sectors will need to integrate ICTs into their everyday activities.

The tourism sector has currently become a key driver of economic growth and job creation. The influence of ICTs on this sector has been twofold. On the one hand, by changing how organisations operate in the tourist market; on the other hand, by developing a new way for customers to interact with these tourism firms. Expressed differently, the future of the tourism sector is going to require a set of skills other than those used at present, namely the so-called 'digital skills.'

Amongst the key challenges to be faced by the tourism sector, the most outstanding ones are both the lack of training and the difficulty to attract and retain highly-qualified professionals. This, along with the increased use of ICTs, directly impacts on the need for skills that can ensure a competent performance at workplaces, which in turn generates training needs (Cerezo and Guevara, 2018).

In view of the above, this work aims to identify the gap existing between the current and future needs regarding digital skills, as well as the training needs for the 2030 horizon in Spanish tourism organisations belonging to five subsectors (Accommodation, Food & Beverage, Destination Management, Visitor Attractions, and Travel Agents & Tour Operators). More specifically, this paper will try to answer five research questions.

The development of this work is framed within the European project called *Next Tourism Generation* (NTG). A mixed-research methodology, which combined qualitative and quantitative approaches, served as the basis for its development. Both methodologies provided interesting results not only about the current and future status of digital skills in the Spanish subsectors analysed but also about the training needs associated with them.

The paper is structured as follows: after an introduction, a review of the literature is performed, analysing the impact of ICTs on the tourism business and the need for new skills by tourism professionals. Then, the methodology section describes the mixed-research strategy applied, the study population and the tools used to collect information. Following this, the results obtained are shown, and the paper finishes with the main conclusions and potential lines of research.

2 Literature review: digital era, digital skills and tourism

ICTs have changed the manner in which we live and do our work, altering the way we buy products, communicate with each other and train students (Stone et al., 2015). In the business context, the use of ICTs has become a strategic asset for corporations, changing the way they communicate and relate to their stakeholders. ICTs and the Internet have

altered the foundations of competition in all economic sectors, leading to the appearance of new products, services, and processes. Therefore, there is no doubt that technology has also affected the tourism sector (Prentice, Dominique and Wang, 2019; Soava, 2015; Hojeghan and Esfangareh, 2011; Minghetti and Buhalis, 2010).

The Internet has changed the value chain of tourism creation, commercialization, distribution and consumption (Capriello and Riboldazzi, 2019; Gretzel, Yuan and Fesenmaier 2000), allowing tourists access to reliable, accurate information, and to make real-time reservations, thus improving service quality and increasing customer satisfaction. In the digital era, tourists are more independent and sophisticated, and can use a wide range of tools to plan their travel (Soava, 2015).

The impact of ICTs on tourism and their potential evolution in the future also seem to be creating a new context for tourist destination management (Ivars-Baidal et al., 2019; Trunfio and Della Lucia, 2019). In turn, Big Data offer challenges and opportunities both for existing firms and for new players in the tourism sector. Big Data make it possible to predict tourist demand, manage knowledge flows and interact with customers. This may lead to higher productivity, increased customer satisfaction, personalized marketing campaigns and more efficient operations (Ardito et al., 2019).

Virtual reality and Artificial Intelligence (AI) systems offer major opportunities for the tourism sector. Simon (1980) defines AI as the science dealing with the design and the development of computer solutions in order to carry out human tasks. Within the sphere of tourism, AI systems will provide users with a choice of virtual reality examples allowing them to see places of interest, hear and even feel the landscape (Soava, 2015). Besides, chatbots applying analytical artificial intelligence in the hotel industry may generate automatic replies to customers' queries (Chung et al., 2018).

ICTs are increasingly becoming a part of jobs in the tourism sector and, together with the evolution of the technology itself and the changes in the productive framework of tourism, are increasing job complexity (some jobs change, many disappear, and new jobs emerge) and demand new types of skills (Cerezo and Guevara, 2018). Tourism is labour-intensive and the customer-employee interface is a key determinant of quality, employees being key assets for tourism organisations. The real challenge is finding and retaining employees with the right skills, knowledge and attitudes (Haven-Tang and Jones, 2008).

In this context, one may wonder if the human capital, a key component of the tourism sector, possesses the necessary skills to use these technological tools, both at present and over the next years. In this line, the European Commission has emphasized the lack of qualifications of tourism employees in the face of the increasing usage of ICTs in this industry (European Commission, 2010).

In this context, training and developing digital skills among tourism professionals becomes a necessary condition for the success of tourism organizations. Therefore, this paper tries to provide a reply to the following research questions: (1) What is the current level of digital skills in tourism organisations? (2) What level should tourism organisations achieve regarding digital skills by 2030? (3) Do tourism organisations

provide training in digital skills? (4) What types of training in digital skills are offered by tourism organisations? (5) What are the reasons why training in digital skills is not provided in tourism organisations?

The following section describes the research strategy implemented in order to reply to the five research questions formulated.

3 Methodology

As mentioned in the Introduction section, the development of this work is framed within the European project called *Next Tourism Generation* (NTG). NTG is the first European alliance meant to improve the collaborative and productive relationship between the educational system and the tourism sector. It is financed with a total of 4 million euros by the European Union and has a four-year duration (January 2018-December 2021). It can be described as a multidisciplinary association that involves 14 partners from 8 countries: 7 industrial partners and tourism sector representatives (Federturismo Confindustria-Italy, UnionCamere-Italy, Eurogites-France, Deutsches Seminar Für Tourismus (DSFT)-Germany, People 1st International-UK, Vimosz-Hungary, CEHAT-Spain), 6 universities (University of Alicante-Spain, Varna University of Management-Bulgaria, Breda University of Applied Science-The Netherlands, Cardiff Metropolitan University-UK, University of Sopron-Hungary, Technological University Dublin-Ireland) and the Association for Tourism and Leisure Education and Research (ATLAS). The NTG Alliance seeks to develop a Blueprint Strategy for digital and sustainability (green and social) skills within the tourism and hospitality sector.

In line with the purpose stated, this work focuses on the development of a part of the NTG project, analysing only the digital skills and the training needs for the 2030 horizon in Spanish tourism organisations belonging to five subsectors mentioned. Spain is the second largest tourist destination in Spain, after France. The Spanish tourism sector grew by 2.4% in 2018 —making a 14.6% contribution to Spain's GDP— and employed 2.8 million people, which accounts for 14.7% of total employment (WTTC, 2019). Due to the economic weight of tourism and the employment it creates, Spain is the ideal context for the study of the topics analysed.

A mixed-research methodology, which combined qualitative and quantitative (QUAL/QUAN) approaches, served as the basis for this research work. We shall now describe each of the methodologies used.

3.1 Qualitative research

The qualitative research took place between April 2018 and March 2019, and was performed in three phases: (1) desk research; (2) focus groups; (3) interviews.

In the first phase (*desk research*), each partner performed, in its country, an in-depth analysis of the situation of digital and sustainability skills in the five subsectors mentioned. For such purpose, secondary data were thoroughly examined, obtained from

corporate reports, academic journals, specialized industry journals, government strategies, handbooks and websites. The purpose was to know the problems and challenges related to gaps in such skills, and also the training needs in tourism organizations (NTG Skills Alliance, 2019).

The second phase was carried out through focus groups, formed by the most representative public and private organizations within each of the subsectors analysed. The focus groups are a key tool to show current practices. Five focus groups were created for each subsector, whose main purpose was to discuss the key challenges, problems and opportunities for the development of staff skills and job descriptions within the corporations. The meetings had an approximate duration of one and a half hours, and dealt with 11 main issues, regarding the need for skills and training in the areas studied (digital, green and social).

For the third stage of the research (interviews), it was decided to use the case study as a research method, since its characteristics allow a closer approach to the subject matter. The multiple case study was used, instead of the single case, in order to find behaviour patterns making it possible to extrapolate the results obtained in various economic, organizational and sector contexts ("replication logic", Yin, 2012). A single case would have a low degree of representativeness and would limit the scope of the conclusions to a specific type of organization and business sector.

The cases were selected using non-random sampling, choosing those that offered the best opportunities for learning. 264 organizations were selected from various tourism subsectors at a European level, 30 of them from Spain (14 Accommodation, 5 Food & Beverage, 6 Destination Management, 2 Visitor Attractions, 3 Travel Agents & Tour Operators).

In order to collect information, a standard semi-structured interview was used, divided into 4 sections, containing 23 questions. The first two sections included 5 questions related to the main characteristics of the organization studied. The third section consisted of 13 questions enquiring into the importance the respondents attached at present to the set of skills analysed, to their future weight and the training currently offered on such skills. The fourth section, consisting of 5 questions, focused on obtaining information on the respondents' view on the future of tourism (skills and training) for the year 2030. The interviews, which had an average duration of approximately 1 hour, were recorded and then transcribed. All organizations studied signed a participant consent form.

3.2 Quantitative research

The quantitative research took place between January and June 2019, and was carried out through an online survey at a European level. The total number of organizations taking place in the survey was 1404, out of which 139 were Spanish organizations (68 Accommodation, 15 Food & Beverage, 22 Destination Management, 27 Visitor Attractions and 7 Travel Agents & Tour Operators).

The questionnaire was developed by a group of experts including both academics and professionals. It was sent to the senior person responsible for each organization using the Qualtrics online platform, together with an introductory letter stating the project goals and the confidentiality terms. The questionnaire consisted of 25 questions of different types (closed, open, dichotomic, ordinal, multiple-choice and Likert scales) divided into 4 sections. The first section, of an introductory nature, included 6 questions; the second section, consisting of 5 questions, focused on obtaining information on environmental management skills; the third section, with 9 questions, dealt with social skills; and the fourth section, consisting of 5 questions, focused on digital skills. As this paper deals with the analysis of digital skills, a description will now be offered of sections one and four, which have been the basis for the empirical work.

Section I: Introduction

- Country where the firm or organization is located.
- Region, within the country, where the firm or organization is located.
- Subsector in which the firm operates.
- Specific activity developed by the firm or organization.
- Respondent's role.
- Size of the organization.

Section IV: Digital skills

- With the first question, each respondent had to assess, within a scale of 1 (no digital skills are possessed) to 5 (expert) the present level of competence of their organization regarding digital skills (13 items).
- With the second question, each respondent had to assess, within a scale of 1 (no skills are possessed) to 5 (expert) the future level of competence that their organization will need by the year 2030 regarding digital skills (13 items).
- With the third question, the respondent had to state if their organization provides any type of training to its employees (internally or externally) in digital skills.
- If the answer was "yes", in the fourth question the respondent had to state the type of training in digital skills provided to their employees (10 items).
- If the answer was "no", in the fifth question the respondent was asked to explain the reasons why they were not providing training in digital skills to their employees.

4 Empirical evidence

This section attempts to provide answers to the research questions proposed. Table 1 shows the results obtained in the qualitative research with respect to the present and future need for digital skills in each of the subsectors analysed. Tables 2 and 3 show the results obtained in the quantitative research.

Research question 1. What is the current level of digital skills in tourism organisations? Research question 2. What level should tourism organisations achieve regarding digital skills by 2030?

In general terms, it may be observed that, almost in all subsectors, basic digital skills (use of operating systems, Microsoft Office, Wi-Fi, sound systems, video projectors and social media) are the most important ones, both at present and for the year 2030. In spite of the fast technological advances, it is worth noting that, in all of them, the least important skills at present are also the least important ones for the future. These include skills related to computer programming, robotics and artificial intelligence and use of virtual and augmented reality. Such skills, which are quite necessary for the near future, will require high degrees of training, in order to reach an optimum level in tourism organizations.

More specifically, in the accommodation subsector, the use of mobile devices and tablet computers for apps related to check-in and check-out activities, and control of air conditioning, heating, TV and lighting, are examples of how the digital sphere is currently playing a major role in its activities. By the year 2030, cybersecurity, domotics and biometrics skills will be a must. Domotics will make it possible to enhance guest experience by creating environments suited to their mood and improving comfort in the facilities. Biometrics will be increasingly used to enable guest identification and access to the various services in each establishment (Espeso-Molinero and Camps, 2019).

In the food & beverage subsector, there is evidence that dietary habits are changing, and both for the present and future generations, it will be usual to eat at restaurants, buy prepared meals or order food online and have it delivered at home (NTG, 2019). Therefore, currently there is a need for marketing and customer interaction skills, mobile apps management, specialization in social media, knowledge of payment systems, and

online security. Due to the large amounts of prepared meals that will predictably be demanded by the market by 2030, one of the most immediate needs will be to industrialize the activity. Also important for the future will be digital storytelling around food and restaurants.

It is expected that Destination Management Organization (DMO) will change from merely providing information to providing inspiration and experiences for visitors (NTG, 2019). In order to manage the large amount of information they possess, they will need to acquire destination monitoring skills through big data analysis and the use of business intelligence tools. This will provide them with a database allowing decision-making and destination monitoring. For the future, it is expected that virtual and augmented reality will improve visitor experience (Espeso-Molinero and Camps, 2019).

In the visitor attraction subsector, visitor experience plays a central role; this is why there is a wide range of virtual and augmented reality apps and software enhancing visitor experience. However, since there is still a certain digital divide among visitors, it is necessary for institutions to maintain device and software usability for all audiences; such devices and software must be easy to use.

In the travel agents & tour operators subsector, it may be observed that many future customers will be digital natives, which will make it pointless to distinguish between online and offline offer, as is done today. Although the average digital skills level appears to be sufficient at present, it will be necessary to face the fear of change, the need to be flexible and quickly learn to manage different technologies. In this subsector, basic digital skills will be complemented by online marketing and communication skills, and also those skills necessary for web development.

Research question 3. Do tourism organisations provide training in digital skills?

Research question 4. What types of training in digital skills are offered by tourism organisations?

Research question 5. What are the reasons why training in digital skills is not provided in tourism organisations?

Because digitalisation has increased very quickly and the trend nowadays is to be more and more digital, a high percentage of respondent organizations provide some training for their employees in digital skills. It is worth emphasizing that 100% of the organizations participating in the study belonging to the travel agents & tour operators subsector, provide training to their employees. At the other end of the spectrum, mention must be made of the fact that almost 50% of the organizations in the food & beverage and accommodation sectors do not provide any type of training in digital skills.

The most common types of training in digital skills are on-the-job courses, followed by online courses, several days on-site training by an external provider and one day on and off-site training by external provider. On-line training provides greater flexibility, efficiency and reduced costs, as compared to more traditional training methods (Stone et al., 2015). The subsector *food & beverage* is the only one that considers that one of the main types of training is higher education, mainly because the digital skills required by

their organisations (higher knowledge of information technology tools and specialization in social networks, marketing tools, CRM and ERP software, payment systems, online security, etc.) need a higher level of education that cannot be achieved through another type of training.

The main reasons why tourism organizations do not provide training in digital skills are mainly due to lack of budget, lack of time, to the fact that managers are not sensitive to digital issues, and to the fact that many of those capabilities are outsourced.

5 Conclusions

The development of ICTs and their integration in the activities of all economic sectors has shown the need to possess digital skills in order to optimize the use of these technologies. Because the tourism sector is at present a key driver of economic growth and job creation, the purpose of this paper has been to identify the gap existing between the current and future needs regarding digital skills, as well as the training needs for the 2030 horizon in Spanish tourism organisations belonging to five subsectors (Accommodation; Food & Beverage; Destination Management; Visitor Attractions; and Travel Agents & Tour Operators).

Within the framework of the NTG European project, and applying a mixed-research method (QUAL/QUAN), answers were provided to the five research questions formulated. The results obtained for Spain are similar to those obtained at a European level. Those findings show that the future tourism sector will require skills sets which in some respects will be radically different from today's, especially in the field of digital skills. These skills should be supplemented by others, mainly those related to social skills.

In spite of the constant technological advances, the tourism organizations analysed consider that digital skills are still an unresolved issue. Employees are more prone to work with a greater number of devices, and are willing to operate in environments where technology has an increasingly leading role. However, organizations believe that there remains a lot to be done until employees have, both at present and by the year 2030, a suitable level of digital skills enabling them to operate in the tourism subsectors analysed. In all these sectors, the need has been observed for staff to be more adaptable, due to the existence of a higher degree of automatization and the use of specific computer software.

The main contributions of this paper are as follows: from a theoretical point of view, a review of the literature has been made, showing the existence of a gap in digital skills (both at present and for the future, in 2030) in the tourism sector, and also the training needs in this area. From an empirical point of view, firstly, a thorough survey was carried out at a European level, combining qualitative and quantitative methodologies, using four research tools (desk research, focus groups, interviews and surveys) in order to identify the abovementioned gaps in digital skills. To date, we have been unable to find a similar study in the scientific literature. Secondly, with the results obtained, a Blueprint strategy will be developed (within the NTG Alliance European project) which will provide employees, employers, entrepreneurs, teachers, trainers and students with a set of core

digital skills represented in a skills matrix with associated content in units/modules. Those modules can be applied using a range of delivery methods, guidelines and tools across different levels of industry jobs and different levels of qualification and training by education and learning providers (NTG Skills Alliance, 2019). Thirdly, the skills matrix and the Blueprint strategy become proactive tools making it possible to anticipate future needs in digital skills in the tourism sector. This results from the need for a consensus among tourism operators of the need to upgrade skills, improve professionalism among employers and employees, and to nurture a training culture as an integral part of overall business performance. At a local level, learning providers and tourism businesses need to work together to understand each other's operating environments and needs, so that tourism and hospitality students develop realistic expectations of the sector and have the skills to ensure competitiveness (Adeyinka-Ojo, 2018; Haven-Tang and Jones, 2008).

In spite of the exhaustive research carried out, the main limitation of this work is that it has focused on the analysis of digital skills in the Spanish tourism sector. Future research should extend the analysis both to green and to social skills in the five tourism subsectors analysed, not only in Spain, but also at a European level.

Funding

The authors wish to express their gratitude for the support received from the European Union in the writing of this paper within the framework of Erasmus + Programme, Next Tourism generation alliance 591982-EPP-1-2017-IT-EPPKA2-SSA-B.

Acknowledgements

The authors would like to acknowledge the collaboration provided by all members of the research team that was in charge of the project, whose ideas turned out to be highly useful to carry out and complete this study.

Thanks are due to Dr. Miguel Ángel Campos-Pardillos, from the English Department at the University of Alicante, for the language revision of this paper.

Abstract

Organization's capability to innovate is closely tied to its intellectual capital; yet, studies addressing this issue have neglected marketing innovation and have mostly focused on technological innovation. However, marketing innovation (i.e., innovation in pricing, product/service design and packaging, placement and promotion) can help attract customers and increase the demand of a firm's products with a relatively smaller investment than technological innovation. In this paper, we test how knowledge generated by means of marketing-specific IT solutions (i.e., marketing-specific IT capital) and other forms of organizational memory in the marketing domain (i.e., marketing-specific organizational memory) can contribute to marketing innovation and subsequent market performance. Using marketing directors-reported data, we empirically test research hypotheses by means of structural equation modelling based on partial least squares. Results reveal that while marketing innovation fully mediates the relationship between organizational memory and market performance, it partially mediates the relationship between IT capital and market performance. Moreover, the study identifies which are the most relevant knowledge resources within marketing-specific IT capital and organizational memory to boost both marketing innovation and market performance. This encourages marketing managers to carefully assess marketing-specific knowledge resources residing in the firm to benefit their businesses.

Keywords – Intellectual capital, Structural capital, Marketing innovation, Market performance.

Paper type – Academic Research Paper

1 Introduction

Despite the relevant role that marketing innovation could play in firm competitiveness (e.g., Ren et al., 2010), there is dearth of empirical studies addressing both the antecedents (Geldes and Felzenstein, 2013; Ramírez et al., 2018) and outcomes (Medrano-Sáez and Olarte-Pascual, 2016) of such innovation.

According to Ramírez et al. (2018), attention has only been substantially drawn on marketing innovation since its inclusion in the third edition of the Oslo Manual (OECD, 2005), i.e., the international reference guide for collecting and using innovation data. According to this guide, "Marketing innovations involve the implementation of new marketing methods. These can include changes in product design and packaging, in product promotion and placement, and in methods for pricing goods and services" (p. 17). In other words, marketing innovation consists of "improvements in the marketing mix" (Naidoo, 2010; p. 1311) and has been positioned in the literature as a type of incremental innovation (e.g., Grewal and Tansuhaj, 2001; Contò et al., 2015).

As Naidoo (2010) points out, marketing innovation provides quick fix solutions emphasizing low-risk product modifications, extension, and design changes. It allows differentiation by enabling companies to address the psychological needs of consumers and the rational needs of business-to-business customers by improving their ability to sell (Gupta and Malhotra, 2013). In short, marketing innovation attracts clients (Medrano-Sáez and Olarte-Pascual, 2016) and increases the demand for a firm's products (Ramírez et al., 2018) with a relatively smaller investment than technological innovation (Medrano-Sáez and Olarte-Pascual, 2016).

Among the array of potential enablers of marketing innovation, intellectual capital (IC) deserves special attention. According to Subramaniam and Youndt (2005), "It is widely accepted that an organization's capability to innovate is closely tied to its intellectual capital or its ability to utilize its knowledge resources" (p. 450). However, a recent structured literature review on the IC-innovation linkage by Buenechea-Elberdin (2017) revealed that no previous study had analyzed the influence of IC on marketing innovation.

Given the proliferation of marketing-oriented IT solutions and the significant possibilities now offered by data analytics to extract marketing-related knowledge from companies' data records, as well as the importance of marketing-specific organizational memory (i.e., stored information from an organization's past; Walsh and Ungson, 1991), the question arises about the real impact of each type of knowledge resources in the generation of new marketing methods (and subsequent market performance). These two elements (IT capital and organizational memory) constitute what is known as structural capital (SC) (Bueno et al., 2011) and, in this case, marketing-specific SC (i.e., all marketing-related knowledge residing in a firm's information systems, databases, documents, manuals, routines, and procedures, as well as in any other physical and/or digital artefacts; Peñalba-Aguirrezabalaga et al., 2020). The aim of this paper is to analyze the influence of both constituents of marketing-specific SC on marketing innovation and market performance.

This paper represents a relevant contribution to the IC, marketing, and innovation literatures because it clarifies how organizational knowledge in the marketing domain can contribute to innovation in marketing methods, and thus to attract and retain customers. Moreover, this study is among the first ones that adopts a contextual approach to IC and that shows how knowledge resources regarding a particular function in the company could contribute to firm performance, hence providing a more fine-grained picture about the specific knowledge resources and IT technology in which managers need to invest.

2 Theoretical background

This study assumes the knowledge perspective of IC (Peñalaba-Arrizabalaga et al., 2020), and thus conceives the former as the sum of all knowledge that firms leverage to gain competitive advantage. Usually, a tricomponent classification is suggested that groups resources according to where they reside: people (i.e., human capital), the organization (i.e., structural capital), or relationships (i.e., relational capital).

Following Bueno et al. (2011), a distinction could be made within SC between IT (or technological) capital and organizational capital. In the context of this paper, IT capital refers to knowledge resources generated by means of IT solutions (e.g., knowledge on behavioral patterns obtained through data analytics), while organizational knowledge (or "organizational memory") refers to knowledge that has not been generated by means of computer-based data processing, although it may be stored in a digital repository (e.g., knowledge on best practices and lessons learned, or information records regarding past projects, deals, and/or campaigns).

As we are interested in marketing innovation and its influence on customer acquisition and retention (i.e., market performance), this paper adopts a contextual approach to IC (Kianto et al., 2018) and focuses on marketing-specific SC (Peñalaba-Arrizabalaga et al., 2020). As Morgan et al. (2009) point out, although many organizational capabilities may cross different functional areas of the firm, capabilities regarding the marketing-mix processes (and, thus, innovation related to them) are usually associated with the marketing function (e.g., Dutta et al., 2003). Therefore, knowledge resources residing in the marketing department should play a prominent role.

Along these lines, Morgan et al. (2009) contend that having a greater understanding of customers' expressed wants and latent needs, competitor capabilities and strategies, channel requirements and developments, and the broader market environment constitutes an advantage that enables the firm to be both more effective and efficient by allowing managers to select the most productive available resource combinations to match market conditions. More specifically, it is the interaction between such knowledge resources and marketing capabilities (e.g., marketing innovation) that allows the firm to outperform its rivals (Morgan et al., 2009).

In the following section, we hypothesize how marketing-specific SC can lead to marketing innovation and market performance.

3 Hypothesis development

As already highlighted in the introduction section, marketing innovation has been positioned in the literature as a type of incremental innovation (e.g., Grewal and Tansuhaj, 2001; Contò et al., 2015). According to Abernathy and Clark (1985), incremental innovations build on and reinforce the applicability of existing knowledge. Hence, an organization's preserved knowledge or SC is a fundamental input for such innovation to occur. As Subramaniam and Youndt (2005) point out, reliance on manuals, databases, and other types of codified knowledge, along with the establishment of structures, processes, and routines that encourage repeated use of knowledge will boost and organization's incremental innovative capabilities.

Regarding marketing-specific IT capital, a plethora of IT-based solutions (e.g., CRM, customer experience management software, customer journey tracking software, social media management software, marketing intelligence software) have emerged (Soltani and Navimipour, 2016; Benítez et al., 2018), which enable companies to extract new knowledge from their data records and guide decision-making. These marketing-oriented technological tools offer the ability to identify potential new customers, customer groups and/or segments, patterns of customer behavior, market trends, and even top industry insiders and influencers, as well as to analyze customer's profitability and product/service performance, all of which could be very valuable to guide marketing innovation decisions.

Moving on to organizational memory (i.e., stored information from an organization's history that can be brought to bear on present decisions; Walsh and Ungson, 1991), previous studies provide empirical confirmation that what has already been stored in organizational memory drives innovation (e.g., Hanvanich et al., 2006; Camisón and Villar-López, 2011). According to Camisón and Villar-López (2011), prior knowledge that a firm possesses about clients and markets can lead to early identification of changes in consumer preferences and facilitate the introduction of novel marketing tools to distinguish the firm's products from those of its competitors. In other words, the storage of marketing-specific knowledge and its easy access by the members of the marketing department facilitates and encourages the generation and implementation of new ideas for marketing practices.

Based on the above, we hypothesize that:

H1a. Marketing-specific IT capital is positively related to marketing innovation.

H1b. Marketing-specific organizational memory is positively related to marketing innovation.

As early as 1960, Theodore Levitt drew attention to the profit possibilities of creating new value satisfactions through changes in the marketing schemes (Levitt, 1960). As Ren et al. (2010) point out, "some marketing managers pay exaggerate attention to product innovation as a source of competitive advantage while neglecting other sources of innovation like marketing" (p. 82). However, the particular style of products, the nuances

of advertisements, the level and availability of after-sales service, and even the cultural implication of a brand symbol may be important means to increase a firm's market share, as the analysis of some leading Chinese companies demonstrated (Ren et al., 2010). In other words, marketing innovation provides a way of differentiating firms from their competitors and adapt to markets in order to gain competitive advantage (Medrano and Olarte-Pascual, 2016; Ramírez et al., 2018). As highlighted by the Oslo Manual, "marketing innovations are aimed at better addressing customer needs, opening up new markets, or newly positioning a firm's product on the market, with the aim of increasing the firm's sales" (OECD, 2005; p. 49). To that end, "the logic of marketing innovation emphasizes shifting consumer demand from elastic to more inelastic market segments through the delivery of better value (actual or perceived) to the consumer" (Naidoo, 2010; p. 1311).

Consequently, we hypothesize that:

H2. Marketing innovation is positively related to market performance.

Marketing-specific SC (both IT capital and organizational capital) are expected to have additional benefits beyond those related to the promotion of marketing innovation that could also improve market performance (i.e., customer acquisition and retention). For instance, knowledge generated by means of marketing-specific IT solutions (e.g., knowledge regarding customer behavior, market trends, or product/service performance) could also be essential to guide product/service innovation efforts by highlighting the type of product/service characteristics and functionalities that need to be reinforced to increase customer acceptance. Likewise, knowledge generated regarding potential customers and existing customer segments may help improve targeting capabilities and thus the effectiveness of commercial actions (e.g., selling the right products to the right customers; Soltani and Navimipour, 2016).

In the case of other types of stored knowledge that do not necessarily involve computer-based data processing, the marketing department controls and retains information flows which are critical to understand the industry complexity where the firm operates (Guilding and Pike, 1990). The importance of these marketing-specific assets and their exploitation and coordination enables firms to develop strategies that match their market environments more effectively (Eisenhardt and Martin, 2000; Makadok, 2001; Morgan et al. 2009). Moreover, well established marketing routines and procedures, easily accessible best practices and lessons learned, and information records about past projects, deals, and campaigns may provide marketers with solid guidance to carry out their work and build durable relationships with customers.

As these additional benefits derived from marketing-specific SC that could also lead to improved market performance (i.e., better focused product/service innovation efforts, superior targeting capabilities, more effective marketing strategies, and improved work guidance) have been excluded from our research, we hypothesize that:

H3. Marketing-specific structural capital – (a) IT capital; (b) organizational memory – is positively related to market performance.

In other words, we suggest that marketing innovation partially mediates the relationship between marketing-specific SC and market performance.

4 Research methods

4.1 Sample and data collection

This research examines Spanish companies with at least 100 employees. We established this threshold to guarantee that companies had a well-established marketing function. The Sistema de Análisis de Balances Ibéricos (System of Iberian Balance Sheet Analysis; SABI) database was used to identify companies that met the criterion. The search resulted in 2,346 firms. Setting out from the above population, we calculated the sample size needed to carry out a representative study (342 firms) and then contacted the target population by phone, guaranteeing total confidentiality. A stratified sampling procedure was applied to ensure that different proportions of company types according to industry (manufacturing vs. service), size, and technology intensity were preserved as in the population. The final sample included 346 companies that answered the provided email or phone survey.

This sample size was large enough to carry out a statistical study based on the partial least squares (PLS) structural equation modelling (SEM) approach. As a first approximation, and according to the level of complexity of the model to be tested, we calculated the minimum required sample size as ten times the number of variables in the most complex regression, which contained seven variables (Barclay et al., 1995). The calculated sample size was 70 firms. Thus, our final sample (346 companies) was well above the minimum threshold.

As data regarding all dependent and independent variables were reported by a single key informant in each company, this presented the possibility of the occurrence of what is known as common-method bias (Podsakoff et al., 2003). To determine the extent of method variance in the dataset, a full collinearity test specially conceived for PLS-SEM (Kock, 2015) was carried out. The above test includes both vertical (predictor-predictor) and lateral (predictor-criterion) collinearity analyses. According to Kock (2015), if all the variance inflation factors (VIFs) resulting from a full collinearity test are equal to or lower than 3.3, the model can be considered free of common-method bias. The highest VIF in our model was 2.023, well below the 3.3 threshold. Therefore, common-method variance was ruled out of our research.

4.2 Measures

Our research model included two independent variables (marketing-specific SC subcomponents), one mediating variable (marketing innovation), one dependent variable (market performance) and five control variables (size, age–year of foundation–, industry–manufacturing vs. service–, technology intensity–high-techs vs. low-techs–, and customer type–B2B vs. B2C). We relied on a newly developed and validated scale for marketing-

specific SC categories (Peñalba-Aguirrezabalaga et al., 2020), while the scale used for marketing innovation was based on traditional marketing mix components, and the market performance scale was adapted from Liozu (2015). All the items were measured by means of 7-point Likert scales.

SC, marketing innovation, and market performance constitute designed conceptual variables. In other words, they are abstractions or human-made conceptual "artefacts" that do not have an autonomous existence in the real world. In this case, the indicators or observable variables define or build up the conceptual variable. They do not cause it, but they make it up (i.e., it is a "definitorial" relationship). Thus, a composite measurement model applies (Henseler, 2017). In such kind of measurement model, constructs are obtained as a linear combination of their indicators without error term, and each indicator enters the linear combination with a specific weight.

4.3 Statistical analyses

The proposed research model was analyzed with SEM based on PLS using SmartPLS 3.2.8 software (Ringle et al., 2015). Unlike covariance-based SEM, which adopts a common factor approach, PLS-based SEM relies only on composites (Rigdon, 2016). There are two stages in PLS-based SEM: (1) assessment of the measurement model and (2) assessment of the structural model. Conducting assessments in this order ensures that the constructs' measures are valid and reliable before attempting to draw conclusions about the relationships among constructs (Barclay et al., 1995).

5 Results

5.1 Measurement model evaluation

In composite measurement, traditional common factor approaches to measurement model evaluation do not apply. Researchers need to analyze convergent validity to determine the extent to which the indicators making up a construct capture the essence of the conceptual variable they are intended to represent. According to Hair et al. (2017), this requires redundancy analysis. To perform this analysis, the survey included one indicator that summarized each conceptual variable under study in order to calculate the correlation between the composite and this summary indicator. Appropriate convergent validity requires a correlation of 0.707 or higher, which translates into 50% of the variance explained for the summary indicator (Hair et al., 2017). Good correlations were found for all the constructs in the research but one: market performance. As the correlation obtained in this case was very close to the established limit (0.692), no changes were made in the model.

Potential problems in the estimation of indicators' weights due to collinearity issues are another aspect that must be considered. Ideally, VIF values should be lower than 3 (Hair et al., 2019), which is the case for all indicators used in the model. Thus, a mode "B" composite has been applied in all constructs, which means that correlations weights are

calculated by means of multiple regression (Hair et al., 2017). This allows assessing the specific relevance of each indicator when it comes to maximizing the amount of variance explained of the dependent variables.

Finally, as far as correlations between latent variables are concerned, none are excessively high. The largest correlation (0.660) was found between marketing-specific IT capital and organizational memory.

5.2 Structural model evaluation

Once the quality of the measurement model was guaranteed, we used bootstrapping to test the strength of the established relationships between constructs. More specifically, we employed a one-tailed 5,000 sub-sample bias-corrected and accelerated (BCA) bootstrap (Hair et al., 2017). Table 1 shows the results obtained.

Table 1: Structural model evaluation

	Effects	*t statistics*	*p-values*	*5%*	*95%*
Direct effects on marketing innovation (R^2 = 38.9%)					
Size	0.042	1.060	0.145	-0.025	0.104
Year of foundation	0.028	0.663	0.254	-0.039	0.100
Industry (manufacturing vs. service)	-0.017	0.371	0.355	-0.092	0.058
Technology intensity (high-techs vs. low-techs)	-0.020	0.442	0.329	-0.096	0.051
Customer type (B2B vs. B2C)	-0.032	0.714	0.238	-0.109	0.041
Marketing-specific IT capital	**0.320**	**4.941**	**0.000**	**0.194**	**0.411**
Marketing-specific organizational memory	**0.349**	**5.181**	**0.000**	**0.237**	**0.460**
Direct effects on market performance (R^2 = 34.6%)					
Size	-0.025	0.592	0.277	-0.092	0.045
Year of foundation	0.045	0.957	0.169	-0.026	0.129
Marketing-specific IT capital	**0.194**	**2.661**	**0.004**	**0.065**	**0.306**
Marketing-specific organizational memory	0.057	0.776	0.219	-0.073	0.165
Marketing innovation	**0.414**	**6.575**	**0.000**	**0.311**	**0.517**
Indirect and total effects of marketing-specific IT capital on market performance					
Indirect effect via marketing innovation	**0.132**	**3.879**	**0.000**	**0.075**	**0.187**
Total effect (Direct + Indirect)	**0.326**	**4.498**	**0.000**	**0.193**	**0.433**
Indirect and total effects of marketing-specific organizational memory on market performance					
Indirect effect via marketing innovation	**0.145**	**3.914**	**0.000**	**0.092**	**0.215**
Total effect (Direct + Indirect)	**0.202**	**2.891**	**0.002**	**0.074**	**0.306**

As can be observed in Table 1, both marketing-specific IT capital (β=0.320) and organizational memory (β=0.349) are positively and significantly related to marketing innovation, while marketing innovation (β=0.414) also shows a positive and significant relationship with market performance. Thus, hypotheses H1a, H1b, and H2 are accepted.

Moving on now to the direct effects of marketing-specific SC on market performance, in the case of IT capital (β=0.194) this is positive and significant, while in the case of organizational memory (β=0.057) is positive but insignificant. Therefore, hypothesis H3a is accepted, while hypothesis H3b is rejected. As the indirect effects of both marketing-specific IT capital and organizational memory on market performance are statistically relevant, the above means that, in the case of marketing-specific IT capital, partial mediation applies (i.e., such component of marketing-specific SC has additional benefits on market performance beyond the promotion of marketing innovation), while in the case of marketing-specific organizational memory, full mediation applies (i.e., marketing-specific organizational memory positively affects market performance inasmuch it contributes to marketing innovation).

Regarding the specific relevance of each of the elements making up marketing-specific IT capital and organizational memory in terms of enhancing both marketing innovation and market performance (detailed tables have been omitted for space reasons), identifying patterns of costumer behavior constitutes the most important functionality provided by marketing-specific IT solutions (γ=0.294), followed by knowledge generated in terms product/service performance (γ=0.274), potential new customers (γ=0.216), existing customer groups or segments (γ=0.208), and top industry insiders and influencers (γ=0.203). On the contrary, knowledge generated on customer profitability and market trends seems to be completely irrelevant (i.e., their specific weights are very close to 0).

In the case of marketing-specific organizational memory, having updated, relevant, and easily information records about competitors shows the highest weight (γ=0.355), followed by having well established routines and procedures (γ=0.257), updated and easily accessible information about relevant trends in the market (γ=0.217), and also about key projects, deals, and/or campaigns so employees can reuse them when needed (γ=0.205). Conversely, having updated and easily accessible records regarding best practices and lessons learned; a "who knows what" directory; and updated, relevant, and easily information records about customers are not significant.

Finally, although all dimensions within marketing innovation are statistically relevant to improve market performance, innovation in pricing shows the highest weight (γ=0.420), followed by innovation in communication (γ=0.317), and in product/service distribution (γ=0.302). Thus, innovation in product/service design, image, and/or packaging is the least relevant, although still significant (0.153).

6 Conclusions

The research carried out shows the relevance of marketing-specific SC (both IT capital and organizational memory) on marketing innovation and market performance and

highlights the specific elements within each independent and mediating variable that are the most influential to maximize the amount of variance explained.

Results confirm that an organization's preserved knowledge is a key input for incremental innovation (and, thus, marketing innovation) to occur (Abernathy and Clark, 1985; Subramaniam and Youndt, 2005). Moreover, our findings highlight existing complementarities between IT-generated marketing-specific knowledge and other forms of organizational memory that do not necessarily involve computer-based data processing.

In the case of customers, results show that IT-generated knowledge constitutes a must to guide marketing innovation efforts and to attract and retain customers. As indicators' weights clearly point out, merely having historical information records about customers is not enough: marketing-specific IT solutions are needed that help extract new knowledge from these records for marketing innovation to succeed. Conversely, in the case of market knowledge, it seems that marketing-specific IT solutions in this regard are not as effective as more traditional forms of organizational memory based on data recording from direct observation.

Following with other forms of organizational memory, the results obtained also suggest that best practices and lessons learned are not effective unless they become embedded in organizational routines and procedures, and that facilitating the recording and retrieval of information regarding past projects, deals, and/or campaigns constitutes a very solid foundation to build new marketing solutions. However, providing marketing employees with a complete and updated "who knows what directory" so they can find the right expert to take advice from when needed proves to be irrelevant. In other words, investing in a project repository seems to be much more effective than having access to expert advice, which seems to highlight that marketing innovation relies more on codified knowledge than on tacit knowledge.

Going back to IT-generated knowledge, the results obtained show that product-performance-related knowledge and knowledge on top industry insiders and influencers complete the recipe to increase the chances of successful marketing innovation and market performance.

This study has a number of limitations that may be addressed in future research. First, survey responses were collected only from Spanish firms, and therefore the study is based on data from a single country. Future research could extend the analysis to other national contexts. Second, a key informant in each company reported the data collected through a structured cross-sectional survey. This allowed us to access firm-level perceptional data and test our hypotheses, but there may be limitations regarding the scope of informants' knowledge and the ability to draw causal inferences. Future studies could thus adopt different types of measurement approaches and combine them with various ways to measure innovation and other types of performance over time.

Performing Openness: How Innovation Performance, Organization, Crowd and Platform interact in Open Innovation

Abstract

The contribution of this paper is to propose that OI theory and practice need to consider how platforms perform relations of accountability and in doing so develop a further understanding of the sociomateriality of accountability. The paper develops a performative theory of openness. It shows how an influential and widespread theory of radically distributed organizational forms performs a global technology company.

While recent streams of research (e.g. Lakhani, et al., 2013; Kornberger, 2016) suggest that the context of distributed innovation shifts the unit of analysis of organization design from the individual firm to networks of actors organized on platforms, we find that the focal firm still remains a key conceptual parameter, which in turn makes it difficult to capture the suggested radicality of 'Open Innovation' (OI). The article uses empirical materials from a spiral case study of the design of, and implementation of OI. Drawing on performativity theory the paper studies how the achievements and values created in OI are measured in practice. Both digital platform designers/providers and an organization implementing OI are included in the context in order to analyze the case holistically.

The ostensive definitions by OI scholarship explains causal models where OI elements predict value creation for the firm. Innovation intermediaries recognize both "OI" and "open collaborative innovation" since their digital designs are an ecology of devices that can enact and afford for both. The question of openness, is from a performative perspective, a matter of how peers, in different situations, mobilize OI elements on platforms, how these OI elements are bent, connected and allowed to do certain things but not other things. We show, that in practice, the firm has to take into account the performance of the external crowd, and at times put resources into its training and education. In heterarchy distributed authority is assumed to be facilitated through lateral accountability, whereby the traditional principles of vertical authority no longer hold, but rather, managers and their team members can be accountable to multiple units, or teams, across the organization. Our case material shows that the ecology of devices and their performative struggles, afford for such distributed authority and lateral accountability. As the paper consolidates theory by Scott & Orlikowski (2012) the contribution adds to a growing body of studies that shows that apparatuses such as platforms are performative. It also investigates platform organization critically by discussing the limits of accountability in heterarchies

1 Introduction

> *Open Innovation starts here.*
> *The Campaign connects Nokia QD and all friend coroperations investing innovations together.*
> *Submit any ideas*
> *(NOKIA Open Innovation Challenge, 2017.)*

Innovators rarely innovate alone. They tend to band together in teams and alliances based on 'swift trust,' nested in communities of practice and embedded in a dense network of interactions (Brown & Duguid, 2000; Laursen & Salter, 2006; Scott & Brown, 1999). Different forms of large-scale collaborative creativity, such as open innovation, crowd sourcing, co-innovation, and commons-based peer production, are new ways of organizing these communities. While earlier research on innovation saw competitive success as dependent upon an organization's successful management of the innovation process, open innovation (OI) happening on digital platforms cannot solely be understood as an internal organizational response of a firm to strategic choices.

While recent streams of research (e.g. Lakhani, et al., 2013; Kornberger, 2016) suggest that the context of distributed innovation shifts the unit of analysis of organization design from the individual firm to networks of actors organized on platforms, in this study we find that the focal firm still remains a key conceptual parameter, which in turn makes it difficult to capture the suggested radicality of the phenomenon. Constructs such as the above "Open Innovation starts here…", point to, and include performance. However, where is the "here" where performance is happening?

While innovation performance in the context of the firm is measured by evaluating for instance innovation strategy, portfolio management, project management and/or organizational culture (for a more comprehensive framework Adams, et al., 2006) the *loci* of OI is organized in "the open" (Kornberger, 2016), "O2O platforms" (McAfee & Brynjolfsson, 2017), in complex organizational boundaries (Lakhani, et al., 2013), and in order to harness the "wisdom of the crowd" (Surowiecki, 2005). In this study, we use the conceptualization 'Open Innovation' (Chesbrough, 2003; Hayek, 1945; Lakhani, et al., 2013; Piller, et al., 2019; Vanhaverbeke & Cloodt, 2006) in order to describe these emerging organizational forms.

This study addresses the emergence of platform organized OI with two motivations. The first specific motivation has to do with understanding the performance of OI better. With a performative orientation, we ask how the achievements of OI are measured in situated practices. The case description draws on different sources from a spiral case study (Gherardi, 2012), as openness is performed by firm, platform, crowd and innovation intermediaries. The methodological disadvantages of not pre-given case selection are partially counterbalanced by the second motivation of the paper, that is to extend on theory (Eisenhardt, 1989) and to examine the question of the how platforms reconfigure relations of accountability (Scott & Orlikowski, 2012). Thusly, this article seeks to

explore the following question: What happens to the distribution of accountability in platform organized OI?

The contribution of this paper is to propose that OI theory and practice needs to consider how platforms perform relations of accountability and in doing so develop a further understanding of the sociomateriality of accountability.

The paper is organized in the following way: section 2 offers a literature review. Section 3 provides the presentation of the research methodology, the details of the fieldwork, the data collection and analysis. In section 4, we dig deep into the case study. The section analyzes the case holistically, and approaches OI as a boundary object (Star, 2010; Star, 1999). Finally, in the fifth section, we discuss the field material in relation to the theoretical insights, based upon which we draw brief conclusions and suggestions for future research.

2 Literature Review

In this study, innovation is defined as the generation of novel ideas or combinations of existing ideas and routines that are perceived as new and valuable by individuals and organization (Nelson & Winter, 1982; Roberts, 1998; Van de Ven, 1986). Open innovation refers to "a distributed innovation process based on purposively managed knowledge flows across organizational boundaries, using pecuniary and non-pecuniary mechanisms in line with the organization's business model." (Chesbrough & Bogers, 2014).

Performance is a concept determined in the context in which it is practiced (Corvellec, 1996). Since Schumpeter (1947), Barnard (1938 [1968]), Chandler (1962) and Myers and Marquis (1969), the context of innovation has been the firm, and scholars have emphasized innovation as a source of a firm's competitive advantage. The measurement of innovation in this context has been the subject of a number of studies (e.g. Adams, et al., 2006; Dziallas & Blind, 2018). However, very few studies address the issue of what happens when innovation is 'open' (Frishammar, et al., 2019).

According to Chen & Vanhaverbeke (2019) external innovation resources do not simply flow into companies as, "open innovation highlights the entire innovation system"(p.192). One of the major contributions of a OI approach is, according to Gassmann & Enkel (2004), the perception "that the locus of knowledge and the locus of innovation need not necessarily be the same" (p. 15). Recent literature has sought to find mapping of concepts of OI to more general theories about the hierarchical firm and its boundaries (Lakhani & Panetta, 2007; Vanhaverbeke & Roijakkers, 2013). The empirical context of OI is to large extent platforms that organize economic activity in a situation when boundaries are complex (Lakhani, et al., 2013), where "performative dynamics" (Barrett, et al., 2016) need unpacking. You need to 'look across' (Hopwood, 1996) organization where one encounters "heterogeneous, ongoing, overlapping *performative* struggles" (Kornberger, et al., 2017) between a multiplicity of devices and people.

2.1 Open Innovation Performance Measurement

A number of studies focus on innovation performance management (De Felice & Petrillo, 2013; Gana, 1992; Huergo, 2006; Tipping, et al., 1995; Van de Ven, 1986) and management control systems have been shown to improve performance in contexts characterized by high levels of uncertainty (Lounsbury, 2008; Rautiainen, 2010; Siti-Nabiha“ & Scapens, 2005; Contrafatto & Burns, 2013) as well as act as boundary objects for engaging the multiple parties that participate in the process of innovation ((Busco, et al., 2017; Johanson & Vakkuri, 2018). In their extensive literature review Dziallas & Blind (2018) outline an indicator landscape consisting of 82 unique indicators to evaluate innovation performance. Building on Becheikh, et al. (2006) they categorize the identified indicators into company specific and contextual dimensions. The problem with many of these indicators is that they are mainly ‘firm centric’. This hierarchical consciousness also dominates OI scholarship (Chiaroni, et al., 2011; Mortara & Minshall, 2011; Piller, et al., 2019; Wang & Hu, 2017; Najafi-Tavani, et al., 2018). Absorptive capacity, collaborative innovation capability, sharing i.e. inter- and intraorganizational transfer of knowledge are identified as indicators of OI performance. Nonetheless, while this literature expands on the indicator landscape, OI requires a ‘eco-system oriented view’ (Frishammar, et al., 2019). OI platforms organize third parties without directly controlling or monitoring them, since the openness of the “open” in OI is often self-organized, or organized by ‘innovation intermediaries’ (henceforth intermediary) on platforms, beyond traditional meetings, hierarchy and central coordination (Benkler, 2002; Benkler, 2017; Bollier, 2016; Chen & Vanhaverbeke, 2019; Kornberger, 2016; Kornberger, et al., 2017; Lakhani, et al., 2013; Laursen & Salter, 2006). In consequence, we scrutinized and adapted the frameworks suggested by Adams, et al. (2006) and Dziallas & Blind respectively and found that the majority of the OI indicators identified in the literature fall under the categories “innovation culture” and “knowledge management”.

2.2 Performativity: Conceptual Background

Demonstrating achievements yields different forms and systems (Johanson & Vakkuri, 2018). The literature on OI performance suggests that performance is linked to ‘openness’ (Frishammar, et al., 2019; Laursen & Salter, 2006). This openness is related to the organizations ability to exploit external knowledge (Laursen & Salter, 2006), an indicator that is identified in innovation performance (Adams, et al., 2006) as part of an organizations innovation culture (Dziallas & Blind, 2018). New OI activities are an insufficient indicator of OI performance and organizational capability has been suggested as a contributing factor in successful OI performance (Podmetina, et al., 2018). Hence a move from firm-centric innovation to OI requires a change in culture (Chen & Vanhaverbeke, 2019). Building on Volkoff, et al. (2007) we adopt the view that this change as embedded in technology. This approach to organizational change sees it as a

three-stage cycle in which the ostensive, performative, and material aspects of organizational elements and routines that interact differently in each stage.

Performativity has emerged as a highly generative concept that has inspired social scientists and stimulated theory building in various disciplines including organizational and management theory (Gond, et al., 2016). In management theory, there coexists several foundational perspectives on performativity (Gond, et al.). In this study, we pull on Silvana Revellino and Jan Mouritsen, who draw on Judith Butlers interpretation of performativity. Performativity is, according to them, a "pervasive movement that proceeds from one stage to another when new information ex-cites the development of even further technologies for provoking and making things real (2017, p. 454)." Inspired by D'Adderio & Pollock (2014) this study threats OI theory as such ex-citing information.

3 Research Methodology

In this study a case is explored in order to provide a body of empirical evidence in relation to the concept of OI. The spiral case study differs from the 'linear school' (Piekkari & Welch, 2018) of Yin (2009) and Eisenhardt (1989). This case study methodology allows, according to Gherardi (2012) technologies to be more vocal, adopting an "ethnography of objects" (Bruni, 2005), which, she argues, enables us to study the performativity of technology as it emerges in situated practices. Iteratively, we did in-depth inquiry (Table 1) in different 'not pre-given' (Gherardi, 2012) units of analysis and then expended the focus to other locations by following emerging relations.

Table 1:Core Case study data

	Individual Interviews/# interviews(2017-2019):		Positions	Observations (2017-2018)	Corporate white papers, Case studies, events, videos and webinars (2010-2019)	Reports	Websites/ Press	Email

TOTAL	18			1	72	10		28

Nicolini (2009), describes this strategy as 'zooming in' and 'zooming out of' practice. Cecez-Kecmanovic et al. (2014,) state that the objective of this practice is to: "develop an appreciation and articulate the dynamics of practice by observing and experiencing from

different angles and perspectives how entities, people and technologies, their boundaries, properties and identities, are continuously performed, what the consequences are and for whom" (p. 821). In the analysis our approach was based on systematic combining (Dubois & Gadde, 2002) grounded in an abductive logic (Timmermans & Tavory, 2012). The literature review guided us in the initial coding (Timmermans & Tavory) along the dimension of performance in terms of ideation rate, innovation process management, knowledge management and innovation culture. The empirical framework was also modified as the boundary of the set of relevant cases shifted (Ragin, 1997). An adjusted focus in coding followed where the empirical material was categorized into ostensive, performative, and material aspects of organizational performance. These focused codes were scrutinized again and again in order to evaluate which ones best explain the empirical phenomenon.

4 Findings: OI interveawing a multiplicity of performances and accountabilities

Although ambiguous, innovation is in a sense a strategic orientation describing how purposive institutional action is instigated and created (March, 1987; March, 1988). In this section we approach OI, and its evolving system of boundary objects which multiple communities of practice interact with. A report called "A maturity model for High Involvement Innovation" published by *Hype,* a provider of digital infrastructure for OI, starts with a contemplation on the 'Innovation imperative' (Hype Inc, 2003):

It's a simple message – innovation matters. In today's environment, organizations need to change (and keep on changing) what they offer the world and the ways they create and deliver that.

Such statements are common in the context of OI, and they are hardly surprising considering that this learning material also functions as marketing communication for the providers of platforms and other software. However, what is striking is that the academic literature also adopts the same rhetoric (e.g. Lerch & Spieth, 2012; Najafi-Tavani, et al., 2018; Wang & Hu, 2017) over 70 years after Schumpeters seminal text. This could be read as a succesful linking between the theoretical realm and the empirical realm, we however choose to approach it through a performative lens, building on work that suggests that theories and models are not simple descriptions of a setting but powerful 'engines' which can profoundly transform the contexts they describe (MacKenzie, 2006; Revellino & Mouritsen, 2015). The chapter is structured as follows, first we introduce agency producing the ostensive and material aspects of OI, then the spiral zooms into the interaction between specific agents and their performative dynamics and struggles (Cabantous & Gond, 2011).

4.1 Innovation intermediaries produce the ostensive aspects of OI

Digital infrastructures are central to Open Innovation. *Hype, 100%Open, Spigit (Planview) and Imaginatik* are companies that offer digital infrastructures and other OI services to organizations who are moving into distributed models of innovation. Clients include organizations like LEGO, Exelon, PWC, Crisis, Unilever, Citi, Pfizer, Siemens, UNHCR, and Nokia.

Based on our analysis of the empirical material, we find that the intermediaries create rules, routines and other artifacts that create *accounts for the ostensive aspect of OI*. The ostensive aspect "guides, accounts, and refers" (Feldman & Pentland, 2006), but how clients actually perform will as one account stated, be all "about different subject matter". Further, as the intermediaries embedd organizational elements in digital infrastructures a *material aspect* is also acquired. As a matter of illustration one account by a CEO describes:

> *The beauty of a platform is that it can be distributed through or accessed through different channels. And the beauty of a well-designed challenge is that it is transparent. The design principle around effective challenges is: "How do you make visible what is invisible?"*

Platform organization solves two of the four central problems of innovation, as identified by Van de Ven (1986). 'Transparency', solves the human problem of managing attention, as well as the structural problem of managing part-whole relationships. Our findings show that a lot of innovation programs and even challenges fail because they are not transparent, and they do not have a closed loop between identifying a challenge and taking up the challenge, assessing and prioritizing the results. A CEO described a well-designed loop as a "trust cycle" that "guarantees credibility and accountability". You have to close the loop with the crowd: "Thank you for your ideas. This is incredibly interesting. This is what we're going to do with this thing now ".

Transparency, is also a factor that Laursen & Salter (2006) identify as an explanation to succesful OI. It addresses how easily and understandably participants can follow and understand what is happening in the collaboration. There are different crowds and they require different OI management. In terms of crowds there are a couple of common practical concerns. The first is IP protection, the second is connected to accountability. External crowds are according to several accounts reluctant to "give up" their IP rights. And, then there's the expectation that comes along:

> *If you're going to invite somebody in to be part of a crowd, and they're an external entity, especially your customers, you have to do something with the ideas that they submit. So that sets an expectation that companies don't always want to be held accountable to.*

The intermediaries legitimate some performances as appropriate to OI routines, and statements of achievements related to factors such as absorptive capacity and innovation culture function as guides to clients. In principal an open culture seems to imply trust, nevertheless, during the research we also found contradictory statements, where external

crowds for instance create "noise" and "nonsense." As illustrated by one account, where it was said:

> *We connect individuals with large organizations. We can get big people to sign non-disclosure agreements or small people to sign up for, or whatever it takes to make sure small people don't feel exploited, and big people get what they need in the end.*

The division between 'big' and 'small' people signals dilemmas in the actual practice of heterarchy. It and other similar accounts also point to where OI is performed: with the support of intermediaries on digital infrastructures, peers produce what clients need. A dilemma occurs since OI communities can also hold "big" people accountable, feel exploited and produce nonsense.

4.2 Technologies configure the ostensive and the material aspect of OI

One way to manage "nonsense" and "make visible what is invisible" is rankings and ratings. All the intermediaries offer different digital evaluation infrastructures, where contributors (Figure 1), as well as contributions are rated since its "useful to get a sense of what people like." Value is connected to some standard criteria—including votes, star ratings, comments, replies, approval ratings, and expert reviews. As a matter of illustration, *Spigit* offers a crowd-based prediction tool in order to "truly make better business decisions based around the combination of human intelligence and data". The 'wisdom' of the crowd is also a dilemma as crowd biases and herd behavior were generally identified as problems in the actual practice of OI. One respondent suggested the possibility that more "interesting ideas" might be "less obvious", and therefore attract fewer votes: "so you need to apply additional level of evaluation of that idea." An example of additional levels of evaluation is offered by Hype. The evaluation is based on an intuitive and direct comparison of two ideas at a time (Figure 2).The metrics in this tool focus on efficiency and not so much innovation as something "new". The "less obvious" in the quote above often represented new and potentially disruptive innovations. The platform collects data, but the challenge is how to analyze this data?

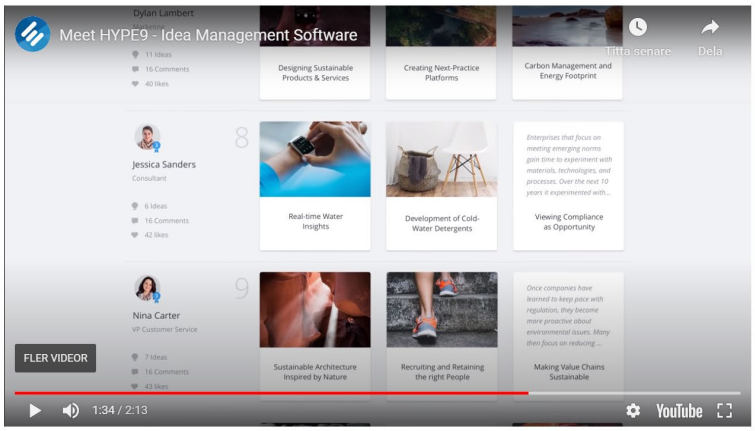

Figure 1: Rewviews of contributors to challenges

As identified in previous quote a quantified evaluation does not necessarily lead to innovation performance especially when one is looking for something 'outside the box'.

There is a lot of data, but as one of our interviewees observed, "it is dark, fragmented and incomplete." And how does one make sense of that? Control of the outcome of OI is difficult, as the "pervasive movement" of innovation extends, in line with Revellino & Mouritsen (2017), innovation into spaces other than those originally forecasted. Which in turn suggests that the value of innovation is not a stable object, but relational and social.

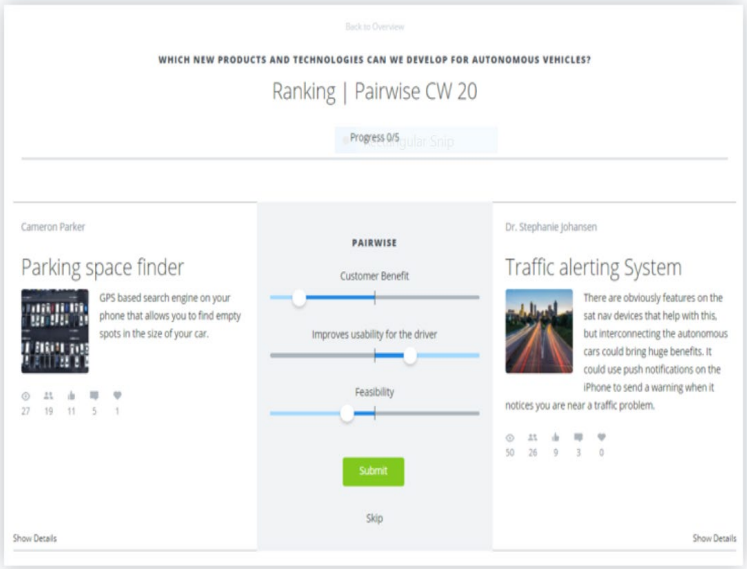

Figure 2: Example of OI evaluative infrastructure

A key performance indicator for the intermediaries is innovation culture, i.e. how you measure in terms of openness. The achievements of OI are described in terms of how you as an organization and peer perform in terms of transparency, iteration, and dialogue with the crowd, be it internal or external (Figure 3). In this way the intermediaries create templates for behavior and normative goals, what Feldman & Pentland refer to as 'guiding'(2006). The platforms bring a material aspect to the ostensive aspects produced by the intermediaries, they help monitor performances, but they do not, as the routines described by Feldman & Pentland "enforce compliance." Rather we find that crowds are being "nudged" as community managers participate in the iteration of innovations by either forming communities around certain ideas or helping refine ideas that were just "the bare bones of an idea." The facilitators "probe, test and question", they can also bring ideas to the project team during a challenge, they can let the crowd work on the surprising, the less obvious:" we're actively exploring with the crowd." This utterance shows that both the loci of the knowledge and the management of it might be outside of the firm which supports Gassmann & Enkels, (2004) claim that the organization that emulates an OI approach has to be prepared to transform its "solid boundaries into a semi-permeable membrane that enables innovation to move more easily between the external environment and the company's internal innovation process." We propose that the platform is this membrane, that we conceptualize as infrastructure. It is the material aspect: the ecology where organizational change that is open to a wider ecosystem of peers can happen.

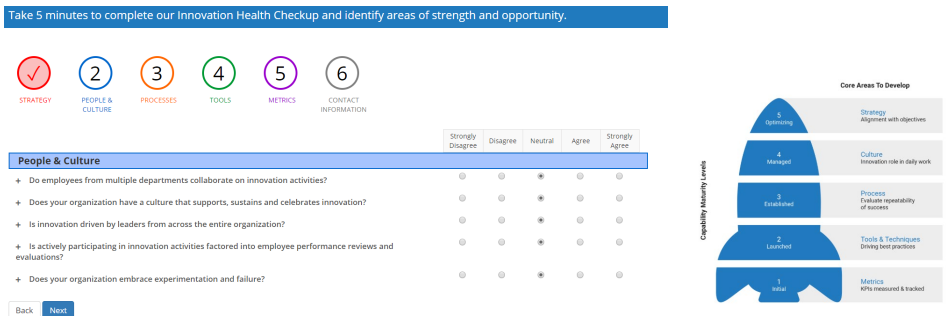

Figure 3OI culture: Example of indicators measuring

4.3 Performativity: the firm interacting with the ostensive and the material aspect of OI

Nokia Open Innovation Challenge (NOIC) is an annual global competition whereby Nokia seeks innovative technologies, products and solutions "that can change the world" (NOIC, 2017-2018).

> *All over the world, there are good initiatives and start-ups coming up with great ideas. But it's very difficult to find them. And of course, these events are one way to*

find out what is happening around the world/…/ There is always this generic, 'looking around thing', that shows that we are not a closed community.

Such accounts indicating accountability and the need to perform 'openness', were reoccurring in the data and point to positive attitude to searching external ideas and tech, as well as open boundaries, all organizational capabilities reflecting on OI culture. One of the many intermediaries *Nokia* uses, *Hype*, describes the relationship between firm and the platform like this:

In my experience, organizations will typically start by building programs and potentially using digital platforms to support them. Software platforms are especially useful because they provide scale, transparency, the ability to store and research knowledge and ensure governance and accountability. When deployed using the right guidance and incentives, platforms amplify meaningfulness.

During the research a number of seminal texts and OI authorities where mentioned in conversations and emails. For example, regarding innovation process and business modelling one account presented the following list (Figure 4).

Taustalla tosiaan on paljon tutkimustietoa ja metodeja paitsi innovointiin, myös prosessikehitykseen ja business mallinnukseen liittyen.
Tässä jotain innovaatio puolen lähteitä:

- Henry Chesbrough (Open Innovation)

- Stanford Research Institute (SRI) (5 disciplines of Innovation / NABC value creation forum)
- MIT Media Lab
- unternehmerTUM (FabLab)

Figure 4: Illustration of OI theory performing a firm

Such findings point, to how OI theory performs an OI organization and consolidates theory of performativity (Callon, 2007; MacKenzie, 2006). In this case, a change in culture was needed since Nokia lacked a "common language" for its innovation activities. The research efforts focusing on the changing landscape of innovation helped, according to the interviewee's, the organization find such a language. Passages and small notes in the case study of *Nokia* and *Hype* (Hype, 2018a) refer to "Chesbrough" and "Lakhani" as inspirational sources in the journey towards a "new innovation culture."

Tools to manage the innovation were also identified, and in order to measure the changes in culture an "internal innovation culture index" was introduced. Such findings

can be read in line with theory depicting how organizational elements such as routines, roles, and data become embedded in technology (Volkoff, et al., 2007). Their material aspect interacts with and affects their ostensive and performative aspects. In Figure 5, a document produced by Hype, illustrates the interaction between performative and material aspects. We learn that Nokia and Hype intend to "create an innovation culture at Nokia, review innovation platform" in 2015, indicating 'cultural change' as depicted by Feldman & Pentland (2006).

Figure 5: Illustration of interaction between the performative (Nokia) and the material (Hype) aspects

After this the platform, however, in line with Volkoff, et al (2007) needs to be redesigned since "that interaction is constrained/enabled and moderated by the material aspects" (p.843).

As to Nokia, innovation culture was not measured specifically at the time of our research, since: "those KPI's do not surface, anymore." There did not seem to be a need

for such an indicator and instead the company measures "cultural coherence", where innovation is part of a bundle of performances supporting the culture of the organization.

In terms of OI and accountability relationships, a difference identified to internal innovation is the managing of diversity: "difficult, impossible…easy" ideas. NOIC uses rating and ranking mechanisms, but only for internal evaluation. There is little transparency as to the evaluation and NOIC does not communicate the assessment criteria to the submitters. An expert jury does the rating, and the intermediaries offer the infrastructure for evaluation and assessment. For example, in Figure 6 the uniqueness of an idea is evaluated on the basis of how the idea compares to what already exists in "the field", where the relative quality "improvement" ranks lower than the quality "fresh", while "unique" gets the highest score of 3. The platform then organizes the ideas according to an average and a detailed score, as can be seen in Figure 7.

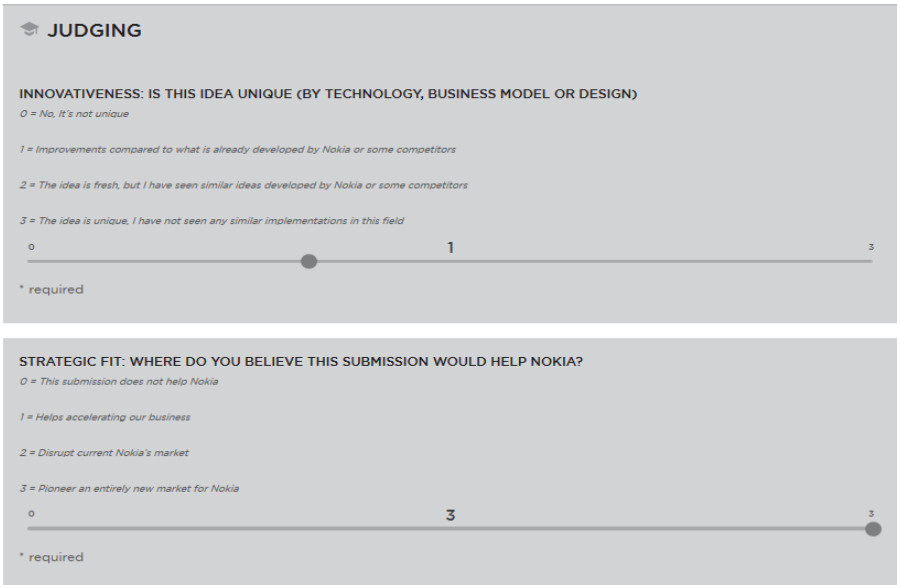

Figure 6: Judging view of assesment of 'innovativeness' and 'strategic fit'

The accounting operating here can be read in conjunction with the evaluative infrastructures described by Kornberger, et al. as it creates relations between actions, behaviors and preferences, "so as to engineer possibilities of a match. (2017, p. 9)" In this case, the match is not mutual, it is the firms "strategic fit". Disruptive innovations are largely disbanded, as it is hard to find commitment within the organization for something that is "really outside of the box". Nonetheless, NOIC invests some effort in trying to find internal contacts, with similar interests that could work on the disruptive innovation with the start-up. These accounts from the practice of OI show that absorptive capacity indicators create 'paradoxical tensions' (Jarvenpaa & Wernick, 2011). As disruptive

innovations are “difficult” or even impossible, ‘good performance’ in terms of absorptive capacity might mean going for less radical ideas that have a strategic fit.

Rank	Entry	Judge progress	Weighted average score	Innovativeness: Is this idea unique (by technology, business model or design)	Strategic fit: Where do you believe this submission would help Nokia?	Business potential: Is the value proposition convincing?
3		43 of 75	1,78	2,23	1,62	1,48
11		39 of 75	1,45	1,3	1,46	1,58
15		39 of 75	1,32	1,66	1,17	1,12
17		39 of 75	1,16	1,23	1,05	1,2
9		41 of 75	1,56	1,9	1,26	1,51
5		40 of 75	1,7	1,8	1,47	1,85
8		40 of 75	1,59	1,55	1,55	1,67
6		40 of 75	1,64	1,65	1,45	1,82
1		41 of 75	2,02	2,31	1,82	1,92
10		41 of 75	1,49	1,95	1,14	1,39
21		38 of 75	1,06	1,23	0,84	1,1

Figure 7: Example of weighted score (judge view)

During the research it became evident that the capability of the start-ups to bring the ideas submitted to realization is emerging as a key factor for NOIC. Questions that related to the management of a crowd or a community where in large part dismissed as irrelevant. This was striking since these same questions resonated well, and produced long elaborations when addressed to the intermediaries. Thus, extending on theory on the differences between ostensive and performative aspects of routines, as suggested by Feldman (2000).

5 Discussion

Studying performativity, aims to “illustrate leakage” from or resistance that is met to the generalizations made in ostensive research (Hansen, 2011). A performative perspective is useful in understanding how actors act in this world characterized by risk and uncertainty, since they do not need to be ‘correct’ or ‘accurate’ in their projections on complex emergent phenomena. How the organizations presented in the paper focus their efforts, can in conjunction with Kumaraswamy’s et al. (2018), be analyzed as an enactment of a constituted world. Or as one account from Nokia phrased the reason for OI:

> *It’s because it’s kind of hype thing at the moment. So, everybody is organizing open innovation and it’s of course, it’s something that just must be there even though the reasoning is maybe a little bit vague but still (laughter).*

An entity like *Nokia* and *Hype*, which engages in the new practice of OI, knows that its efforts are part of a larger ecology of relationships and interactions among heterogenous actants. In terms of accountability our findings consolidate theory, as presented by Scott & Orlikowski, (2012). OI platforms perform a redistribution of accountability in order to meet increased demands for transparency. We extend on theory by Gassmann & Enkel (2004) and Kornberger, et al. (2017), as we propose that the platform is a membrane, that we conceptualize as infrastructure. It is “here” in this infrastructure with its ecology of devices, where organizational change that is open to a wider ecosystem of peers happens.

The findings in the paper demonstrate accountability relations on platforms as a sociomaterial configuring of strategy (challenges formulated by firm plus innovation intermediaries), platform (designed by innovation intermediaries) and external crowd where the entities doing OI are accountable to the crowd. Technology embeds a multiplicity of accountabilities into the organization. Relations of accountability are understood by innovation intermediaries and OI theory as issues of 'knowledge management' and transparency, which the digital infrastructure affords. In this ideal of transparency, the platform guarantees that anyone can observe from different perspectives how organization, people as well as "technologies, their boundaries, properties and identities" (Cecez-Kecmanovic, et al., 2014), are continuously performed. However, what are the consequences of 'sociomateriality' (Orlikowski & Scott, 2014) in terms of the distribution of accountability? Drawing on Messner (2009) notion of the limits of accountability, we examine what and "who is doing what to whom here" (Suchman, 2002) and whether more accountability is always and unambiguously desirable.

The question of openness is from a performative perspective, a matter of how peers, in different situations, mobilise OI elements on platforms, how these OI elements are bent, connected and allowed to do certain things but not other things. The field study illustrates, how the material aspect frames accountability as it configures the intelligible identity as an accountable in certain 'regimes of truth' (Butler, 2001). In Nokias case, internal 'sponsors' also trained and educated finalists to give better accounts to the jury. In terms of accountability, multiplicity is not a problem if the evaluative infrastructures afford for diverse accounts. Which they often do. A dilemma occurs when OI peers face 'multiple demands of accountability' (Messner, 2009), where the accountable self does not have alternatives of how to give an account. In the heterarchies we studied managers and their team members are, as has been observed in similar settings, "accountable to multiple units, or teams, across the organization" (Taylor, et al., 2019, p. 1639) but also, *to* and not *for* (difference discussed by Messner) the crowd. We argue that the reluctance to be held accountable that makes the firms 'afford' (Bygstad, et al., 2016) different levels of openness on platforms be understood as a problem of 'conflicting accountabilities'. Thus, the devices concentrate observations in certain ways, their representations make certain properties become *determinate* (Barad, 2007), while others are specifically excluded (Orlikowski & Scott, 2014). The firm can argue away different types of accountabilities by embedding a hierarchical organizational logic is in the platform, and accountability is not evenly distributed as there is an absence of mutual accountability. The 'transparency' found in the ostensive definitions of OI, we interpret in line with Flyverbom, et al. (2015), as a productive force, which is both "*conditioned upon* and *conditions* a host of relations, actions, and norms for conduct is informative". Being 'open' is, from the perspective of the firm considered vital for employee and customer satisfaction, accountability and legitimacy. The narrative of achievements (Corvellec, 1996) produced by ostensive definitions of OI 'condition upon' those doing OI, thus they can be understood as 'exposed' in Messner's (2009) sense of the term. The peers are also 'mediated' they have

to speak "several languages at the same time" (Messner, p. 931) which can result in conflicting accountabilities.

The field study also depicts how the desire to make visible inter- and intradependence leads to the development of a culture of innovation. Nevertheless, it is good to consider that control increasingly works through culture, and the transparency ideal afforded by the digital infrastructure, also regulates identities by producing particular cultural and normative conditions for human conduct (Flyverbom, et al., 2015). Crowd accountability and IP are often intertwined in the accounts, as well as indication that the crowd could also be held accountable for the evolution and result of a contribution posted on a OI platform. For example, in one account, an external crowd member is likened to an 'author', who owns the idea and can be confronted about it, since the " author is accountable to the rest of the community". Such findings are interesting since they point to a practice where OI builds on the expectation that the author be open and share contributions, and is, also, responsible for the idea in a process that involves both serendipity and 'relational drift' (Revellino & Mouritsen, 2015). Such observations raise questions as to both the limits of traceability and accountability as we are expecting that author to measure up to multiple *and* conflicting accountabilities, which is in itself ethically questionable. A dimension of temporality is introduced to disruption and innovation, IP is a way, to 'end' an author being held accountable, but transparency could also imply that an author is held accountable for as long as her or his digital reputation trail exists, i.e. for a very very long time.

6 Conclusion

In this study we answer calls made by Kornberger, et al. (2017) and Stark (2006) for scholarship to extend analytical focus from hierarchical settings to heterarchical. Stark (2009) describes two features of heterarchies that enable innovation – distributed intelligence, co-ordinated through lateral accountability, and an organizing dissonance that enables "productive friction" by recognizing and managing the interplay between multiple, competing evaluative principles. Our study consolidates theory by Scott & Orlikowski (2012) that a presumed shift to digitally enabled openness, brings its own issues as the platform performs a redistribution of accountability.

By considering both innovation intermediaries and a firm, the paper examines practices of openness as transparency, as well as practices of relative openness characterized by opacity. Nokias 'openness" performance, is a careful balancing act where transparency and opacity are combined to create excitement and curiosity about its new products as well as its innovation culture. Nonetheless, this transparency is performative and different framings of OI creates overflows (Callon, et al., 2009) and works back upon those subject to it (Roberts, 2009), which in turn creates new questions in terms of accountability relations. According to Hultin (2019) responsibility, viewed from a sociomaterial perspective, is the ability to be responsive to the possibilities of becoming in each moment, where one has to ask 'Is this what I am doing?', or 'Did I do that?'. However, as

Schumpeter (1947) observed already 70 years ago, disruption can take considerable time in revealing the true features and ultimate effects of an innovation's performance, one might ask, as we do in this study: what are the limits of accountability in heterarchies?

Abstract

Since the beginning of the century an increasing demand for regional products have been observed in the EU, that eventually lead to the intense development of the regional labelling schemes. These systems were primarily built as a form of the support for the local small and medium producers and agriculturists. Based on available literature and authors' longitudinal research focused on evolution of Czech regional labels and their impact on regional development, the aim of this article is to model a set of relations and dynamic mechanisms associated with variables relevant to the regional labelling. Such approach allows the formulating and justifying of viable dynamic hypotheses, which can later serve as strategic development scenarios. On a sustainability model we demonstrate a need for systematic institutionalization of regional labels management system. During the development of labeling system, we suggest to concentrate of sophisticated joint marketing, combing regional and product-related features and addressing different needs of wide group of prospective customers. A predictive scalar label productivity index, which can be incorporated into regional controlling processes, is proposed.

Keywords – Conceptual Modelling, Regional Labeling Scheme, System Dynamics, Regional Development

Paper Type - Academic Research Paper

1 Introduction

The increasing global interest in the regional food market runs parallel to rising supply and promotion of such production, also reflecting consumers' concerns about food quality, authenticity and health safety issues (Bowen, Mutersbaugh, 2013; Doherty, Campbell, 2014; Bryla 2015; Fornay, Häberli, 2016). To capture this increasing trend and market potential a large variety of regional labelling schemes has been introduced in the EU food market in the last thirty years (Albuquerque, Oliveira, Costa, 2018; Kos Skubic, Erjavec and Klopčič, 2019; Gracia, De Magistris, 2016). In general, the purpose of the food labelling schemes is to provide information to consumers about certain aspects of the food or its production method, often in the form of a logo and / or a statement on the product. It should clearly inform the consumer that the food meets the standards of that scheme e.g. the food is produced in a certain geographic region or has been produced in accordance to additional requirements (Gracia, De Magistris, 2016). It is common that food labels strive to signal more than one major characteristic. Regional labelling schemes, that primarily aim to label and signal the origin of the products, may also ask the producers to meet requirements for sustainability (Hashem, Migliore, Schifani, Schimmenti and Padel, 2018; Nicolosi, Laganà, Laven, Marcianò, Skoglund, 2019).

The functioning regional labelling system requires cooperation among local businesses - small and medium producers and agriculturists (Stoklasa, Starzyczna, 2016). Local and regional authorities, development agencies, nature conservancy administration and non-governmental organisations often contribute to introduction and maintenance of the system in various forms – information circulation, financial and material support, active involvement in the system's coordination or implementation of the projects (Čadilová, 2011). However, as Bingen (2012) or Ratinger and Bošková (2018) have pointed out, there is more often an adversarial, not a collaborative, relationship between especially SMEs and most governmental agencies. Dempsey (2011) have identified the critical elements in the planning, developing and resourcing of the regional labelling scheme (based on the case study of the West Cork Fuchsia brand): engagement and communication within the network to build strategic alliances, the ability of the label to build and maintain competitive advantage and network's emphasis on longer term strategic planning and coherent strategy. With the wide variety of stakeholders and policy targets, regional labelling schemes may face various issues at the strategic management level, f.e. Ikuta, Yukawa and Hamasaki (2007) have observed how difficult it may become for local governments' measures to control the regional schemes, which may result in lowered effectiveness.

The authors who have studied regional labeling schemes have focused on variety of themes connecting them with various aspects of regional development – economical (f.e. Hashem et al, 2018; Van Ittersum et al., 2007, Spilková, Fialová, 2012), social (Fornay and Häberli, 2015; Long, Murray, 2013) and environmental (Marsden, Smith, 2005; Onozaka and McFadden, 2011). However, the research on relations and mechanisms within these networks remains underdeveloped. Presented article aims to model a set of

relations and dynamic mechanisms associated with variables relevant to the regional labeling that would allow to formulate a viable dynamic hypotheses as a basis for a strategic development scenarios. Its effective and broadly understood structural simplification represents a prerequisite for correct establishment of practically applicable, reliable and scalable managerial platform (Davies and Davies, 2016). Generic planning cycle of non-profit organisations has following stages (Chalupová et. al., 2014):

- Organizational planning, defining mission, establishing shared vision and outlining particular goals, objectives and strategies.
- Alignment of planned activities with available or assumed finances
- Allocation of capacities (incl. human resources and operational infrastructure)
- Definition of key enablers for success (processes, projects, initiatives and frameworks)
- Implementation and execution
- Continuous performance tracking, feedback review and necessary improvement

Created model model may represent a useful device in understanding how the regional-based system functions, as well as a tool that the decision-makers in regional development planning may benefit from.

2 Regional Labeling in the Czech Republic

A study, funded by the European Comission, identified 901 voluntary food labelling schemes operating on European market; the highest number (20%; 180) of them were found in Spain, 12.5% (113) in Germany, 7.8% (70) in Italy, the next largest number of schemes were identified in Portugal (61; 6.8) and the Czech Republic, France (5.9%; 53). This study, with focus on the functioning of voluntary food labelling schemes for consumers in the EU, classified the schemes by the attribute claimed in the label. The most claimed characteristic was the origin of production, which was covered by 60% (540) of all schemes (901) (Ipsos - London Economics Consortium EAHC, 2013). In the Czech Republic there are three major umbrella regional labeling schemes. At the EU level there are schemes of geographical indications: Protected Designation of Origin (PDO) and Protected Geographical Indication (PGI). These labels still suffer from relatively small awareness among the Czech consumers (Velčovská, Del Chiapa, 2015; Margarisová et al., 2018). Also Grunnert and Aachman (2016) or Skubic, Erjavec and Klopčič (2018) have suggested that the role of these labels is still relatively low in the consumer decision-making within the EU.

The national level is represented by the project Regional Food of the Ministry of Agriculture of the Czech Republic (and its State Agricultural Intervention Fund) established in 2010, it runs as a top-down scheme. As an important outcome of this project is the label ‘Regional Food’ present in all the Czech regions at the NUTS 3 level (14). It has a form of competition for local small and medium producers and agriculturists. The project aims to improve the consumers’ awareness of the regional food, communicate its benefits, emphasizing the advantages of consuming local food in

relation to the development of a region - support of employment, tourism, etc. (Czech Ministry of Agriculture, 2019).

Association of Regional Brands (ARB) represents 27 regional and microregional labels, it is a nonprofit organization that associates the coordinators of the member regional labels, it runs as a bottom-up scheme. The first regional labels were established in 2005 (Krkonoše, Beskydy Mts. and Šumava Mts.), the ARB has been created three years later. All of the labels associated in ARB have unified graphic design and common granting principles, such as guaranteed origin, respect for the environment in all phases of both production and sale proportion of manual or mental work and local raw materials, the certificates can be obtained by SMEs, producing food and handicraft, as well as service providers within tourism (Čadilová, 2011). Each regional label within ARB represents the subsystem of regional or microregional network (referring to smaller than administrative regions, usually the landscape protection areas or touristic regions). There is a regional coordinator in each region that manages the label, communicates with local producers or service providers and the ARB. The label is awarded to products or services by an independent certification committee (separate in each region). The ARB is open to any region with defined borders - , an initiator must be a local organization or institution that, by consensus of potential label holders and other stakeholders, takes on the role of regional coordinator (www.regionalni-znacky.cz, 2019). According to Čadilová (2011) the labels associated in ARB differ in the numbers of certificates as well as conditions in which the individual coordinators work. Along with the type of organisation that performs this function (usually in the form of local action groups (LAGs of LEADER) or a destination management associations), financial sources that the coordinator can use are quite substantial, usually using the sources from EU, national or regional subsidy programmes. Additional funds are collected directly from the labels' users (SMEs), which are paid for the duration of the certificate validity – for three years, it can be renewed multiple times. The sub-schemes, operating under their own regional label, are quite autonomous. The ARB helps the coordinators by sharing experience and through the common marketing communication (funded mostly by its own budget with occasional supplement from development and structural funds). The role of the National Office of ARB is also to supervise the certification processes and their outcomes in the member regions, to promote regional labels on the national level and to make and maintain connections with other national authorities and stakeholders, such as Ministry of Regional Development and of Agriculture or the Association of Small and Medium-Sized Enterprises and Crafts CZ.

3 Methodology

The model represents a regional-level strategy-planning task, it is based on available literature and authors' longitudinal research focused on evolution of the various Czech and international regional labels and their impact on regional development (e.g. Chalupová, Prokop, Rojík, 2016; Chalupová et al., 2017; Rojík et al., 2018). Structural

analysis of regional labels, as well as their proper management, is a complex dynamic task with significant involvement of subjectivity in the form of personal or group preferences, perceptions, relations, or attitudes. These limitations can be minimized with the utilization of knowledge-based techniques, which are holistic, i.e., work with bounded, internally structured and interconnected elements, internally understandable and architecturally scalable. Related implementation techniques, stimulating teamwork and creativity, results in straightforward, user-friendly solutions. In this phase, we followed the traditional spiral development lifecycle, consisting of the following generic stages:

- Formulation of the real-world problem, serving as a set of functional and qualitative requirements for subsequent analysis and design phases, as well as the primary validation platform before the routine utilization of generated output.
- Knowledge elicitation, including the collection of adequate amount of information, data, domain, and expert knowledge, characterizing the original problem.
- Knowledge specification, i.e., structuring and formalization of outcomes from the previous stage into a conceptual model, suitable for qualitative analysis of the studied phenomenon.
- Experiments, namely sensitivity and scenarios analyses, outlining the internal operational range of invented solution, its limitations and robustness with respect to changes of external environment.

In the presented research, we transformed the results of the literature review directly to the Causal Loop Diagram (CLD), characterizing the dynamics of the underlying problem as a result mutual effects of interconnected causal loops of different complexity and duration. Single loops are either balancing, i.e., stabilizing or limiting, and reinforcing, i.e., guaranteeing growth of involved variables. In the real-world problems, the number of reinforcing loops is typically higher, but there must also be some balancing ones, introducing the natural limits and restrictions. Presented model within a system-thinking framework describes the problem as a system, shows boundaries and level of model aggregation, elements, and relationships between them. Through them, it is possible to communicate information about endogenous and exogenous variables (Sterman, 2016).

4 Results and Discussion

As Dempsey (2011) emphasized, a regional labeling scheme should represent a comprehensive integrated development strategy, creating a prime infrastructure and supporting system, that should be delivering exceptional benefits to the certified businesses. In order to analyze all aspects of development of regional labelling processes, they must be placed into the right context and delimited against the surrounding environment. Only under such circumstances it is possible to plan and control their impact, usefulness and importance. Because we studied primarily the regional labels, an

independent region was selected as the compact target platform. Consequently, the related research questions were formulated:

- How to include the system of regional labelling into the traditional regional development structures?
- How to quantify the impact of regional labels to the regional performance?
- What are the most productive ways of inclusion of regional labels among the traditional regional development policies and strategies?

We were also fully aware of the related risk of underestimation, because the impact of this task is relatively small in comparison with standard agenda, but believed, that although globally minor, this framework has a strong development potential and deserves to be conclusively institutionalized and standardized. To be able to answer our questions based on the knowledge, presented in the literature review, we started from the concept of regional sustainability. These processes, summarizing and confronting internal and external factors, are integral part of regional governance, striving to preserve and develop local resources with particular emphasis on the non-renewable ones. The specificity of this task insists in its slow dynamics, incomparable even with duration of several election periods. Moreover, continuous postponement of sustainability agenda can easily slip to irreversible losses (Mol, Lauber, Liefferink, 2000; Ramos, Squeff, 2020).

Sustainability is composed from the three fundamental pillars, economic, social and environmental, called the triple bottom line (Alhaddi, 2015), which are further refined and validated in numerous implementation frameworks. For example, ISO standard 37120 (International Organization for Standardization [ISO], 2018) proposes 17 sustainability themes and 100 indicators. In the past decade, the administrative ways of sustainability achievement were extended with data, information and technology driven so called smart solutions, which increase the overall efficiency of realization processes.

The way of our embedding of regional labels into a sustainable holistic framework is shown in Figure 1. It contains causal loop diagram, with six key sustainability sectors, *Management and governance*, Society, composed from *Population, Effectiveness policy* and *Quality of life* components, *Environment, Land, Economy, Transport* and *Energy*. Despite the representational simplicity, the diagram contains more than 100 loops with the length varying from 2 to 10 underlying elements. It is evident, that longer loops with more mutually shared variables require careful justification and produce more complex behavior. The sector of *Governance and management* forms the most important part of our study, because it is responsible for inclusion and management of regional labels. For detailed analysis, we partially unrolled two backward (causes) and forward (effects) levels of all loops, passing through this variable, as it is illustrated in Figure 2.

There are two inputs, determining the suggested decision-making policies - *Budget*, represented with incomes from regional *Economy* and governmental subsidy per capita (*Population*). *Population,* or rather society, consists of *Quality of life, Effectiveness policy*, expressing quantitative features of *Population* and *Economy*, serving as a salaries

paying regional employer in this context. This particular input *Population* can be also considered as an instantiation of participative democracy.

Resulting recurrent policies, strategies and decisions on the right side follow the two main directions – *effective*, establishing the basic functionality and *efficient*, introducing qualitative features up to the rest of available budget.

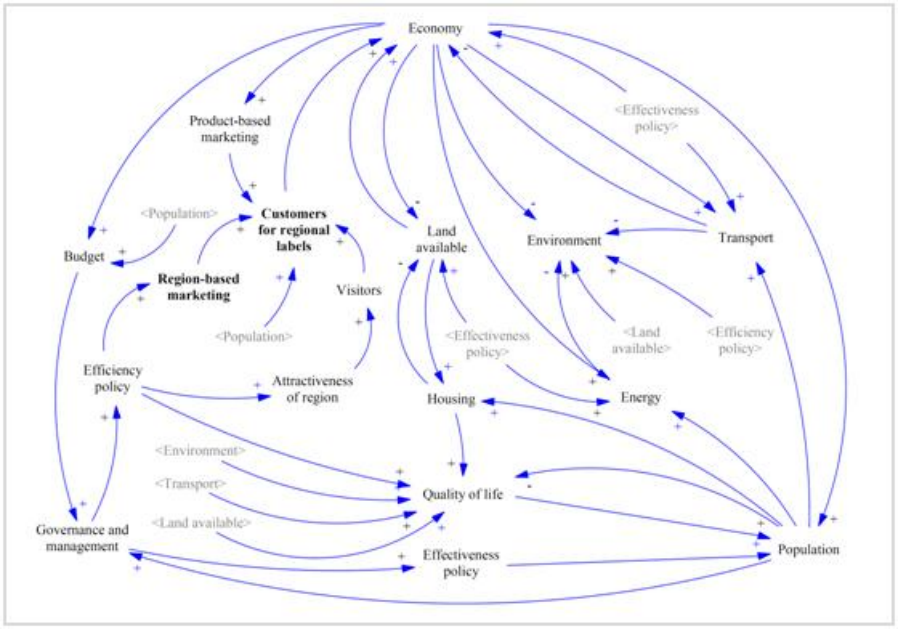

Figure 1 Causal loop diagram of regional labels management system in context of sustainability

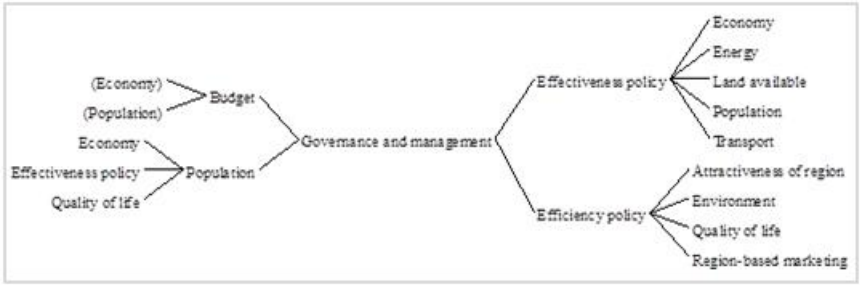

Figure 2 Unrolled loops for regional Governance and management sector

From this overview it is evident, that the regional labeling belongs to the latter branch. We believe, that comprehensible, imaginative, straightforward and multifaceted marketing is the best way how to promote these labels, preferably in parallel with other topics of regional interest. Only such colorful and natural persuasion can activate broad

spectrum of purchase motivation, insisting in, e.g., identification with region, preference of its traditions, natural, cultural or historical features and monuments, perceived familiarity, quality, safety, uniqueness or exclusiveness of regional products.

Figure 3 shows, that we suggested to address prospective customers both with specific *regional messages and stories*, altogether with *standard industrial marketing practices*. Beyond the local *population*, these campaigns target on tourists and people on business or shopping trips (*Visitors*). It is also useful to develop packages of thus originated sets of services and products. Overall *Attractiveness of region* is yet another indirect lever, stimulating the successfulness and permanence of regional labels. Finally, although rather distant, *Quality of life* is also important attractor for regional labels because happy people have tendency to support local products. From the fan of consequences of variable *Customers for regional labels* it is evident, that properly established labelling system can positively contribute to all key segments of sustainability.

Figure 3 Unrolled loops for temporal development of number of Customers for regional labels

Figure 3 also shows that the performance of regional labelling system can be measured with a scalar Labels Productivity Index (LPI), which is normalized ratio of impacts, propagated to single key sustainability sectors, divided by particular inputs as follows:

$$LPI = \frac{f(Budget, Energy, \dots, Transport)}{g(Total\ marketing, Attractiveness)}$$

Let's assume the following three strategies of label management:

- A: no label management,
- B: moderate level of label management, which is aware of single activities, but lacking their systemic view,
- C: optimal level of label management, integrating properly all its aspects into the existing regional governance and management processes.

Illustrative qualitative diagram of temporal evolution of particular LPIs is in Figure 4.

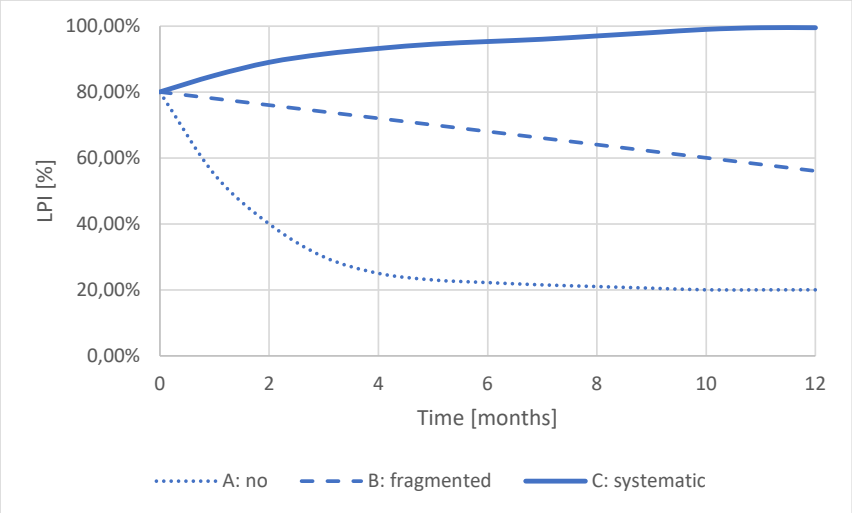

Figure 4 Development of label productivity index (LPI) for different label management strategies

It is seen and justified by our model, that productivity of systematically unmanaged labels drops rapidly. This is, however, typical example of the current sustainability policies. Distributed knowledge and nonsystematic maintenance of isolated structural LPI components can eventually result in its slower deterioration. Finally, an optimal holistic management could achieve the planned level of LPI. The rest of causal loop diagram serves as a background stub for the above-characterized system. Because it deals with large and well-known structural items, particular meanings of which are easily traceable from the Figure 1, detailed description is omitted.

5 Conclusions

On a sustainability model we demonstrated that there is a need for systematic institutionalization of regional labels management system. Only in context of other key sustainability indicators the usefulness and profitability of regional labels can be achieved. During the development of labelling system, we suggest to concentrate of sophisticated joint marketing, combing regional and product-related features and addressing different needs of wide group of prospective customers. Finally, we propose a predictive scalar label productivity index, which can be smoothly incorporated into regional controlling processes. A process of dynamic modelling of relations and mechanisms within a regional labeling networks may aim at, for example, finding solutions in the form of qualitatively better plans, better information in the system (more information or better transfer of information, sharing of relevant information, etc.), building a better business environment, better coordination, or a more significant and better role for the small and medium producers and agriculturists. Fragmented activities,

especially in the field of marketing communication activities may result in poor performance of the umbrella regional labelling scheme (such as ARB). To overcome this bottleneck, the following improvements may be suggested: (i) establishment and systematic management of the planned activities, with emphasis on brand management and focused marketing, to build an awareness and trust in the regional labels and attract the consumers, building the functioning distribution system in the form of network of specialised shops that would offer certified regional food. (ii) more focus on counselling and help with fundraising, with focus on development and structural funds. (ii) Shortening of delays in basic managerial cycle, including identification of needs of the stakeholders - local stakeholders - authorities, LAGs, environmental distribution and performance management.

In or future research, we will concentrate on sample implementation of presented framework in the language of system dynamics.

Abstract

We propose a conceptual dynamic policy-modelling framework for sustainable development of international students' mobility in higher education. This model provides a transparent internal representation of this phenomenon, influenced by various external factors with particular respect to terrorism. Based on extensive literature review, available data and personal experience, we sequentially structure and refine related knowledge from initial mind map through business model canvas and system diagram to final causal loop diagram. These partial outputs allow formulation and justification of viable policies and related strategies. Our main contributions include (i) holistic interconnection of particular performance sectors and their alignment with university core processes, (ii) continuous identification, quantification and management of risk of terrorism and (iii) distinguishment between steady level of terrorism and its emergency effects.

Keywords – Terrorism, Students' mobility, Conceptual modelling, Dynamic hypotheses

Paper type – Academic Research Paper

1 Introduction

Over the past decades, students' mobilities have increased significantly due to globalization of higher education institutions (HEIs), as they represent a valuable opportunity for students to gain considerable skills, knowledge and experiences by staying abroad to study or execute training (Beine et al., 2014; Roy et al., 2019; Tosi et al., 2019). Results of the European Universities Initiative survey, that analysed data from 219 HEIs from 34 systems across Europe, that internationalisation has been a strategic issue at most institutions for quite a while: more than half of respondents have 10% or more international students (Claeys-Kulik, Jørgensen, Stöber et al., 2020).

Terrorist attacks, as unexpected events that cause damage, fear, and increased uncertainty, represent a global challenge of huge proportions (Estrada et al., 2018; Nail, 2016; Papakyriakou et al., 2019). Universally accepted definition of terrorism does not exist, but it is commonly defined as *'the deliberate use of violence and intimidation directed at a large audience to coerce a community (government) into conceding politically or ideologically motivated demands'* (Krieger, Meierrieks, 2011). Obviously, terrorism affects diverse aspects of social interactions in general, including the internationalisation of higher education. Historically, higher education institutions have been founded in the centres of the vibrant regions, important for the business and culture. Dostál et al. (2018) have pointed out that terrorists usually attack the same cities to achieve their political goals: to cause societal shock with and extensive publicity. It can be predicted that future terrorist incidents will quite likely impact cities or areas with a HEIs. A sense of urgency requires for the HEIs managements to create a supportive infrastructure, that should be composed of the basic elements of leadership, including systems of decision making, that can be swift in responding to external (and internal) pressures (Bain, 2007).

The concept of internationalisation is strongly anchored in institutional mission statements, policies and strategies, including national policy frameworks, it represents a complex of issues and policies with different approaches and strategies in constantly changing contexts (Knight, de Wit, 2018). Wihlborg and Robson (2018) call for readjustment of research approaches of the HEIs' international activities, becoming more cross-disciplinary and transversal, to be able to address various types of modern challenges. De Wit and Hunter, (2015) focused on the future of internationalisation of higher education in Europe and suggested that the main challenges are international strategic partnerships and increasing outgoing student mobility, which remain a key activity of institutional and regional policies in the EU. Other forms, such as academic programmes (i.e., cross-cultural training, exchange programmes, visiting lectures, joint/double degree programs,) collaboration on the research projects or extra-curricular, such as students' associations and external relations (domestic and cross-border), help build the complex international activities (Maringe, Foskett, 2010). Our article focuses on the student mobility, in the form of degree mobility (for an entire study programme) and

credit mobility (for a half-year or a year - e.g. Erasmus+ Programme), as they are the most visible and far more important form of internationalisation (Teichler, 2015). The statistic published by Statista (2013) shows a prediction that by 2025 there will be at least 8 million students pursuing higher education abroad. In 2017, 5.3 million tertiary students crossed an international border for an education (OECD 2019).

The aim of this research is to propose a conceptual dynamic policy-modelling framework for sustainable development of international students' mobility in HEIs. This model provides a transparent internal representation of this phenomenon, influenced by various external factors with particular respect to terrorism.

1.1 Literature overview

Terrorist attacks aim intentionally at non-combatant targets, such as civilians, chosen randomly (Hoffman, 2006), to achieve significant publicity for political, religious or ideological reasons (Matusitz, 2013), the meaning of terrorism is socially constructed Sloan, 2006). Events, such as 9/11 attacks on the US or in Paris in 2015, and the response they provoqued, has attracted academic attention. Some contributions have focused on various dimensions of counter-terrorism policies (Argomaniz, Bures and Kaunert, 2015; Bossong, 2013), others studied impacts of terrorism on tourism – identifying fear and insecurity as major barriers to international travel (Liu, Pratt, 2017; Seabra, Reis, Abrantes, 2020), or economic impacts, i.e. investments, foreign trade, consumption, GDP growth (Estrada et al., 2018) or individual welfare (Clark, Doyle, Stancanelli, 2020). However, studies of how the threat of terrorism impacts HEI internationalisation (student mobility) are still sparse (Chalupová et al., 2017; Dostál et al. 2018).

When considering international activities, HEI management must take into account a wide range of factors. Starting at the macro level (political, cultural, social, technological, economic factors), mezzo factors (connected with regional conditions) as well as inner context (Cairns, 2019; Curaj et al., 2018; Van Mol and Timmermann, 2014). To manage complex processes connected with internationalisation, HEI management should prepare additional structures and processes to be able to guide, inform and support their incoming and outgoing students and academics/staff, to minimise impacts of unpredictable and complex events and changes, such as terrorist attacks (Dostál et al., 2018), local crises and conflicts (Cervantes-Duarte, Fernández-Cano, 2016), protectionism or various forms of inequalities (Choudaha, 2017) or the health crises, such as COVID-19 pandemic (Wang et al., 2020). It is certain, that HEI internationalisation and the various types of external risks can be managed with the methods similar to those used for business processes (Al-Zoubi et al., 2018). The benefits might include (Polak, 2018) improvement in management of the internationalisation process, better rationale for decisions, more realistic planning and increased risk and opportunities awareness.

The scope of the HEIs internationalisation in the EU has evolved considerably (de Wit, Hunter, 2015). The most frequent forms include various types of academic programmes

(exchange programmes or joint/double degree programs, lectures from visiting academics, cross-cultural training, etc.), research collaboration, or extra-curricular activities, such as students' associations (domestic and cross-border) (Altbach et al., 2006; Maringe, Foskett, 2010). Research, that analysed data from 34 systems across Europe showed, that internationalisation is considered to be a strategic element at most institutions, almost 90% of HEIs are engaging in the students' credit mobility, EU research projects and staff mobility, and 80% of the respondents aim to attract international degree students and about three-quarters of respondents collaborate on joint degree programmes, and bilateral research activities (Claeys-Kulik, Jørgensen, Stöber et al., 2020). HEIs in Europe act within the European Higher Education Area (EHEA),that was established in 2010 as a part of the Bologna Process; Erasmus+ represents the EU's key programme to support education, training, youth and sport. More than 10 million people have participated in Erasmus+ over the last three decades. In May 2018, the European Commission proposed to double the Programme's budget to €30 billion for the next 7-year period, which. It should aim to enhance mobility and cooperation, in EU and with the rest of the world (European Commission, 2018).

1.2 Student mobility

Choudaha (2017) has divided changes in international student mobility into three overlapping 'waves', spreading over between 1999-2020, with the major events and trends in international politics and economics as a cornerstone. The first two waves coincided with terrorist attacks on the USA in 2001 and the global financial recession, which triggered financial motivations for recruiting international students. The most recent one is being shaped by the slowdown in the Chinese economy, BREXIT and change in immigration policy after the 2017 American presidential elections. It can be predicted that the COVID-19 pandemic will have an enormous impact on the recent forms of HEIs internationalisation.

Beine et al. (2014) studied the determinants of international mobility of students. The authors specified among other things the motivation for going abroad, for example the socialization, the development and the destination country. Heirweg et al. (2019) states it depends on the disabilities of the students, there are financial, organisational, linguistic, psychological, technical and practical barriers to participation.

Cairns (2019) describes the student mobility in Europe like means of providing measurements of programmatic success to stakeholders and policymakers. The author claims institutions are responsible for the number of students going abroad and there are big differences between approaches of individual universities. It depends on organizational support, image of the university and the possibility of choosing schools where to go. According to Beine (2019), the studying abroad opens the access to the local labour market.

Agarwal et al. (2008) and Caruso and De Wit (2015) defined the push and pull factors of international student mobility, composed from (i) educational, (ii) political, cultural, social and (iii) economic factors. Shields (2019) extends this scale also with environmental impacts.

2 Methodology

Real-life implementations of high-level organizational policies and strategies result in complex, dynamic, heavily interconnected systems with a considerable portion of human-related soft factors and accompanied by uncertainty, nonlinearity, and parametric nonstationarity. Such kinds of nontrivial problems cannot be solved purely formally. Still, researchers have to search also for modern representational and computational techniques, facilitating the modelling in such naturally ambiguous environments. Because of the qualitative and time-varying nature of studied phenomenon, we applied dynamic knowledge-based tools and methods for analysis and design of the proposed conceptual model. These innovative methods are holistic and systemic, i.e., work with properly bounded and internally structured problems, allow straightforward inclusion of domain and expert knowledge, are representationally transparent, user friendly, and architecturally scalable. Their application range is extensive and varies from the support of an individual or team decisions through parametric prediction and explanation of expected behaviour to the provision of a safe training and improvement platform.

Consequently, related methodology combines theoretical foundations and methods from the following domains:

- Systems thinking and organizational learning
  According to (Senge, 1990), modern management must be holistic and systemic with a large involvement of human-related factors, namely personal mastery, mental models, shared vision, and team learning. His concepts were extended, practically focused, and also introduced to the academic domain (Bui, 2020).
- Knowledge elicitation, specification, modelling and management
  This resource covers a wide range of miscellaneous activities, from psychology to technology. Influential texts with direct applications to management are, for example (Diaper, 1989), (Firlej & Hellens, 1991), (Pasher & Ronen, 2013) or (Milton & Lambe, 2019).
- Business modelling, value management, and strategic planning
  All these activities represent sound outputs of knowledge engineering, transforming so far abstract structures into the real value for stakeholders. Sophisticated awareness concerning the value originating mechanisms and their supportive structures directs managers towards the well-justified targets prioritizations and focusing them on the right things (Osterwalder et al., 2014), (Allison & Kaye, 2015), (Bryson, 2018).

Numerous specialized tools are available to explore, represent, and interconnect these areas. We selected and gradually applied the following ones:

- Mind map (Buzan, 2018) creatively summarizing and structuring processed concepts. The central theme is distinctly placed in the middle of the diagram and surrounded with several main branches, further expanded to thematically disjoint sub-trees. After facilitated interaction with stakeholders, the resultant chart shows potential subsystems, altogether with their approximate internal stricture. The absence of loops drives users to focus on fundamental aspects, and a minimalistic set of formal rules results in a fast design.
- Business model (Bock & George, 2017) characterizes the main structural and parametric aspects of value creation and delivery. From numerous templates and frameworks, we adopted the Business model canvas (Osterwalder & Pigneur, 2010), introducing the following sectors and subsectors:
    - Key infrastructure: partners, activities, resources
    - Value proposition
    - Customers: segments, channels, relations
    - Finances: costs, revenues

  This diagram is somewhat complementary to the mind map as it already shows the leading strategies and resources in the context of surrounding environment.
- System diagram (Ferrario et al., 2016) identifies particular key performance subsystems and factors with respect to their internal structure, including fundamental interconnections and loops. It represents an aggregate overview of qualitative dynamics.
- Casual-loop diagram (CLD), described, e.g., in (Sterman, 2014) opens boundaries of subsystems and shows their most important structural features. Relational directionality optionally applied already in system diagram, is extended to the whole system and completed with the polarity of arrows. The plus sign represents direct proportion, minus holds for the indirect one. Mutual influence of contributions of internal loops, delays, and time constants establishes the dynamics of the whole system.

The last modelling stages include verification and validation. In qualitative modelling, verification represents mainly testing of logical functionality and validation checking the level of compliance with initial assumptions, resulting from the literature review and accompanied with experts' opinions. During the routine utilization, various strategies can be proposed and either justified or refuted with the help of the model. Such usage can happen under different scenarios, realizing selected configurations of external environment. Described methodological procedure is in accordance with the generic research framework proposed in (Mitroff, 1978).

3 Results and discussion

The majority of achieved results are represented in a graphical format. Mind map in figure 1 shows the four key components of students' mobility concept. Although the other "standard" aspects of university management and governance were omitted in the mind map, they still can be considered in the subsequent modelling stages. Thus, the *University* and *Students* branches contain characteristics, particularly crucial for internationalization and mobilities. Also, *Environmental* aspects thoroughly evaluate the situation and future trends in target countries. *Terrorism*, as particualy analysed phenomenon, is excluded from the general environment and described with indicators, which should be of specific interest of internationally cooperating universities. Thus, they can efficiently indicate either smouldering or immediate risk of terroristic threat.

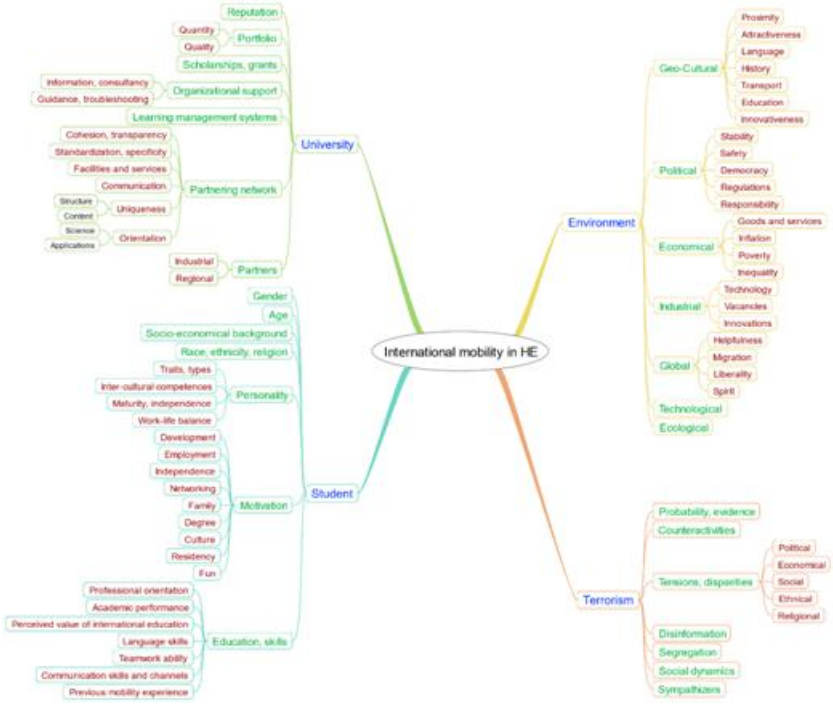

Figure 1 Mind map of analysed domain

Investments into the safety of incoming or outgoing students cause additional costs, which should be compensated with reasonably added value for all involved parties, i.e., stakeholders. These strategic decisions must be evaluated in the context of existing business strategies, evolving in accordance with changes of the surrounding environment, as it is shown in figure 2. Internal business model canvas are in its centre and marked with a white background. Selected endogenous sectors, generating alternative scenarios,

incorporate mobility *Domain* subjects, *Environmental* descriptors including terrorism, characteristics of students' mobility *Market,* and *Economic* background of original and target countries.

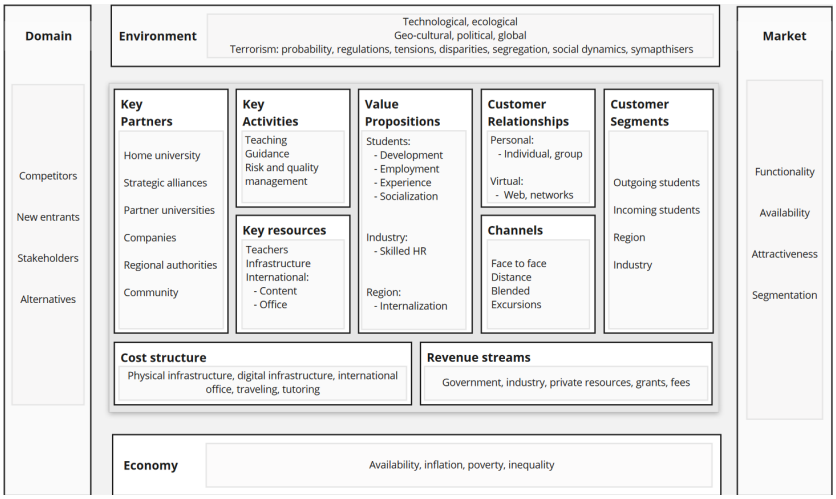

Figure 2 Business model of academic mobility subsystem

The system diagram in figure 3 takes over the most important variables and relations from the previous two graphs and structures them following the aim of this research. The key relations are marked with bolded arrows. The upper part of this diagram shows two directions, how the *terroristic* attacks can affect university students. The first possibility is their pervasive, indirect, evolutionary perception through other *environmental* factors, listed in the mind map. Relative advantage of this input is its slow and generally anticipable dynamics, giving university board and *management* time for strategic planning of adequate resilience. The second entry of consequences of terroristic activities is direct and fast. In this case, immediate reactions, according to pre-prepared scenarios, must be applied in close cooperation with international partners.

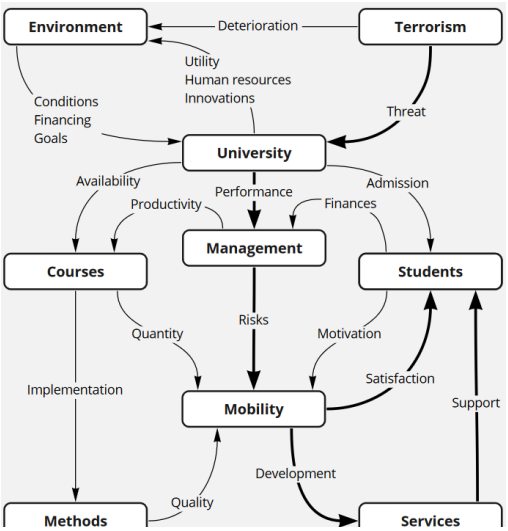

Figure 3 System diagram of the proposed mobility management system

Although no emergency plan can fully reflect reality, in conjunction with systematically applied risk management procedures, it can efficiently minimize undesirable implications. Such additional activities, elementary dynamics of which is shown in the right lower quadrant of figure 3, are provided, altogether with standard *mobility*-related duties, by a local *services* unit, responsible for international relations. Disregarding particular details, primary goal of this department is to motivate *students* to travel. Mobility is further determined with the availability of appropriate *courses* and related set of applicable teaching *methods* and technologies, facilitating students' exchange.

Our final dynamic model, represented with the Causal loop diagram in figure 4, provides a more detailed insight into these mechanisms. Its upper part with textually annotated dashed arrows (*induce, influence,* etc.) serves as an informative interface to the external world. The same holds for activities, characterizing *Research,* and *Third role* of universities, which are out of scope of this study. These factors are included mainly for completeness, and related loops do not contribute to the overall dynamic of modelled phenomenon. Overall *Performance* of *University* operations is composed of several fundamental factors, including also *International services* and is limited with available *Finances*.

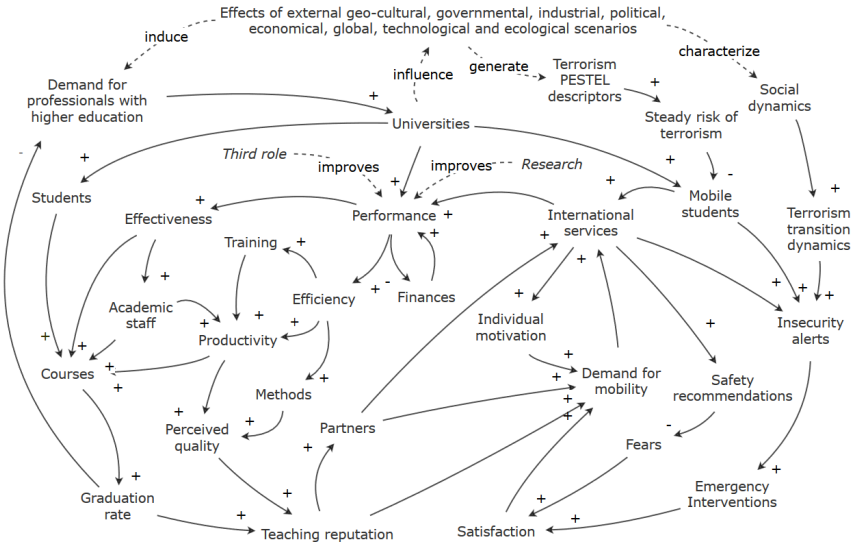

Figure 4 Causal loop diagram of the proposed mobility management system

Performance is traditionally decomposed into *Effectiveness* and *Efficiency* parts focused on quantity and *Perceived quality* of provided *Courses*. These factors increase *Teaching reputation* and address international *Partners*. The slow dynamics of terrorism propagation (*Steady risk*) affects the total number of *mobile students*, which is out of university control. Anyway, all other students, who are in charge with international services, are continuously motivated to travel and informed about actual threats and limitations, minimizing the fast *Transition dynamics* of terrorism through the rightmost loop implementing *Emergency interventions*. Because the nondecreasing *Demand for mobility* is one of the key performance indicators of *International services* unit, all related loops are reinforcing (growth supporting), which is represented with absence of zero or odd number of arrows' minuses along particular loops. *Fears* resolving loop is balancing (stabilizing) and strive to maintain the level of *Safety recommendation*s on an appropriate level.

Even such a simplistic Causal loop diagram has 32 loops with adjustable parametrization, which can be either linear or nonlinear – for example, in case of subjective or risk-related variables. Also, the duration of particular loop cycles can affect the resultant behaviour and performance significantly.

4 Conclusions

To summarize the usefulness and applicability of the proposed framework, let's consider the following scenarios and strategic decisions (situations):

- S1: Operations in an externally safe environment without explicit internal anti-terroristic activities (base run),

- S2: Operations in an externally safe environment with a minimalistic level of anti-terroristic risk management and partially applied set of corresponding preventive and reactive rules,
- S3: Operations in an externally safe environment with an optimal level of anti-terroristic risk management and fully developed set of corresponding preventive and reactive rules,
- S4: Operations under particular risk of terrorism without explicit anti-terroristic activities, implemented on the university level,
- S5: Operations under particular risk of terrorism with a minimalistic level of anti-terroristic risk management activities and partially applied set of corresponding preventive and reactive rules,
- S6: Operations under particular risk of terrorism with an optimal level of anti-terroristic risk management activities and fully developed set of corresponding preventive and reactive rules.

Evaluated with the following set of relative indicators, changing from 0 to 100%:

- Terrorism risk index (TRI), regularly evaluated by international services unit (external lagging indicator),
- Impact resilience index (IRI), given by university governing board and maintained by its management (internal lagging infrastructural indicator),
- Demand for mobility (DFM), planned by international services unit as its key performance indicator (internal leading process indicator),
- Performance (PER): planned by university management as a cumulative internal measure (internal leading overall indicator). This quantity is used for mutual comparison of the below presented cases S1 – S6.

Qualitative conclusions, estimated under the presented innovations of mobility system management, are outlined in Table 1.

Table 1 Qualitative comparison of sample scenarios and strategies

Situation	TRI [%]	IRI [%]	DFM [%]	PER [%]
S1	0	0	100	100
S2	0	20	100	95
S3	0	80	100	90
S4	80	0	20	80
S5	80	20	50	90
S6	80	80	80	95

The first three situations S1 – S3 illustrate the fact that preventive activities require additional resources in comparison with the base run, simplistically assuming that other

performance drivers and enablers remained untouched. In a stable, quiet world, additional processes logically cause security overhead.

Unprepared university in situation S5 faces not only a considerable drop of mobile students but also loses its own performance because of forced invention of mandatory ad-hoc recovery solutions. Finally, the proposed extension of international infrastructure supports more sophisticated quantitative (S5) and qualitative (s6) responses on the gradual escalation of terrorism or direct attacks.

Consequently, our main recommendations are the following: (i) universities must classify destination countries according to the steady risk of terrorism occurrence, (ii) systematically prepare outgoing students for this eventuality, (iii) continuously monitor transition part of social dynamics in risky destinations and (iv) altogether with international partners design immediate and efficient counteractivities. Although our research deals mostly with EU related resources, we believe that the identified conclusions can be applicable in a broader context.

Abstract

The main goal of management is the gradual fulfilment of company vision with respect to the changing environment. This capability is also an essential prerequisite for continuous maintenance of desired levels of performance and competitiveness. The later metrics, reflecting responses on internal and external changes, is defined, justified and aligned with the organisational structure in this paper. The inherent complexity of competitiveness planning and management resulted in the introduction of specialised frameworks, decomposing and formalising related managerial tasks, both structurally and temporally. Consequently, this paper also compares and finally conceptually combines two widely used but qualitatively different approaches: heavyweight, top-down, strategy-based Balanced Scorecard system (BSC) with the nowadays-reinvented Objectives and Key Results approach (OKR). In contrary, OKR is a representative of agile, decentralised and bottom-up planning and execution methods. As management is a dynamic task with different durations of decision-making cycles, the positives and drawbacks of both methods are analysed and discussed. Finally, a theoretical concept of their beneficial integration is proposed.
Based on the literature review and the latest methodology of the World Economic Forum, we designed qualitative competitiveness monitoring and evaluating framework, compatible with BSC architecture. To demonstrate its applicability, we projected single indicators through a sample strategy map to a causal-loop representation of BSC. Such way of qualitative modelling allows transparent representation of structural and behavioural aspects of analysed phenomena, as well as formulation, justification and discussion of underlying dynamic hypotheses and suggestion of viable scenarios for problem elimination. For the OKR-related alternative, we proposed an agent-based framework, mimicking the fulfilment feasibility of particular objectives for concrete structures and skills of single teams. Finally, we suggested a simple process model, integrating both presented techniques. Although the problem of bidirectional and two-speed competitiveness management is nontrivial, we believe that our knowledge-driven explanation can overcome this inherent complexity and attract the interest of the research community.

Keywords – Competitiveness, Balanced scorecard, Objectives and key results, Agility

Paper type – Academic Research Paper

1 Introduction

The essential goal of management is to keep the organization continuously competitive despite any internal changes and within a considerable range of external disturbances. Dramatic environmental dynamics results from multiple interrelated factors, such as globalization, hypercompetition, continuously increasing role of innovations or introduction of new technologies. Complexity and variability of modern businesses force managers to make high-quality strategic plans and related complex decisions and in a short time. Thus, the main related difficulties are given by the dramatic difference between well-established internal processes and properly formalized cooperation with suppliers or partners and generally decentralized, global character of the market with numerous vague or ambiguously defined structural elements and rules. It is evident that such complex, turbulent and non-deterministic processes require the introduction of advanced managerial procedures, capable of projecting business dynamics into the systematic execution of appropriate competitive strategies.

Consequently, this research aims to propose and justify an innovative managerial framework, capable to efficiently execute optimal and permanently aligned competitive strategy, as well as flexibly minimise impacts of internal and external changes.

1.1 Competitiveness

The Longman Advanced American Dictionary (Duckett, 2007) defines competitiveness as "*the ability of a company or a product to compete with others and the desire to be more successful than other people*". In other words, the term deals with the ability of firms to stay competitive, which insists on their potential to develop and retain position among the competitors operating in the same market. It means that firm competitiveness can manifest its capability to function better than comparable institutions in term of sales, market shares, or profitability (Lall, 2001).

The scientific foundations of national competitiveness were formulated in the theory of comparative advantage (Ricardo, 1817), which was gradually developed over decades and finally put into the strategic management context as the Theory of competitive advantage (Porter, 1990). From then on, various theories and qualitative models of competitiveness were proposed like the Resource-based view (Madhani, 2010) or Six forces model (Brandenburger & Nalebuff, 1997). There is also extensive research concerning the dynamic nature of competitiveness, arising from persistent offensive and defensive interactions among market competitors (Ketchen et al., 2004), (Zhang & Gao, 2014), (Efrat et al., 2018), (Baden-Fuller & Teece, 2019) or (Ferreira et al., 2020). The importance of sustainable competitiveness is emphasized by (Barney, 2016) or (Kalender & Vayvay, 2016). As a result of analysis of competitiveness with limited internal resources, Barney suggested a necessity of a unique product which cannot be replicated by competitors and forms the desired competitive advantage.

Another influential input from this category is the factor-based competitiveness research. In contrast to above-mentioned qualitative, larger-scale top-down models, this approach investigates and composes competitiveness from selected specific components. Employed empirical, statistical, mathematical or business intelligence methods usually identify most influential internal relations, frequently appearing attributes or typical patterns as particular performance drivers. Sometimes they even transform the original data into a new system of coordinates, which leads to the brand new, compositional set of competitiveness factors. For example (Cantele & Zardini, 2018) proposed layered unidirectional network, constituting competitive advantage from partial dimensions (social, environmental, economic, formal practices, organizational commitment, reputation and customer satisfaction) and evaluated the strength of determinism of selected intermediate connections. Methodologically similar research was conducted, e.g., by (Andrews & Boyne, 2010), (Artiach et al., 2010), (Sun et al., 2010), (Valdez-Juárez et al., 2018) or (Likumahwa et al., 2019). A general structural framework for synthesizing and structuring both reflective and formative resources of competitiveness was proposed by (Becker et al., 2019).

1.2 Dynamics

Competitiveness arises from perpetual interactions between market, consisting of buyers, sellers, structure, rules and information, and individual performances of single involved subjects. As a result, a dynamic market price equilibrium is established. To be competitive, the company must continuously innovate competitive strategies in accordance with external changes and also reflecting its internal dynamics. There are several behavioural archetypes (Senge, 1990), knowledge of which can facilitate this effort.

1.2.1 Information latency

This apparent phenomenon, illustrated in figure 1 and described, e.g., by (zur Muehlen & Shapiro, 2010), results from slow decision-making cycles, produces by non-optimal business architecture. This effect also corresponds with the Mathematical theory of information (Shannon, 1948), according to which the rare and recent events have higher information content. The longer time passes from their occurrence; the lover value can be obtained from their exclusive ownership as the initial message gradually become public.

1.2.2. Delay

Another undesirable result of slow business cycles is the forced harmonic response in control loops, technically caused by the presence harmonic components in the analytic solution of transition response. This feature is illustrated in figure 2. The corresponding causal loop diagram in its left part has single balancing loop, saying that the larger

(negative) difference between the current and desired value, the larger need for correcting decisions, positively affecting the original value.

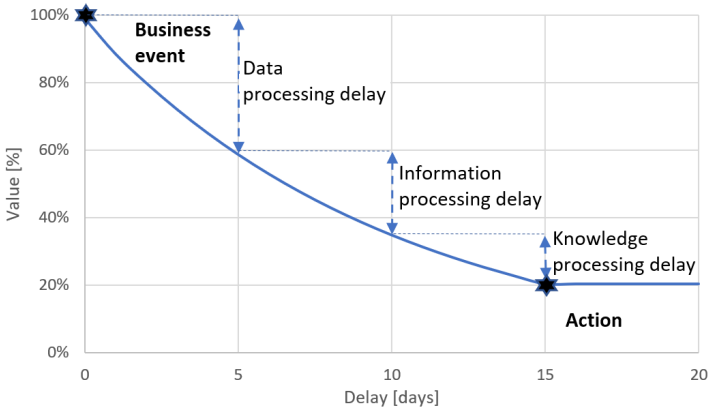

Figure 1: Eroded value as a result of slow internal processes

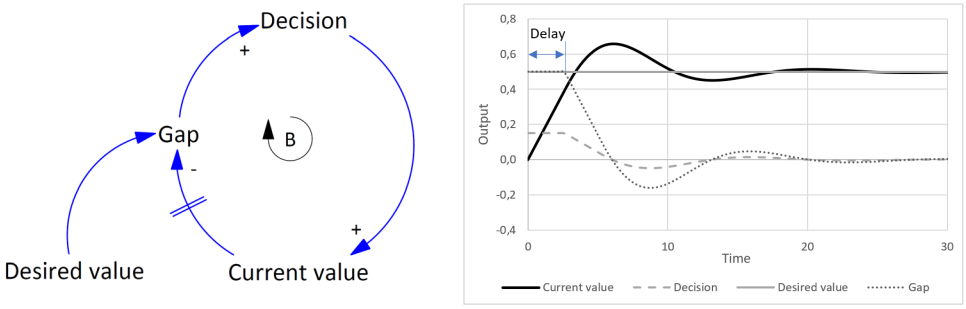

Figure 2: Schematic causal loop diagram and time response of delayed control decision

This loop is balancing (B), as it has an odd number of indirectly proportional (minus) connections. The delay of recognition of the gap existence is marked with the double-crossed arrow. Time graph says that disregarding the history, need for correction of difference 0.5 between current and desired value was recognized after three days of its appearance. During this time, output (current value) was out of control. Then the delayed decisions started to act against the gap, which resulted in the achievement of the desired state 30 days after the first occurrence of this need, which could be too much. Compensations of oscillatory behaviour represent yet another managerial burden.

1.2.3 Competition

The basic situation in the market can be represented with the behavioural archetype Success to successful (Senge, 1990), in figure 3. It consists of two unlimited growth supporting (reinforcing) loops, sharing the same resource, i.e., customers. Because of market closeness, the success of one competitor means the lost for the other and vice-

versa. Price equilibrium must be carefully maintained by both companies; otherwise, the winner can quickly undertake the whole market. Time graph shows the situation when market share is 80:20 in favour of A, which also mainly dictates the price policy (similar phases of price fluctuation and growth of A). Also, the success of B is opposite to the success of A.

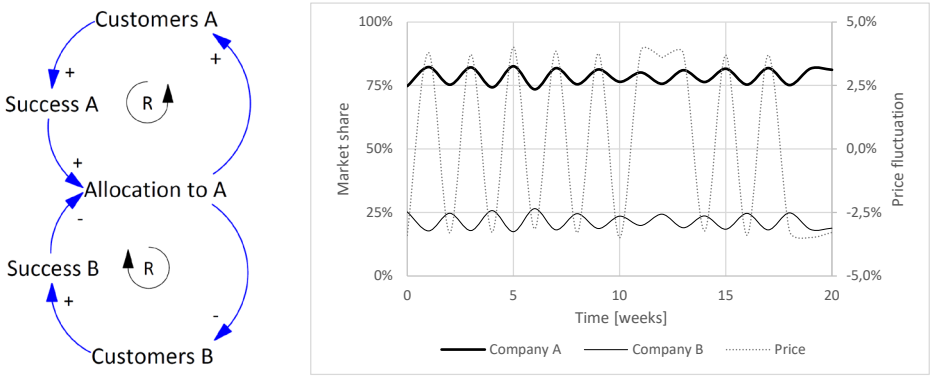

Figure 3: Schematic causal loop diagram of price fluctuation due to market competition

1.2.4 Agility

The introduction of agility represents a powerful way of minimisation of unavoidable side effects of business dynamics. It can be understood as the result of integrating vigilance to change management by recognizing opportunities, challenges and threats using both external and internal resources in a relevant, timely, accessible and way (Elkareem et al., 2011). The favourable conditions for being agile ban be summarized as follows:

- Changing market environment,
- Collaboration with customers,
- Need for continuous innovations and improvement – problems are complex and solutions are unknown, product specifications changes, time to market is crucial,
- Cross-functional cooperation is beneficial,
- Value can be delivered incrementally, and changes are manageable,
- The organization can learn from history.

Well formalized needs for agility appeared first in the software industry. In (*Manifesto for Agile Software Development*, 2001) there are formulated the following four foundational values of agility:

- Individuals and interactions over processes and tools,
- Working software over comprehensive documentation,
- Customer collaboration over contract negotiation,
- Responding to change over following a plan,

further defined with twelve supporting principles, including:

- Customer involvement and satisfaction, accommodation of changes, frequent delivery, teamwork, motivation, face to face communication, working outcomes, constant pace, sound design, simplicity, self-organization, reflection and adjustment,

and implemented through different team-based frameworks, among them Scrum (Hossain et al., 2011), (Rubin, 2012) and Kanban (Brechner, 2015) are the most significant. Over the time, agile principles moved from the level to organizational level, which was reflected with the invention of the Scaled agile framework (SAFe), characterized, e.g., by (Dikert et al., 2016), (Rigby et al., 2018), (Barroca et al., 2019). The current final phase of agility penetration is the business agility (Mathiassen & Pries-Heje, 2006), (Waldock, 2015), (Nejatian et al., 2018), which naturally supports also the main topic of this research.

1.3 Strategy

Regardless of particular implementations, management processes must always address three essential questions: *Why, What* and *How*. Answering the *Why* is rather straightforward as it is connected with company vision, mission and business values. Mechanisms behind the other two questions are, however, more complicated. The *Whats* are related to objectives on different levels while the *Hows* are projected into actions, or, more precisely, corresponding metrics. Although all management frameworks start to form the top posting *Whys*, they differ in scope of *Whats*, because objectives can be defined for different business levels, from operations to particular visions. Accordingly, also the related metrics, i.e. *Hows*, must unambiguously cover a wide range of internal and external quantitative and qualitative variables. They can be either leading (predictive, evolving, related to inputs and states) or lagging (retrospective, static, related to outcomes). Sometimes, they are attributed as "key" which means that their total number should not exceed five. In case of competitiveness, numerous sets of indicators, characterizing past or future evolution of company finances (profitability), operations (capacity, time to market, quality), customers (market share, price) or growth and innovativeness (productivity) can be used. This topic was studied, e.g., by (Díaz-Garrido et al., 2011), (Turi et al., 2014), (Torjai et al., 2015) or (Šegota et al., 2017). The indicated values must be somehow originated. For this purpose, the concept of performance drivers was established.

In contrast to the more or less direct and well-focused indicators, drivers are usually composite and hierarchical. They are primarily formed with business-aligned and continuously developing processes, consisting form resources, capabilities and skills. For example, (Christensen, 2010) proposes the value for customers as a competitive advantage, (Henderson, 2011) recommends sustainable event management, (Reed et al., 2012) suggest open innovations, (Finch et al., 2016) opt for dynamic capabilities. In (Delbari et al., 2016) performance is composed of the bargaining power of customers and

suppliers and the threat of substitutes, new entrants and competitors. Finally, (Singjai et al., 2018) describe the competitive power of green initiatives in the hotel industry.

Exhausting set of strategic drivers and indicators, altogether with related processes, form standardized multifaceted planning and management frameworks. This research combines two of them, Balanced scorecard (Kaplan & Norton, 2005) (BSC) and Objectives and key results (Doerr & Page, 2018).

1.3.1 Balanced scorecard and strategy map

Although BSC was initially designed for cross-sectionally balanced measurement of organizational performance, over years it developed into a dynamic tool, supporting all stages of strategic management. It represents a holistic, exclusively top-down acting platform with a yearly planning cycle. Optionally, BSC can be merged with company vision and strategic documents through the corresponding Strategy map (Kaplan & Norton, 2004). The later, binding structured diagram acts mainly as a systemization and communication tool, helping managers to sort, prioritize and explain significant objectives in a simplified, layered graphical way. Strategy map, as well as BSC, combines the following four levels:

- Financial (generation and use of financial resources),
- Customer (attracting customers and meeting their expectations),
- Operations (excellence of internal processes),
- Learning and growth (innovativeness, skills, knowledge, development),

the order of which can be rearranged in accordance with organizational mission. In the case of for-profit organizations, the performance is driven by human resources, their development and innovations, which leads to growing productivity of internal processes, stimulates market share and improves financial results.

Balanced scorecard follows and refines the flat structure of the strategy map. It newly incorporates significant interconnections among selected performance drivers and key performance indicators (KPI).

In our case, the resultant BCS diagram includes loops with different length, complexity and duration, altogether forming dynamic behaviour of the modelled business. This feature is frequently used for subsequent computational modelling and simulation of performance, either in its planning or execution stage (Forrester, 1961), (Sterman, 2014).

1.3.2 Objectives and key results

The main difference of the Objectives and key results (OKR) framework in comparison with BSC is its support of decentralized design and execution of desired performance. It evolved from the Management by objectives approach (Drucker, 1954) and gradually developed especially inside innovative, technological companies to its current form (Wodtke, 2016), (Niven & Lamonte, 2017), (Klanwaree & Choemprayong, 2019). Typical OKR lifecycle is two-speed, including yearly directing cycles, when company-wide business objectives are presented to single teams or, sometimes, individuals. Based

on them, sets of the quarterly business-aligned team objectives are formulated and from the bottom implemented with the corresponding SMART (i.e., specific, measurable, achievable, relevant and time-bound) key results (KR) and daily individual initiatives. Thus, the typical OKR lifecycle includes regularly recurring set, align and achieve activities.

1.3.3 Comparison of BSC and OKR

From the previous brief introduction, it is evident, that both methods differ in cadence, which favours OKR from the agility viewpoint and helps to execute up-to-date strategies more efficiently. OKR also accommodate decentralization, individual preferences and attitudes. It primarily does not focus on everyday business, but rather on challenges, improvements, changes or innovations to provide sustainable growth of performance. These features are also reflected in the nature of corresponding metrics. The objectives in OKR framework have dynamic character and express changes like increase revenue, improve a service or implement a process. That is why also the related key results need more frequent monitoring in comparison with BSC-like key performance indicators, which are rather steady, have lagging nature and usually does not require daily revisions.

On the other hand, OKR introduces the risk of not seeing the forest for the trees, while the systematic viewpoint of BSC naturally put all activities in the right context. It also assures that the final impact of a single OKR-driven target does not induce unintended changes in other areas of performance. It is evident that both techniques are complementary, and in specific cases, KR can even correspond with KPI. Accordingly, their creative combination could contribute to competitive advantage, as it is presented in the rest of this paper.

1.3.4 Execution

The term competitiveness can be more precisely characterised as the competitive advantage (Sigalas et al., 2013), (Davcik & Sharma, 2016), (Lee & Yoo, 2019) and implemented with appropriate competitive strategy (Pisano & Hitt, 2012), (Czakon, 2013). (Porter, 1985) divided them into the four main groups, including cost leadership, differentiation leadership, cost focus and differentiation. Thus, the problem of competitiveness can be considered as a problem of the continuous implementation of the most convenient (competitive) strategy, which is not such a straightforward task as it might look at a glance. Morris Chang, Taiwanese-American businessman and former CEO of Taiwan Semiconductor Manufacturing Company it appropriately characterized as follows: "*Without strategy, execution is aimless. Without execution, strategy is useless*." This phenomenon was researched by (Kaplan & Norton, 2008),(Srivastava & Sushil, 2017), (Duggal, 2018) or (Radomska & Kozyra, 2020) and various related reasons and recommendations were suggested. It is estimated that 50-90% strategies fail not because they are wrong, but because they are not executed (Jones & Parker, 2008), (Rumelt, 2011), (Cândido & Santos, 2015), (Busulwa et al., 2018), (Rodríguez et al., 2019),

(Oliveira et al., 2018). Also, Gartner's (*Personalization Strategy and Execution Survey*, 2019) concluded that more than 80% of contacted strategists consider strategy execution more import than three years ago. Only 30% of them claim the alignment between regular execution efforts and strategy, as well as the belief that they really drive this execution. This resource also suggests the following three main reasons for this unsatisfactory situation:

- Strategic managers are generally unaware of the operational impacts of their decisions.
- Because of recurrently appearing unexpected events, they have a problem to keep mainline of execution.
- Shifts in execution suffer from limited information of their bearers. Senior leaders are usually too far from operational realities, and middle or front-line managers lack the big picture concerning the overall business impacts.

2 Methods

This research is based on a gradual formalization of information, collected from the literature review and enhanced with expert and domain knowledge, represented namely by The World Economic Forum (WEF) methodology for ranking of national competitiveness. Because our long-time goal was to design an applicable computational model of competitiveness, also the methods and tools used later in this study, supported this strategic orientation. As a unifying platform we adopted the System thinking approach, dealing with bounded, internally structured and interconnected problems with emergent behaviour, arising from either centralized (loops-based) or decentralized (agents-based) interactions (Sterman, 2014), (Morecroft, 2015). In the initial analytic stages, ill-structured and creativity encouraging techniques were used to elicit the relevant knowledge and facilitate its common understanding. It usually happens through a set of intuitive diagrams, describing the structure and behaviour of analysed problem.

For the introductory overview, we used mind mapping (Chik et al., 2007), (Buzan, 2018) and achieved results further structured with the competitiveness characterizing strategic map and casual-loop diagram. Such outputs provided adequate support for possible further detailed qualitative analyses of competitiveness and improvements of the initial model (Warren, 2008), (Meadows & Wright, 2015).

For conceptual formalization of the decentralized way of strategy execution, corresponding with OKR framework, we selected the agent-based approach, principles of which can be found in (North & Macal, 2007), (Wilensky & Rand, 2015) or (Abar et al., 2017). These models synthesize the behaviour of a complex system from mutually interconnected contributions of continuously evolving, structurally layered and spatially movable elements, called agents. Hereby encoded domain knowledge is dynamically reused during the execution stage, when single agents are interacting, evolving or moving according to their expected utilities. Such solutions are built from the bottom, whilst the

resultant mission of the simulated system is synthesized from thousands or even millions of local interactions. Beyond the direct functionality, agents move among explicit states and inherit their specific features. A state-transition diagram usually models these discrete conditional changes. Besides the immediate response on activities in the nearest neighbourhood, agents' decisions can also be influenced by external stimuli.

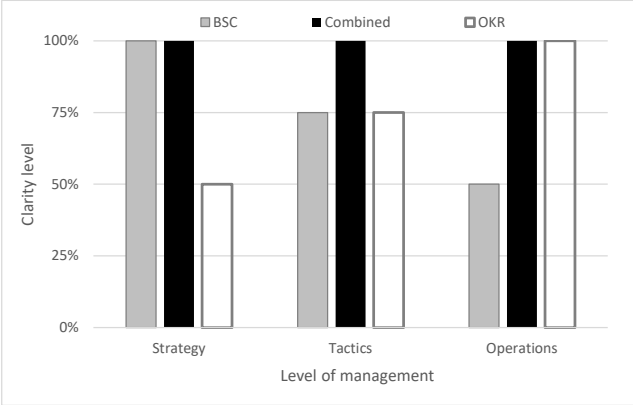

Figure 4 BSC and OKR, comparison of executive clarity

Because we believe that for the efficient execution of competitive strategies it is necessary to combine both aggregated (BSC) and decentralized (OKR) viewpoint, we finally outlined a sample process model of such compound interactions. Figure 4 schematically shows uneven organizational clarity of BSC and OKR approaches, as well as usefulness of their combination. Related heterogeneous solutions were recommended, e.g., by (Elsawah et al., 2015), (Pluchinotta et al., 2019) or (Lai et al., 2020).

3 Results and discussion

3.1 Mind map

The main components of the studied concept are shown in figure 5. Due to the market nature of competitiveness and compatibility with WEF methodology, they are divided into the group of internal aspects, located in the left part of the map, and the set of external ones on its right side. The proposed managerial framework can structurally and parametrically adjust internal drivers, a resultant combination of which determines the viable strategy. Although the external factors cannot be affected, their power must be considered, e.g., in the form of scenarios.

3.2 Quantification of organizational competitiveness

In its innovated (*Global Competitiveness Index 4.0*, 2019) (GCI 4.0), The World Economic Forum (WEF) evaluates the national competitiveness according to 103 indicators distributed within 12 pillars from 4 sectors. Our idea was to propagate these cumulative metrics to the company level. This assumption is based on the linearized model of national competitiveness, which is accordingly understood as a weighted sum of partial contributions of single market subjects. That is why the transposed WEF indicators are applicable also on single companies, which makes partial evaluations more transparent and comparable. Sample correspondence between WEF and BSC variables is shown in table 1.

Table 1 Relation between WEF index of competitiveness and its organizational counterpart

WEF GCI pillar	**Competitiveness**	
	National level (GCI 4.0)	**Company level (BSC)**
Enabling environment	Institutions	Organizational structure
	Infrastructure	Infrastructure, capacity
	ICT adoption	Enterprise content management
	Macroeconomic stability	Stability of performance
Markets	Product market	Market efficiency
	Labour market	Labour market
	Financial system	Financial health
	Market size	Market size
Human capital	Health	Organizational culture
	Skills	Organizational learning
Innovations ecosystem	Business dynamism	Governmental regulations
	Innovation capability	Innovation capability

3.3 Strategy map and dynamic balanced scorecard

Strategy map in figure 6 merges general characteristic from mind map with concrete indicators of competitiveness and organizes them in accordance with the layered BSC architecture. This structure is projected into the corresponding causal loop diagram, shown in figure 7. The dynamics behind the execution of competitive strategy is composed of mutual interactions of 20 loop with the lengths varying from 1 to 6. The majority of them have reinforcing character, and *Finances* are used as the overall limiting factor. Balanced are also the primary direct strategic outcomes, *Customers, Operations* and *Productivity*. For representational clarity, branches with their desired levels were omitted. External variables, which are out of organizational control, are boxed, and their dashed edges lack the directionality. The causal loop diagram shows that the formulation

of Competitive strategy must primarily reflect external factors, including *Collaborative relations, Market efficiency, Labour market and Regulations*.

The execution of Competitive strategy can in a selected combination and timing influence the following factors: Price, Customer relationship management, Staff, Learning and growth, Quality, Technology and Innovations and Corporate social responsibility. All these activities require financial resources, the amount of which determines the type and range of currently realized strategy.

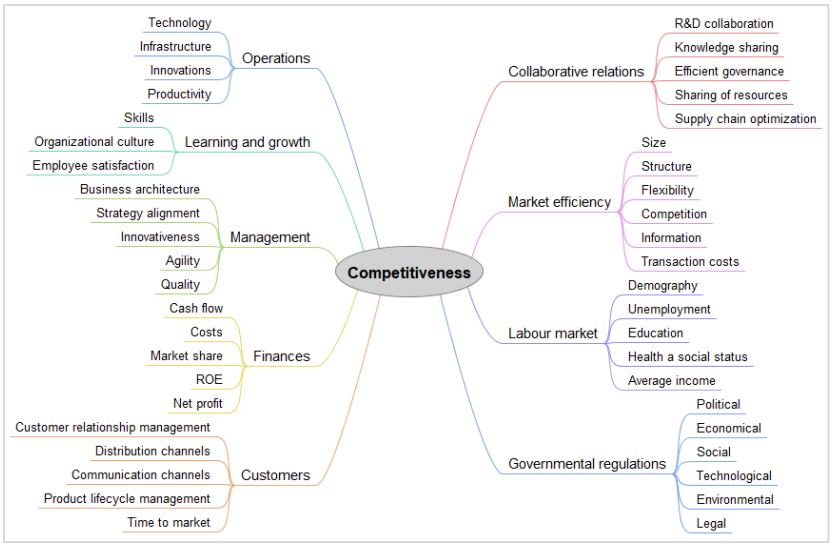

Figure 5: Mind map of selected internal (left) and external aspects of competitiveness

3.4 Agent-based architecture

The unique feature of agent-based modelling insists in its representational transparency. Agents are considered either as standard human beings or, more generally, as specific services, devices or subjects. That is why the agent-based definition of a real-world problem is similar to the formal principles of object-oriented business process modelling. Thus, every agent has attributes and functionalities, which can be either internal (individual decisions and actions) or external (perceptions, communication, services). Some of these characteristics can be inherited from its momentary role. During lifecycle, an agent can move among different states with specific transition probabilities. This nontrivial structural and behavioural environment can be in terms of presented research formalized as follows:

- Roles: manager, leader, team member, customer representative.
- States: core work, administrative work, training, learning, communication, idle.

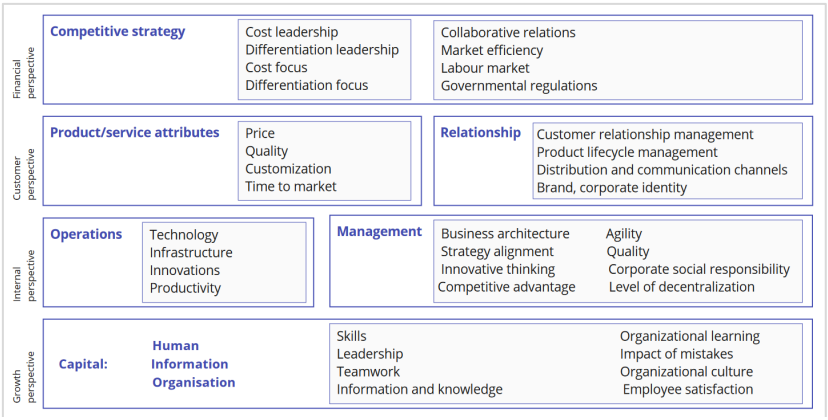

Figure 6: Strategy map of the proposed framework for execution of competitive strategies

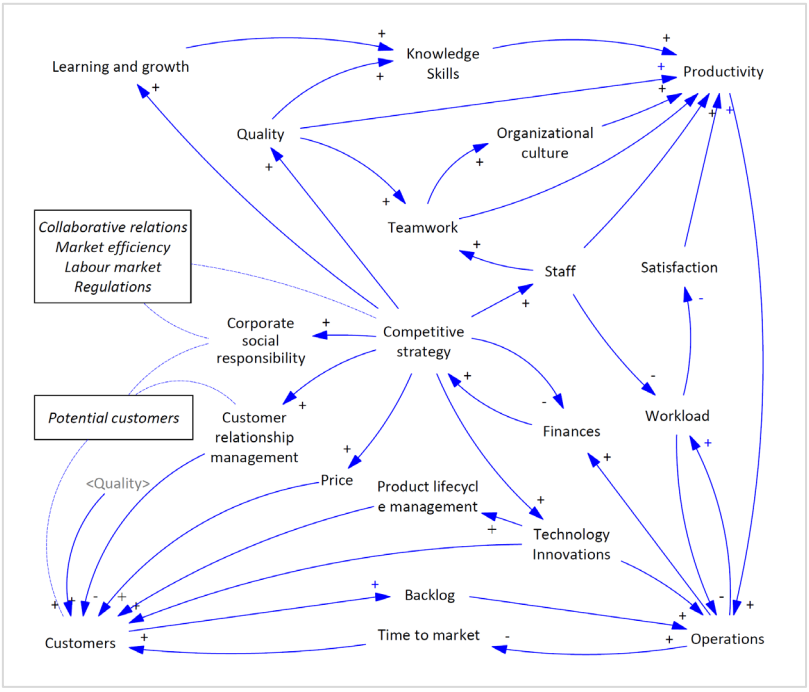

Figure 7: Causal loop diagram with sample execution dynamics of competitive strategy

- Tasks characteristics: state (to do, work in progress, done), priority, complexity, innovativeness, interconnectedness, communication, business criticality, confidence.

- Attributes: personal status (age, education, social status), professional capabilities (knowledge, skills, learning ability), general personal and team/social behavioural features, e.g. according to Myers-Briggs classification (Kuipers et al., 2009).
- Behaviour: specific functionalities, required for agent's updates, decisions and collaborations.

For the initial simplicity, we expected that the teams are established administratively, which means that the necessary characteristics are known in advance. The emergent development of competitiveness index assumes that in every computational cycle, each agent, aware of own role, state and attributes, collects available external information and accordingly maximises own utility, also incorporating the team priorities. These actions update parameters of the whole population and establish initial conditions for the next round of calculations. Simulations can run either for a predefined number of cycles or until stopping criteria are met. In contrast to the aggregate causal loop diagram, the behaviour of the agent-based model is significantly less predictable. Also, technical adjustment of such models is harder, because the order of their internal dynamic is many times higher in comparison with CLD.

3.5 Process proposal

The proposed frameworks and tools can be used in the following way:

- Define and publish yearly strategic company-level objectives (CYO) and execute them within a traditional, centralized, top-down framework.
- Quarterly refine and specify CYO into the company quarterly objectives (CQO) and publish them.
- According to publicly available CYO and CQO, single teams formulate own quarterly objectives (TQO), altogether with the related key results (KR).
- During the planning and execution stages, the immediate efficiency of strategies towards CSO and CQO can be parallelly monitored using the suggested computational tools for BSC and OKR frameworks. Undesirable steady differences or improper trends between levels indicated by CSO and CQO can be eliminated in the subsequent quarter.
- These corrections can affect the next planning cycle in both directions:
    - Team initiatives and preferences can be added to the next set of CQO by executive management,
    - Discovered discrepancies are discussed during the team quarterly retrospectives to eliminate them in the next cycle.

Organizations, adopting this process, can prepare and evaluate responsive plans in a safe environment and immediately and systematically react on substantial external of internal changes.

4 Conclusions

Frequently toothless realization of strategies prevents firms from higher performance achievement. Authors showed that the long strategic management cycles, accompanied with overall complexity, rigidity, non-personality or weak institutionalization of a competitive strategy, are the main reasons for company market failures. Decentralized, transparent and agile approaches, like OKR, do not suffer from such strategic deviations, as their overall strategy is synthetized from particular contributions from single teams and individuals. Due to their frequent revisions and gradual specifications, the problem of delayed responses and silent erosions of centralized objectives is minimized. Business value is delivered gradually, and flexible architecture can efficiently accommodate the changing environment. There is, however, a risk of losing the global vision because of inappropriate horizontal a vertical synergy of single objectives.

Thus, this paper suggests symbiotic collaboration of both frameworks. BSC key performance indicators can serve as steady long-time targets, while OKR key results are useful for the inclusion of internal innovativeness and market appeals. In case of any considerable deviations, management has can efficiently identify their causes and quickly respond. Moreover, proposed supporting aggregate and decentralized tools and processes can serve as dynamic simulators, capable of explaining and enhancing conclusions, obtained from traditional analytical or statistical methods. This is namely because the knowledge-based modelling and simulations can recognize emergent behavioural features, identify counterintuitive patterns or simplify and visualize multidimensional nonlinear relations.

Abstract

Faced with a new kind of presence of digital knowledge carriers because of the digitalization and Industry 4.0 settings, research agendas need to be updated by arising research challenges. Particularly novel kinds of knowledge-intensive interactions among individuals, teams and autonomous systems need to be addressed in contemporary knowledge modelling approaches and a state-of-the-art knowledge management.
This research presents the most relevant research challenges gathered by experts from relevant at the 15th International Business Informatics Congress 2020 in Potsdam in an interactive workshop. Based on a reality check, their relevance has been confirmed in scenarios and first ideas about solution approaches have been identified. Due to individual-based, team-based and plenum-based expert evaluations, a research agenda has been set up, to whom the research community's attention shall be drawn to, so that the most beneficial research steps can be issued next and research streams can be realized efficiently.

Keywords – Knowledge Management, Process Modelling, Research Challenges.

Paper type – Academic Research Paper

1 Introduction

The effective and efficient diffusion of knowledge within organizations is one of the most important performance indicators of contemporary knowledge management. It demands for numerous knowledge-intensive interactions among individuals, teams and - being enabled by the digitalization - autonomous systems as well as further ontological entities. Thus, new research challenges must be addressed at knowledge flow modelling or rather the modelling of knowledge-intensive business processes (BP) in organisations. In particular, the process- and activity-oriented modelling (Davenport, 1992; Hammer and Champy, 1993) of tacit and explicit knowledge (Nonaka and Takeuchi, 1995) as well as the differences between the two types of knowledge, should be addressed appropriately in the new contexts of digital work, a cyber-physical collaboration and human-intelligence-based as well as artificial-intelligence-based decision making and knowledge generation and forecasting (Grum and Gronau, 2018) and the process prediction (Rehse et al., 2019).

Faced with plenty attempts for outlining a research agenda, one can find relevant agendas in the following: First, agendas issuing the act of modelling, such as the collaborative modelling (Render et al, 2008). Secondly, the design of corresponding process models is issued, such as the inter-organizational BP design (Legner and Wende, 2007) or the external acquisition of knowledge (Hausschild, 1992). The third kind of agenda focus is put on the act of management BP, such as by agenda outlines about the process management (Ghose et al., 2010) and the knowledge management (Varun Grover, 2001). Fourth, agendas issuing the design of process supporting systems, such as by agendas about knowledge-flow addressing systems (Al-Mashari, 2003) and performance measurement systems (Neely, 2005). Lastly, a specialized focus is set on trend topics, such as by agendas about process mining (Van der Aalst and Weijters, 2004). Since the role of new technical and digital actors as well as the corresponding modelling of knowledge-intensive interactions has not been addressed by any relevant agenda. Thus, potentials for companies and science, which can result from the in-depth analysis of knowledge flows, remain unexplored and untapped at contemporary research agendas.

So, it is not remarkable, although being well-appointed with attempts for a process-oriented knowledge modelling, that these do not adequately consider challenges from the knowledge flow modelling. Faced by the following examples, it becomes clear that the allocation of knowledge resources within business processes still is insufficient: First, the conceptualization of machine-based knowledge. This overcomes the contemporary opinion of having humans as the only kind of knowledge carrier (Gronau, 2019). Second, the embodiment of knowledge in physical objects, as these can represent a further kind of knowledge bearer. This overcomes the contemporary opinion of only issuing material flows of physical objects (Scheer, 2012). Third, the quantitative characterization of knowledge and its artefacts. This includes but is not limited to the dimension of time and quality of knowledge transfers as well as knowledge-based process outcomes (Gronau and Grum, 2019) and, thus, overcomes the missing of quantitative analyses as well as simulations of knowledge transfers. Fourth, the anchoring of knowledge models within

the real world, which considers physical as well as virtual dimensions (Grum and Gronau, 2017). This overcomes limitations of a modelling only in two dimensions.

Faced with numerous challenges in the knowledge flow modelling and outdated research agendas, the following research question is pertinent: *How can issues emerging from the digitalization and future horizons in the area of modern knowledge modelling be transformed to a research agenda?* If it would possible to draw the attention of the research community to these kinds of issues, the most beneficial research steps can be issued next and research streams can be realized efficiently.

This paper is structured as follows: The second section provides the methodological approach, which is based on a workshop-method. Workshop outcomes are discussed in a third section, so that a research agenda can be presented at a fourth section. The final section concludes the research presented.

2 Methodology

Being framed by a workshop design, experts from the domain of knowledge management (1), process modelling (2) and practice (3), were faced with the analysis of the theoretical background of business process modelling and knowledge management. Then, in a plenum session, a clear and joint objective understanding was created. The workshop structuring and its basic parameters have been visualized by Fig. 1. The following describes its phases in more detail and presents background information.

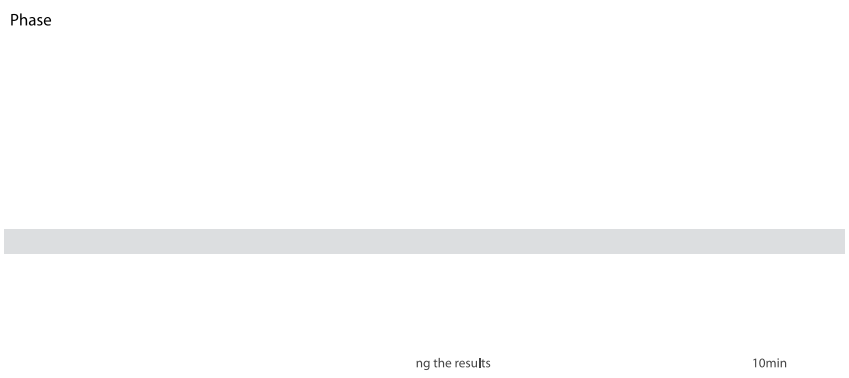

Fig. 1 – Basic Information of the Workshop Methodology Designed.

The first phase was structured by the method called "*Conversation Carousel*" (Klippert, 1995). As can be seen at Appendix 1, experts were asked to sit opposite each other and discuss in teams of two the most important current challenges from their point of view. After two minutes of discussion, the experts of the inner circle were asked to switch to the next discussion partner on the right, which was repeated for three times. Then, the experts have had ten minutes for the documenting of the most attractive ideas with the aid of the "*Research Issue Template*" (see Appendix 2). By this, the

identification of the most relevant research issues was supported because first, ideas were relativized by practical discussion partners, second, the variety of topics was increased by experts from different fields, and third, the preciseness of topics was increased by experts from the same field. In the first phase, this carousel has been realized for two times. The final issues were pinned on the pinboard for the further proceeding (Appendix 3).

In a second phase, the relevance of issues identified in the first phase were addressed for process modelling scenarios, so that the relevance was addressed. Since experts have been assigned to teams of not more than three persons, they were asked to first individually work out a scenario for each research issue documented in the first phase. This was realized with the aid of the "*Scenario Template*" (see Appendix 4). Then, they were asked to present the issues and corresponding scenario description within the groups. If new ideas came up, the templates were to be supplemented. Best research issues were selected by the group, so that a focus on the key issues was established.

As a kind of inspiration, first attempts to overcome relevant issues have been developed by a group work in phase 3. For the documentation of the solution designed, the template called "*Solution Design Template*" (see Appendix 5) was used. Then, solutions have been evaluated individually with the aid of the "*Evaluation Template*" (see Appendix 6) and discussed. Finally, this kind of solutions was selected by the teams that seemed to have the most potential for the research community and the highest relevance for practitioners.

In phase 4, the selected set of research issue, scenario-based relevance description, first solution attempt and team-evaluation was presented within the plenum. Here, the templates were used, that have been created in previous phases. After each presentation, the plenum has discussed challenges and opportunities for the exploration of research issues presented. Further, the complexity and dependencies of the issues presented so far were characterized. As a kind of research issue specific conclusion, the entire group of experts was asked to finally characterize the agenda item by supplementing the documentations on the pinboard individually. This was realized by walking from pinboard to pinboard. If questions occurred, the plenum attention was drawn to the corresponding agenda item.

Finally, in a frontal teaching setting, the outline for a research agenda has been derived, which refers to the temporal ordering of agenda items and their connecting to a solution path.

3 Workshop Outcomes

Having realized the methodological workshop design presented at the previous section, the following presents the most important workshop outcomes from the viewpoint of the workshop plenum. Because of the relation of the outcomes of (1) research issue, (2) scenario description, (3) solution attempt and (4) evaluation, these are interpreted as agenda items from hereon and presented jointly per agenda item. They will build the base for the derivation of a research agenda in the next section.

Agenda Item 1: *Dimensioning and measurement of the knowledge transfer quality*.

Since an instrument is missing, which measures the quality of knowledge transfers, the relation of the quality of knowledge transfers on knowledge transfers has not been issued, yet. The challenge here is to objectively evaluate the quality of knowledge transfers and to develop an instrument, which is usable in various knowledge transfer situations, such as different tasks. As the quality of knowledge transfers can be found at all SECI conversions of Nonaka and Takeuchi (1995), any knowledge intensive process is affected. Hence, the relevance for organizations is very high. A first attempt to design an adequate instrument can be identified by an empirical approach similar to (Gronau and Grum, 2019): in an experiment setting, different kinds of influence factors on knowledge transfers can be examined. This was evaluated to refer to a complex fundamental research having a duration about 30 months.

Agenda Item 2: *Dimensioning and measurement of the quality of knowledge*.

Since an instrument is missing, which measures the quality of knowledge transfer outcomes, the relation of any kind of influence factor on knowledge transfer outcomes has not been issued, yet. For example, one can assume a relation of the quality of knowledge transfers on the quality on knowledge transfer outcomes. The challenge refers to the distinct and clear definition of knowledge quality because its operationalization follows the definition. Similar to Agenda Item 1, this can be addressed in an experimental setting and result in knowledge transfer optimization (Albers et al., 2019). Hence, it was evaluated to demand for a high priority and to have a duration of 30 months.

Agenda Item 3: *Modelling of the knowledge transfer situation*.

To what extend modelling items are to be considered within a knowledge transfer situation needs to be conceptualized (Agenda Item 3a) and empirically proven (Agenda Item 3b). Faced with a variety of influence factors, the challenge refers to the consideration of adequate principles of modelling: It must guaranteed that models stay clear and efficient, e.g. Further, it is essential that items are generalizable and thus describe the majority of specific knowledge transfer situations. Attempts can be found at Grum et al. (2019). Since training situations occur often in organizations, the relevance of this issue is very high. Being characterized as fundamental research, the feasibility was evaluated to be moderate. Its realization demands for a systematic experimentation of relevant situation components, which is assumed to last about 15 months.

Agenda Item 4: *Comparability of knowledge among persons*.

In order to compare knowledge of any kinds of knowledge carriers, the context-independent and person-unbound description of knowledge must be enabled, which is adequate from knowledge management perspectives. Faced by heterogeneous knowledge domains of contemporary contexts, such as the Industry 4.0 context, in which all the trainees know a different kind of bit, the comparison with a required reference knowledge has a high relevance. Blended learning methods seem attractive for the verification of comparison concepts created. Particularly the suitability of survey methods and

ontologies seem attractive for comparisons. Being evaluated as complex fundamental research project with a duration of 20 months, its priority is high.

Agenda Item 5: *Automatization of the modelling of knowledge flows*.

Faced with the huge effort of identifying and modelling of knowledge flows in business processes, its automatic modelling has a high practical relevance. Since concepts for an automatic recognition and modelling of knowledge flows are missing, this research has a fundamental research focus, which was evaluated to be complex. First ideas refer to the derivation of knowledge flows from the mapping of tasks and enterprise resource planning systems. Because of this interim research step, the feasibility can be lowered. Having a high research priority, the realization time was estimated with 22 months.

Agenda Item 6: *Process prediction*.

Intending to predict the process behaviour with the aid of artificial intelligence techniques, a research focus lies on the identification of next process steps, risks arising, task duration, artefact outcomes, etc. Since it is not clear, which kinds of concepts, methods and tools are suitable for these purposes, this research follows fundamental research characteristics. Although insights are relevant for numerous organizational situations and the probability of occurrence is high, one still can identify challenges in the availability of huge datasets, small datasets and unknown causal relations. A solution approach should follow design-oriented research methods and could be based on deep learning techniques that represent process sequences (Grum and Gronau, 2018). An alternative research path can be identified at big process analytics approaches, with which situations are not arduously modelled, but simply prediction are created for next process steps (Evermann et al., 2017). Because of a complex research having risks to provide outcomes, the duration refers to 4 years.

Agenda Item 7: *Objectivation of the assessment of knowledge*.

Facing contemporary approaches to assess knowledge, one can identify subjective influences on the evaluation of knowledge. Ideally, with the aid of a tool, the assessment can be realized on an objective level. The challenges refer to the conceptualization of an objective kind of knowledge assessment and the development of an adequate infrastructure. Hence, this research was evaluated to be a fundamental research. Since its outcomes would enable the entire value chain of organizations, results will have a high impact in business processes. The feasibility was evaluated to be complex and have an expected realization time of 30 months.

Agenda Item 8: *Efficient recognition of tacit knowledge*.

Further research issues refer to the recognition of knowledge that is not observable by third parties. As tacit knowledge is known to be difficult to observe, ideally, a self-recognition is supported. The most promising solution approach referred to the development of a guided self-critical surveying method. Since the feasibility was evaluated to be moderate and to be a translational research, the realization duration was evaluated to be one year. Based on the digitalization of knowledge transfers in Industry 4.0 settings, in which workers are instructed by context-sensitive video tutorials and

remote workers, the research has a high priority because the autonomy of workers is supported.

Agenda Item 9: *Automatization of the identification of knowledge deficits*.

Intending to recognize the knowledge base of employees automatically, so that knowledge deficits can be recognized, the development of a task- and context-sensitive system is required. Since this kind of system was able to analyse any kind of task realization, the occurrence in business process scenarios is high. The most promising solution approach refers to the derivation of knowledge deficits if employees get stuck at certain tasks. Because of the dependency to Agenda Item 8, the realization duration is expected to be around 30 months and the research has a high priority.

4 Research Agenda

Based on research challenges identified by the workshop, the following outlines a research agenda. Fig. 2 presents agenda items in accordance with the numbering of in section 3 presented agenda items.

In a first step, these have been put in a sequential ordering, so that research paths consider the dependencies that have been identified by the plenum evaluation of the workshop. Then, agenda items have been arranged, so that their positioning with regard to the x axis schematically reflects durations, that have been identified by the plenum evaluation of the workshop. Please remark here, that the realization duration of the entire collection of research issues does not have to consider a semi-sequential examination having a duration of about 15 years. It refers to one of many possible arrangements assuming to have one starting stream of research. Hence, although having created and discussed the schematic visualization of Fig. 2 at the wrap up session with the plenum, in a post-processing, each research path has been re-evaluated in regard with the identification of individual research streams. From the perspective of the authors of this contribution, this is promising since the provision of different research paths supports the accessing of research challenges from various sides.

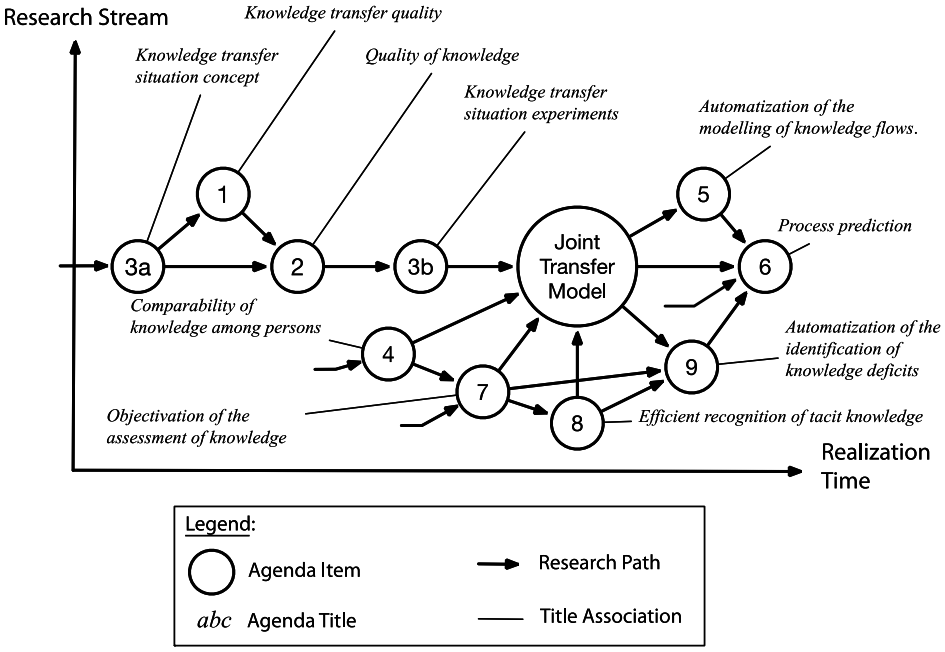

Fig. 2 – Research Agenda.

Although one can access research issues via different research streams, the research agenda does not demand for completeness or rather to be the one and only agenda possible. Further, it does not claim to present the most realistic as well as efficient kind of realizing the research proposed. In the limited context of knowledge flow modelling and the challenges because of digitalization and its future horizons, the research agenda represents the recommendations of the workshop group of experts.

5 Conclusions

As an outcome of this research, a list of emerging issues coming from the digitalization and future horizons in the area of modern knowledge modelling has been set up. This includes the characterization of individual research issues. Further, since complexities and dependencies of them have been characterized on behalf of concrete scenarios as well as challenges and opportunities for their exploration have been emphasized, their arrangement by research streams has been set up. Jointly, they form the proposed research agenda.

With regard to the research question proposed (*How can issues emerging from the digitalization and future horizons in the area of modern knowledge modelling be transformed to a research agenda?*) has been answered as follows: experts from the domain of knowledge management (1), process modelling (2) and practice (3) have been

faced by a workshop design, with which emerging issues and its scenario-based relevance has been characterized. Further, the joint evaluation has been identified with regard to the research characteristics and dependencies and durations have been estimated. The results have been transformed to a rough research agenda, so that the sequence of research has been based on a by content plausible and by dependencies required ordering. Although the results do not claim for completeness or rather to be the one and only possible research agenda, the authors intend to draw the attention of the research community to these kinds of issues, so that the most beneficial research steps from the viewpoint of the group of experts can be issued next and research streams can be realized efficiently.

The resulting agenda must be limited in the representativeness, which is due to the limited number of workshop participants. As experts were mainly part of the German community, the research agenda outlined is intended to serve as a starting point for discussions.

Abstract

This conceptual study seeks to bridge established theory on maturity models (MMs) and business model innovation (BMI). Extant literature discusses BMI as a source of competitive advantage (Casadesus-Masanell and Ricart 2011; Chesbrough 2007; Mitchell and Coles 2003) and potentially the most challenging type of innovation (Björkdahl and Holmén 2013, Lindgardt et al. 2009). A study by Christensen et al. (2016) shows that the BMI success rate for firms is low, which is reflected in high error indices. The high degree of uncertainty, ambiguity and complexity associated with BMI carries a high risk of corporate failure in the transformation of business models, especially due to the lack of required skills, knowledge as well as suited processes and mechanisms to support successful BMI. Moreover, De Fazio (2017) suggest that in order for companies to reap the full benefits of innovation, it should be ubiquitous, controlled, measurable and strategically implemented, and must therefore be supported by appropriate analytical models, processes and tools.

Whereas BMI is often triggered by unpredictable changes in an organization's external environment (Brasseur et al. 2017; Şimşit et al. 2014; Steinhöfel et al. 2016), we base our study on the assumption that organizational change and development occur in predictable patterns. MMs represent theories about how organizational maturity evolves in a stage-by-stage manner along an anticipated, desired, or logical maturation path (Röglinger and Pöppelbuß 2011). Following this rationale MMs are utilized as diagnostic tools that enable organizations to describe maturity in the context of an as-is assessment, thus providing guidelines on how to reach the next, higher maturity level (Ofner et al. 2009; Röglinger and Pöppelbuß 2011). Röglinger and Pöppelbuß (2011) suggest that attention to MMs is expected to increase a prediction corroborated by the numerous proprietary models proposed by software companies and consultancies (Scott 2007). Recent literature also

reports an increasing academic interest in maturity models (Becker et al. 2010). Despite the existence of various innovation MMs, there is, to the best of the authors' knowledge, no specific MM for BMI.
This study contributes to the innovation management and business model literature by assessing how BMI and MMs can be conceptually bridged. The aim of the paper is to identify boundary conditions for a subsequent design of an integrated MM for BMI that enables the assessment, benchmarking and progress of organizational maturity with regard to BMI.

Keywords – Business Model Innovation (BMI), Innovation Management, Innovation Maturity Model (IMM), Maturity Model for Business Model Innovation.

Paper type – Academic Research Paper

1 Introduction

In today's fast-changing and unpredictable business environment, companies are increasingly confronted with globalisation of markets, dynamic technology developments, short product life cycles, shifting patterns of demand, growth demands and new regulatory requirements (Brasseur et al. 2017; Şimşit et al. 2014; Steinhöfel et al. 2016). To succeed in this fast-changing environment, companies are forced to grow, outperform and adapt at a rapid pace (Şimşit et al. 2014). As a result, companies are under constant pressure to innovate for remaining competitive (Brasseur et al. 2017). As products, services and processes tend to become quickly obsolete due to imitation, innovations in these areas can only provide firms with short- to medium-term competitive advantage (Amit and Zott 2010; Chesbrough 2010). BMI has recently attracted increasing attention as a promising approach for providing sustainable competitive advantage, particularly in the face of saturated markets, inter-industry competition, and substitutability of product and process innovations (Brasseur et al. 2017; Steinhöfel and Inkinen 2016; Steinhöfel et al. 2016). Thus, the literature discusses BMI as a main determinant of competition and at the same time as the most challenging type of innovation (Brasseur et al. 2017; Minatogawa et al. 2018) with a high rate of failure (Christensen et al. 2016), especially due to the lack of the required skills, knowledge as well as suited processes and mechanisms to support BMI (Brasseur et al. 2017). Any innovation, including BMI, must be ubiquitous, controlled, measurable and strategically implemented, which is why it must be supported by suitable analytical models, processes and instruments (De Fazio 2017).

Maturity models (MMs) are helpful tools to assess the maturity (i.e. competency, capability, level of sophistication, degree of progress) of a selected domain based on a more or less comprehensive set of criteria (de Bruin et al. 2005; Ofner et al. 2009; Becker et al. 2009; Röglinger and Pöppelbuß 2011). Based on the assumption that organizational change and development occur in predictable patterns, MMs represent theories about how organizational maturity evolves in a stage-by-stage manner along an anticipated, desired, or logical maturation path (Röglinger and Pöppelbuß 2011). Despite a large number of

different types of MMs in various application domains and different levels of detail, the structure of these models is very similar: They define a number of discrete stages or maturity levels for one or multiple dimensions, with descriptions of the characteristic performance per level building upon each other (Fraser et al. 2002). The value for organizations applying such models varies according to the application-specific purpose. First, MMs are diagnostic tools that enable organizations to describe maturity in the context of an as-is assessment. Secondly, a MM provides guidelines on how to reach the next, higher maturity level. Descriptions of higher maturity levels can be seen as best-practice guidance. Finally, MMs can be used for the purpose of comparison and facilitate, for example, internal and external benchmarking (de Bruin et al. 2005; Ofner et al. 2009; Röglinger and Pöppelbuß 2011).

Despite the existence of various innovation maturity models (IMMs), there is, to the best of the authors' knowledge, no MM available related to BMI, yet. Therefore, this study provides an assessment of how theory on MMs can be fused with theory on BMI in order to establish a foundation upon which subsequent research can propose a MM for BMI that allows managers to assess and guide BMI in their company. This paper aims to contribute by systematically assessing current literature to establish ontological consistency in our bridging attempt, as well as defining boundary conditions for subsequent model development.

2 Methodology

In order to identify and select appropriate IMM frameworks that could be fused with BMI theory, we applied a three-step approach.

2.1 Identification of MMs and methodologies for developing a MM

The expediency of MMs, even if they differ with regard to the field of application, granularity, number of dimensions or maturity levels, lies in the demarcation between clearly defined levels of maturity, which are building upon each other and represent a logical evolution path (Igartua et al. 2018; Röglinger and Pöppelbuß 2011). In this way, MMs offer a good balance between standardisation and flexibility (Achi et al. 2016), which is necessary for the successful application in different types of organisations of various industries. Another advantage is the simplicity that comes with the structure of MMs that makes them very easy to understand and communicate (Igartua et al. 2018). This simplicity is at the same time the starting point for criticism regarding the concept of MMs. They are, for example, often characterised as 'step-by-step recipes' that oversimplify reality and lack empirical foundation (Igartua et al. 2018).

Against this background, management research increasingly addresses MMs from a product design process perspective, and thus a great amount of research focuses on methodologies for developing MMs (Igartua et al. 2018). Table 1 shows various articles on the methodology of developing a MM systematically.

Table 2: Identified articles on methodology of developing a maturity model systematically

Author (Year)	Name of Article
Ahlemann et al. (2005)	Kompetenz- und Reifegradmodelle für das Projektmanagement
Becker et al. (2009)	Developing Maturity Models for IT Management
de Bruin et al. (2005)	Understanding the Main Phases of Developing a Maturity Assessment Model
Fraser et al. (2002)	The use of maturity models/grids as a tool in assessing product development capability
Kulkarni and Freeze (2004)	Development and Validation of a Knowledge Management Capability Assessment Model
Mettler (2011)	Maturity assessment models: a design science research approach
Ofner et al. (2009)	Dealing with Complexity: A Method to Adapt and Implement a Maturity Model for Corporate Data Quality Management
Röglinger and Pöppelbuß (2011)	What makes a useful maturity model? A framework for general design principles for maturity models
Simonsson et al. (2007)	Model-based IT governance maturity assessments with COBIT
Solli-Sæther and Gottschalk (2010)	The Modeling Process for Stage Models

Among the approaches listed in Table 1, those were sought that offer both practical and pragmatic support for a systematic MM development. Using this selection criterion, only two approaches meet our requirements, namely: Mettler (2011) and Röglinger and Pöppelbuß (2011). Both approaches propose a framework aimed at supporting the design, improvement or application of MMs for researchers and practitioners in a pragmatic yet substantiated way. For further consideration the framework by Röglinger and Pöppelbuß (2011) was selected based on the number of citations in Google Scholar.

Röglinger and Pöppelbuß (2011) propose a framework which consists of general design principles (DP) and several related sub-aspects of DP, that are helpful to design useful MMs for specific application domains and purposes of use. According to the different application-specific purpose of MMs[1], the proposed DP are grouped into (1) basic principles, (2) principles for a descriptive purpose of use, and (3) principles for a prescriptive purpose of use (see Figure 2). Röglinger and Pöppelbuß (2011) have deliberately not considered the comparative purpose of use in their framework. In their opinion, DP for this purpose of use largely depend on external factors, such as standardized and publicly available specifications, and can therefore only be partially influenced during MM design (Röglinger and Pöppelbuß 2011). Röglinger and Pöppelbuß (2011) neither require a maturity model to meet all proposed DPs (basic, descriptive and prescriptive DPs) nor their sub-aspects. Instead, the framework intends to assist practitioners and researchers in comparing existing maturity models (see part 3) and

[1] *As described above, MMs are tools for as-is-assessment (descriptive), best-practice guidance (prescriptive) and/or benchmarking (comparative).*

serves as a "checklist" for designing new maturity models. Due to the scope and objective of the paper, focus is on basic DPs (see Table 2) when comparing IMMs as well as when defining boundary conditions for developing a MM for BMI.

Table 2: Framework of general DP for MMs according to Röglinger and Pöppelbuß (2011)

Group		Design Principles
(1) BASIC	1.1	**Basic information** a) Application domain and prerequisites for applicability b) Purpose of use c) Target group d) Class of entities under investigation e) Differentiation from related maturity models f) Design process and extent of empirical validation
	1.2	**Definition of central constructs related to maturity and maturation** a) Maturity and dimensions of maturity b) Maturity levels and maturation paths c) Available levels of granularity of maturation d) Underpinning theoretical foundations with respect to evolution and change
	1.3	**Definition of central constructs related to the application domain**
	1.4	**Target group-oriented documentation**

	2.2	**Target group-oriented assessment methodology** a) Procedure model b) Advice on the assessment of criteria c) Advice on the adaptation and configuration of criteria d) Expert knowledge from previous application
(3) PRESCRIPTIVE	3.1	**Improvement measures for each maturity level and level of granularity**
	3.3	**Decision calculus for selecting improvement measures** a) Explication ofrelevant objectives b) Explication of relevant factors of influence c) Distinction between an external reporting and an internal improvement perspective
	3.3	**Target group-oriented decision methodology** a) Procedure model b) Advice on the assessment of variables c) Advice on the concretization and adaption of the improvement measures d) Advice on the adaptation and configuration of the decision calculus e) Expert knowledge from previous application

2.2 Literature review and identification of existing IMM

For the identification of existing IMMs, a systematic literature review was conducted. The objective of the literature review was to identify articles presenting and discussing one or various MMs related to innovation in general or BMI in particular in the context of business and management topics (inclusion criterion). For this purpose, scientific

databases[1] such as ECONIS (ZBW), Scopus and Wiley Online Library were searched using the meta-search engine Fraunhofer eLib, as well as Google Scholar was searched for relevant literature. In this context, the following six search terms and combinations of search terms using the operator 'and' were applied: (1)'innovation maturity model', (2)'innovation maturity models', (3)'innovation' and 'maturity model', (4)'innovation management' and 'maturity model', (5)'business model innovation' and 'maturity model' and (6)'business model' and 'maturity model'. English publications until June 24th, 2019 were examined to determine whether the defined search terms appear in the title. As a first result, 210 potentially relevant publications were obtained. It is particularly noteworthy that no results were found for the search term (5)'business model innovation' and 'maturity model'. This can be seen as an early indication of the fact that no MM for BMI has been published yet. In subsequence, duplicates as well as master and doctoral theses were removed by hand and a total of 82 articles was obtained. These articles were examined in 3 screenings, first the title, then the abstract and finally the full text. Through screening 33 articles whose titles indicate that they present and discuss one or more MMs related to innovation in general or BMI in particular were identified. By screening their abstracts the number of articles was further reduced to 25 articles. The subsequent screening of the full text was to verify the positive rulings of the screening of titles and abstracts. Since six articles could not be retrieved and three articles did not meet the inclusion criterion of presenting and discussing one or various MMs related to innovation in general or BMI in particular in the context of business and management topics, 16 articles were identified by screening the full texts. Using these 16 articles, 13 further articles were identified by forward/backward referencing, that meet the inclusion criterion as well. Therefore, 29 articles were finally considered. As some MMs are dealt with in more than one article (Achi et al. 2016; Carlson and Gupta 2014; Jansson 2011b), the 26 MMs that have finally been discerned are listed in Table 3.

2.3 Selection of identified innovation maturity models

In order to reduce the number of IMMs identified through the systemic literature research for our analysis, six IMMs were selected in a two-stage selection process.

The first selection step focused on the dissemination of the different IMMs in the scientific community. Therefore, the number of citations in Google Scholar was used to determine which of the identified IMMs are most prevalent. These were the IMM by Enkel et al. (2011) with 117, Essmann and Du Preez (2009) with 84 and Gupta (2011) with 59 citations, respectively. In a second step, additionally to the before selected IMMs a further three were considered that represented the most current state of research. According to the publication year these were the IMMs by Demir (2018), Igartua et al. (2018), Narcizo et al. (2019) and Rübel et al. (2018). Two of these IMMs were selected for their underlying definition of innovation and for establishing a link to BMI. Both Demir (2018) and Igartua et al. (2018) understand both, the transformation of value propositions such as products and services as well as of business models, as innovation

(Demir 2018; Igartua et al. 2018). Although the MM by Rübel et al. (2018) does not focus on innovation, but on process mastery it was taken into account due to the explicit consideration of business model management. The IMM by Narcizo et al. (2019) was discarded as it does not establish any link to BMI.

3 Analysis of selected innovation maturity models

In the following part, the six selected IMMs are analysed regarding the group of basic DPs and their related sub-aspects proposed by Röglinger and Pöppelbuß (2011) illustrated in Table 2 as well as regarding considering aspects related to business models.

3.1 DP 1.1 - Basic information

The analysis regarding the application domain (DP 1.1a) shows that the major domain of the MMs is innovation management apart from strategic management with focus on innovation in terms of products services and business models (Demir 2018) and business model management towards Industry 4.0 (Rübel et al. 2018). In this context, the MMs with the domain of innovation management focus on open innovation (Enkel et al. 2011), innovation of products, processes and/or strategies (Essmann and Du Preez 2009), product, service, process and business model innovation (Carlson and Gupta 2014) as well as services, products as well as business models in the light of innovation (Igartua et al. 2018).

Regarding the intended purpose of use (DP 1.1b) it shows that the majority of MMs pursue a descriptive, prescriptive and comparative purpose of use. Exclusively, Demir (2018) and Rübel et al. (2018) do not consider the comparative purpose.

With regards to the target group (DP 1.1c) it shows that focus is mainly on executives and in addition on decision makers in SMEs (Igartua et al. 2018) or more broadly practitioners (Rübel et al. 2018).

The analysis of the MMs regarding the class of entities under investigation (DP 1.1d) shows that some MMs are intended for any type of organization in any industry (Carlson and Gupta 2014; Demir 2018; Enkel et al. 2011; Essmann and Du Preez 2009) while Rübel et al. (2018) refers to organizations which can implement Industry 4.0 components and Igartua et al. (2018) to micro-enterprises and small SMEs.

In line with the before mentioned application domains (1.1a), which is often indicated by the name of the respective MM, all MMs elaborate on differences regarding related maturity models (DP 1.1e) of the same or similar domains.

A major difference can be observed with regard to the documentation and communication of the design process and extent of the empirical validation (DP 1.1f). Some authors document and communicate the design process in detail (Enkel et al. 2011; Essmann and Du Preez 2009; Rübel et al. 2018) whereas others touch the design process more briefly (Demir 2018; Carlson and Gupta 2014; Gupta 2011; Igartua et al. 2018). In this context it shows, that the scope of the design process differs greatly. While all authors

consider existing MMs and the majority conducts literature research to some degree for developing their MM, Enkel et al. (2011) and Essmann and Du Preez (2009) additionally conduct qualitative, exploratory research in the form of workshops or interviews for this purpose and for refining their MM. Furthermore, Essmann and Du Preez (2009) applied Latent Dirichlet Allocation (LDA) based topic modelling analysis to identify structures for their MM in the relevant literature in addition to manual research. Besides, it is noteworthy that Igartua et al. (2018) also applied the framework by Röglinger and Pöppelbuß (2011) while Rübel et al. (2018) used the procedural model by Knackstedt et al. (2009). According to the articles, empirical validation has so far been provided for 50% of the MMs (Enkel et al. 2011; Essmann and Du Preez 2009; Igartua et al. 2018).

3.2 DP 1.2 - Definition of central constructs related to maturity and maturation

The analysis regarding maturity and dimensions of maturity (DP 1.2a) shows that only one MM is one-dimensional comprising maturity levels for 'culture of innovation' (Carlson and Gupta (2014); Gupta (2011), whereas the other MMs are multi-dimensional. The latter, MMs differ greatly with regard to the number of dimensions, which ranges from three to eleven dimensions, and descriptors as well as the respective descriptions. These differences can be assigned differences of the MMs with regard to the respective application domain and the purpose of use. In this context, it is noteworthy, that it is difficult to determine the number of dimensions for the MM by Essmann and Du Preez (2009). According to Röglinger and Pöppelbuß (2011) a one-dimensional MM comprises for example process or object maturity (one axis) whereas a multi-dimensional model comprises multiple dimensions for which maturity levels are defined individually (two axis). Thus, each dimension has a different description for each maturity level (own maturity path). The MM by Essmann and Du Preez (2009) does not comply with either of these descriptions, as it combines maturity with an innovation capability construct and an organisational construct (three axis), making it obviously more complex and difficult to comprehend.

With regard to maturity levels and maturation paths (DP 1.2b) it can be observed that all MMs end at level five, whereas Demir's (2018) MM can be considered a minor exception as it formally suggests six maturity levels, starting at level 0. With regard to the descriptors and the description of the maturity levels, there are differences depending on the application domain and purpose of use. The almost only common feature is that they start at level 1 except Demir (2018) and end at level 5.

The available levels of granularity of maturation (DP 1.2b) show a large variance. Essmann and Du Preez (2009) provide several levels of granularity of maturation and thereby a very high level of detail. As outlined above, the framework comprises three axes whereas the innovation capability construct is further broken down into three capability areas and 11 underlying items and the organisational construct comprises five items. The IMM of Enkel et al. (2011) present a high level of detail with a detailed

matrix, in which a maturity level description is provided for each dimension and the operationalization of dimensions takes place through underlying sub-elements. Similarly, Rübel et al. (2018) measures maturity through underlying items of the business model building blocks. A lower level of detail can be determined for the MM of Demir (2018) and Carlson and Gupta (2014)/Guptas (2011) as they assess maturity on the level of dimensions providing different level descriptions for each dimension. Igartua et al. (2018) provide the lowest level of detail, as maturity levels apply to all dimensions and are only listed in the form of key points.

The analysis regarding the underpinning of theoretical foundations with respect to evolution and change (DP 1.2d) is complied with by all selected models as they build op on previous work and expedient literature from the respective application domain as well as about drivers and barriers of maturation.

3.3 DP 1.3-1.4- Definition of central constructs & target group-oriented documentation

The definition of central constructs related to the application domain (DP 1.3) is predominantly provided by the different authors. In this context it shows thought that the different constructs related to the application are not all defined explicitly. Often the constructs are explained and thereby defined to some degree. As outlined by Röglinger and Pöppelbuß (2011) the definition of central constructs secures understandability and language adequacy. The analysis regarding target group-oriented documentation (DP 1.4) shows that all MMs document basic information as well as central constructs (see above) and their interrelations are mainly documented in a target-group-oriented manner complying with the quality of communication.

3.4 Consideration of business model aspects

The analysis regarding business model aspects shows that four of the six MMs take into account business models to some degree. Demir (2018) considers the business model as an aspect of one of seven dimensions, namely the dimension “structure & model”. Here, organizational structure and business model are understood as tools to foster innovation and to support corporate strategies. The maturity levels of this dimension with regard to BM aspects are defined as follows: At level 0 the BM is unknown, at level 2 some of its components are known, at level 3 the BM is not innovative and strategies are not supported, at level 4 the BM is redesigned to foster innovation and empower strategies and at level 5 the BM is unique/innovative and fully integrated into strategies.

Rübel et al. (2018a) use the building blocks of the business model canvas according to Osterwalder und Pigneur (2010) as the structure for their MM. In this context, maturity is determined by the degree of process mastery with regard to Industry 4.0 of 28 business model elements underlying the nine building blocks. Each element is assessed using five generic maturity levels. Igartua et al. (2018) take into account the business model through

the MM category "Value propositions and business model", which is focused on the definition of offered products and services as well as the related benefits for customers and differentiation potential. To assess the maturity of each of the in total 11 categories, five generic maturity levels are defined. Carlson and Gupta (2014) state that their model aims at innovating products, services and business models and in the frame of the first (lowest) stage's description it is mentioned that organizations must develop a dynamic portfolio of innovations that include product, process, services and business model innovations. Additionally, the description of the fourth stage comprises that most departments are innovating new solutions on an activity, process, product, or business model level as a lever of that stage. Besides, no specific BM aspects are taken into account.

4 Boundary Conditions and Steps towards a MM for BMI

The above analysis revealed several important insights that can be used to define a first set of boundary conditions and outline further steps to design an integrated MM for BMI. Doing so in the following, the structure of basic design principles for MM according to Röglinger and Pöppelbuß (2011)is used.

The application of the envisioned MM focuses on the domain of BMI putting the process of innovating business models in the foreground (DP 1.1a). The purpose of the model persists in enabling the analysis of organisations or organisations' units' business model innovation capabilities and in providing them with guidance on how to prosper with regard to BMI as well as to allow benchmarking (DP 1.1b). The target group of such analysis, derivation of measures and comparisons may comprise executives, managers, business developers as well as entrepreneurs (DP 1.1c). In this context, organizations no matter of which age, size, and industry, ownership, public or private as well as units of such organizations are potential entities under investigation (DP 1.1d). Considering that no MM to date focuses on the domain of BMI and follows the above described purpose of use a clear differentiation from existing MMs is evident and will become even clearer once maturity, respective dimensions and maturity levels are defined (DP 1.1e). At this point of the MM conceptualisation, the design process of the MM is not concluded and has so far been documented in detail. The research and development process of the envisioned MM will be guided by the framework according to Röglinger and Pöppelbuß (2011) and the procedural model to develop MM by Knackstedt et al. (2009) as well as further approaches to MM development will be considered. In this context, the empirical validation is planned as a fundamental step in subsequence to conceptualising an initial version of the envisioned MM for BMI (DP 1.1f).

The conceptualisation of maturity and dimension of maturity needs to take into account different aspects related to the application domain of BMI. On the one side, the content and architecture of business models (business model components and relationships) as well as the process of innovating business models (e.g. analysis and design) and organizational (e.g. culture) as well as environmental aspects (e.g. partners) will be taken

into account. For this purpose the application of LDA on BMI literature and related fields and qualitative, explorative research represent promising approaches (DP 1.2a). Maturity levels should orientate on existing models for ease of understanding and be complemented by detailed maturation paths for the same purpose (DP 1.2b). As the MM for BMI is intended to support organizations in applying it, the available levels of granularity of maturation should allow a detailed analysis but should not be complicated by unnecessary complexity (DP 1.2c). Through this study, the underpinning theoretical foundation with respect to evolution and change (DP 1.2d), are commensurable between the two domains of MM and BMI, and thus the ambition to fuse the two withheld. Central constructs related to the application domain that will be defined in detail in course of the conceptualisation comprise the business model construct and the construct of BMI (1.3). In the frame of the conceptualisation all results will be documented target-oriented to comply with the requirement of communication.

5 Conclusion

As outlined in the above sections the objective of this paper is to define the boundary conditions for the conception of a maturity model for BMI. For this purpose, a suitable framework to develop maturity models was selected and applied to analyse six of 26 identified IMMs by means of a literature review. This approach constitutes a first step towards the conceptualization of a MM for BMI and provides some first valuable insights on how to proceed. One fundamentally important finding is that no maturity model exists to date that is dedicated to BMI, justifying this research endeavour. In addition, we defined fundamental boundary conditions in the form of design principles according to Röglinger and Pöppelbuß (2011) which will guide the subsequent steps towards developing a MM for BMI. This study thus contributes with an important foundation for subsequent model development for a MM for BMI. The envisioned model should support executives (target group) from established as well as new ventures (class of entities under investigation) in assessing the maturity of a company's BMI capabilities Furthermore, the envisioned model should provide indications of necessary adjustments and possibilities for improvement (purpose of use) and enable benchmarking of organizations or units.

Abstract

Over the last years there has been a relevant increase of large scale data. "Volume", Velocity", "Variety", "Veracity" and, more importantly today, "Value" are the dimensions that characterize Big Data. Big data are increasingly important in the real world. In this paper, we deal with bibliometric datasets which represent relevant information and value for applications, usually difficult to identify. In economic analyses, bibliographic networks are useful to represent the data and provide relevant insights on research findings. In this work we will propose to apply a framework based on symbolic data and, in particular, one based on data-based symbolic observation interval which represent relevant patterns and information from complex data. These results are important because they consider a relevant case of complex information which is transformed into a representation useful to be analysed as network data. From these network representations of the information (considering a co-occurrence network from the relevant concepts of the studied literature of "regression discontinuity") we are able to identify the most relevant patterns in data, as "communities" of concepts maximally connected to each other. From the communities we are able to represent the semantic cores of the literature.

Keywords – Bibliometric Analysis, Big Data, Symbolic Data Analysis, Regression Discontinuity, Causal Inference

Paper type – Academic Research Paper

1 Big Data Analysis and Bibliometrics in Economic Science

Over the past 20 years, there has been a strong increase of large scale data in many different businesses. In this context the use of big data represents a relevant possibility and it could be very promising. Big data is the term which is generally used to describe large data sets and more generally large amount of data (Chen Mao Liu 2014). Big data represent a revolution in management for various reasons, which typically are described as "the five "V": "Velocity", "Variety", "Volume", "Veracity" and more importantly today "Value". The last dimension is particularly important and it is recognized in literature as one of the most recent V dimensions of Big Data.

In fact, during the last years there has been a relevant exigency to transform the large existing data quantities in profits for businesses (Hadi et al. 2015). Social big data is another relevant concept. In fact, if data are everywhere, social big data are at the same time a relevant possibility to be exploited in order to obtain advantages (Bello-Orgaz, Jung and Camacho 2016).

In this sense, big data and social big data should be seen as a revolution in many different contexts not only the business one, but also contexts such as government, science etc. (Kitchin 2014).

Big data are increasingly common in data analyses in different contexts. In Scientometrics, for instance, big data are pivotal in allowing the study of the increasing corpus of literature. Bibliometrics can be considered a big data science and the approaches need to be implemented by considering methodologies of big data analysis. A first relevant point is an increasing availability of bibliometric data (Moed Luwel and Deraio 2014). The datasets can be also combined and reconsidered in order to address different research questions. Secondarily, there is the availability of different types of structured, unstructured and semi-structured data (Gandomi Haider 2005) which can be merged differently. So, in past years, there has not only been a growth of large scale databases, but also the growth of different typologies of data types as full texts, abstracts, citations, keywords, co-authorships etc. (Halevi 2014).

Scientometrics is a relevant field which is developing. Mingers and Leydesdorff (2015) show the different evolution phases of fields. According to the work of the authors, there are different phases of the development of the field. Scientometrics has relevant phases which can be explicitly defined in this way: Garfield defined the citation relevance and proposed the Science Citation Index (see Garfield 1955). However, the relevance was relate to the network analysis of the different papers, considering the work of de Solla Price (1965), which stressed the relevance of the paper networks. After year 2000, there was a great development of different analytic techniques which was useful to measure some bibliometric relevant factors. We can consider the h-index by Hirsch (2005) a relevant way to measure the scientific impact of a specific author. Another phase that may be considered is the 1964-2011 period, which led to a greater development of analytical techniques, and in the latest years also computational techniques to perform some specific and important statistical analysis to extract relevant insights from the data. In the

literature on Symbolic Data Analysis (Billard and Diday 2003) there has been an approach to work with aggregate observations ("higher observations" representing "concepts of higher level") and not only dealing with single observations. The approach was considered by Drago (2005). In this sense this approach allows to take big data into account.

The aim of this work is to show some analytical techniques in bibliometric big data analysis that are useful to extract relevant information from this type of data. In particular, we will show how it is possible to use symbolic representations to adequately represent relevant concepts which can be extracted from big data. These concepts can be very relevant in order to extract knowledge from the relevant corpus.

The impact of the bibliometric and scientometric analyses is significant because of their capability to underline the relevant impact of the scientific research (Halevi 2014). From the richness of the data available in these contexts, we want to show how it is possible to extract the relevant "signal" from the data and the relevant meaningful patterns that emerge from the big datasets. The context is Economics, in which there often is the need to synthesize the relevant literature available.

So the relevance of this work needs to be considered in different contexts. Bibliometrics can be applied in every different scientific field and so its relevance cannot be undervalued (Ball 2017). In fact, Bibliometrics can help to analyse and explore the impact of innovative ideas and technologies in various fields. More in particular, in this work we will explicitly consider and we will analyse the experimental design literature and more in particular regression discontinuity (White Raitzer 2017). The topic is growing in importance in modern economic analysis and econometrics. An example of the application of the bibliometric big data analysis in practice is in Harle, Vest and Menachemi (2016) with the analysis of the research productivity in health policy and management.

The different classical quantitative methodologies of data analysis need to be reconsidered in this context. Classical data analysis should be reconsidered to take in to account this data volume. Big Data lead to relevant new challenges which need to be tackled by researchers and practitioners in every field.

A relevant problem is how to represent the original bibliometric datasets. In this sense, it is very important to also consider the different data typologies which can be observed in these analyses.

A relevant problem to be considered is the analysis of the relational data, which are very useful to understand the structure of the research and literature for a specific topic in a certain sector. In this sense, various possibilities arise in order to evaluate the different relationships of the different statistical units in the original data. We can consider citations, co-authorship, collaboration, co-occurrence networks between the others.

In this sense the use of social network analysis techniques can help to extract the relevant knowledge from these data. Various big data analyses can be performed in this context. For instance, networks of co-authorship, co-citation, and collaboration can be

usefully considered. These datasets can be considered by taking into account different topics and can be easily merged.

In this way, a problem in managing these big data arises very quickly, which is the difficulty of extracting the relevant information from these data. A relevant approach can be the use of symbolic data analysis (Billard and Diday 2003) and more in particular interval data, which allow to keep the relevant information from the networks. Drago in 2016 and 2019 considered this approach to network communities which can be considered as the leading elements of the analysis. The final result is that we are able to compose and decompose the network considered to extract the information from the data.

The relevant aspect of the networks considered are the communities which determine relevant patterns to be analysed (Drago 2017). In this sense the approach proposed is relevant to represent in a meaningful way these networks and extract the relevant information from the data. In this sense the expected results from this work are related to the possibility of managing these datasets and extracting the relevant information on the regression discontinuity design literature (which is very relevant in Economics and in Social Sciences).

2 Data and Methodology

We started with the creation of the bibliometric dataset. In this sense, data were collected by SCOPUS database on 1/6/2020 considering the query "regression AND discontinuity" which was subsequently restricted to the Economics area. In this way, we were explicitly searching papers which are part of the Economics, Finance and Econometrics area. At the end we collected 969 papers. These papers were collected considering at the same time different bibliometric information such as the "title" of the work, the "authors", the "abstract", the "keywords" etc. At the end we obtained a first summarization of the literature considered, by analysing the general bibliometric trends of the considered literature. It is important to note that we explicitly took into account different types of data: numeric (the year for instance) textual (the abstract), etc. A first relevant transformation on the initial data matrix is the possibility to obtain a network which represents the co-occurrences of the keywords considered in the works. From the network considered, we were able to perform a community detection analysis, in order to extract from the network the relevant communities which represent interesting patterns that it is important to extract from the literature. We used the walk trap community detection approach (Pons Latapy 2006) which has shown relevant results in literature.

The symbolic data analysis (Billard Diday 2003) approach allows to identify the relevant communities of symbolic data which can be considered as "data" of their own. So we could compare the different groups of observations and of course interpret them as a relevant group. R was extensively used for the computations (Aria Cuccurullo 2007 and Csardi Nepusz 2006).

A limitation of the approach is related to the generability of the proposal. Probably, the adoption of a big data approach can be useful in a theoretical field where the dimension of bibliographic resources is assumable as big data.

3 Results

The analysis was conducted from the initial network which is visualized in figure 1 "keyword co-occurrences network" (with 50 vertices as keywords to visualize) performing a network analysis useful to characterize our networks. The network analysis was conducted to consider the general characteristics of the networks examined. In particular, we have considered the keyword co-occurrence network as a key network to be analysed. The co-occurrence network considers if in the same text there is a co-occurrence of two keywords.

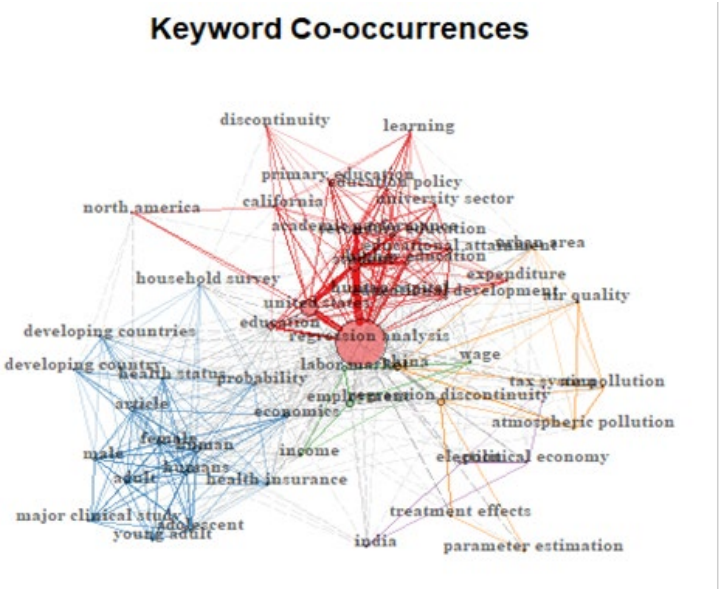

Figure 1. Keyword Co-occurrences network (number of vertices as keywords to visualize: 50)

So in the end we took into account 1207 keywords in our network analysis (see Wasserman and Faust 1994, Hannemann Riddle 2011). The different keywords were analysed considering centrality indexes such as Freeman degree, betweenness and etc. These two specific approaches are particularly important in our analysis because they allow to represent the centrality patterns in our network. In literature centrality on a network can be characterized by considering various measures. In particular, betweenness is a global measure of centrality and it is based on the ratio of the paths through which it is possible to pass from the specific node to the whole. The degree is a local measure of centrality and measures the number of connections of the node with its neighbours (the

different nodes which are connected to it). So the degree is simply the number of connections (also defined as "edges") a single node can have with other nodes (Wasserman and Faust 1994, Newman 2008).

Most importantly the community detection is aimed at identifying the groups of keywords maximally connected in the works (Fortunato 2010). This could be relevant to visualize and detect the relevant groups of keywords between the different works. The results allows the identification in literature of a number of 40 communities related to different groups of keywords.

The general results on the interpretation of the communities show the interconnection between different topics, in which regression discontinuity is applied specifically, and different methodologies, which are connected to the regression discontinuity or characterize them. The symbolic data itself allow to give the comprehension of the interval of centrality considered for each specific community or group. In this sense, each community can be considered as a sort of "semantic core" of the literature. The fact of identifying the variability of the centrality of the different keywords which are part of the semantic core allows to understand if the keyword components of the semantic core are relevant or not in the development of the literature. In particular, it is interesting to note that the community "1" that is very central to the development of the literature, is based on the regression, and has relevant applications in policy designs and also in labour markets and education. The community "8" shows relevant elements on health issues. So this community is related to topics which are part of the relationship between health economics and regression discontinuity. This community, at the same time, is based on the fact that in health it is crucial to consider the approach of regression discontinuity, or in general in this field the causality analysis is very relevant. In general, it is interesting to note that the word "propensity score" is also part of this semantic core. That means there exists, in this specific field, a call for the use of this specific methodology. In this sense it is interesting to detect this fact.

4 Conclusions

In this work we have considered a relevant a problem in the application of big data. We have considered big data based on bibliometric datasets. These datasets show relevant problems and they need to be adequately managed in order to extract the relevant knowledge from the data. In particular, we have considered an approach based on symbolic data analysis and an approach which transforms the different communities of the networks representing the original data into symbolic observations. These "special" data typologies allow us to consider in our case the semantic cores opposed to the single keywords considered on their own. In this context we were able to identify the different communities by means of the walk trap community detection technique (Pons Latapy 2006) and to transform the original data into interval observations. The interval observation was very useful to identify and interpret the real concept based on the interval measurement of the network centrality characteristics as well. In this sense the final result

was to identify the general characteristics for the semantic cores defined as the communities in the analysis. In particular, the general relevant result is the fact that we identified both the most relevant characteristics of a literature in Economics related to the "regression discontinuity" in term of important applications and methodologies used. At the same time, we detected relevant raising fields of new implementation of the approaches and also new insights on this literature. The value extracted from the literature is based on the results which can be obtained by examining the different topics and keywords which are part of the different communities extracted. In this sense, the value is obtained directly by considering the results related to the different communities and the different applications and methodologies which can be taken into consideration from the communities extracted.

Abstract

Images and metaphors are an integral part of knowledge in the world around us. Therefore they can be put to a purpose in knowledge management. Images, including metaphorical ones, can serve as arguments in the decision-making process. To increase efficiency of this process by the means of comparative analysis, they should be used in the form of image tuples. Differences in the elements of the image tuple should be evaluated by experts with the use of confidence factors. In future, context-image-based knowledge management systems can be used in a variety of directions from archaeology to painting to medicine.

Keywords – knowledge management, arguments, image rows (tuple), healthcare, art.

Paper type – Academic Research Paper

1 Introduction

Images are integral elements of a holistic view of the world. In natural sciences and in humanities, holistic images take an important place. The value of holistic images is determined by the fact that the verbal equivalent is often too crude or erroneous. An attempt to decompose them often leads to loss of content, of identity. In turn, visual recollections or pseudo-memories (altered, or deformed visual images) and metaphors reinstate the meaning of a name – a concept, and return to the original essence. Such images are part of the knowledge. They can be either clear or vague or sketchy. However, intact core of an image allows you to identify a phenomenon or a scene, that undergoes a

change in time. Comparison of a "new", unfamiliar image with a known one may permit some uncertainty of the details; however, the key concepts must coincide to allow the identification.

The inclusion of visual images in the knowledge bases of intelligent systems can significantly increase their effectiveness in a number of areas, such as, for example, archaeology or art. They have distinctive meaning n medicine: in the diagnosis of a number of diseases according to the appearance of patients, and also to the images obtained during instrumental studies of human internal organs. The images of patients may be paralleled with images in art, and this approach should also have a place in artificial intelligence systems. Art, as Karl Popper writes [1], is in some sense different from science, but alike in other. The same can be said for other fields such as medicine or history of arts.

The situation in artificial intelligence is determined by the search for new approaches to reflect the mental activity of a person in making decisions. An attempt is made to transgress from the analysis of entities to an integral reflection of verbal and visual images, including the metaphor of human thinking. We have to create a hybrid version that includes both approaches used by natural intelligence, and to ensure a free transition from one type of situation recognition to another in artificial intelligence systems.

An image as a symbol can become, and should become the centre of logical-linguistic-imagery or imagery-contextual knowledge bases, with argumentation systems based on visual images.

The purpose of this study is to analyse the use of the imagery approach in knowledge management. This can serve as a foundation for new ideas in healthcare, in art history and management, and in other areas.

2 Knowledge management and images

The knowledge-driven system is constructed upon a unified knowledge base, that involves the technology of component design and stores information in a systematic form [2]. In this paper, the concept of image rows [3] is considered as an additional principle of systematization, i.e. when many close or relatively close images are embedded in logical-linguistic models in various loosely structured areas (history, archaeology, art, medicine). Image rows are discussed in more detail further in the text.

Application of the modular principle to the representation of knowledge serves to increase the management effectiveness in information systems [4]. This approach provides an efficient search and exchange of knowledge in modular form (semantic and / or image blocks). Integration "from above", that is, a general field of knowledge in a subject or problem domain, in combination with "internal" modules for displaying various specific information in certain areas will accelerate the creation of integrated knowledge bases or supermodules for solving new problems (provided that the principle of semantic interoperability is fulfilled).

The managing metabase of knowledge through special modules or sub-bases of knowledge associated with databases of relevant subject areas will allow, based on the generated hypotheses, to ensure the identification of necessary facts or the selection of necessary data, including images. As follows from the figure 1, the storage system of domain meta-knowledge manages lower located knowledge bases of problem areas and sub-bases of knowledge in narrower directions. If we turn to such a subject area as painting, then as examples of the first level we can consider, for example, the following problem areas: the Renaissance, the impressionism, the abstract art, and as examples of the second level – the high Renaissance, the pointillism, the suprematism. In medicine, respiratory diseases, cardiovascular pathology can be examples of problem areas, and subclasses or individual nosologies (types of diseases) – respiratory infections, bronchial asthma can be examples of subbases. It is possible to organize metabases in art by epochs, and diseases by their causes (trauma, etc.).

A module or a knowledge subbase in a specific area includes knowledge about images and the corresponding context. On this linguistic-imagery basis, the generation of rules and output mechanisms for knowledge bases is possible.

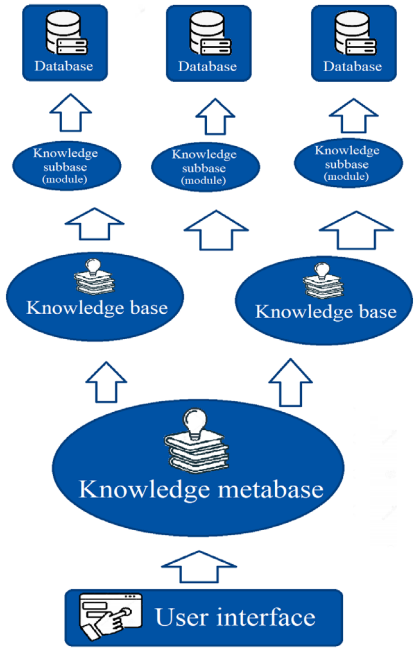

Figure 1. Knowledge-driven information systems (databases)

The transition to knowledge-driven systems involves the formation of image rows in completely different subject areas – like art, or museology, or medical diagnostics.

3 Arguments in knowledge systems

Knowledge systems can be constructed in various ways, including using argumentation trees, which present a sequence of features that argue downward on the tree [5]. Let's take as an example a medical database of lung diseases, constructed with argumentation trees. After we consider a combination of such characteristics as moderately elevated temperature, headache, muscle pain, dry cough, which are arguments to look for harsh respiration and isolated wheezes in the bronchi simultaneously with the reticular opacity on x-ray, we can argue for the hypothesis of an acute respiratory illness. A similar set of signs in the presence of a wet cough is an argument to check the second branch – for the presence of moist fine crackles the lungs and a shadow on the lung on the x-ray, which indicates to the hypothesis of bacterial or typical viral pneumonia. The third branch is focused on shortness of breath with fever and dry cough. These signs are arguments for identifying specific changes in the lungs observed on computed tomography (an image referred as ground-glass opacity or "frosted glass"). In this case, the diagnostic hypothesis is Covid19 (Fig. 2). The actual number of argumentative branches is much larger. And as you can see, they include facts (signs) and radiological images.

In argumentation systems, the metaphorical concept of a "dialectical image" introduced by the German philosopher Walter Benjamin [6], which is considered to be a "snapshot" of the past in the superposition of the present, can be used. This concept will serve as a basis for discussion in the formation of competing hypotheses that take into account the dynamics of facts.

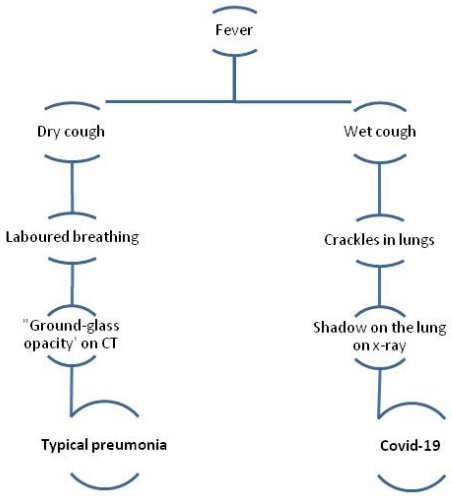

Figure 2. Schematic representation of the argumentation tree

4 Symbolic images and arguments

The first symbolic images were petroglyphs, which can be considered pictorial symbols-messages about the surrounding world. Karl Popper calls them images of stories [1]. Petroglyphs can be considered as a transitional version of imagery-symbolic representations.

The word "symbol" comes from the Greek "symbolon", which means “token, watchword”: in Ancient Greece, a so-called half of a thing cut in half (plates, sticks, clay bowl, coins, medallion, etc.), combining which their owners or descendants could recognize each other. A symbol is also something which stands for something else: an image created by the author, and its designation, content, interpretation, secret meaning. A symbolic image can be an independent artistic image that embodies an idea. Images that correspond with the concept of a symbol can be considered as arguments, and allow us to put forward hypotheses.

A mental image is an alloy of imitation of visual representation with the knowledge in this field, i.e. a kind of fact with a logical conclusion. In the context of this study, the logical-argumentative thought process includes signs and images or imagery-argumentative constructions with an alternating order of including signs and images.

In a person’s memory, an image “surfaces” under the influence of a similar image observed in the past. A characteristic lip fold in women can evoke the image of Mona Lisa in memory and then, by association, other paintings by Leonardo da Vinci. Symbolic images in the form of masks (for example, a threat – the Gorgon, Giotto's fresco depicting anger in the church in the Arena in Padua, frightening African masks) can serve as highlights of essential knowledge in the image, giving the prominence to characteristic features.

In the similarity association, notes A.A. Bogdanov [7], the most intense are the common parts of the combined complexes (the “synthesis form"), and the differences are blurred, merging into a vague mass of experiences. In the contrast association, the attitude is quite the opposite: common features recede into the background and are only vaguely recognized, and the “differences” seem to be emphasized, standing out with ever greater brightness and distinctness (the “form of discrimination”). Thus, in a person, associations are involved in the process of identifying similarities and differences, in the mentally constructed sequence of images including.

In a knowledge-based system, an assessment of the similarities and differences requires an imitation of human thinking, which is impossible without taking into account associative relations, including the imagery characteristics of the view of the world. Thus, in the knowledge system, a combination of arguments with reasoning by analogy and reasoning based on hidden associations is possible.

5 Image Rows

Artistic images, holy icons and faces of people are complex (multidimensional) signs, in contrast to the primitive people's petroglyphs, which are simple (one-dimensional) signs, and in principle can be converted into symbols without significant loss of meaning. However, this cannot be done with multidimensional or polysemantic signs, which are integral as images. At the same time, a number of close or relatively close images — a series of images — can correspond to a certain visual image. Let us consider as an example the various image rows, or tuples, in Figure 3. In the first row we see a tuple of images of sphinxes of different times and peoples (Great Sphinx in Giza; sphinx with the face of Hetepheres II, 25th century BC, Egypt; sphinx with the face of Hatshepsut, 15th century BC, Egypt; sphinx of the 18th century, Spain). In the second row there is a tuple of sculptures depicting chimeras (the gargoyles of Notre Dame Cathedral). In the third row are the faces of patients with hereditary diseases (mucopolysaccharidosis, mucolipidosis).

Figure 3. Image rows.

In an analogy with the topology of the possible [8], the genotype in hereditary diseases can be compared with the archetype image and a number of more or less similar phenotypic images. This "genotype-phenotype" situation demonstrates a one-to-many

relationship. Such an approach corresponds to the formation of image rows in medicine and in other fields. A variety of manifestations of diseases with a progressive course presents, i.e. determines the age-related dynamics of changes with a more severe manifestation of previously detected symptoms an example from the medicine.

A series of images of patients with the same disease or images of angels is a quasicontinuum. A vivid example of an image series characterized by fuzzy transitions can be found in the Ancient Roman coins. As the distance from Rome grew in every next province, the emperor's face was less and less distinguishable due to image disintegration (Fig. 4). Such a series of images can also be associated with a rough set [9; 10] for the description and presentation of the uncertainty of similarity. On the other hand, a tuple of images can be viewed as a multiset [11], i.e. a set with repeating images, where representatives of individual groups can be considered as subsets. Sets and subsets can characterize different art schools, artists of the same school (the master and his students, his followers). In medicine, it can be various forms of the disease, various manifestations of one pathological process in dynamics.

Figure 4. Fuzzy image row of ancient Roman coins

Image rows or tuples (including fuzzy ones) represent cognitive-imagery systems. In medicine, they can serve as markers of disease. In combination with context, they can be considered as a special design option for visualized ontologies, as a development of the paradigm of knowledge structuring [12].

Temporal (dynamic) image series is characterized by the transformation of images while maintaining the general and characteristic features. Everyone changes throughout life. Nietzsche's imaginative series of Zarathustra demonstrates the god's diverse guises, the change in his thinking when addressing various aspects of life on the way to the ultimate goal. The transformation in the appearance of Zarathustra in different periods of his life can be seen in a large cycle of paintings (Fig. 5) by the Russian artist Pyotr Fateev [13]. With the use of knowledge bases containing image series illustrating certain fragments of literary works, literary and art exhibitions can be arranged.

Figure 5. A series of paintings by Peter Fateev from the cycle "Zarathustra"

Artistic image rows can be accompanied by musical ones, which was typical for the works of the Lithuanian artist and composer Čiurlionis [14].

The dynamics of the image and the resulting series of images can be associated with a change in the human face during a serious illness, leading to metamorphoses of a particular image. Cases of cognitive impairments in representatives of creative professions can present a particular version of displaying changes in a person's appearance. In a series of self-portraits written by American artist William Atermolen after he was diagnosed with Alzheimer's disease, he tried to trace the degradation of his consciousness (Fig. 6). Pronounced changes are observed in the course of his illness. Similar image rows created during ilnesses can be used to predict pathological processes in intelligent systems.

Figure 6. Self-portrait metamorphosis with artist's Alzheimer's disease

In general, objects of the image series are characterized by a certain similarity, while images from various differentiable (comparable) series show a difference. In the painting of one row, there can be, for example, similar repeating elements or the type of brushstroke in the paintings of a certain artist or an artist and his followers.

6 Images and metaphors

The impression received from the visual image helps to put forward a certain assumption, to form a primary hypothesis. Pattern recognition can be considered a perceptual concept. Information received is multi-valued and symbolic in nature. At the same time, when the image is associated with the metaphor of a clearly defined phenomenon or object, metaphorical representations, which are inherently a univocal concept, may contain hidden polysemanticity. The identification and presentation of the essential image features of the subject, and metaphors as the mental transfer of the generally accepted name from one phenomenon to another, can serve as a breakthrough element of innovative solutions in various areas of management.

In medicine, it is extremely difficult to convey in a verbal (linguistic) form undoubtfully unambiguous perceptions of such visual images as a "cloverleaf skull syndrome" or a diverse "beaked nose". Metaphorical terms in the form of images can be interpreted differently by doctors who did not see them, but only heard of them, in a linguistic form. In any case, there is at least a partial loss of information. For example, there are extremely significant images that are characteristic and important for the formation of diagnostic hypotheses, such as the 'bird-headed' facial appearance for Seckel syndrome, or the frog leg position for floppy baby syndrome or the 'elf's face' in Williams syndrome, which could have led to the emergence of a legend about the so-called elven changelings. Images of patients with Hurler syndrome, with rough faces, until long called gargoyle-like, were associated with gargoyles at the Notre Dame Cathedral in Paris, shown in Figure 3. In all these cases, previously acquired metaphorical knowledge was extracted.

The idea of involving image information in knowledge systems in the context of the development of modern digital technologies is of particular interest. Computer-aided image analysis is becoming increasingly important to efficiently and safely handle large amounts of high-resolution images generated by advanced medical imaging devices [15]. There is also a tradition of metaphorical association of medical concepts with images from the world of art, cinema and poetry. For example, leukoaraiosis or "periventricular luminescence" observed in computed tomography in the form of a bilateral change in the white matter of the brain around the front horns of the lateral ventricles of the brain is sometimes called. 'Mickey Mouse ears. At the same time, this phenomenon of the luminous substance of the brain can be metaphorically associated with the radiance around the candle flame and the snow gloom outside the window, like in Russian poet Boris Pasternak's poem "Winter Evening": And all was lost in snowy murk / Snowgrey and blurry. / A candle on the table burned, / A candle, burning. [16].

Detection of brain damage should be done as quickly as possible, and physician's intuition is often crucial in these cases. As Leonardo da Vinci [17] wrote: "All our knowledge has its origins in our perceptions". In the end, it seems possible to talk about associative-rational activity on the basis of memories of similar image situations. In this

regard, the importance of an associative approach for medical decision management systems should be noted.

Another area where imagery approach to the analysis of phenomena and style can be applied is museology, in which both scientific research and the construction of expositions take place. Also, a promising area for the study of associative series is management and marketing, since the promotion of various services and goods is often based on the impression [18].

7 Confidence factors for image rows.

True and metaphorical images presented in the form of image rows or tuples in various subject areas can be provided with confidence factors [0,1] of the Stanford model [19]. These factors will indicate the degree of similarity with the archetype (the most typical representative of the considered image tuple). It is possible to assess the similarity with the metaphorical image of this series. The measure of confidence in the similarity is especially important due to the fact that in life we often deal with fuzzy imagery.

For an archetype image, a confidence measure of 1.0 should always be used, and fuzzy images in a series should measure from 0.1 to 0.9. These similarity confidence measures put forth by experts can be applied to any image series. In a pictural series it can be, for example, the early Giotto and Giotto in his height, or Giotto and his students and followers (Giotto school). In medicine it can be externally phenotypically distinct patients or radiological images of patients with one disease.

Image rows can be embedded in frame structures where the frame must correspond to the traditional representation of a certain image (typical representative of a visual series, archetype, parent frame or class frame), and slots are represented by various variants of an image of this type (‘individuals’), which differ in individual characteristics (appearance, visual data of specific studies).

Thus, the inclusion of visual series as a second component, along with the linguistic one, in traditional semantic knowledge bases will serve as the foundation for two symbolic representations – linguistic and iconic.

8 Knowledge management in art

Intelligent control systems with logical-linguistic-imagery knowledge bases can find application in various directions in the field of art.

(1) Attribution of paintings with the use of a metabase, individual modules or sub-bases of which will provide hypotheses for searching databases of information systems that are similar in style, presentation of perspective, prevailing colour scheme and other characteristics of paintings by artists of the same period or direction. At the same time, the possibilities of building databases of different problem areas will be combined. It can be:

– art schools (Florentine, Venetian, Flemish, etc.),

– periods (baroque, classicism, romanticism, etc.),
– individual artists or periods of their creativity.

(2) Arrangement of exhibitions, during the preparation of which databases will be viewed, including collections of various museums and private collections. When selecting paintings, information about the requirements should be reflected in the knowledge management system. Accordingly, the selection of paintings for the arrangement of exhibitions will be carried out:

– by movements (icon painting, pre-Raphaelites, avant-garde, art installations, etc.),
– by periods (neoclassicism, 19th-century European art, post-impressionism, etc.

(3) Film festivals in retrospect. It can be avant-garde, surrealism, neorealism, etc.

9 Images in marketing

There are stable long-term elements of identity that can be considered: colour, shape, type, texture, which are the end product of the deconstruction of the elements and can characterize a certain style. Combinations of these stylistic elements define the emotional 'core' of identity. Similarly, you can approach the choice of brand. The book on marketing aesthetics [20] cites interesting studies that show the appropriateness, or the possibility of separating consumer reactions caused by acquaintance with the brand, its recognition, caused solely by design elements.

10 Conclusions

Creation of non-traditional models of knowledge representation for expert systems suggests that within the framework of a general formalism not only classical quantitative and qualitative characteristics can be used, but also cognitive visual indicators of expert knowledge. One of the options for the implementation of arguments on images is the construction of logical-linguistic-imagery intelligent systems in which hypotheses are based on images and the context that accompanies them in a network of frames or ontologies. Visual imagery can be used at the stages of putting forward and confirming of hypotheses. This will allow the inclusion of poorly verbalized or non-verbalized concepts corresponding to holistic images in the knowledge bases. Multilevel management systems will allow us to move to large distributed knowledge bases and increase the efficiency of their use in practice.

Beyond Half a Staff: Promoting Authentic Knowledge Diversity through Organizational Justice and Collective Intelligence

Andrea Smith *

School of Business and Leadership
Regent University

Virginia Beach, Virginia, 23464 USA

Abstract

The acquisition of marketable knowledge and insight is a key driver of resource decisions among many a corporation in today's highly competitive, global business market. Through knowledge sharing, leading organizations seek to leverage the diverse capacities of their workers in ways which will maximize performance and profit. Paradoxically, there seems to be a cultural dynamic at work within many organizations which runs at cross-purposes with corporate calls for knowledge diversity. That dynamic—personality bias—is one which may be robbing organizations of the diverse employee strengths which they so diligently seek to mine. The current work reviews a modest cross-section of theoretical and empirical papers with an eye toward explicating two constructs—organizational justice and collective intelligence—which are believed to represent promising strategies for addressing personality bias and unequal knowledge sharing in the contemporary workplace. More specifically, the paper suggests that if organizations strengthen and sustain earnest commitments to creating environments which promote interactional justice and group intelligence, increased knowledge sharing—and true knowledge diversity—will be the result.

Keywords – knowledge sharing, organizational justice, collective intelligence, introversion.

Paper type – Academic Research Paper

1 Introduction

The acquisition of marketable knowledge and insight is a key driver of resource decisions among many a corporation in today's highly competitive, global business market (Simmons, 2011). That organizations deem the diversity gained through the regular, open exchange of ideas among employees of great value seems obvious (Simmons, 2011). During the first decade of the 21st century, for example, manufacturing giant 3M is believed to have increased its spending on creativity-boosting pursuits by some 20 percent–a move which pushed their research and development (R & D) budget to a breath-taking $1.5 billion (Simmons, 2011). Around the same time, *BusinessWeek* reported that nearly 20 percent of organizations engaging in mergers and acquisitions did so based on the belief that the employees joining their ranks were creative and innovative

(Simmons, 2011). Paradoxically, a handful of business practitioners and theorists posit that there is another, lesser known dynamic at work in global organizations which works at cross-purposes with corporate calls for the democratization of information, knowledge sharing, and enhanced productivity (Cain, 2012; Howes, 2016; Mauroner & Zschau, 2019; Oram, 2016). That troubling dynamic–personality bias–is one which may be robbing many of the world's leading organizations of the intellectual richness and diversity which they so desperately seek.

2 Personality-Based Bias: True or False?

In 2012, Susan Cain, author of *Quiet: The Power of Introverts in a World That Can't Stop Talking*, posited that Western civilization—along with much of the world which it has so heavily influenced—had a tendency to favor extroverts over introverts across a broad range of contexts (Smith, 2019; Cain, 2012). In order to substantiate her claim, Cain (2012) recounted some of the major historical developments in American psychological research. Two of those developments—(a) the early 20th century promotion of what Cain (2012) has termed the "extrovert ideal," and (b) the subsequent tendency to pathologize introvert-like characteristics (p. 295, "Briefly Noted," 2012; Smith, 2019)—are factors which the author has conceptualized as helping to comprise the cracked foundation upon which extrovert privilege rests (Oram, 2016). Though organized collections of data supporting Cain's bias hypothesis remain outstanding, a cursory review of contemporary literature suggests the plausibility of her claim.

In 2009, for example, Caligiuri & Tarique tested the relations between extraversion, high contact cross-cultural leadership development experiences, and global leadership effectiveness. Drawing on theories of social learning and contact to guide their analysis, the team found that extraversion moderated the relations between high contact cross-cultural leadership development experiences and global leadership effectiveness (Caligiuri & Tarique, 2009). According to the authors, extroverted leaders were the most effective in global leadership activities (Caligiuri & Tarique, 2009). As a result, Caligiuri & Tarique (2009) recommended that corporations use personality testing to identify the individuals most likely to succeed on the global stage–namely, extroverts—and groom them to assume the coveted leadership positions.

One year prior, Anderson et al. (2008) tested the long-held assumption that structural factors (e.g., formal position) were more relevant determinants of organizational influence than personal factors (e.g., personality). Using theoretical conceptualizations of power, influence, personality, and person-organization fit (P-O fit) as a guide, the researchers posited that in organizations where an employee's personal characteristics synergized with corporate values (e.g., outgoing individuals in team-oriented businesses), individuals would achieve higher levels of personal power than those who experienced characteristic-based mismatches (e.g., shy workers in team-oriented cultures) (Anderson et al., 2008). Empirical results were confirmatory (Anderson et al., 2008). In an organization that valued teamwork, extroversion was a significant predictor of individual influence and had

greater impact than formal authority (Anderson et al., 2008). Notably, other research indicates that individuals often perceive extroversion as contributing to superior (a) interpersonal skills (Funder & Sneed, 1993 as cited in Salminen, Henttonen, & Ravaja, 2016), (b) leadership (Judge, Bono, Ilies, & Gerhardt, 2002 as cited in Salminen, Henttonen, & Ravaja, 2016), (c) earnings (Jonason, Koehn, Okan, & O'Connor, 2018), and (d) attractiveness (Meier et al., 2010). Clearly, the aforementioned studies lend some credence to Cain's suggestion of a personality-bias favoring extroverts (Smith, 2019).

According to The Meyers-Briggs' Company (2019), the world's population is nearly evenly split between introverts and extroverts. If that estimate—and Cain's hypothesis—both hold true, then it is highly likely that a great many introverts regularly find themselves on the receiving end of a broad range of organizational processes which play up the strengths of their more gregarious counterparts while simultaneously casting them in a less than favorable light (Cain, 2012; The Myers-Briggs Company, 2019). In organizations where bias may be pushing many to the fringes of the workgroups which they might otherwise strengthen—and robbing them of the intellectual richness which is key to market competitiveness—how might forward-thinking theorists address the problem of personality bias? I wish to suggest sustained commitments to organizational justice and collective intelligence as avenues ripe for exploration.

3 Theoretical Framework and Propositions

3.1 Knowledge Sharing

Organizations are knowledge-integrating (Ibragimova, 2006). When knowledge is withheld, employers are deprived of valuable intellectual capital which holds the promise of enabling greater efficiency, effectiveness, and profit (Ibragimova, 2006; Serenko & Bontis, 2016). Alternatively, when organizations succeed in their efforts to leverage the valuable knowledge which each member possesses, increased organizational performance, capacities for innovation, and profits are the result (Cuguerot-Escofet, 2019; Pfeffer and Veiga, 1999).

Knowledge sharing occurs when employees voluntarily exchange their explicit and tacit knowledge (Serenko & Bontis, 2016). According to Ibragimova (2006), explicit knowledge is that which is easily codified. It includes reports, videos, charts and diagrams, and the like (Serenko & Bontis, 2016). Tacit knowledge is intrapersonal in nature (Serenko & Bontis, 2016). According to Serenko & Bontis (2016), tacit knowledge includes "know-how, know-where, and skills" (p. 1199). Knowledge sharing is dynamic, central to the knowledge management literature, and believed to be driven, in large measure, by interpersonal factors (Ibragimova et al., 2012; Serenko & Bontis, 2016).

3.2 Organizational Justice and Knowledge Sharing

Organizational justice is essentially a study of fairness (Ibragimova, 2006). Fairness refers to equity perceptions which relate to organization practices and bears meaningful impact on a whole host of employee attitudes and behaviors (Ibragimova, 2006). Notably, fairness is recognized as an antecedent to employee cooperation (Ibragimova, 2006; Podsakoff et al., 2000). Given the discretionary nature of knowledge sharing—and the fact that employees who perceive their organizations as just tend to cooperate—contemporary leaders would do well to pursue fairness in earnest (Ibragimova, 2006; Podsakoff et al., 2000).

Mainstream scholarship suggests that organizational justice is multidimensional (Cuguero-Escofet, 2019; Ibragimova, 2006; Konopaske et al., 2018). According to Cuguero-Escofet (2019), four operative dimensions comprise the construct: a) distributive justice, b) procedural justice, c) informational justice, and d) interactional justice (Cuguero-Escofet, 2019). Distributive justice is related to questions of distribution—both tangible and intangible—across individuals within an organization (Cuguero-Escofet, 2019). Procedural justice treats process-related questions (e.g., Are the decision-making procedures which control the distribution of resources in my organization fair and equitable in their conduct and ultimate effect?) (Cuguero-Escofet, 2019). Informational justice is concerned with the fairness perceptions which surround an authority figure's overall communication (Cuguero-Escofet, 2019; Konopaske et al., 2018). Finally, interactional justice refers to the perceptions' of fairness which attend the relatively informal aspects of interaction within the workplace (Cuguero-Escofet, 2019; Ibragimova, 2006). According to Ibragimova (2006), "explanation content and the persuasive features of communication" (p. 25) help to define interactional justice. When dignity and respect are upheld, individuals are more likely to perceive interactional justice (Ibragimova, 2006). When incivility or downright abuse are allowed to take hold, interactional justice perceptions will likely plummet (Ibragimova, 2006; Konopaske et al., 2018). The interactional dimension of the organizational justice construct is a focal point of the current paper.

Recent scholarship indicates that interactional justice is a "strong predictor of subordinates' attitudes and behaviors" (p. 226, Li et al., 2016) and that it may be more predictive than both procedural and distributive justice in certain contexts. In 2016, Li et al., in discussing the importance of encounters and exchanges, helped to underscore the dimension's importance:

> *Procedural and distributive justice are somewhat bounded in resource exchange contexts that may be relatively infrequent. In contrast, interactional justice can be judged in virtually any encounter between managers and subordinates, regardless of whether resource allocation decisions are being made…interactional justice has 'day-in day-out' significance that the other justice dimensions may not possess (pp. 226-227).*

According to Eisenberger et al. (1986), when supervisors engage with subordinates in ways which are fair and just, those subordinates are likely to reciprocate through knowledge sharing. In alignment with the theory of social exchange, I wish to suggest that interactional justice can also be judged through encounters between co-workers and impact knowledge sharing (Fang & Chiu, 2019; Ibragimova et al., 2012; Li et al., 2016; Omilion-Hodges & Baker, 2013). If high levels of group cooperation are to be established and maintained, each member must pass on the temptation to prioritize their own self-interests and look, instead, to create "mutually beneficial scenarios" (p. 22, Ibragimova, 2006). When individual group members do so, justice norms are the result and serve as a guide for productive, intra-team knowledge sharing (Ibragimova, 2006). As members choose to uphold those norms, the sphere of interactional justice should necessarily come to comprise relations between co-workers and, following the logic of exchange and reciprocation, promote knowledge sharing (Fang & Chiu, 2019; Ibragimova, 2006; Ibragimova et al., 2012; Li et al., 2016; Omilion-Hodges & Baker, 2013). As such, I assert:

> *Proposition 1: Interactional justice is positively related to employee knowledge sharing.*

3.3 Collective Intelligence and Knowledge Sharing

For more than a century, psychologists have proven time and time again that a single statistical factor—*g*—provides a reliable measure of individual human intelligence (Woolley et al., 2010). General intelligence, as it is commonly described, demonstrates that "people who do well on one mental task tend to do well on most others, despite large variations in the tests' contents and methods of administration" (p. 687, Woolley et al., 2010). In 2010, Woolley et al. (2010) tested a group of 699 individuals working within groups in an effort to determine whether a similar measure of intelligence might exist among collectives. The results of their research were groundbreaking. Subsequent to the study of nearly 200 groups of varying sizes (i.e., each group included between two and five members), the research team found converging evidence for the existence of a general measure of group intelligence which they termed *"c"* (p. 686). This *c* factor which conveys a group's collective intelligence is analogous to *g* (Woolley et al., 2010). As is the case with individuals, a group's *c*—or collective intelligence—is indicative of the group's general effectiveness on a wide variety of tasks (Woolley et al., 2010). More than that, *c* presents as "a property of the group itself, not just the individuals in it" (p. 687, Woolley et al., 2010). Indeed, it is notable to observe that while Woolley et al. (2010) did not find *c* to be strongly correlated with individual group member intelligence, they did find it to be correlated with group members' social sensitivity and "the equality of distribution of conversational turn taking" (p. 686). Later studies involving MBA students (Aggarwal & Woolley, 2014), online gaming groups (Kim et al., 2015), multicultural groups (Engel et al., 2015), and other collectives (Engel et al., 2014)

replicated the initial work of Woolley et al. (2010) and provided strong support for the existence of *c* (Woolley et al., 2015). While Woolley et al. (2015) conceded that the field was far from achieving a complete process theory of the phenomenon, they observed that groups with higher levels of collective intelligence:

> *"Participate[d] more equally than other groups [such that] collective intelligence was predicted by how equally communication and work contribution were distributed among group members in both face-to-face and online groups…In other words, groups in which one or two people dominated the activity were, in general, less collectively intelligent than those in which the activity was more equally spread among group members" (p. 422).*

Put another way, teams which behaved in a manner which allowed for the equitable sharing of knowledge and work across all members—and teams which were free of dominators—have proven to be effective in performing a broad range of tasks (Woolley et al., 2010; Woolley et al., 2015).

As discussed earlier, knowledge sharing is conceptualized as discretionary behavior which takes place at the behest of individual knowledge holders (Serenko & Bontis, 2016). Collective intelligence, by definition, suggests the regular, equitable sharing of knowledge across groups (Woolley et al., 2015; 2010). In 2015, Woolley et al., in reporting their most recent findings related to collective intelligence, issued a call for research to determine whether and how collective intelligence might be increased for groups. In a most intriguing way, recent findings published by Theobald et al. (2017) suggest that collective intelligence—and knowledge sharing by extension—can be engineered through tactical manipulation.

In "Student perception of group dynamics predicts individual performance: Comfort and equity matter," Theobald et al. (2017) described an intervention designed to explore how group dynamics effected student learning in a university biology class (Theobald et al., 2017). Study participants engaged in one of two types of structured group activities: a) a "loosely-structured activity" (p. 1, Theobald et al., 2017) which required teams to collaborate for an entire class period, or; b) a "highly-structured 'jigsaw' activity" (p. 1, Theobald et al., 2017) which required team members to peer-teach. "Importantly, the two activities were identical in terms of topic and content, but differed in how groups were structured and in how instructions specified how the learners should interact" (p. 4, Theobald et al., 2017). In connection with the loosely-structured activity, student teams were instructed to work through three sections of a worksheet sequentially (Theobald et al., 2017). Jigsaw group members, on the other hand, were instructed to: a) master an assigned section of the worksheet independently; b) confer with other students who had been assigned the same topic, and finally; c) join in groups of three with students who had been assigned other topics in order to teach the material which they had been assigned and discuss the material which had been assigned to others (Theobald et al., 2017). Jigsaw group members were also provided with explicit prompts designed to ensure dialogue, individual accountability, and turn-taking (Theobald et al., 2017).

Subsequent to the group activities, students were surveyed regarding their perceptions of group work (Theobald et al., 2017). Each participant also completed a pre-test before the scheduled activities and a post-test immediately afterward (Theobald et al., 2017). Both tests assessed conceptual knowledge related to worksheet content (Theobald et al., 2017). In all, 770 students participated (Theobald et al., 2017). Study results were striking (Theobald et al., 2017). Students who noted the presence of a dominant group member demonstrated lower levels of content mastery (Theobald et al., 2017). In addition, students who reported feeling comfortable in their groups——a factor which correlated with reports of working with a friend and may be considered analogous to the well-known psychological safety construct—demonstrated higher levels of content mastery than those who felt uncomfortable/unsafe (Theobald et al., 2017). Finally, students who participated in the carefully structured jigsaw activity reported the presence of a dominant group member less often—*nearly 70 percent less often*—than those engaged in the loosely-structured group activities (Theobald et al., 2017). Theobald et al.'s (2017) findings were clear: a) dominators influenced groupwork and student performance negatively; b) comfort/safety influenced groupwork and student performance positively, and; c) carefully structured activities designed to ensure cooperation and interdependence significantly reduced instances of dominance (Theobald et al., 2017).

In alignment with the logic and empirical findings related to collective intelligence, it seems that Theobald et al.'s (2017) higher performing teams attained higher levels of knowledge sharing and overall group success as a function of relatively higher levels of *c*—a condition which the researchers engineered through the administration of a highly-structured jigsaw activity. As such I assert:

> *Proposition 2: Collective intelligence is positively related to employee knowledge sharing.*

4 *Authentic Knowledge Diversity: A Way Forward*

Though the matter of knowledge sharing has rarely been considered through the lens of personality, the literatures spanning multiple disciplines (Duan et al., 2018; Li et al., 2019; Theobald et al., 2017; *Venkataramani et al., 2016)* confirm that working groups are often plagued by disparate levels of member participation which can be traced, at least in part, to unique and characteristic differences in thought, feeling, and behavior ("Personality," n.d.). While some theorists imply that the disparate participation problem is owing to some character deficit on the part of quiet group members (*Caligiuri & Tarique, 2009; Mauroner & Schau, 2019)*, a more balanced view of the available scholarship suggests that a whole host of nuanced contextual factors may provide a more reasonable explanation (*Fang & Chiu, 2019; Ibragimova, 2006; Ibragimova et al., 2012; Li et al., 2016; Omilion-Hodges & Baker, 2013).* Two such factors—interactional justice and collective intelligence—have provided the foci of this paper.

Simply put, when individuals perceive that the treatment which they are receiving within a workgroup or workplace is inconsiderate, unfair, or abusive, the chances that

they will actively participate are diminished (*Fang & Chiu, 2019; Ibragimova, 2006; Ibragimova et al., 2012; Li et al., 2016; Omilion-Hodges & Baker, 2013)*. In the same way, when individuals are assigned to groups with little or no structure with the expectation that they will "sink or swim," those less accustomed to the water may, in fact, sink (Theobald et al., 2017). In workplaces where behavioral norms establish quick thinking, quick speaking, and interpersonal dominance as the measure of professional success, introverts who naturally tend toward thoughtful reflection, metered communication, and interpersonal cooperation may ultimately experience groupwork as unjust and unintelligent (Cain, 2012; *Ibragimova, 2006; Ibragimova et al., 2012; Woolley et al., 2015)*. If they do, the likelihood that they will engage in knowledge sharing will probably prove quite slim. Thankfully, the empirical results presented here suggest that organizations have the capacity to create tailored environments which support knowledge sharing on the part of all of their employees.

Abstract

Improving variety of business aspects such as operations and innovation are often accomplished via systematization that taxonomies provide. Taxonomies have been proven effective in many industries e.g. medicine, material science etc.; recently also becoming adopted in aviation – IATA airline taxonomy was created in 2019. Availability of multiple taxonomies is beneficial since each provides a different view. We aim at developing taxonomy with the following important differentiations: customer-centric bottom up development via customer questionnaires and interviews (vs top down approach of IATA where taxonomy was created by a governing body), focusing on innovation and new value creation (vs operational focus of IATA of standardizing the descriptions and contexts of products and services of multiple providers). We show that our taxonomy is conductive to identifying novel innovation opportunities, which could then be integrated into existing operations by being partially aligned with the IATA's taxonomy.

Keywords – COVID-19, Value Proposition, Taxonomy, Air Transportation

Paper type – Academic Research Paper

1 Introduction

Taxonomies are important as a foundation in any scientific endeavour. The reason for this is that it is necessary to agree on a common and unambiguous frame of reference to advance the understanding of the nature, origins and causes of a specific phenomenon of interest. Only by agreeing on a particular set of classifications can research results be

compared and knowledge be accumulated (Bove, 2002). There are different types of taxonomies used in the aviation industry focusing on:

- safety and security
- products and services.

The typical representatives of the safety and security taxonomies are The International Civil Aviation Organization (ICAO) ADREP (ADREP, 2013) and HEIDI (HEIDI, 2014). These are complex and detailed taxonomies used by industry experts in the process of event description and categorization. Standardization Workgroup of the Safety Management International Group (SMICG) introduced another one, called SMICG hazard taxonomy, which was further developed by Civil Aviation Safety Team/ICAO Common taxonomy Team (SMICG, 2013). Another group of taxonomies could be the one consisting of those primary oriented on the human factor and its relations to specified events and errors. Such taxonomies are HFACS, CHIRP, or TEM taxonomy (Stojić, Vittek, Plos, and Lališ, 2015).

Taxonomy type standardizing the descriptions and contexts of products and services was introduced only recently by the International Air Transport Association (IATA) in late 2019 (IATA Airline Taxonomy, 2019). IATA gives the following description of the taxonomy: The Taxonomy is a hierarchy of related items which is used to convey the context of the product or service, and serves as shared language for describing products and services (IATA Airline Taxonomy, 2019).

This paper creates a new type of taxonomy with the focus on Value Proposition (VP) in Air Transportation (Figure 1); a taxonomy that reflects hierarchical classification and relations between conventional kinds of the categories and entities that exist in the society, aim at air transportation industry and could be proved by empirical investigation. (Goodman, 1978) states that a taxonomy shows the hierarchy and relationship between the different elements and capabilities that exist. All objects, properties, relations and, propositions make sense and justification only within the framework of a specific conceptual scheme.

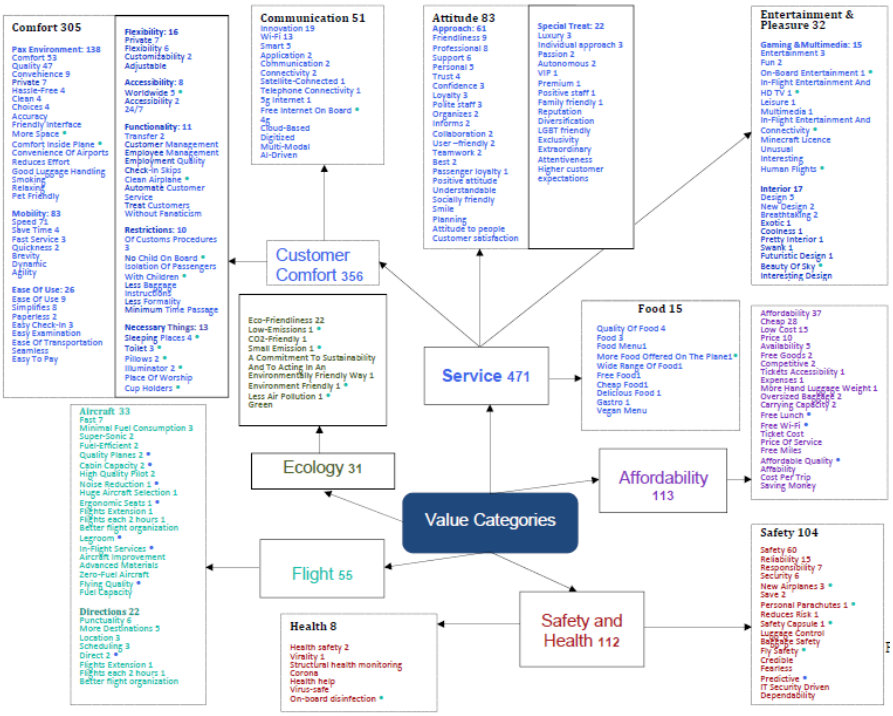

Figure 1. Air Transport Value

The authors of this paper conducted research in the time of a dramatic change in the circumstances (COVID-19) that has a great impact on the norms and practices in aviation. The research reflects both pre-COVID and COVID-time value proposition assessment. The proposed taxonomy is limited by opinions of millennials related to transportation area (students of a transportation university). Categories of comfort, safety, health, affordability are general for human wellbeing and are a natural claim of air transport consumers. Of practical importance are the weights of those general characteristics and their relative importance, evaluated by the potential consumers.

The significance of the taxonomy lies in its potential application to aviation management and industry analysts. There are lots of benefits to adopting this disciplined approach (Product Focus, 2019) to what air transportation industry can offer, including:

• A better focus on clearly defined value proposition generates revenue based on customer value

• Improved allocation of the scarce commercial product management resource

• Clarity around strategic vs legacy products and platforms

• Help in the adoption of consistent and transparent prioritization frameworks

• Clarity for Sales on whom a request for changes and features should go to

• Better ownership and proactive management of internal products, platforms, and enablers.

To evaluate comprehensiveness and contextual factors we adopted empirical-to-conceptual approach (Nickerson, R. C., Varshney, U., and Muntermann, J., 2013): if the researcher has little understanding of the domain but significant data about the objects is available, then starting with the empirical-to-conceptual approach is appropriate, that is shown in Figure 2:

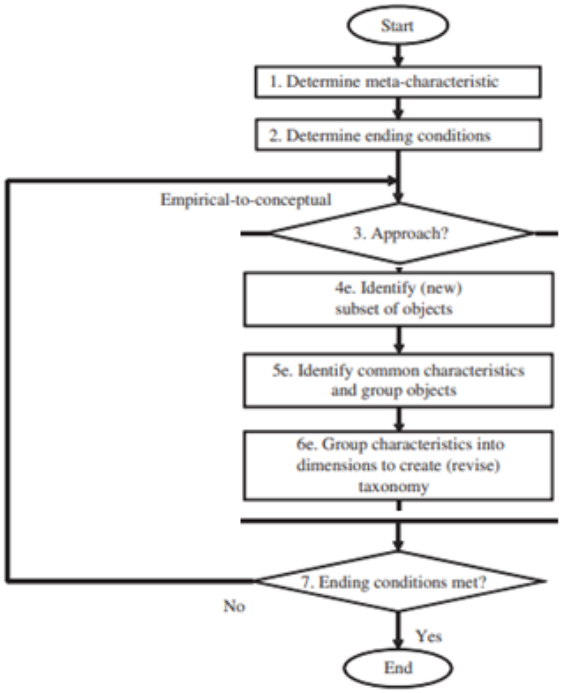

Figure 2. The taxonomy development method (Nickerson, R. C., Varshney, U., and Muntermann, J., 2013)

Following the empirical-to-conceptual approach, we identified a subset of objects (terms) that we wished to classify: low priced, friendly, multiple destinations, Wi-Fi on board, etc. These objects were value propositions from the surveys. Next, we identified common characteristics of these objects. The characteristics were logical consequences of the meta-characteristic. Thus, the authors started with the meta-characteristic and identified characteristics of the objects that follow from the meta-characteristic. Once a set of characteristics had been identified, were grouped formally using statistical techniques. The resulting groups formed the initial dimensions of the taxonomy.

The research interest of this paper is limited by the possibility of adding new value proposition through education not considering Added Value or Value for Money; for

incremental operational improvement IATA's taxonomy and regular surveys would probably be more efficient.

2 Background and related work

Taxonomy in air transportation are primarily developed according to the industry requirements and gained experiences. The experts engaged in the taxonomy development are those actively involved in the reporting or analysing processes. The main reason for such approach in taxonomy design is a desire for achieving a higher level of the taxonomy quality, which will enable effective provision of relevant and valuable data concerning reported events. Logically, this state could be reached in case that reporting system and appropriate training are set in a way convenient for personnel actively involved in the processes (Stojić, Vittek, Plos, and Lališ, 2015).

The suggested in this paper value proposition taxonomy is a combination of Services/Products with Innovation reflected by values from surveys. As the aim of this paper was to develop a taxonomy focusing on innovation and value proposition in air transportation, two existing taxonomies seem related; and their different focus could be interesting to examine. Also, a recent development in Value Proposition theory is worth of mentioning.

2.1 IATA Airline taxonomy (AT)

The IATA Airline Taxonomy (IATA Airline Taxonomy, 2019) is a codeset managed by Airlines through the Standards Settings Governance. The Airline Taxonomy is a shared language for Airlines to describe their products and services to Sellers and a way for Sellers to optionally request specific features in an Offer. It was adopted in October, 2019 and according to the experts' it is yet not of common usage by airlines.

Airline Taxonomy (AT) offers 4 major categories: Ground, Airport, Journey, and Flight and 108 basic level terms. Here is a top down approach of IATA where taxonomy was created by a governing body and an operational focus of IATA for standardizing the descriptions and contexts of products and services. AT does not provide any weight for its categories, as it offers a universal approach to enlisting all existing product and services experts accounted, as it stated in AT Codeset (IATA Airline Taxonomy codeset, 2019):

Table 1. Sample of IATA Airline Taxonomy codeset

Taxonomy ID	Parent ID	Name	Description
0000		Airline Taxonomy	
0064	0000	Flight	Any Product or Service related to a Flight

00C8	0064	Servicing	Any Product or Service related to Servicing of that Flight
012C	00C8	Change	Any Product or Service relating to Change Conditions
0190	00C8	Refund	Any Product or Service relating to Refund Conditions
01F4	0064	Entertainment	Any Product or Service related to Entertainment on board a Flight
0258	01F4	WI-FI	Any Product or Service which is transmitted through
02BC	01F4	Television	Any Product or Service which plays Video related Content

2.2 A Taxonomy of Innovation

A comprehensive Taxonomy of Innovation (Figure 3) was created by (Luma Institute, 2014). Thousands of tools and methods are available to help innovators discover what users want and how to deliver on their expectations. The challenge is to figure out which ones to use when. Luma Institute has created a framework to help you choose the best tool for each step of the innovation process, based on the people you're designing for and the complexity of the systems in which you operate.

(Luma Institute, 2014) distilled the portfolio down to 36 of the most effective tools for innovation - the majority of them in common use - organized in three categories: looking, understanding, and making. Each category contains three subcategories, and each subcategory contains four innovation tools. This hierarchical model makes it much easier to identify the tools you need and then put them to use.

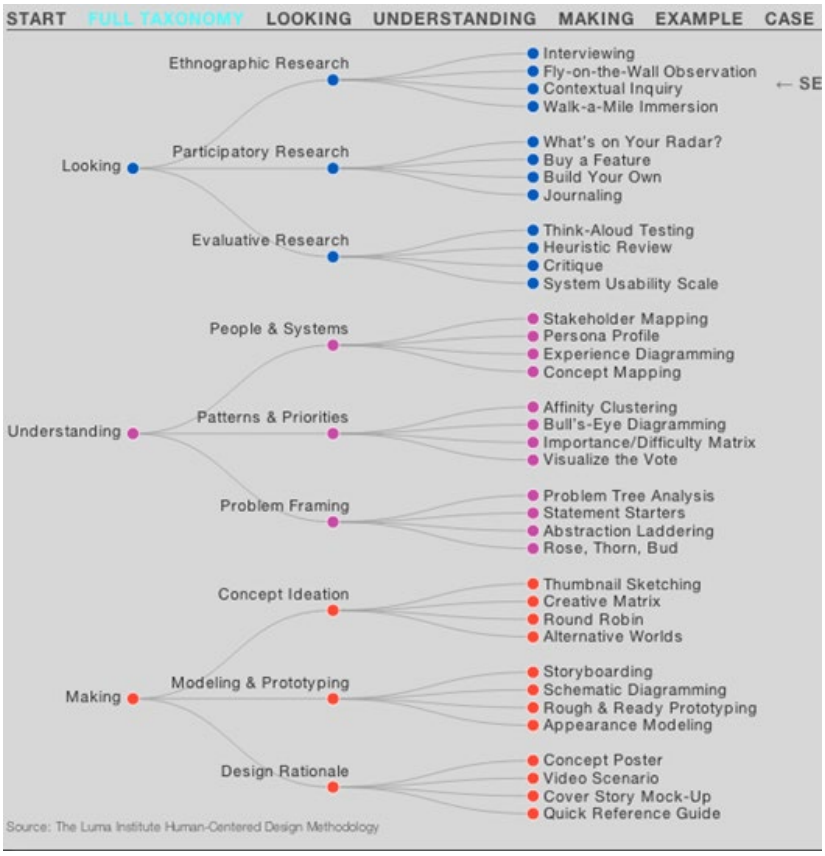

Figure 3. Taxonomy of Innovation by (Luma Institute, 2014)

Both above mentioned taxonomies seem to be ready inclusion of for new elements. (Nickerson, 2013) stated that a useful taxonomy should allow for inclusion of additional dimensions and new characteristics within a dimension when new types of objects appear. A taxonomy that is not extendible may soon become obsolete. Value Proposition Taxonomy allows extensions at every dimension level. As an example, the concepts of affordability, comfort, eco-friendliness, health & safety, and flight can be viewed as not sufficient enough applying for cargo flights or companies offering technical maintenance for private jets. Classes of technical maintenance or cargo handling can be included without loss of general idea of the Value Proposition Taxonomy.

2.3 Value Proposition

A rich theoretical and empirical literature can be applied to the question on how to identify Value Proposition in start-ups texts. As the current research focuses on linguistic patterns of start-ups landing pages, the authors reviewed theoretical and empirical

literature on specific online text features, textual value proposition methods, value proposition comprehension by consumers of different level of expertise.

(Lanning and Michaels, 1988) first used the expression "value proposition" (VP) in a 1988 work document for the consulting company "McKinsey and Co". In the article, which was entitled "Delivering value to customers", the authors define value proposition as "a clear, simple statement of the benefits, both tangible and intangible, that the company will provide, along with the approximate price it will charge each customer segment for those benefits".

(Almquist, 2016) suggested a strategy based on a differentiated customer value proposition. A suggested set of value was called Elements of Value. Elements of Value (Figure 4) where categories are based on the classic Maslow's Hierarchy of Needs.

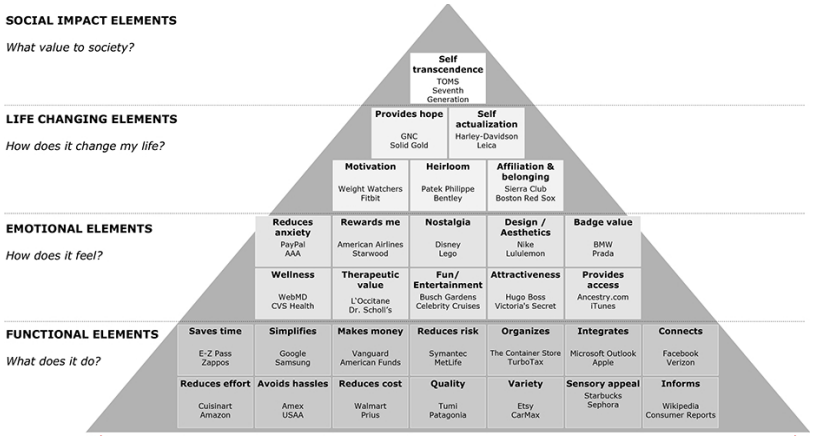

Fig. 4. Heuristic model of value with examples of companies exhibiting elements of value (Almquist, 2016)

There are comparatively few researches on analyzing value propositions in online startups. (Su-C Li, 2007) argues that a properly constructed value proposition is essential to the value creation process in e-business, and value co-production is the building blocks for value protection mechanism in network economy.

(Äyväri, Anne, and Jyrämä, 2017) provide a conceptual analysis on value proposition tools to be used in future empirical research and in building managerial insight. The conceptual analysis focuses on a living lab framework and recent theoretical developments around the concept of value that are reflected in the context of three managerial tools for creating value propositions. Among findings in the context of the living labs approach, the Value Proposition Builder seems to conflict with the ideas and premises of user-centric innovation processes (Äyväri, Anne, and Jyrämä, 2017). (Guo, Hai, Jun Yang, and Jiaping, 2019) examined the fit between value proposition innovation and technological innovation (exploitative vs explorative) for the performance of start-ups in the digital environment. They based their research on on-site survey data of 285 digital

start-ups in one of the world's largest digital economies and found that explorative innovation strengthens the positive impact of value proposition innovation on the performance of start-ups, but exploitative innovation weakens this positive effect (Guo, Hai, Jun Yang, and Jiaping, 2019).

3 Research design

For internal value study, authors showed the possibility to improve value adoption via training via the following steps: (1) baseline values, (2) wide variety of values identification, (3) values adoption. Baseline was established via a pre-survey where participants were asked to list as many values as possible (in the context of air transportation). For value identification, authors designed an exercise where participants were tasked with identifying wide variety of values (100+) by looking at 1,000+ startups' landing pages (startups are frequently the first to identify novel values). Finally, to evaluate how well participants were able to adopt the values that they were exposed to (the previous step) as well as improve their creative thinking (values that they haven't been exposed to), authors conducted a post-survey.

The last step was interviews with 20 participants. They discussed the learning outcomes and the impact of COVID-19 pandemic on their answers.

3.1 Participants

In order to collect generalizable observations on air transportation value proposition, we recruited 100 students from transport university with a connected, but still diverse range of majors and/or professional roles in a transportation field: Aviation Management, IT, Logistics.

All participants were between 20-42 years of age. Many participants had multiple years of experience in different types of professional roles, including 13 aviation mechanics (1-15 years), 14 middle level managers (1-5 years), 21 programmers (1-5 years), 16 administrators (1-7 years), and others. Most participants were not aviation management experts - 65 reported that they had never heard of Value Proposition before, but never built a model, 35 reported that they had taken some classes about marketing and management with value proposition as a study material. No one reported being an expert in the field of air transportation marketing or management.

Three industry experts from the top air transportation organizations' management were introduced with the research results and interviewed: two commercial directors of international airports and one IT director of an international airline.

3.2 Procedure

There were four stages of the procedure:

1.Pre-Survey

2. Trainings

3. Post-Survey + interviews

4. Taxonomy construction

A total of 800 different start-ups in the field of air transportation were chosen, their landing pages consist the research base for analysis on Value Proposition. 100 participants - IT, Aviation, and Management undergraduate and graduate students – were involved in a preliminary survey, post-survey, training and post-training annotation of start-ups' landing pages. A separate webpage was created for conducting surveys, two-level training and annotation process. The quality of annotation was re-assessed by industry experts.

The aim of a preliminary survey is to understand the level of expertise for non-trained participants and to determine value proposition volume and structure before the education process. The students were told about the basic concept of value proposition. Also, they were given some examples of Value Proposition such as typical ones: affordability, quality, speed; less typical: eco-friendliness. After that they were asked to list as many values as they can, that are provided by the Air Transportation start-ups and companies.

After the participants are told the start-up concept, they learned existing Value proposition major theories. After that they were offered two trainings. Training 1 shows five relatively simple examples of how to determine VP on start-ups landing pages. Training 2 presents five landing pages where the VL cannot be easily identified due to its vague expression or the creators of the webpage use non-standard ways to promote their start-up, e.g. video or non-trivial words.

The participants have options to identify a landing page as not a start-up, can state that the value is very difficult to identify, and can name the page as not from the air transportation industry. Also, they are asked to click a Like button if they think this start-up clearly deliver the VP.

Categories are not collapsed by excluding partial synonyms as to preserve semantic difference might be important for marketers and customer service.

15 interviews were conducted online on a Moodle chat platform, 5 respondents were interviewed face-to-face.

4 Results

We modelled the taxonomy as a tree diagram. A term in the taxonomy is either an object term (e.g., seat), or an attitude term (e.g., friendly), or an approach term (e.g., no child on board, save time). Taxonomy groups of all levels contain all types of terms and are united by the same concept.

Differentiating object terms from approach or attitude terms is natural in our taxonomy and does not influence on the concepts.

Taxonomic classes, divisions, subdivisions, and categories (Figure 5) were developed from the 241 values describing activities, procedures, objects, emotional experience and considering the context in which they could be possibly associated with in air transportation.

By analyzing the terms and the context, five taxonomic classes, one subclass, three divisions, and eighteen categories have been developed. Each of the 241 lowest level terms fits into at least one taxonomic group. However, many of them belong into more than one taxonomic group. Categories are not mutually exclusive.

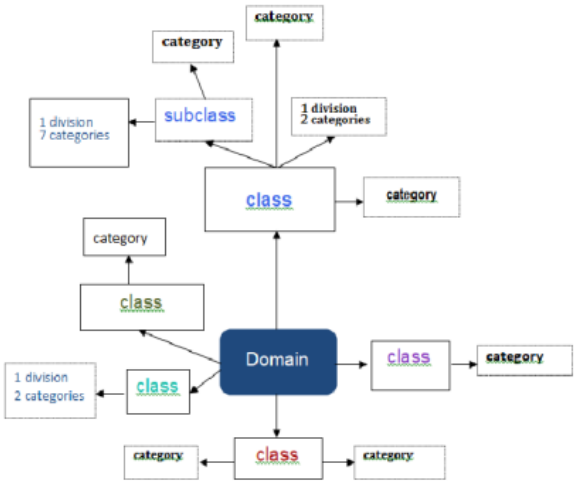

Figure 5. Taxonomy grouping

Every group and each term present a number of people that name this value / group of values. The most frequent terms are:

- speed 71
- safety 60
- comfort 53

The weight of each group is a sum of its components. The biggest group is Service with 356 and the smallest one is Ecology with 31.

Terms that could belong to several classes are noted with a bullet of a corresponding class' color.

5 Discussion

Primary purpose of companies is to create value; in aviation traditional dominant values are price, quality, and speed (IATA Passenger Survey, 2019). Taxonomies usage and help and the degree it can be useful for industry and analysts is a subject of a special discussion.

5.1 IATA and Value Proposition taxonomies

There is an overlap with IATA taxonomy: categories are partially overlapping, but terms are different. This can facilitate industry implementation, as categories are quite familiar from previous taxonomies. So, requires less department coordination.

Table 2. Number of categories in IATA taxonomy and Value Proposition (VP) taxonomy

IATA Taxonomy		**VP Taxonomy**		**IATA Taxonomy**	**VP Taxonomy**
1st level categories				2nd level cat.	2-4th level cat.
Ground		Service		Meal	Comfort
Journey				Beverage	Pax Environment
Flight		Affordability		Medical Equipment	Mobility
Airport				Escort	Ease of Use
		Flight		Loyalty	Flexibility
				Upgrades	Functionality
		Ecology		Charity	Restrictions
				Purchases	Necessary Things
		Health&Safety		Cabin Baggage	Communication
				Checked Baggage	Attitude
				Seat	Approach
				Assistance	Special Treat
				Lounge	Entertainment&Pleasure
				Terminal	Gaming&Multimedia
				Check In	Interior
				Boarding	Aircraft
				Security	Directions
				Medical	Health
				Escort	Safety
				Transport	
				Parking	
				Accommodation	
				Insurance	
				Visa Services	
				Book and Hold	
Total:	**4**	**5**	**5**	**26**	**19**

Authors aim at developing VP taxonomy with the following important differentiations: customer-centric bottom up development via customer questionnaires and interviews (vs top down approach of IATA where taxonomy was created by a governing body), focusing

on innovation and value (vs operational focus of IATA of standardizing the descriptions and contexts of products and services of multiple providers). Authors show that VP taxonomy is conductive to identifying novel innovation opportunities, which could then be integrated into existing operations by being aligned with the IATA's taxonomy.

Some of our classificatory categories and practices though they may appear inevitable are actually contingent and relative to the practice of classification in the context of social institutions and norms (Hacking, 1999). As an example, the category of entertainment during air travel seems to be constructed by marketers, however, according to (Hacking, 1999), some constructed categories reflect real divisions, and so we need not be constructivists in the strong sense. There is still room to distinguish between constructed kinds that reflect real categories and those that do not. Human beings start to present extra worries when evaluating the naturalness of their human kinds. That way there is a place for a question if the value, for example, of eco-friendliness is a human kind or a natural kind from the given world. And if it is possible to educate consumers to feel the necessity of proposed values.

Kinds in the social sciences, such as economics or sociology, are problematic, since the changing norms and practices of individuals and societies may also be held to be constitutive factors in kind membership, and these norms and practices may themselves respond to our classification of people into kinds (Stanford Encyclopedia of Philosophy, 2017).

Evaluation of taxonomy's utility is difficult, since there isn't a recognized sdandart criteria. However, (Wiegmann and Shappell, 2005) have suggested that for an error check framework to be successful it should be able to satisfy the following main requirements or product criteria among others:

Comprehensiveness For any given taxonomy it is important to consider whether the framework is able to cover all of the relevant variables that it purports to cover. In the current context this means that it should cover all the relevant categories related to the individual error event and its surrounding context. It also important that the framework is able to analyse both normal and abnormal situations since important lessons about error management might be obtained by not only focusing on critical events, but also normal everyday events where most errors are prevented from developing into serious consequences (Helmreich et al., 2001; Maurino, 1999). Even though it is important that the framework is able to capture all relevant categories it is at the same time also important to avoid irrelevant categories (Wiegmann & Shappell, 2002). The proposed Value Proposition Taxonomy was revised by industry experts to align researchers' categorization skills with practitioners' expertise.

Contextual factors. Since errors and their capture do not happen in a vacuum but in the interaction between people and the general work environment – including the technological, psychosocial and organisational context – it is critical that the framework is able to capture the dominant characteristics of the context that affects performance. The

proposed Taxonomy offers some terms to belong to different groups considering the potential context.

5.2 Business aspects

Improving variety of business aspects e.g. operations and innovation are often accomplished via systematization that taxonomies provide. There are a number of activities air transportation management and industry analysts can take to think about the Value Proposition Taxonomy:

• **Define – define and** clarify what value proposition is being offered to customers. Also, which elements are less visible to customers but essential for delivering products and services.

• **Structure –** logically structure the elements within organization and its procedures. For example, which elements are common for many products but not specifically visible to purchase by customers.

• **Responsibility –** consider what department is in charge with various elements across the organization – Product Management, Technology, Operations, Support, Services, Technical Sales Support, etc.

• **Promotion –** use the taxonomy as the basis for product proposition, i.e. the definitive source of what can be valued by customers.

• **Education and Communication –** communicate across the company to make key professionals aware of customers' expectations from the industry. This helps to create a consistent understanding of the business.

5.3 COVID-19 impact

Comparing results from pre/post survey gave authors a unique opportunity to see how the external factor (COVID-19) influenced the value adoption. Surprisingly, the results show that recent dramatic change in circumstances (COVID-19) has little affected the participants' general idea on value proposition in air transportation; in particular health value was not explicitly mentioned (8 terms were named) and seems to have been simply accepted as a "new reality". The hypothesis is that it is due to overly positive view (such as happened after WWII - baby boomers; art, style, and culture dramatic liberalization). However, the sampling is biased to participants that closely related to transportation area as well as age (millennials); this might not generalize to wider population and e.g. the overly negative reaction might be possible as was the case after WWI (Lost Generation, Dadaism).

5.4 Industry Experts on taxonomies

Three air transportation industry experts of a high level of expertise were asked to compare our Value Proposition taxonomy with IATA Airline taxonomy. They also shared

their ideas about the way taxonomies can be useful for industry and COVID-19 surprisingly little significance from respondents in April, 2020.

IATA and Value Proposition taxonomies difference. Value Proposition taxonomy focuses on innovative values, reflects consumers' requests for new technologies and attributes like speed, super-sonic, unmanned. IATA taxonomy is more conservative. Also, IATA AT offers top down approach where taxonomy was created by a governing body and reflects the aviation industry ideas on products and services, while Value Proposition is created using bottom driven approach asking what consumers' wants and needs are.

COVID-19 and consumers' expectations. Experts admit that the inertia plays a great role in such conservative industries as air transportation. Consumers may still not realize their expectations for health issues. Also, little attention towards COVID-10 could be due to the well-known fact that in a pandemic, all industry participants (airports, airlines, handling companies, etc.) give priority attention to the safety issues for the health of passengers and employees; therefore, by all passengers / clients (including respondents), this is already taken for granted (the must) and is no longer perceived as a value (added value).

Benefits for the industry. These taxonomies are extremely useful for the following purposes: to understand the essence and systematization of services / services, to formulate KPIs by directions, to distribute areas of responsibility between all the links in the value chain. Also, the unexpected finds and formulations of values that were not previously in sight are of great interest for marketers. Good perspective can be seen in using VP taxonomy in Project Management.

6 Conclusion

There already exist different classification systems that could be of relevance in relation to developing a Value Proposition taxonomy. Even though there are some variations in the structure of the main groups and the level of detail in the individual frameworks their overall structure is fairly similar, but the Value Proposition taxonomy is the only one that has been extensively validated and that has been directly aimed at Value Proposition in Air Transportation. It is also characterised by the fact of having been derived in the time of substantial external change of circumstances. Widening values is being considered as one of the main purposes for constructing Value Proposition taxonomy.

Ability to operationalize rapid identification and adoption of new values allows corporations not only to improve profitability; but even to become resilient to unexpected external factors that suddenly impose new values.

Acknowledgements

Authors are very grateful for the insights and comments given by the Aviation Industry experts:

Vjacheslav Cheglatonev, Commercial Director of Odessa Airport (Ukraine)

Aleksej Ogorodnikov, IT Director of Smartlynx Airlines (Latvia)

Arturs Saveljevs, Board Member and Commercial Director of Riga International Airport (Latvia)

Assistance provided by students of Transport and Telecommunication Institute (Latvia) is greatly appreciated.

Abstract

The current paper is dedicated to analysis of the ICTs as an important educational tool through gender perspective. Nexus between Gender, Education and ICT is explored. Comparative analysis of situation in Moldova and EU countries in the ICT and education through gender lens is provided.
ICTs were recognized as tools through which gender equality and women's empowerment can be advanced in many ways (Intel, 2014). Therefore, the gender ICT gap is valid globally, including in Europe, in Moldova (P8_TA(2016)0204*;* NBS, 2019a).
Women are significantly under-represented in ICT, accounting for only 3% of ICT graduates globally. In Europe, only 29 out of 1,000 female graduates have a degree in computing in 2015, and only four went on to have ICT careers (European Union, 2013).
In the Republic of Moldova, women and girls occupy only 31% of jobs in the ICT sector and only 19% of digital professions. Only 4.6% of the girls studying in higher education choose STEM as their study profile. As a result, women get jobs with a lower level of qualification and, respectively, of remuneration in this sector (NBS, 2019a).

Several publications analyse the impact of ICT on girls and boys education, gender differences in ICT use in the school, women's access in ICT sector etc. At the same, there are few studies regarding the ICT use in architecture education through gender lens. This paper aims to present some of the recent research's findings on gender and ICT and education (based on architecture education in Moldova). The novelty of the research – for the first time the interlinkage between ICT use in the architecture education and gender are clarified.
Based on countries' comparative analysis and focus group with architecture female and male students we note the similarities and differences on ICT use and ICT perceptions. The research found that there is a significant association between the levels of education and skills of use of computers and gender. At the same time, the importance of "gender friendly" environment in educational institutions was identified as important condition to maintain female students in the system.
The recommendations how to explore ICT in education sector in gender sensitive ways are proposed.

Keywords – ICT, gender, education, architecture, development

Paper type – Academic Research Paper

1 Introduction

The importance of access to Information and Communication Technologies (ICTs) in order to ensure full participation of all people in new opportunities related to employment, education, health, governance and other sectors is recognised by several international documents (United Nations, 2015; P8_TA(2016)0204).

It has been shown in different sources that women's active participation in the ICT sector is essential for long-term growth and economic sustainability (European Union, 2013) of any country. The importance of ICT for gender equality is acknowledged in SDG target 5.b "Enhance the use of enabling technology, in particular information and communications technology, to promote the empowerment of women" (United Nations, 2015).

We would like to mention the increasing number of researches dedicated to interlinkages between gender and ICT. While some progress has been made in increasing the number of women in top jobs in business and in narrowing the gender pay gap, major challenges remain. Therefore, the gender ICT gap is valid globally, including in Europe, in Moldova (confirmed by evidences provided in many studies (European Union, 2013; NBS, 2019a; UNESCO, 2017).

At the same time, education is essential for the training of women and men with the necessary competencies (including digital competency) to enter the labour market, to face the challenges in regards a competitive economy.

Despite of increased number of international documents and researches in ICT and gender, there are several arguments in favour to continuously explore the subjects.

First, due to the increasing importance of ICT in the society and in daily life in the context of the information era, exploration of different dimensions such as gender, age,

education, inclusiveness and other is needed to ensure equal opportunities for all to benefit of ICTs.

Furthermore, taking into account disruption of the educational process (classes have been ceased) due to the COVID-19 epidemic and the fact that distance learning allows students to continue the study process, the forming/strengthen skills to use ICTs is strongly needed.

Information and communications technology sector (ICT) is one of the most important sectors of the economy of the Republic of Moldova (contributes annually at the formation of GDP by about 11-12%) (NBS, 2019a). Considering the demographic prevalence of women in the country, but also the higher share among persons with higher education, women need to fully participate in all spheres of society and economic development, from execution phases to decision-making level. At the same time, in the context of dynamic socio-economic transformations, the formation of digital competences is necessary, to contribute ICT-related productivity growth and development. Thus, ICT can be both a goal and a tool for increasing participation of women in society and in the workforce (especially ICT-connected sectors).

The publication aims to contribute to debates on interconnections between Gender and ICT, with special focus on Education at regional and national level. More specifically, the objectives are as follows: 1) analyse ICTs and Education through gender lens (comparing Moldova and the EU regional context); 2) establish interconnection between ICT and architecture education and gender; 3) explore the perceptions of architecture students on ICT use and identify recommendations to engendering architecture education.

As **Methodology**, desk review of documents and researches; gender analysis of statistics and materials were used to identify nexus between ICTs, education and gender. Also, two focus groups with participation of 16 females and 16 male students from the upper years from Technical University of Moldova were organized in order to explore the youth's perceptions on ICT in architectural education through gender lens.

The following hypotheses were formulated and tested based on desk analysis and focus groups:

- There is an association between the level of education and use of computers and the gender of the students.
- There are similarities and differences in female and male students' perceptions of ICT in architecture education.

Thus, the research questions are the following:

- What is nexus between Gender, ICT and Education?
- What is the specificity of Moldovan experience in the EU regional context?
- What are the perceptions of girls and boys about ICT in architecture education?

The first paragraph includes introduction information about the importance of ICT and Gender and Education based on international documents, arguments in favour of theme,

methodology of current research. The second paragraph presents nexus between ICT, education and gender, based on comparative analysis of situation in Moldova and the EU regional context. The third paragraph provides an overview on interconnection between ICT and architecture education and gender. The perceptions of female and male students about ICT in architectural education are presented. The final paragraph includes conclusions and a set of key recommendations.

2 Nexus between ICTs and Gender and Education

Education is recognised as an indispensable part of the development process. The importance of education has been widely recognised in the process of forming necessary competencies to enter the labour market, in a competitive economy and social transformations. We note that competence in the fundamental basic skills of language, literacy, numeracy and in ICT (digital competency) is an essential foundation for learning (2006/962/EC).

At the same time, Gender equality is inextricably linked to the right to education for all, that ensures that girls and boys, women and men not only gain access to complete education cycles, but are empowered equally in and through education (Education 2030, 2016). In such a prospect, we reiterate the fact that ICT is recognised as an important tool to women and girls' empowerment (Intel, 2014), giving them access to knowledge about importance of multifunctional gender roles (productive, reproductive and community roles), as well as forming skills how better to apply the knowledge in professional and personal development.

Based on mentioned and other documents, the nexus between Education and ICT and Gender is clearly outlined. However, the subject should be analysed taking into consideration several factors such as: countries' socio-economic context, cultural norms, access to ICTs, family's impact on education and career strategies, opportunities for education and job in ICTs-relating sectors and others.

Researches on ICT, gender and education identifies gender differences in several fields, like learners' performances, attitudes towards computers and skills as well as the impact of teachers, parents and peers (UNESCO, 2017; Intel, 2014; Becta, 2008 etc.).

The differences between women/girls and men/boys in terms of time consumption, frequency and patterns of use of ICT have often been used as possible explanations for why girls do not choose education in computing nor become ICT professionals (Ferreira, 2017; Cristei, 2017 etc.). As consequence, much of the focus has been on what kind of efforts that have to be taken into action to help girls reach the same level as boys within the field of ICT (Tømte, 2008).

Some aspects related to connection between education, gender and ICT are explored in Moldova: PISA 2018 results through gender perspective (MECC/ANSA, 2019); gender differences based on PISA 2015 (Cristei, 2017); education in ICT through gender perspective (NBS, 2019a).

In this regard, it is crucial to highlight the gender gap in the field of education for several reasons. First, persistence of gender stereotypes conducts to visible gender segregation of high education and career's choice. For example, in the Nordic countries girls are, on average, attaining higher marks than boys in all subjects, except physical education; in addition, girls are approaching 60% of university student population (Tømte, 2008). Research and reports also indicate that boys experience more problems in school, drop out of school to a higher degree than girls, and this appears to be a problem in many countries (Becta, 2008; Tømte, 2008; UNESCO, 2017 etc.).

In Moldova we note the similar situation: on average, girls are attaining higher marks than boys in majority of subjects, girls are approaching 56% of university students and 65% of Master Degree students; the rate of drop out of education system for persons aged 18-24 years constitutes 21.0% of men as compared to 17.6% of women (NBS, 2019b).

PISA 2018 suggests that amongst the 15-year-olds assessed by PISA, only 1% of girls reported that they want to work in ICT-related occupations, compared with 8% of boys who so reported, on average across OECD countries. In Bulgaria, Estonia, Lithuania, Poland, Serbia and Ukraine, more than 15% of boys reported that they expect to work in an ICT-related profession; but in no PISA-participating country or economy did more than 3% of girls so report. It seems even when they excel in mathematics or science in PISA, boys and girls have very different expectations for their future occupation. More than one in four boys reported than they expect to work as an engineer or science professional when they are 30 years old, but fewer than one in six girls so reported. Almost one in three high-performing girls, but only one in eight boys with the same proficiency reported that they expect to work as health professionals (OECD, 2019a).

PISA 2015 also found that boys spend more time playing video games and less time doing homework than girls. While excessive video gaming is shown to be a drag on student performance, a moderate amount of video gaming is related to boys' better performance in digital reading than in print reading (although boys still lag behind girls in both types of reading) (OECD, 2019b). Thus, the parents should know how to discuss with children to combine homework and playing video games, in order to offer more opportunity for learning-oriented and career strategies.

In fact, Moldova faces the same situation. Data shows some differences between girls' and boys' performance in PISA 2018 in the Republic of Moldova (table).

Table. Girls' and boys' performance in PISA 2009-2018 in the Republic of Moldova (points) (MECC/ANSA, 2019)

Discipline /year	**2009**		**2015**		**2018**	
	Boys	Girls	Boys	Girls	Boys	Girls
Reading	366	411	390	442	404	445
Mathematics	399	396	419	421	420	422
Sciences	406	420	425	431	423	434

Thus, it is attested that during the period 2009 - 2018 in the Republic of Moldova the differences in performances of girls and boys in mathematics have not changed significantly (3 points difference in favour of boys in PISA 2009; 2 points in favour of girls in PISA 2015 and in PISA 2018). Similarly, girls, on average, accumulate higher scores than boys in science.

PISA 2018 emphasize that girls perform better than boys in all three areas. The biggest difference between the performances of girls and boys is attested to reading / reading (41 points difference). On average across OECD countries in 2018, girls outperformed boys in science by two score points. In Albania, Bulgaria, Finland, Georgia, Greece, Israel, Malta, the Republic of Moldova, North Macedonia, Norway and Thailand, the gender gap in science performance, in favour of girls, ranged from 10 to 24 score points (OECD, 2019a).

On the other hand, boys and girls in Moldova record about the same performances (difference of 2 points in favour of girls) in mathematics, and in OECD countries boys accumulate 4 points more than girls.

A few initiatives in this respect would be mentioned: GirlsGoIT (a national program that provides access, education and promotion for girls in technology), Cariera IT, Generatia Z, events dedicated to start-ups and local innovation hubs, etc. As result of GirlsGoIT, during 2015-2018: from total trained 544 girls 132 (24,26%) pursuing STEM studies at Technical University (GirlsGoIT, 2018). All mentioned non-formal initiatives are great, but with limited possibility to cover the entire country.

In the last years, in the context of international commitments, Moldova adopted The National Strategy "Digital Moldova 2020", that includes strategic education directions, such as the Digital Education Program "Digital Skills for All". Also, Educational standards of digital skills and Methodology for assessing the digital competences of students in general education were elaborated. Several courses to improve teachers' digital skills were organised. Despite of positive measures in the ICT education field, an insufficiency of ICT skills and a low level of digital literacy are noticed (MEI, 2020).

One of the major problems in Moldova and at international level is the decline in the number of young people, especially women, who study science, engineering and technology. Within the female student population in higher education globally, only around 30% choose STEM (Science, Technologies, Engineering and Mathematics) related fields of study. Differences are observed by disciplines.

Female students' enrolment is particularly low in ICT (3%), natural science, mathematics and statistics (5%) and engineering, manufacturing and construction (8%); the highest is in health and welfare (15%) studies (UNESCO, 2017).

In Moldova, the probability that the graduating girls would choose a job in the field of science and engineering is 5 times smaller, and that they would choose a job in the field of IT - 10 times smaller. Women are more represented in higher education, but under-represented in the scientific and technical education. Women who graduate from higher

education are more numerous, but those who graduate from scientific and technical education are far fewer (NBS, 2019a).

Based on data mentioned above, we conclude many similar aspects regarding gender differences and similarities in the education system in Republic of Moldova and regional European context.

3 Interconnection between ICT and architecture education and gender

International documents and reports, researches clearly emphasized the enormous demand for the informatics people (P8_TA(2016)0204; Education 2030, 2016 etc.). As mentioned above, several publications analysed the impact of ICT on girls and boys education, gender differences in ICT use in the school, women's access in ICT sector etc.

However, most research explored the view that the girls are falling behind the boys, when it comes to ICT; in terms of perceptions/attitudes, self-attainment, ICTs' use models and so on. Thus, the gender differences support has been based on this claim.

The influence of peers, parents, teachers and the media, based on gender stereotypes, were noted as major factors affecting girls' confidence, self-efficacy and attitudes towards ICT in different countries, including Moldova (Becta, 2008; Ferreira, 2017; Cristei, 2017). Gender stereotypes begin at an early age with parents, based on cultural norms/traditions, and are reinforced by peers, the media/social media and, in some instances, by teachers at different education level. One of the strong idea refers to that ICT is the boys' domain due to the relation with games and programming. Thus, at school level there are visible differences between boys' and girls' ICT use and ICT perceptions.

In this regard, it is important to stress attention on the fact that gender should be analysed not as separate category but in combination with number of factors – socio-economic status, age, ethnicity, identity, family, education (including management) and labour market – which can influence how boys and girls use technology and the impact that use has on them. The mentioned factors can contribute to the perpetuation or reduction of gender stereotypes. For example, ideas such as technology is engaging and appealing to all boys affect girls' ICT use. Promoting successful female models in ICT-related business can encourage more girls to use ICT.

At the same time, in the context of social development digitalization, the problem lies not so much in the education of pure computer scientists, but especially of the people of various disciplines who are better educated in the field of informatics.

Thus, if schools through ICT education aim to provide children with tools for personal development and career guidance, universities through informatics education contribute to the professionalization of students. That's why the universities should pay special attention to the ICT education of students and teachers.

In this regard, this paper aims to present some of the recent focus groups discussions' findings on gender and ICT and education (based on architecture education).

We note some researches dedicated to role of ICT in Architecture Education (Sariyildiz and van der Veer, 2000; Gushchin & Divakova, 2016 etc.).

Some authors refer to gender issues in architecture education (Kurjenoja, 2013), to feminine paradigm (Niculae, 2012; Reisinger & Schalk, 2017 etc.). Specifically, referring to architectural practice or architectural education, women's lack of visibility is recognised as an important issue that reveals the fact that architecture is still defined by a masculine paradigm (Niculae, 2012).

In Moldova, despite of increased percentage of female graduates of higher architectural education for the last few years – to around 50%, is not yet equivalent to the number of women enrolled in the national Union of Architects. For example, in Moldova out of 227 members of the Union of Architects only 37 are women (16.29%).

According to Dubeissy (2020), the macho culture dominating architecture uproots from the architectural education, continues to practice and leadership. Education can contribute to diminishing male dominance by capitalizing of new learning strategies.

The above ideas were the landmarks for exploring the interlinkages between ICT and Architectural Education and Gender, based on Moldova case.

Taking into consideration the increasing number of women in architectural education, the perceptions of female and male students from the upper years of ICT in architectural education were analysed. Based on focus group discussions, we conclude the following results.

Today indisputable architectural practice is closely connecting with ICT. At the same time, gender perspective of ICT use in architectural education remains as important issue.

Due to multi-sectorial connection of architectural education, female and male students use computers as a tool mainly for following purposes such as: information processing tool, knowledge integration and knowledge transfer tool, communication tool, planning tool, architectural design process tool etc. The mentioned categories of computer use have the purpose of improving quality and efficiency of the students' competences as architects. From students' perspective the computers are not only a tool for the architects but more than that, computers and Internet are becoming a life style and medium of personal and professional development.

The findings of the study found that all students – female and male - use computers for their academic purposes. All students confirmed a positive attitude towards the use of ICT. Both women and men mentioned the significant impact of computers and Internet on their academic performance.

Female and male students use at large the different tools such AutoCAD, Revit, 3ds Max and other. Similar tasks by complexity, working in mixed teams together, girls and boys, can contribute to the development of career-related competences of both genders. We note that career-related competences refer to the knowledge and skills required to operate specialized hardware/software for a particular field (UNESCO, 2018), specifically in architecture. In this regards, there are no significant gender differences in ICT use for learning tasks focused on career-related competences.

At the same time, students' opinions were divided with reference to ICT skills. Thus, most boys, recognizing the good digital skills of girls, are in a position that men are better

at ICT. In fact, male students reproduced stereotypes of how women and men interact with technologies. Most girls consider that they have digital skills no weaker than boys, only that their interests are sometimes different. Thus, out of the courses, male students acknowledged that they more often download software related to cars, ICT equipment, various applications with games. Girls more often use ICT in terms of communication, training, health services, fashion, entertainment, etc.

Also, based on findings of others researches (Becta, 2008; Tømte, 2008) the interlinkage between the ICT use and self-confidence, quality of life was explored.

A few of students opined that the use of computers has improved their overall quality of life: more male students compared to female students. The answers were based on students' involvement in the workforce (part-time).

At the same time, a majority of female students and only some male students reported that the use of computers and Internet has made an impact in developing self-confidence.

The students also mentioned that the use of ICT has enhanced student-teacher interaction (a majority of female and few male students). It is interesting that boys come from school to university with skills to use ICT more developed compared to girls. Thus, they are sometimes more self-confident and underestimate the role of university teachers in training on the use of ICT in disciplines related to architecture. And girls need to work harder to fill the gaps in ICT work. Moreover, female students recognised that due to the persistence of gender stereotypes regarding girls and technology in the society, sometime the education environment press it – they need more efforts to demonstrate good skills in ICT use; the education environment the is not gender friendly.

In this respect, the role of teachers at the initial stage is crucial in motivating and mobilizing female and male students to study and use ICT on equal base. The accomplishment of the learning tasks in mixed groups of girls - boys, oriented towards the formation of the professional competences based on the use of the ICT from the 1st year of the faculty - is an important precondition of equal opportunities for professionalization of female and male students. Moreover, this methodology, leading to the narrowing of the gap between girls and boys regarding the use of ICT, must be extended to other educational fields. ICT can motivate both boys and girls to explore better knowledge and skills in architecture and not only. Thus, for long terms impact – this practice can contribute to women's better career opportunities and wellbeing. It is a real tool to contribute to gender transformative approach - approaching girls not as 'victims' of gender stereotypes but as active actors within educational system and the whole society.

We note that all students learned to use computers in architectural design process with the help of university teachers. This clearly indicates the role of university teachers on students' motivation to learn to use a computer and its specific applications. Thus, teachers can be mentioned as active agents for change. The success of using ICTs for educational purposes relies heavily on teachers' abilities to select, create and manage adequate digital resources in order to implement innovative and inclusive teaching

strategies in a specific context (Redecker, 2017). This idea was confirmed by strong necessity of online tools during the COVID-19 pandemic.

In the frame of focus groups, female and male students recognised the influence of a number of socio-economic, institutional, cultural, family, and last but not least, personal factors. With regard to the prioritization of factors, both female and male students highlighted the economic possibilities for purchasing computers and licensed programs, the impact of friends/peers and social networks, but especially employment/ career opportunities.

4 Conclusions

In the last years, the several documents and literature have largely stressed the importance of ICT in education of boys/men and girls/women. At the same time, the research area should be extended and cover the subject of ICT use through gender lens at different levels and types of education.

The current research found that there is a significant association between the levels of education and skills of use of computers and gender. If in the case of schools there are gender differences in the use of ICT, these differences become insignificant in the case of architectural education due to the involvement of female and male students on equal base in the career-related competences tasks. Thus, from gender transformative perspective female students in architecture can be as active agents for change.

At the same time, at individual level out of university tasks the differences are more visible. Despite of recognition of female students' skills to ICT use, male students often reproduced gender stereotypes. Research findings confirmed similarities and differences in female and male students' perceptions of ICT in architecture education, including impact on self-confidence, relation student-teacher and others.

The results confirmed the findings of some mentioned above studies on teachers' positive influence on the pupils' ICT behaviour. At the same time, the majority of training programs on ICT are focusing on school teachers. Therefore, university teachers should have access to different programs in order to strengthen skills on ICTs use in the frame of different disciplines. The relevance is high especially in the context of architectural education where men predominate, so women need more effort for professionalism.

The research' findings confirm that the experiences of using ICT through co-creation, collaboration on an equal basis between female and male students in accomplishing tasks related to career competencies, integration of ICT in all disciplines at school level ensuring connection and complexity at university level, can be beneficial for girls and boys, and in the long run - for the whole society.

At the same time, the emphasis must be on preventing and eliminating gender stereotypes in relation to ICT. Addressing the nexus between ITC and Education through gender equality perspective requires sufficient awareness and strong co-operation across stakeholders, promotion of best models of successful women in the Architecture, organisation of awareness-raising, training and gender-mainstreaming campaigns.

Abstract

The complexity brought by digitalization in operations is disrupting blue-collar and technical jobs, increasing levels of knowledge required to perform them. When workers such as electrical grid operators become "smart grid operators", the breadth of knowledge required to them increases. The shift from I-shaped to T-shaped profiles has been described by literature (e.g. Demirkan, 2015), and the need for a shift from T-shaped to Pi-shaped profiles, with a second "depth" of knowledge in data science, has been discussed for skilled jobs such as researchers (Faris et al., 2011). In this work we show how, with the advent of digitalization, also operational job profiles will need more depth in a second field of knowledge: not only domain knowledge, but also digital literacy. This study intends to explore the benefits of integrating IoT technologies in a Challenge-Based Learning approach to innovate Education and develop pieces of the new digital knowledge that will be required to operational jobs of the future. By means of an action research, we explored how the operational firm-specific knowledge needs of an electric distribution firm are evolving, and provided an off-the-job Challenge-Based training to two classes of students involved in its dual apprenticeship. Our findings show how such experiential learning activities based on IoT technologies can be fostered by concurrent dual apprenticeships, which act as the "concrete experience" phase of the experiential learning cycle (Kolb, 1984; Morris, 2019). Its two tacit phases, namely "experience" and "experimentation" (Raelin, 1998), were the two that benefited the most from complementing on-the-job and off-the-job training. Last, we disentangle the contributions of firm and the technical high school, and discuss how such structured collaboration can be effective in co-creating effective Challenge-Based activities. Further studies will be needed to explain in detail benefits and rationales of involving a university as off-the-job provider in such educational paradigm.

Keywords – Education in the Digital Age, Innovative Education, Experiential Learning, Challenge-Based Learning, Internet of Things.

Paper type – Academic Research Paper

1 Introduction

With a data-richer task environment enabled by technologies like the Internet of Things, drones, or database architectures for analytics and visualization, operational jobs are experiencing new needs in terms of knowledge. Blue-collars and other professional workers are in direct contact with such work environment, of which they accumulate on a daily basis domain and tacit knowledge through on-field experience, essential for a proper sense-making of data (Helper, 2018). Therefore, especially in high-involvement work environments, consulting them in any decision-making process related to maintenance and line management is becoming a common and needed practice. This is the case, for example, of electric grid workers, who have now to deal with the digitalization of the grid. With smart grids and remote control, their contribution will be vital to provide insights to engineers who control the grid from distance. Such change implies the need for an upskilling (Helper, 2009) and requires a new approach to education and new training models for these workers (Fuller, 2014). Experiential learning approaches such as Challenge-Based Learning (CBL), if based on emerging digital technologies such as the Internet of Things, represent a promising opportunity to train "off-the-job" the skills related to digitalization, and provide learners with the domain and digital knowledge required. However, notwithstanding such practices are diffused and wide adoption is reported among practitioners, scant literature has been published on them. In particular, to disentangle how such approaches can enable knowledge development, rigorous frameworks such as the experiential learning cycle of Kolb (1984) need to be used. Moreover, sound empirical evidences are needed to contribute to experiential learning theory. With this aim, the electrical sector – which is facing little automation but a heavy digital transformation through sensors – turns out to be the most convenient research setting to explore the use of IoT technologies as enablers of experiential learning.

This paper is structured as follows. In section 2, we provide a conceptual framework to introduce the new operational needs brought by digitalization and innovative teaching approaches which could help develop such knowledge. In section 3, the research setting and the action research phases which led to design an innovative education method, based on the exploitation of IoT technologies and a Challenge-Based Learning approach, are reported. Section 4 shows the findings related to the new operational needs and the four phases of the experiential learning cycle in the IoT-based CBL activity. In section 5, such findings are discussed: the importance of experiential learning in exploiting and generating knowledge, the contribution of each the actors involved, with a focus on the link between dual apprenticeships and Challenge-Based Learning activities. In the conclusion section we draw conclusions on the role of IoT and Challenge-Based Learning on developing new operational knowledge, whereas the disentanglement of the role of university in such off-the-job training is left to next steps for research.

2 Conceptual Framework

Drawing from labor, organization and education literatures, in this section we review the new needs of operational jobs in terms of knowledge, and the opportunities to develop it through technology-based innovative teaching methods.

2.1 The need for new operational knowledge in the digital era

The awareness of a greater need for knowledge and skills due to technology development and adoption has to do with the so-called "Skill-Biased Technological Change" theory, for which information technologies are believed to increase the demand for highly skilled workers (e.g. Violante, 2008). However – in contrast with this theory, more concerned about computerization and automation – with digitalization, all skill levels will be affected by such upskilling. Studies in Labor Relations and on high performance work organizations (e.g. Whitfield, 2000; Helper, 2009) show how the evolution towards high-involvement production systems is requiring a shift also for blue-collar workers and professionals. Therefore, in such organizations digital technologies are requiring an upskilling at all levels of educational attainment. Operational jobs will need basic knowledge on IoT architectures and databases, analytical and interpersonal skills, and an attitude towards long-life learning to deal with ever-evolving jobs.

However, "despite the emphasis on training, many organizations report a failure to effectively develop skills and anticipate future needs" (Grossman, 2011), and education struggles in keeping up with such increase in complexity (Cedefop, 2018). Training should produce "permanent cognitive and behavioral changes", and develop critical knowledge for job performance. Moreover, "the conditions of transfer include both the generalization of learned material to the job and the maintenance of trained skills over a period of time on the job" (Baldwin, 1988). This is why, in the current context of rapid change in digital technologies, companies are developing dual apprenticeship programs to better match their firm-specific needs while students are still acquiring general knowledge at school. This is achieved by parallelizing the generation of occupation-specific know-how and knowledge-based "know why" provided by schooling. However, this kind of occupation-specific training programs have been widely criticized. In Germany, for instance, they have been considered "unable to provide sufficient general knowledge to enable workers to adapt to technological progress" (Jacob, 2015).

2.2 Experiential Learning to leverage IoT in knowledge development

Such effect could be reduced by integrating on-the-job and off-the-job training, being the latter a way of providing a broader set of industry-specific competencies. The term "off-the-job training" dates back to 1950 (Fryer), referring to the development of a particular skill or piece of knowledge through a course, in a protected environment.

In this wake, two examples of trending off-the-job teaching methods, according to the need for process-oriented curricula and direct interaction with the real world of operational action (Gebhardt, 2015), are Problem-Based Learning and its evolution, namely Challenge-Based Learning. Problem-Based Learning (PBL) is a curricular active learning (Silberman, 1996) approach aimed at making learners face real-world problems on which apply and develop their competencies by integrating theory and practice to solve them (Savery, 1995). It promotes team work and collaboration (Duch, 2001), develops communication skills thanks to the final presentation of results (Hasanefendic, 2016), and enhance problem solving skills and interest in design and technology (Mettas and Constantinou, 2008). It allows to create interdisciplinary connection, and develop the attitude towards learning to learn (Allen, 1996). It also involves project-oriented research and interdisciplinary work, which makes it congenial to be carried out in a university environment. Trials of applications of Problem-Based Learning in the workplace proved to have potential in addressing long-standing firm problems (making it cost-effective), facilitating continuous learning and developing skills such as problem-solving and communication (O'Brien, 2019). Challenge-Based Learning (CBL) was ideated by Apple in 2008 to incorporate 21st-century skills into problem-based learning, with which it shares also all the above-mentioned effects. In CBL, students are required to "make something happen" through "solutions that are both credible and realistic in light of time and resources" (Johnson, 2009). Typically, they are asked to solve complex problems with technology finding concrete, real-world solutions, thus going beyond the "mere" critical thinking exercise proposed by PBL. Briefly, it consists of a process in which students identify a real-world problem, develop a set of activities to analyse it, and eventually propose an actionable solution, which is evaluated by the trainers (Nichols, 2008). In some cases, students are encouraged to publish their results.

Both of the described teaching methods use concrete experience and problem-solving as enablers of learning. Cohen and Levinthal (1990) argue that problem solving and learning capabilities are so similar that there is little reason to differentiate their modes of development, although exactly what is learned may differ: learning capabilities involve the development of the capacity to assimilate existing knowledge, while problem-solving skills represent a capacity to create new knowledge. According to them, the prior possession of relevant knowledge and skill is what gives rise to creativity, permitting the sorts of associations and linkages that may have never been considered before. Such constructive approach to absorptive capacity is related to prior studies of Piaget (1973), for which new knowledge has not just to be told to students, but rather has to be learned, rediscovered and placed by the students themselves into existing conceptual structures. Learning is not about behavioral outcomes, but a continuous process based on the experiences of the learner who resolves conflicts between opposing ways of dealing with the world (Kolb, 2005). These assumptions proceed from his experiential learning theory, first published by Kolb in 1984, for which learning occurs in a four-stages cycle: concrete experience, reflective observation, abstract conceptualization, and active experimentation.

Raelin (1998) goes further, synthetizing new findings on tacit knowledge to add a "work" dimension to Kolb's model. In his work-based model, the four phases of individual learning are categorized into theory vs practice and explicit vs tacit dimensions as follows: experience (practice, tacit), conceptualization (theory, explicit), experimentation (theory, tacit), and reflection (practice, explicit). Investigating what makes a "concrete experience", Morris (2019) recently proposed a revision to Kolb's experiential learning model, by adding an attribute to each phase: "contextually rich" concrete experience, "critical" reflective observation, "contextual-specific" abstract conceptualization, and "pragmatic" active experimentation. Being the IoT a relatively recent technology, its role in the experiential learning cycle to develop operational knowledge has still to be explored.

3 Research Methodology

The empirical setting of this study is a leading electric power distribution operator. With the advent of smart grids, the electricity sector is facing heavy digitalization; as a consequence, operational tasks like inspections, maintenance and use of the electrical grid can be conducted using IoT systems to monitor and control the grid. Such advances are posing the question for further upskilling and new operational knowledge. A pillar of this transformation is the use of dual apprenticeship schemes, where students in the last two years of vocational school are involved in workplace training with the firm. In 2018-2020, the dual apprenticeship to train its future smart grid operators is being carried out jointly with two vocational schools with a path in electronics and electrotechnics.

The selected methodology followed an action research cycle (Lewin, 1946), whose four main steps can be summarized in two macro-phases: phase 1 (reconnaissance stage) and phase 2 (planning, implementation and evaluation of the intervention). Phase 1 aimed at exploring the work-based knowledge needs of the firm. This involved delving into the current training practices by means of interviews and a focus group with operating unit managers and grid operators. Also the dual apprenticeship tutor on the school side was interviewed. Phase 2 involved the two classes participating in the dual program. Based on the findings of Phase 1, this phase involved planning, execution and evaluation of a one-week Challenge-Based IoT laboratory, co-designed with the contribution of the firm to complement "off-the-job" the ongoing workplace training. Apprentices were challenged to design IoT-based solutions to real problems of the grid on which they worked during their workplace training, and explore how IoT will change their task environment in relation to inspection and monitoring. Two separate interventions were carried out in the summer period between their fourth and fifth (last) year of high school, namely at halfway of their two-year dual apprenticeship. Class 1 was involved at the beginning of the summer, whereas Class 2 at the end, i.e. after six additional weeks of on-the-job training, which has been taken into consideration in the analyses. The evaluation phase consisted in the triangulation of direct observation and a survey issued at the end of each of the two weeks.

4 Findings

The interviews to the two dual apprenticeship tutors have been coded inductively into categories, and two second-order themes were identified: knowledge and skills currently provided (no gaps) and needed (gaps); limitations and opportunities of innovating teaching and training methods (Table 1).

Table 3. Findings from interviews to the dual apprenticeship tutors (both firm and school sides)

Knowledge and skills provided by dual apprenticeship and current needs	**No gaps:** • **Awareness that deep theoretical domain knowledge is needed to understand new phenomena of RES** • **Firm-specific skills are provided on the job through the dual apprenticeship scheme** • **Dual apprenticeship provided an approach towards continuous learning** **Gaps:** • **Operational knowledge about primary transformers, three-phase, technical English, proper Italian language for technical communication and interaction. Statistics are not taught. New, transversal knowledge ("breadth") is needed to acquire new knowledge on smart grids;** • **No coding skills are taught; problem solving skills have to be strengthened; lack of manual dexterity. Second-guessing and critical spirit on algorithm outcomes.**
Innovation of teaching and training methods: current limitations and opportunities	Limitations: • While training is customized, learning is generalized, not individual, though there are differences in learning capabilities • IT providers have a role in shaping curricula • Teaching gap: no use of innovative teaching tools. Opportunities: • Schools can freely act on curricula, and firms can have a voice on that • Companies need external laboratories and technologies

What emerges is that the dual apprenticeship is providing firm-specific skills and an approach towards continuous learning, whereas school is struggling in providing the necessary new knowledge. This is due to a lack of new technologies in the laboratories and the necessity to level all students. Opportunities are opened by the possibility to act on school curricula, as IT providers are already doing by providing their technologies and user manuals as text books. In the focus group, 13 electrical grid workers were asked to state their impressions on what becomes more important with the digitalization of the grid. Results are reported in Figure 1.

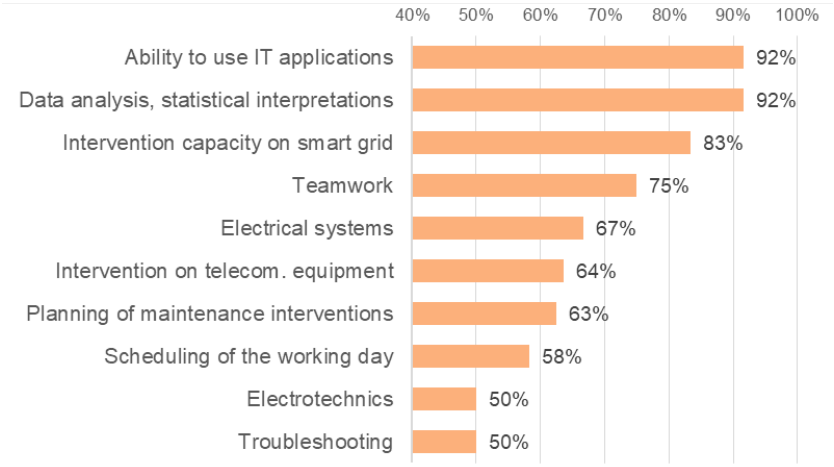

Figure 8. Aspects that are becoming more important due to grid digitalization (from focus group)

IT literacy and the ability to analyze and interpret data were considered the most important knowledge and skills to possess with the upcoming increase in complexity of the grid. Moreover, what emerged is that there will be more need of theoretical knowledge to make sense of data. The ability to interpret natural phenomena is crucial for second-guessing and critical spirit on algorithm outcome:

«If you know theory, it helps you.You already know where to look»

Another insight came from the operating team leader, who expressed the concern for being exclusively data-driven, without knowing theory, in troubleshooting:

«An installer told me: 'no, there is excessive tension, I have to make another cabin'. I replied: 'how is it possible? Looking at electrotechnics theory, there is no need of another cabin here' [...] In the end, I found out that there was a dummy load and his calculations were wrong, but he only looked at data»

Findings from Phase 1 were used as an input to design the Challenge-Based Learning activity for the two classes. Results of the IoT-based challenges were analyzed in turn. Table 2 reports the learning outcomes perceived by the apprentices at the end of each week, concerning domain knowledge and digital skills deployed in the challenges.

Table 4. Perceived impacts attributed by students to the IoT Challenge-Based activity

	Mean	St. Dev.	Mean class 1	Mean class 2	Difference
Management of data generated by sensors	4.12	0.69	4.1	4.14	.04
Secondary cabins' breakdowns causes	3.91	0.83	3.75	4.14	.39
Ability to manage and interpret data coming from measuring instruments	3.71	0.76	3.75	3.64	-.11

Secondary cabins' functioning and equipment	3.68	0.84	3.35	4.14	.79***
Ability to assembly IoT-based measurement tools	3.38	0.85	3.45	3.29	-.16
Ability to program IoT devices	3.03	1.17	2.8	3.36	.56

Overall, class 2 shows higher values, though difference between the two groups is statistically significant only for "feeling more knowledgeable about secondary cabins' functioning and equipment". Since developing IoT coding skills was not the focus, but rather an enabler for the challenges, the perception of having developed such skills registered the lower values. Last, questions aimed at assessing apprentices' perceptions on the four stages of the experiential learning cycle were computed by means of a principal component analysis. Table 3 reports totals and differences between the two classes.

Table 5. Apprentices' perception of learning from the four phases of the experiential learning cycle

	Mean	St. Dev.	Mean class 1	Mean class 2	Difference
Experience	3.35	.70	3.11	3.69	.59**
Conceptualization	3.54	.73	3.58	3.50	-.08
Experimentation	3.63	.69	3.43	3.93	.50**
Reflection	3.76	.77	3.65	3.93	.28

Values of "experience" phase are the lowest, due to the fact that such learning phase pertains to the dual apprenticeship rather than the CBL activities. Statistically significant differences for "experience" and "experimentation", however, suggest that having received more on-the-job training allowed Class 2 to learn more from the CBL activity on what Raelin (1998) considered to be the "tacit" part of learning. Figure 2 reports the box plots, in which it is possible to appreciate the variance by class.

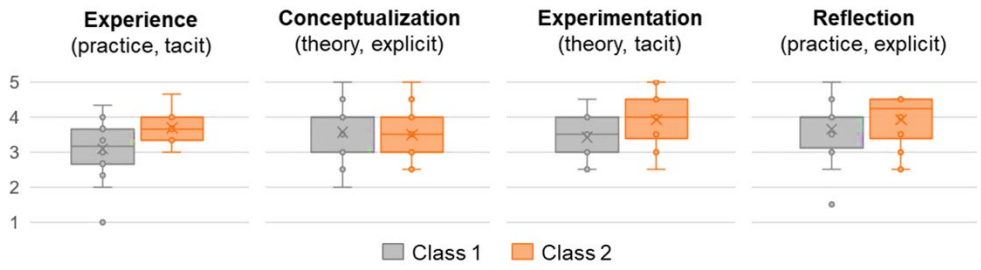

Figure 9. Differences in stepping on the four experiential learning cycle phases

5 Discussion

The increasing content of digital technologies and data-driven practices is making smart grid workers shifting from T-shaped to Pi-shaped profile of competencies. On the vertical axis of the greek pi is depth of knowledge, and on the horizontal axis is breadth with transversal knowledge (Faris et al., 2011). The second "leg", in this case, is digital literacy with knowledge on IoT architectures, data management, fundamental of statistics and interpretation of charts. However, depth in domain knowledge (in this case, electrotechnics) will remain vital for the sense-making of data. Therefore, experiential learning approaches to train off-the-job line workers and technicians will need to take this into consideration, and incorporate technologies which could enable a bridge between domain and digital knowledge. On this, IoT technologies showed to hold a huge potential. In a protected environment, producing very trivial demonstrators, based on sensors and on basic commercial processors, it was possible to emulate the whole data flow that will be experienced by operational roles on a daily basis with the advent of smart grids. From the natural phenomenon (temperature, humidity, electric field intensity), to the data collection through sensors, to its digitization in a computer, to data visualization and basics of statistics with averages, time series, charts. Given the fact that such Challenge-Based Learning needs to be based on brand-new digital technologies that have not been absorbed by vocational schools yet, and the benefits of CBL being carried out in post-secondary environments (Shuptrine, 2013), a technical university was needed along with the firm and the two classes.

When a new technology, calling for new knowledge, emerges in an industry, external providers need to be included, especially for companies that might be less experienced in training (Smith, 2002) or not have the necessary resources or competencies in terms of training transfer (Hill and Stewart, 1999). In uncertain transition phases like the ongoing digital transformation, a part of the training might therefore give better returns if outsourced. Integrating on-the-job (dual apprenticeship) and off-the-job (Challenge-Based Learning) training allows to provide both work-related skills (firm-specific, occupation-specific human capital) and attitude towards breadth of knowledge and continuous learning (general human capital). Such integration has proved to be a best practice to transfer knowledge since it offered "a great opportunity to understand the why of the process rather than just the how" (Sparkes, 2000) and helps develop intellectual skills, particularly in apprenticeships and traineeships (Smith, 2002). Challenge-Based Learning, motivated the apprentices by creating connections with real-work practices that were relevant to them (see also Shuptrine, 2013), engaging them in the training activities. According to Morris' (2019) expansion of the experiential learning cycle, the dual apprenticeship constituted the "contextually rich" concrete experience, enabling the CBL in which the apprentices had the opportunity to perform a "contextual-specific" abstract conceptualization, a "pragmatic" active experimentation and a "critical" reflective observation. Completing the cycle with a CBL training based on IoT technologies allowed to make explicit part of the tacit knowledge acquired during the dual

apprenticeship, especially through reflection and conceptualization phases (Raelin, 1998). As shown by findings, especially for those who carried out more on-the-job training, IoT sensors proved to be an effective tool to link the "know-why" and the "know-how", allowing a more "pragmatic" active experimentation (Morris, 2019) in a protected environment. Using a new technology – of which the apprentices did not know anything – to solve problems coming from the "real world" allowed them to focus on theory and successfully transform tacit knowledge into explicit knowledge (Raelin, 1998), through "critical" (Morris, 2019) reflective observation. Such transition from tacit to explicit is of paramount importance, and must be achieved in every effective training program aimed at fully developing the new, complex and multifaceted operational knowledge needed in the digital era.

6 Conclusions

With the advent of digitalization, including IoT technology in a Challenge-Based Learning approach can have a strong impact on developing (and exploiting, in a constructivist approach) the new operational knowledge needed by blue-collars and technicians. The challenges brought by a new technology, with which the learners are completely unfamiliar, proved to be functional to the development of new knowledge and skills to perform. Moreover, the concurrent dual apprenticeship in which the learners were involved was the perfect "concrete experience" setting which enabled a complete experiential learning cycle. Confirming this, apprentices who underwent more workplace training showed to benefit more from the Challenge-Based Learning, as the involvement in a dual apprenticeship provided the students with higher willingness to learn and a broader set of knowledge and skills, allowing them to build more new knowledge upon it (see Piaget, 1973; Cohen and Levinthal, 1990). Each of the two parts involved in the dual apprenticeship had its role. The school was fundamental in providing both domain (depth) and cross knowledge (breadth) on which to build new knowledge. The firm was fundamental in enabling informal learning (see Eraut, 2004), bringing challenges from real work situations, and transferring location-experiential knowledge to trainees during the laboratory. Further qualitative analyses, based on post-intervention interviews to tutors and apprentices, are needed to better disentangle the contributions of each of the actors involved, especially concerning the rationales for involving a university in the co-creation process of education and training of operational profiles, which we feel goes way beyond the "mere" expertise on IoT technologies.

Abstract

The continuously growing importance of cybersecurity is an unavoidable consequence of the rapid development of innovative technological solutions, including, e.g., ubiquitous networking, mobile computing, Internet of things, or various forms of cloud services. Every new solution, however, gradually threatens electronic data, accessible practically from anywhere. Such vulnerability is critical, particularly in the industrial domain, where single firms and institutions must remain competitive and cannot ignore business advantages if of modern platforms. Although strategic managers are generally aware of cybersecurity risks, they frequently have problems with the efficient implementation of efficient managerial solutions. Thorough characterisation and minimisation of this bottleneck, based on qualitative dynamic modelling, is the primary goal of this research. We see the main reason for this discrepancy in a mainly technical nature of cybersecurity and related tools and policies in comparison with qualitatively oriented frameworks and techniques of strategic management. The existence of such vertical inconsistence naturally reflects knowledge asymmetry between business, architectural and logical views of enterprise architecture on one side and explicit ways of network communication, configuration of related components and other physical aspects on the other.

Consequently, the cybersecurity planning power of strategic managers tends to be limited and unfocused. Such a lack of specific technical knowledge can result in the adoption of risky and possibly limiting strategies of cyber under- or overprotection. Beyond the internal vertical gap, there is also a horizontal gap, influencing company interoperability in external networks, like supply chains, critical infrastructures, keiretsu groups, or international partnerships.

We believe that both kinds of problems could be minimised with transparent and holistic integration and continuous bidirectional understanding and sharing of related business and technical

knowledge. That is why we conducted a literature review, reflecting typical structural and behavioural aspects, related to all investigated levels and directions of cybersecurity management in a business context. Collected results were visualised and analysed using the mind map and system diagram. Based on these findings, we formulated a set of typical dynamic hypotheses and validated it quantitatively through the corresponding causal loop diagram. Because of the adopted knowledge-based approach, we propose a generally transparent, but still reasonably comprehensive solution, addressing both strategic decision-makers and technicians.

Keywords – Cybersecurity, Business alignment, Qualitative modelling

Paper type – Academic Research Paper

1 Introduction

Cybersecurity is a pervasive phenomenon, attracting the increasing interest of authorities, industry, researches and end-users (Lezzi et al., 2018), (Pala & Zhuang, 2019), (Sánchez et al., 2019), (Fitzgerald, 2020) as a side effect of progressively escalating development of information and communication technologies (Leszczyna, 2018), (Habibzadeh et al., 2019), (Corallo et al., 2020). Importance of cybersecurity on all levels is widely reflected by international and national legislation, e.g., (Directive (EU) 2016/1148, 2016), (Commission Implementing Regulation (EU) 2018/151, 2018), (Council Regulation (EU) 2019/881, 2019) and industrial standards (International Organization for Standardization ISO/IEC 13335-1:2004, 2004), (ISO/IEC 27002:2005, 2005), (ISO/IEC 27002:2013, 2013), (ISO/IEC 30111:2019, 2019), supported by specialised institutions (ENISA, The European Union Agency for Cybersecurity, ECSO, The European Cyber Security Organisation) and implemented through wide range of different frameworks and up-to-date tools (Li et al., 2019), (Bland et al., 2020), (Williams et al., 2020).

Despite this effort, the number, intensity and impact of cyberattacks growth as a natural consequence of the increasing number of interconnected devices (Arumugam & Subramanian, 2019). Thus the contemporary orientation on smart spaces and people-centric approaches (Elmaghraby & Losavio, 2014), (Rawat & Ghafoor, 2019) considers the systematic embedding of security principles to any kind of interaction with information and communication (ICT) resources as an unavoidable must. The inherent complexity of this task, however, lies in its two-folded nature. Disregarding whether we deal with the private, industrial or public traffic, there is an evident gap between the technical and user level of computer applications, which our research strived to fill. To narrow the spectrum of the addressed target audience, we concentrated only on security aspects of enterprise information systems and on the qualitative level answer the following question:

Is it possible to present cybersecurity matters also to the non-technical strategic manager makers in a transparent, applicable and profitable form?

Such formulation anticipates the following assumptions:

- Transparency means that the structural and functional formalisation of the analysed phenomenon must be generally understandable, easy to interpret and discuss, as well as precise and concise. All these criteria can be met on the knowledge level of representation, which integrates and creatively summarises available data and information resources (Lai, 2007), (Brusoni et al., 2009), (Malhotra & Nair, 2015). If done correctly, significant characteristics remain preserved and selected specific details are omitted.
- Applicability and profitability are based on a seamless inclusion of proposed model into standardised performance management frameworks. These arrangements expect realistic definition and quantification of all involved variables.

To fulfil these goals, we adopted the balanced scorecard framework (BSC) and extended it with knowledge-based aspects of cybersecurity, including the threat intelligence, measures of cyber risks and security-supporting architectures, orchestrated in the following context:

- Value engineering as a transparent way of company value-creating processes requires systemic utilisation of standardised performance architectures (Kiran, 2017), (Egbuhuzor & Port, 2019), (Yihong et al., 2019). They must reflect its two-folded structure, incorporating effectiveness, i.e. measure of success in doing the right things and efficiency, quantifying the level of embedded quality. Because of cyclic, i.e. dynamic nature of management, related frameworks must use temporal indicators from all internal domains of business, because single time slice can hardly explain complex relations among its key leading (predictive, drivers-related) and lagging (output-oriented) indicators (KPIs) (Badawy et al., 2016), (Domínguez et al., 2019). This research used mainly strategic mapping and dynamic balanced scorecards techniques (Kaplan & Norton, 2005), extend with selected features of next generations of BSC (Sofiyabadi & Nasabb, 2012), (Nielsen & Nielsen, 2013) and inclusion of cybersecurity performance features into this framework.
- Cyber threat intelligence (Abu et al., 2018), (Wagner et al., 2019), (Shin & Lowry, 2020) can be considered as a complementary initiative to the researched topic. Generally, the threat intelligence is evidence-based, must deliver expected value and allow to formulate efficient counteractions. Its main goal to collect and distribute information about passed threats and their actors to strengthen the current level of cyber resilience. Its outputs can be in the form of technical recommendations, traditional and advanced data analyses or comprehensive knowledge-based representations, depending on the level of discovered behaviour. Final recommendations are composed of internally collected data and knowledge and extended with experience form external partners and security-related communities of practice. They include strategic suggestions for board members and C-type of managers, tactical hints for security architects,

operational information, characterising defenders' behaviour and finally also technical data, quantifying incident parameters.

- Cybersecurity/cyber risk indexes transform diverse and interlinked cybersecurity aspects into a single number, which is convenient for governance and strategic planning (Lewis et al., 2012), (Bunker, 2020), (Hoffmann et al., 2020). There are several recognised approaches, combining internal cybersecurity capabilities with the country and industrial sector-specific characteristics (Sammut-Bonnici & Galea, 2015). Typical final formulas consider data from the following areas:
  - Level of preparation, including cybersecurity-related business alignment, strategic context, governance and leadership, investments or resilience and response readiness,
  - Characteristics of historical security incidents,
  - Exposition of cybersecurity risks, given by actual ICT infrastructure, impacts of cyber threats, or portfolio of core businesses.
- Enterprise architecture: structural implementation of strategic management tools and techniques, gradually transforming business processes and organisational structures into particular services, provided by specific IT applications, and running on appropriate technical infrastructure (Moeller, 2013), (Mowbray & Shimonski, 2014), (Dhingra, 2017), (Bhattacharya, 2018). There are numerous applicable frameworks, addressing specific types of management. Because this research dealt mainly with the inclusion of cybersecurity into the governance, strategic planning and change management levels, the following frameworks were of our specific interest:
  - Control Objectives for Information and Related Technology (COBIT) is a direction-level framework, proposed by The Information Systems Audit and Control Association (ISACA) for ICT governance and management (Bartens et al., 2015), (Arief & Wahab, 2016), (Almeida et al., 2018), proposing tools and processes, minimising the gap between technical issues, business risk and process requirements and, consequently, reflecting and supporting business processes. Its mission is to get optimal value from enterprise ICT infrastructure by balancing related benefits, risks and resources. These goals are achieved through the following principles: (i) meeting stakeholder needs, (ii) covering the enterprise end to end, (iii) applying a single integrated framework, enabling a holistic approach and (iv) separating governance from management. Moreover, COBIT scalable structure supports straightforward inclusion of new business processes, including the cybersecurity. Although the main strength of COBIT insists in the direction level, it covers also change management (enterprise architecture) and partially touches also design and management of operations. Because for the business alignment of last two levels is frequently used Information Technology Infrastructure Library (ITIL),

companies usually combine both platforms to cover the whole range of business activities equally (Sauve et al., 2006), (Huang et al., 2009), (Hermanto et al., 2019).

- The Open Group Architecture Framework (TOGAF) is a framework and a set of supporting tools for developing enterprise ICT architecture and aligning it with business objectives (Winter & Fischer, 2006), (Hermawan & Sumitra, 2019), (*The TOGAF® Standard, Version 9.2*, 2020).
  It is based on the Architecture Development Method (ADM), which can also accommodate cybersecurity requirements. As an intermediate layer, TOGAF takes requirements from governance and strategic planning and transforms them into the design and implementation matters, convenient for operational, e.g. ITIL-based level.
- From the security architecture point of view, particularly interesting is also Sherwood Applied Business Security Architecture (SABSA) framework, suggesting an optimal methodology for the development of risk-driven enterprise information security architectures and for delivering security infrastructure solutions that support critical business initiatives (Coetzee, 2012), (Pleinevaux, 2016).

2 Methods

Although the routine utilisation of knowledge-driven solutions belongs among the most perspective performance drivers, there are still some open questions, related mainly to appropriate ways of their implementation. Beyond the already mentioned representational clarity, practical solutions must be holistic, user-friendly, scalable, intuitive or easily shareable in teams. Logically, also the set of applied tools and techniques must reflect these non-functional requirements. Based on such assumptions, we conducted initial qualitative research, discovering state of the art in knowledge-based inclusion of cybersecurity aspects into standardised strategic planning and management frameworks. Thus, we followed the general principles of system thinking and design, including holism, purposefulness, openness, multidimensionality, hierarchy, interdependence, equilibrium, counterintuitiveness, ambiguity or entropy, introduced and refined, e.g., by (Bertalanffy et al., 2015), (Forrester, 1961), (Sterman, 2014) or (Meadows & Wright, 2015). These aspects were employed in both main phases of the presented research, including knowledge elicitation (Diaper, 1989) and modelling (Firlej & Hellens, 1991). Resultant findings were considered in the context of organisational learning, divided in (Senge, 2006) into the following five disciplines: personal mastery, mental models, shared vision and team learning, integrated through the principles of systems thinking. Organisations with properly implemented learning principles can also profit from knowledge management (Massingham, 2019). As a result, related findings were summarised in the mind map (Buzan, 2018), providing a loosely structured graphical representation of analysed phenomenon. Due to its visual straightforwardness and clarity, this technique

represents an efficient way of representation, communication and sharing of comprehensive outputs of literature review. In parallel, the collected conceptual artefacts are further structured with the system diagram. In contrast to the linearly structured mind map, system diagram already uses feedback loops and more sharply distinguishes between parameters (connections) and state variables (boxes). I

Invented assumptions concerning internal dynamics were incorporated into dynamic hypotheses and modelled with the causal loop diagram. The behaviour of the resultant model was discussed for selected scenarios, the feasibility of which also proves model validity. Thus, the achieved qualitative results and recognised limitations can facilitate managerial decisions and modifying the existing reality. Although the presented outputs were simplified because of their readability in this document, full versions of all modelling diagrams are more comprehensive and serve as resources for currently developed computation model.

3 Results and discussion

3.1 Mind map

The mind map in figure 1 characterises the main pillars of our understanding of the business alignment of cybersecurity. In its left part, the risk related factors are structured into selected types of threats, which can spoil both company data and ICT infrastructure and affect its business processes in different ways with explicitly quantifiable impacts. To minimise their occurrence, duration and consequences, selected aspects of cybersecurity risks must be appropriately included into the existing system of company governance and management, summarised in the right part of the map. It covers the particular levels of governance, extended with related cybersecurity policy and high-level structure for strategic planning and management. Achieved cybersecurity performance, in our case integrated into BSC framework, can be evaluated with a selected metric from the left part.

Then the detailed CS strategy can be composed as a weighted mixture of listed components, to maximise the goals, listed in the underlying branch. It also shows the specific cycle of CS management, which differs from the generic plan, organise, staff, lead and control quintuplet. Finally, structural foundations of EU governance are shown as unavoidable external factors.

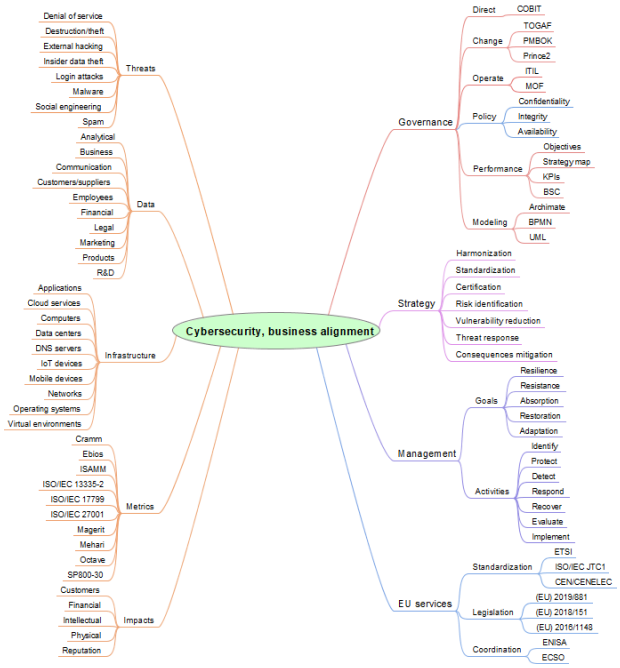

Figure 1 Mind map of analysed domain

3.2 System diagram

Following the adopted way of implementation, figure 2 presents the related system diagram is the system dynamics notation. We extended four BSC sectors with the cybersecurity one because it simultaneously and nontrivially influences segments of customers, operations and learning & growth, and indirectly also finances. The diagram is composed of the following elements:

- Rectangles, stocks or capacities are time-varying state variables, expressed with nouns. Mutually coordinated development of their levels is crucial for the final performance.
- Clouds are dummy external resources, which do not belong to the system.
- Annotated hourglasses are valves, filling or draining the stocks through the oriented double arrows (pipes). Because their turning represents an activity, are expressed with verbs.
- Regular variables without borders are stationary parameters, generally represented with linear or nonlinear functions (risk, utility, subjectivity).
- Oriented single arrows constitute a parametric setting of the system. Double-crossed ones denote considerably slower transfers from start to end.
- Phantom variables in angle brackets only increase the visual clarity of the diagram by removal of possibly intersected graphical elements.

System-level interpretation of BSC considers the main system variables of single sectors as stocks, filled or drained with parametrically controlled valves. Interconnection of subsystems is demonstrated with binding stock levels. Strategic decisions are realised through Finances, primarily collected from sold products or services, i.e. *Operations*.

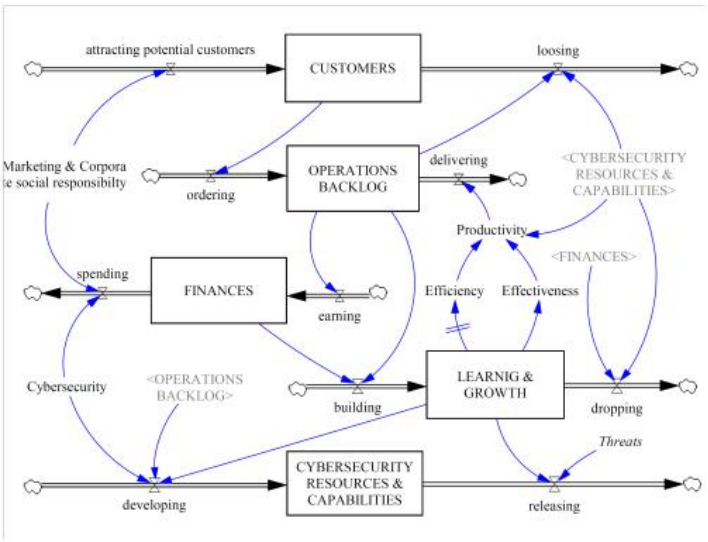

Figure 2 System diagram of cybersecurity in BSC-like performance framework

Thus, the constant level of *Operations* backlog is one of the desirable planning targets. Available level of *Finances* directly determines the most expensive *Learning and growth* subsystem, including both performance drivers (mostly human resources) and infrastructural performance enablers. This sector generates both components of productivity, efficiency and effectiveness, which, altogether with market-related activities, maintain the level of *Customers* and generate backlog. *Cybersecurity* was separated from *Learning and growth* sector, because of its broader impact, which is, moreover, oriented mainly in the opposite direction from the performance. Beyond productivity, cybersecurity incidents can discourage both customers and employees, as well as damage infrastructure or business data.

3.3 Dynamic hypotheses

For simplicity, let us expect that the performance is expressed with a normalised function of quantitative and qualitative indicators from all fours BSC sectors, i.e.,

Performance (Customers, Operations, Learning and growth, Finances) [%],

and its target value should be 100% at the end of the planning period. This situation represents the basal dynamics hypothesis H1 in figure 3. Let us also introduce an overall

normalised index of company cybersecurity level (CSI), structured in accordance with the left side of figure 1. This relative indicator can be used in the following ways:

- Independently from performance to provide decision-makers compound information concerning this matter.
- As a part of more or less independent risk management, where the risk is normalised function of threat probability or likelihood, level of vulnerability and impact of consequences, i.e.:

  Risk(exposed CSI).
- Fully integrated into existing performance management framework, which is approach, presented in this paper. In such case, CSI must be distributed into particular BSC sectors.

To illustrate this last option, we considered a scenario, when single cyberattack appeared at the end of the fourth month. With this situation, we interlinked the remaining four dynamic hypotheses, H2 – H5 as follows:

H2: If company does not systematically invest into own cybersecurity, an average security incident can negatively and irreversibly affect its performance. Although an immediate recovery is possible, the slope of performance graph remains negative until the further managerial event or threat occurrence.

H3: Even a low level of systematic inclusion of cybersecurity into a performance framework can eliminate performance decrease and preserve its steady level.

H4: Optimal level of systematic inclusion of cybersecurity into a performance framework can eliminate performance decrease and originate its next growth.

H5: Extensive level of systematic inclusion of cybersecurity into a performance framework can quickly eliminate performance decrease and originate its next growth. However, this level of security and fast adaptability is expensive, which, it turns, negatively influence the performance. That is why it is generally difficult to overcome a smaller growth slope, caused by extensive investments to cybersecurity.

Exact implementation strategy of particular hypotheses can be derived from the corresponding causal loop diagram, serving as a qualitative dynamic model of integration of cybersecurity into the business.

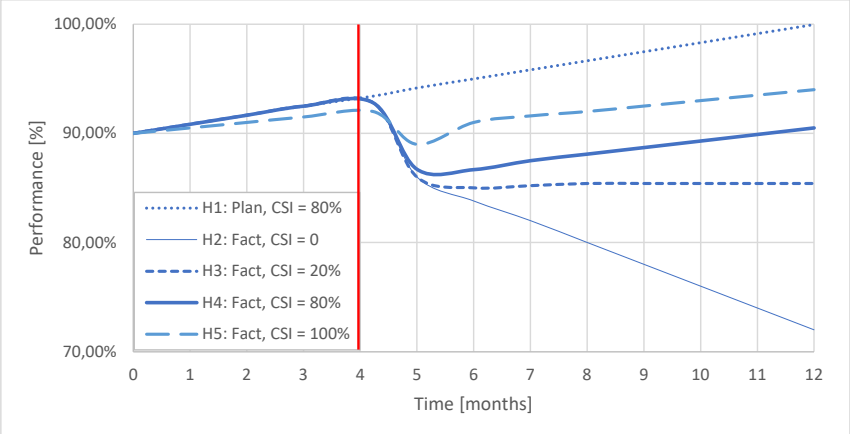

Figure 3 Dynamic hypotheses for sample scenarios and strategies

3.4 Causal loop diagram

The diagram of qualitative dynamics in figure 4 approximately refines the system diagram and suggests conditions, satisfying the above-outlined dynamic hypotheses. Sample resources for strategic decisions are shown in its lower part in the form of several stabilising loops with for clarity omitted settings of desired levels. The exact values of single parameters depend on adopted strategy and are limited mainly with available finances, generated by operations backlog, maintained with an appropriate combination of orders, technology and productivity. Productivity, i.e. input to output conversion ratio, is composed of the quantitative part, including staff and infrastructural changes and the qualitative one, achieving efficiency through organisational learning and development of teamwork and individual capabilities.

The upper right quadrant illustrates sample structure of the cybersecurity sector. It includes own quantitative and qualitative loops, establishing the desired level of resilience and decreasing vulnerability. Marketing focuses purely on the attraction of potential customers. Corporate social responsibility has, however, a broader scope and introduces external Political, Economic, Social, Technological, Environmental and Legal factors (PESTEL) to the model. They can be interpreted, e.g., as a competitive advantage, reputation, customers' satisfaction, interoperability or public awareness. From the dynamic point of view, cybersecurity is included in seven loops, chronologically ordered as follows:

Single balancing loop of strategic planning:

- L1: CS → Resources for strategic decisions → CS

Four reinforcing loops for building and using CS capabilities:

- L2: CS → General CS training → Resilience → Vulnerability → CS
- L3: CS → Specific CS training → Resilience → Vulnerability → CS
- L4: CS → CS staff → Resilience → Vulnerability → CS

- L5: CS → CS architecture, compliance, infrastructure → Resilience → Vulnerability → CS

Two balancing controlling loops:

- L6: CS → Effectiveness → Productivity → Operations backlog → Resources for strategic decisions → CS
- L7: CS → Quality of services Efficiency → Productivity → Operations backlog → Resources for strategic decisions→ CS

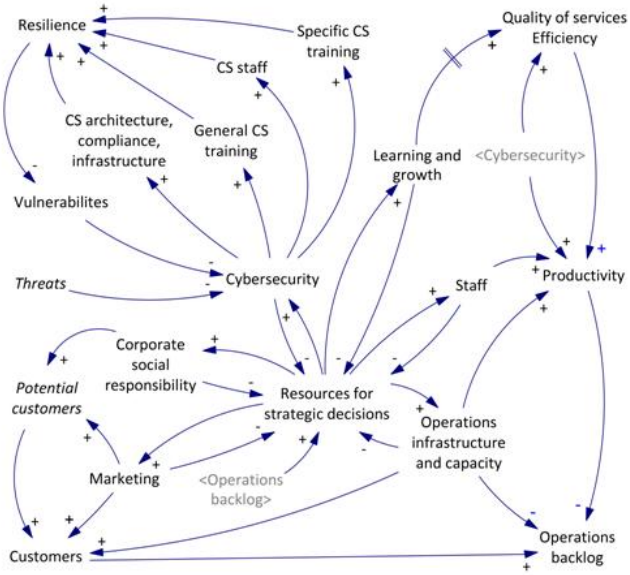

Figure 4 Causal loop diagram summarising dynamics of cybersecurity integration

These loops constitute behaviour, assumed by the specicic dynamic hypotheses:

H1 represents a sample output from the planning phase, and functionally corresponds with H4. Without external or internal threats, there is no need for any reactive actions, and the performace develops steadily during the whole period.

H2 does not expect any explicit cybersecurity infrastructure, which means, that loops L1 - L7 are missing. Such solution is cheaper and in a safe environment influences performance positively. However, when an accident happens, a vulnerable system is not prepared for a prompt recovery and loses performance gradually.

H3 assumes only development of mandatory cybersecurity quantities, represented with the loops L1, L2 and L6. These resources are enough for incident recovery, but cannot guarantee the recurring performance growth.

H4 benefits from the existence of all cybersecurity loops L1 – L7 and their optimal adjustment. Well-developed qualitative aspects of cybersecurity through loops L3 - L5 and L7 result at least in a renewal of original growth. Additional managerial decisions can this situation even improve.

H5 is the opposite extreme to H2. Excessive level of cybersecurity is a costly alternative, restricting performance growth because of budget limitations. On the other hand, minimisation of impacts and fast recovery are its evident advantages.

4 Conclusions

This research provides a qualitative dynamic analysis of an enterprise cybersecurity inclusion into a standardised performance framework. Its main goal was to propose a knowledge-based interconnection of technical and business aspects of the studied phenomenon. Practically it means that traffic data, outputs of network analysing tools as well as cybersecurity-related technical knowledge and threat intelligence are integrated into particular key performance indicators. In parallel, employees are educated in cybersecurity matters and trained to identify and mitigate cybersecurity risks early. Such a joint approach can result in a generally understood, systemically governed and safe growth of the business, capable to minimise consequences of incidents and efficiently reflect a continuous expansion of external and internal threats.

To establish such framework, we adopted the dynamic system approach and reviewed the latest related resources. Collected conceptual information was modelled and gradually structured using the mind map and system diagram. Then we proposed five dynamic hypotheses and justified them through the related causal loop diagram. The main findings were:

- Because of the fast dynamics of cybersecurity, caused by technological development, increasing diversity and frequency of cyberattacks, companies must be able to adopt systemic, scalable, transparent and well-justified, preferably knowledge-based solutions.
- From the governance point of view, cybersecurity represents a specific area of interest, directly or indirectly addressing all standard sectors of performance. That is why it cannot be merged with existing processes and requires specific structural arrangements.
- Strategic management of cybersecurity requires should be based on compound metrics, summarising its quantitative and qualitative aspects.
- Adequately unsecured organisations can face significant problems even after a single attack. On the other hand, massive cybersecurity investments slow down core business development. Optimal system of cybersecurity management has well-balanced its effectiveness and efficiency components.

Finally, the main advantage of knowledge-based modelling insists in its ability to find key behavioural features in the context of the whole system, identify counterintuitive patterns or simplify and visualise multidimensional nonlinear and delayed relations. Realistic transformation of real-world problems into a software form also establishes an intuitive platform for acquisition and sharing of knowledge among distributed research teams and supports professional education and training. Thus, the obtained qualitative model currently serves as a group decision-support tool, based entirely on domain knowledge and primarily validated with expert opinions. Its is intuitive and scalable architecture supports its continuous development. Our future research will concentrate mainly on the quantitative system dynamics implementation of the presented qualitative concept.

Abstract

The spread of new Financial Technologies, better known as Fintech, offers many opportunities and challenges for entrepreneurs, however little is known on Fintech development. This study describes five areas in order to improve our knowledge on Fintech development: regulation, infrastructure, technologies, finance, innovations. Crowdfunding (CF) platforms are among the main players of the so-called Fintech revolution and many entrepreneurs use these platforms to get both funds and new knowledge for their ventures. The two main CF models are reward crowdfunding (RCF) and equity crowdfunding (ECF). Our study proposes four research propositions to compare these two models. In particular we focus on several campaigns characteristics: video, images, updates, comments. Hopefully this study sheds some lights on Fintech development and will have several implications for scholars and practitioners.

Keywords – Crowdfunding, Entrepreneurship, Fintech, Equity-model, Reward-model

Paper type – Academic Research Paper

1 Introduction

In the last few years, many entrepreneurs leveraged Open Innovation Platforms and in particular crowdfunding platforms (Troise et al., 2020a; Troise and Tani, 2020).

Crowdfunding (CF hereafter) is a new and popular financing mechanism that entrepreneurs use to fund their early stage businesses (Mollick, 2014; Schwienbacher and Larralde, 2010; Vulkan et al., 2016; Troise, 2019a; 2020). CF is one of the most promising initiatives in the so called "Fintech revolution" (Gomber et al., 2018). The term "Financial Technologies or Fintech" is used to describe a variety of emerging technologies and new innovative business models, including crowdfunding, that have the potential to transform the financial services industry (Huang et al., 2016; Carney, 2017; IOSCO, 2017).

The number of countries that pay attention to the development of Fintech has been growing lately. Many of them - e.g. Italy and United Kingdom - consider its potential role in fostering economic growth, which is currently weak (Chen, 2016). Two of the main areas of financial innovation that have great potential and have seen strong developments in recent years are reward crowdfunding (RCF hereafter) and equity crowdfunding (ECF hereafter) (Kirby and Worner, 2014). Financing platforms of these types are included in the innovative business models and emerging technologies that are transforming the financial services industry. The present study focuses on both RCF (Mollick, 2014; Courtney et al., 2017; Parhankangas and Renko, 2017) and ECF models (Ahlers et al., 2015; Troise, 2019b; Troise et al., 2020b), which show significant growths and several benefits (IOSCO, 2017).

According to Belleflamme et al. (2014: 588), crowdfunding mechanism "involves an open call, mostly through the Internet, for the provision of financial resources either in the form of donation or in exchange for the future product or some form of reward to support initiatives for specific purposes". Davis et al. (2017: 90) provided a specific definition for RCF and argued "Rewards-based crowdfunding enables entrepreneurs to garner funds in support of a specific purpose, which often centers on the development or distribution of a new, unfinished, or unproven product".

With regard to ECF, Ahlers et al. (2015: 958) highlighted that "Equity crowdfunding is a method of financing, whereby an entrepreneur sells a specified amount of equity or bond-like shares in a company to a group of (small) investors through an open call for funding on Internet-based platforms".

Entrepreneurs leverage the "wisdom" of the crowd (Belleflamme et al., 2014; Polzin et al., 2018; Troise and Tani, 2020) in order to have a faster product development process, increase their market knowledge, define a business growth strategy and expansion into new markets, improve the access to networks, and increase public awareness of their business (Di Pietro et al., 2018; Estrin et al., 2018; Wald et al., 2019).

In CF contexts, knowledge sharing is a critical driver of success that helps entrepreneurs to get a competitive advantage in a social economy (Wang and Noe 2010;

Hartono and Sheng 2016). One of the major challenge for entrepreneurs in this scenario based on the crowd inputs is manage knowledge.

Currently there is little knowledge on both the Fintech development and the main differences between CF models. The present study aims to fill these gaps. Firstly we describe the Fintech development in order to identify the main characteristics and areas. Second, we propose several research propositions to compare two well-known CF models, i.e. RCF and ECF (Troise et al., 2020c). These propositions will offer the opportunity to test hypotheses. Hence a next study will allow us to verify them and disclose the differences in terms of campaigns' characteristics.

2 Fintech Development

The Research Report on Financial Technology (Fintech), published by the International Organization of Securities Commissions (IOSCO) in February 2017, provided a definition of Fintech: "the term Financial Technologies or 'Fintech' is used to describe a variety of innovative business models and emerging technologies that have the potential to transform the financial services industry" (2017: 4).

Also a recent report (2017) by the Committee on the Global Financial System (CGFS) and the Financial Stability Board (FSB) focused on the new and innovative aspects of Fintech and reported that: "Fintech can be broadly defined as technologically enabled financial innovation that could result in new business models, applications, processes or products with an associated material effect on financial markets, financial institutions and the provision of financial services" (Carney, 2017).

While for Fintech there are specific notions, this is not the same for its development. In fact there is not a precise and univocal definition of "Fintech development", so this study considers several works on this theme and provides a summary description of the main aspects that characterize it. Among these contributions the most recent are considered, and in particular two of them: "The rise and development of fintech", a book edited by Teigland et al., and "On the Fintech Revolution: Interpreting the Forces of Innovation, Disruption, and Transformation in Financial Services", a paper authored by Gomber et al. (2018). The first, focused on Sweden, deals with many topics related to Fintech development (e.g. categories, regulations, process innovation developments, technologies, etc), with the Internet as key driver. The second analyses changes, transformations and new developments associated with the Fintech Revolution. The authors of this second work pay particular attention to three aspects of the Fintech Revolution, called "key forces": technology innovation, process disruption and services transformation.

Figure 1 reports the main elements of the Fintech development, while definitions of each factors are provided in Table I. Five areas of Fintech are highlighted in the present work: regulation, infrastructure, technologies, finance, innovations. Their development represents an opportunity for companies, especially for start ups and SMEs, and an important source for innovation in the industry. The Fintech ecosystem is quickly growing and is composed of many actors (e.g. firms, policy makers, consumers, financial

players) and some interrelated technologies. Each financial technology has a specific role which evolve to improve the transformation of products and processes. Also innovations spread in this context and they help the evolution of business models. According to Gomber et al. (2018: 228), Fintech innovations "*seem to fit into both categories of innovation - radical and disruptive*". These innovations are emerging in many facets of finance, for example financial market infrastructures, credit provision and equity capital raising (FinTech credit report by CGFS and FSB, 2017). The growth of the ecosystem and the development of Fintech are supported by specific regulations that vary by jurisdiction and by features of the Fintech model. The accelerating advancement in Fintech, in particular internet crowdfunding, is favored by policy packages (Chen, 2016). Considering the ECF model, for example, the stakes in companies acquired by investors have different legal forms and the financial law, which is based on "boxes" (such as financial instruments like MiFID II/MiFIR), varies by country (Zetzsche and Preiner, 2018). The number of countries that pay attention to the development of Fintech and consider its potential role in fostering economic growth - currently weak - has grown lately (Chen, 2016).

One of the main areas of financial innovation that has seen strong developments in recent years is CF. CF platforms are included in the innovative business models that are transforming the financial services industry. CF shows a significant growth and several benefits (IOSCO, 2017). This growth might support companies to close (or diminish) their capital needs, and it is driven by supply and demand factors including: reduced technology costs (e.g., internet interfaces used by founders and investors to show or view documentations and business scopes), previously underserved market segments (SMEs and start ups can attract capital more quickly through CF platforms) and low interest rates. The main benefits include: greater access to capital, cost advantages (funds and equity financing raised by entrepreneurs without the costs and procedures of an IPO; low cost of capital and high returns also for investors), market-driven system (platforms operate through an open system and a large number of people - including traditionally penalized segments - choose whether or not a company should receive funding), investor choice/diversification (a new asset in the early stage of innovative businesses that can interest both to crowd and to institutional investors for portfolio diversification), early validation (successful campaigns are positive for the company, its product, and its chances to attract further investments), network effect (exchanges between founders and investors that can support the company through contacts, experience, insight and information) and increase of competition (in a space traditionally dominated by a few providers). This latter aspects concerns the benefits for firms and in general for the economy. Companies access to financing in a timely manner and reducing transaction costs (typically there is only a platform fee applied on the funding amount collected), while traditional entities are incentivized to innovate, thus increasing efficiency.

The growth of CF is important since it might support entrepreneurs to close (or diminish) their capital needs and to receive several benefits. These benefits are additional

respect to those of government or traditional systems (e.g. banks, Venture Capitalists or Business Angels), and mainly are the support of informal networks and the opportunity of a marketing tool (Teigland et al., 2018).

CF platforms are a type of multisided platforms and can be interpreted as community-driven platforms, with entrepreneurs and investors on the two sides. Their value grows attracting more users (network effect) and the quantity or variety of agents on the sides (network externalities) (Rochet and Tirole, 2006). The development of CF platforms attract both projects and investors.

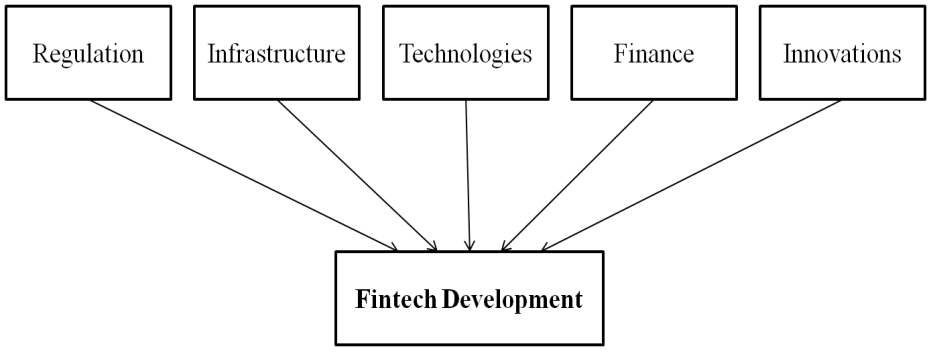

Figure. 1 Fintech Development

Table I. Fintech development: factors and descriptions

Factors	Descriptions
Regulation	Jurisdictions implement new regulatory regime tailored to the case. Regulatory changes influence companies (e.g. service processes and technology platforms). Regulators promote the formation of capital and supervise the risks for investors. Regulators increase their policy focus by issuing new regulations on specific Fintech areas.
Infrastructure	Development of a physical infrastructure for the Internet. Creation of new digital infrastructures which bring products and services to a wider public. Evolution of market infrastructure, connectivity, data infrastructures and integrated systems. Modernization and sharing of infrastructures (e.g. tech or business), platforms growth.
Technologies	Spread of emerging technologies (e.g. cognitive computing, machine learning, Regtech, DLT*) Application and synthesis of technological capabilities to reduce entry barriers. Speed of technological developments (artificial intelligence, big data analysis, cloud computing)

	The use of technology to automate processes, protect consumers, increase product breadth.
Finance	Dissemination of alternative finance models (e.g. crowdfunding). Democratization of finance, new support for entrepreneurship and collectively finance activities. Changes and new services for the finance industry and the global finance ecosystem (e.g. digital). Different actors in finance have been influenced by technologies and innovations in the sector.
Innovations	Development of innovations (e.g. technological and digital) which create value in the ecosystem. Innovations evolve in a market (industrial sectors) Fintech emphasizes how innovation empowers finance. Evolution of innovation strategy. Innovations transform finance and its infrastructure (e.g. services with mobile internet or big data)

*DLT = distributed ledger technologies; Regtech = regulatory technologies

3 Reward Crowdfunding and Equity Crowdfundings

Some studies compared the investment decision criteria of crowd investors, i.e. small and amateur investors, with other traditional investors such as Venture Capitalists (VCs) and Business Angels (BAs) (Lukkarinen et al., 2016; Vulkan et al., 2016).

Lukkarinen et al. (2016: 26) found that "the investment decision criteria traditionally used by VCs or business angels are not of prime importance for success in equity crowdfunding", the scholars in fact argued that ECF "success is related to pre-selected crowdfunding campaign characteristics and the utilization of private and public networks".

Vulkan et al. (2016) explored Seedrs, one of the most important ECF platform in Europe (UK), and leveraged the Mollick's results in the RCF context as a benchmark to ECF. The scholars compared the outcomes of ECF campaigns posted on Seeders with the outcomes of RCF campaigns posted on Kickstarter, a leading RCF platform (U.S.). Their study highlighted both similarities (such as the average number of backers and the campaigns' failure rates) and dissimilarities (such as average investment goal; the average pledge; success rates) when comparing the two models.

However, the scholars focused on campaigns' outcomes, while less investigated are the differences between RCF and ECF in terms of campaigns' characteristics. Hence, we focus on four main elements of the campaigns (Mollick, 2014; Bi et al., 2017; Davis et al., 2017): video, images, updates and comments. We propose the following propositions:

P1*: RCF campaigns differ from ECF campaigns in terms of video length.*

P2*: RCF campaigns differ from ECF campaigns in terms of number of images.*

P3*: RCF campaigns differ from ECF campaigns in terms of number of updates.*

***P4**: RCF campaigns differ from ECF campaigns in terms of number of comments.*

We focus on Italy, a country where CF is widely used and widespread, especially the ECF model (Troise and Tani, 2020). In fact, Italy was the first country in Europe to regulate ECF through the D.L.179/2012 or Decreto Crescita Bis.

At this stage of our study, we can only propose several propositions as we will perform the analyses after the end of data collection.

4 Conclusions

In the last years, CF models are spreading all over the world and many entrepreneurs leverage several types of CF to support their business.

Hopefully, this research could improve our understanding on entrepreneurship in a new field like the Fintech one, and contribute to increase our knowledge about the CF and Fintech development. In particular, Fintech development is an emerging topic and the studies that address this theme are still few and limited. Thus, this paper aims to provide insights in the nascent research stream that specifically focuses on entrepreneurship in Fintech.

Hopefully, this study will have interesting implications for several players of the entrepreneurial ecosystem, such as entrepreneurs, managers, policy makers, authorities, investors, Fintech operators and so on.

This study just represents a first attempt to compare two players of the Fintech landscape, i.e. RCF and ECF. However, at this stage, the study offers only several research propositions and this represents the main limitation. The most suitable research method could be a quantitative methodology leveraging quantitative data in order to test the hypotheses related to our research propositions. This will allow us to have objective findings and confirm or not our hypotheses.

This study will favor the development of a full investigation of Fintech development and shed some lights on RCF and ECF that are among the most representative models of the Fintech landscape..

Abstract

Nothing could seem more at odds than to think of a connection between a prestigious university institution, what was once critically labelled as an ivory tower and a car body shop. What could have in common an institution of high culture, and, those places, which, according to the collective imagination are associated with rust, burnt oil, and perhaps, a little spreading level of ignorance?
This is undoubtedly the case of rethinking stakeholder engagement of a public university (Politecnico di Torino) at its margin through a project intensively tighten with the local territory. Conducted by the Research Group "Competitiveness and Business Value", the case herein explored involves a multi-stakeholder network of local actors operating in the business sector of car body shops. The exogenous variables affecting the local area are crucial, especially for the historical background of the local economy grounded in the automotive sector. In this research, the multi-stakeholder network is composed by ten local Car Body Shops, a few dozen of their suppliers as well as, two Regional Chapter of Italian associations of handcrafts and Small and Medium Enterprises. The research project aims to drive the sector of car body shops towards the adoption of a sustainable business model among a real competitive leap with new keys to accessing the competitive-strategic, social and environmental, and economic-financial balance. Recurring to a

case study (Yazan, 2015; Yin, 2003), the dialogue between the Politecnico and the car body shops is investigated using the lens of their sustainable business model.
Key performance indicators are identified. Therefore it allows to apply the most appropriate statistical analysis models and to identify the market trends, the areas of managerial tension, the structure of investments and loans, the level of professional skills, the employment dynamics, the best practices, etc. and to disseminate, also through managerial and technical-professional training courses, information and knowledge to the entire national system of car body shops.

Keywords – University, Shared value, Small Business Social Responsibility (SBSR), Stakeholder engagement, Sustainable Business Model

Paper type – Academic Research Paper

1 Introduction

The University has the chance, and also the duty, as a centre of natural integration and of knowledge innovation, to represent an extraordinary development way for the social and economic context in which it operates. The keystone consists of the will and ability in looking for and finding the synchronicity between institutions and enterprises, by creating, as a common factor, a bijective flow of energies, methods, experiences and passions, in a temporal continuity. This is the inner meaning and the goal that has been animating the Research Department of Entrepreneurial Competitiveness and Value, of Politecnico di Torino, since 2009, the year of its birth. The goal of identifying the most efficient solutions for measuring performances of the economic entrepreneurial activities, has found a suitable laboratory for the automotive aftermarket industry, with high focus on the so called 'Independent After Market' segment, whose economic role is to produce and provide spare parts as the alternative or the equivalent to those originals, sold by the Parent Companies of cars, trucks, motorbikes etc. with their own brand. A historical, technological discontinuity affects the car product, from the thermal engine to the electric/hybrid one and from the use of ADAS (advance drivers assistance systems) to autonomous driving. Besides, a powerful competitive acceleration is in progress, in terms of services provided, organisational structures, professional skills, investment intensity, business size, and regulatory changes, legislation on pollution, traffic, infrastructures, road safety, etc. A business sector often stigmatised, 14,000 operating companies are operating in Italy with an average of 4 direct and 16 indirect employees (service companies, manufacturing companies of equipment, paints, spare parts, etc.). The contribution of this industry to the Market, in terms of Gross Domestic Product (GDP) and Employment is really impressive: suffice it to say that the car fleet in Italy counts towards 40 million of cars, 4,5 million of trucks and furthermore all those enterprises that produces machines for the production of spare parts and tools for all the car body shops and their maintenance enterprises, all around the country (Osservatorio di Mercato IAM, n.d.).

2 Literature backbone and overview on method

As noticed by Spence (2014), when it comes to small business social responsibilities, the focus of the research mainstream is to leaving beside single entrepreneurs and micro-companies, to focus more on medium organisations that can scale up. This attitude of research has led to the ignoring of the needs of smaller companies, not only in terms of competitiveness and market presence but also in terms of social and environmental impacts. Nevertheless, concerning the data reported in the latest Eurobarometer research, small businesses have enormous development potential for adopting sustainable and green business models. As a backbone of the European economy, SMEs are undergone a smooth, but evident transformation on two important directions, their greening (in terms of becoming more circular economy-oriented) and their progressive digitalisation (European Commission, 2016, 2017).

The research conducted is particularly interesting, as it traces an unusual direction of creating a dialogue with the territory, moreover with a part that can be considered disadvantaged, stigmatised and ignored (Brown & Dillard, 2015; Dillard & Vinnari, 2018; Dillard, Yuthas, & Baudot, 2016). How has such a dialogue between the university and the territory undergone? Pivotal on the notion of Creation of Shared Value (M. E. Porter & Kramer, 2011; Michael E. Porter & Kramer, 2019), car body shops will benefit from the synergies created with Politecnico unlocking a new level of competitiveness for the local economy.

With the word sustainable business model, we incorporate a triple bottom line approach and consider a wide range of stakeholder interests, including environment and society (Bocken, Short, Rana, & Evans, 2014). An adaptation of the definition of the sustainable business model for car body shops has been co-created during the research, capitalising on the knowledge shared by actors and defining guidelines on organisational / management quality, competitive-strategic and economic-financial balance, ethical, social and environmental criteria. A sort of integrated performance is then determined, and the knowledge created has been concretised into a disciplinary, that identifies the standard requirements for being certified as an Excellent Car Body Shop.

Social and practical applications are impacting the national state of the art of the such marginalised sectors, but also the case sheds light on a peculiar and unconventional channel of dialogue between higher education institutions and their territory that broaden the concept of an entrepreneurial university (Pugh, Lamine, Jack, & Hamilton, 2018).

In such a sector and in the deep aim of the entrepreneurial university (D'Este & Perkmann, 2011; Elia, Secundo, & Passiante, 2017; Gibb, Haskins, & Robertson, 2013), a case study will be presented the one of the above-mentioned Research Department and the Spin Off of the Politecnico di Torino Standard & Testing (Yazan, 2015; Yin, 2003). Born in 2019, it have identified the market segment of the Car Body Shops as an additional object of analysis for both the performances of the same and the improvement of their management path to follow, in order to react against competition.

3 The Assertion Process for the Sustainability of the Business Model of the Car Body Shops

The goal of the Assertion Project of the Car Body Shops is to certify, through an integrated system made of several KPIs (Key Performance Indicators), the sustainability, over time, of the business model of the enterprise. The Car Body Shop that has been asserted as sustainable is a warranty of an economic-financial equilibrium and of wealthy economical relationships with and for all the people involved (stakeholders), from the suppliers to the users, from the collaborators to the institutions. Moreover, asserted Car Body Shops mean higher guarantees in professional car body repair, decrease of death level on the streets, greater respect of operational safety standards, greater respect of social security and tax regulations, thus, higher resources for the community, higher attention to the environmental regulations which means the quality of life rised up, better organization and more awareness about professional competences, loyal selection for those supplier who respect the standards, etc. Asserted Car Body Shops mean be aware about the right professional behaviour with the belief that if the source of the matter is virtuous, there are no other ways that the shared activity is virtuous too.

3.1 Innovation and competitiveness

The reasons why excellent Car Body Shops might support and participate in this Project are countless, but it is possible to distinguish among the followings:

1. technological innovation of the car product (but also of the truck): nowadays there is a real technological discontinuity that can be described through three main sections: a) the engine evolution from the thermal one of hydrocarbon combustion, to the other electrically propelled and/or hydrogen-powered; b) the transition from context in which the driver must pay attention to everything without electrical support, the so called zero-level, to the other where the vehicle is completely autonomous and for which the human intervention is no longer needed, the so called fifth-level; c) the introduction in the market of a vehicle with more and more interconnected functions both within the machine and with the external environment;
2. a common up-growing environmental sensibility strengthened by more and more restrictive standards about pollutant emissions into the environment and circulation in metropolitan areas;
3. the progressive expansion of the principle of the possession instead of the one of the property, thus the possibility to make car rental also for private users, for both short and long terms, for both used and new cars, will make the rental companies the most important client for the Car Body Shops, which, at the same time, must be ready and well organized to efficiently process higher and higher volumes;

4. the direction of Car Body Shops market segment towards the multi-service approach, that means satisfy nearly all types of requirements of the client with respect to their cars, starting from the traditional activities about car body repair, to the mechatronic, from the classic inspection to tyres substitution, from the pose of glass parts to the selling of insurance policies etc.;
5. the dual necessity, with respect to above mentioned considerations, for the Car Body Shops of investing more and more money in tools (think to the calibration of ADAS, advanced driver assistance systems), spaces, business management, professional competences (training courses etc.), business intelligence systems, managerial programming and control culture etc. on the one side; to dispose of a financial structure well balanced between financial debts and equity on the other;
6. the need to make visible the communication to the end users about the professional quality of the Car Body Shops, in terms of technical competences, of service, high quality of materials and components used, in order to give them the possibility to appreciate a different value proposition related to the price/quality relationship.

All those aspects lead the Car Body Shop Market segment following an evaluative path, starting from an handmade dimension, about which it is surely fundamental to preserve the professional quality, to a real business setting through which it is possible to acquire specific competences and coded process dispositions, expressed through standardized performances of efficiency and strength, that would be recognized as the reference for the excellent Car Body Shop and thus, shared to the public as such. One of the most reliable effects will be at the same time, totally for the advantage of the clients, the growth of the performance quality of these enterprises and a greater competitiveness that will lead to a scenario composed by less Car Body Shops in the Market, numerically speaking, but of bigger dimensions. All the models and the analytic algorithm for the market dynamics underline, for the next ten years, a decrease of the Caro Body Shops all over the country of nearly 4% per year, and a doubling increase in dimensions and spaces for the remaining: numerically speaking, over the time window 2020-2028 the decrease of the enterprises in Italy will be towards -33,52%, lowering the number of businesses all over the country to “just” 9.970 units. In parallel the earnings will increase for nearly +165,93%, at a Compound Average Growth Rate (CAGR) of +10,28%.

3.2 The methodological directives

About the methods adopted for the Assertion Project under analysis, the process is focussed on three main conditions that are considered fundamental and qualifying, not negotiable, and other two guidelines to satisfy based on precise performance indicators created ad hoc. With respect to the first point, to declare a Car Body Shop as ‘assertable’, it must respect the following three qualifying conditions:

1. respect of the laws, being those environmental, about security and hygiene on the job, equity of genders, social, fiscal etc. and linked compliances such as DURC (Documento Unico di regolarità contributiva), SCIA (segnalazione certificata d'inizio attività), GDPR (general data protection regulation), visura camerale, MUD (modello unico dichiarazione ambientale: denuncia annuale rifiuti), DVR (documento di valutazione dei rischi), CPI (certificato protezione incendi), dichiarazione di conformità di impianti elettrici, di messa a terra e dispositivi di protezione contro le scariche atmosferiche, note informative e verbale di consegna dei dispositivi di protezione individuale (DPI), l'Autorizzazione emissioni in atmosfera, etc.;
2. the possession of the basic qualifying tools to perform: there have been identified at least twelve different tools such as painting and drying booths; preparation plants, templates benches, dust extraction plants, lifting bridges, tintometric areas, welding fumes vacuum cleaners, rotoorbital for preparation and polishing, spotters, complete kits aerographs for painting, software estimators, etc. These tools are considered essential for a Car Body Shop to perform as such, otherwise the activity cannot be considered compelling;
3. The last point is a little bit more sensitive than the previous ones, because it is related to the amount of external work that a Car Body Shop makes: this percentage must not override the threshold of 40% about the total amount of goods and direct services purchased. By this way are not considered as assertable all those businesses based on a high level of externalized performances.

Concerning to the three guidelines above mentioned, it is possible to identify two main sections:

1. the first related to the organizational quality in terms of physical spaces, distinction among areas dedicated to the production, investment innovation, programming and control activities of the process flows, service level, types of estimates, turnover of the spare parts and components, productivity level of the human resources, kinds of tools a part from the ones prior mentioned as essential, level of competences, professional training activities, customer relationship management models, key-to-key time (time span between the moment the client leaves his car in the Car Body Shop, and the moment when he picks it up), etc.;
2. the second point is related to the economic-financial equilibrium expressed in terms of strategy, profitability, financial sustainability, development rate, economic elasticity of the structure, patrimonial level and relative financial independence strength of the business, days sales outstanding coherent with the days purchasing outstanding, operating and recurring financial dynamics, value added created by resources on work, value creation for the stakeholders etc.

For each one of the two guidelines just now described, there have been created appropriate performance indicators: more precisely 31 KPIs for each guideline. These

indicators must have three main characteristics to be considered reliable: the must be measurable, impartial, and verifiable. Furthermore, for each of them a coherent scale of values have been created (starting from 0- worst performance, to 10 – best performance), with the aim to confer to the value of each KPI the relative score pointed on the scale. When the positivity value of a KPI among two consecutive years is confirmed or even improved, there have been considered some point bonus, to award this performance; as well as some point as malus are subtracted in case the outcome crosses from positive into negative or if e bad score is confirmed among two consecutive years. The formulas of the 62 KPIs, the scale of values connected to them and all the variables involved for their calculation are part of the so called 'Disciplinary of the Assertion Process'. other two methods are taken into considerations: the former consists of pointing out, for each KPI whose scores would be lower than the minimum admitted for the assertion, which variables are better off to intervene on and the time horizon in which operate to rise u the value of the KPI involved. The latter is to compare, always for each KPI, the performances of the Car Body Shop under analysis with respect both to a sample of comparable enterprises and to the best performer of that sample. In more details, there have been identified three criteria to build up the comparable samples: the distinction is made upon the number of employees of the Car Body Shop, its geographical location (distinguishing among metropolitan areas, extra metropolitan areas and rural areas) and the kind of activity performed (car repair only, multiservice etc.) with the availability or not of the tow truck.

4 Operating process

The operating process of the Assertion project is composed by six different phases: of which four are useful to obtain the certificate and the other two for the maintenance over time of the same assertion. More precisely:

1. the first phase consists of the verification of the three qualifying conditions with linked documents acquisition to let the validation process to be made;
2. the second phase, so called 'Competitive Equilibrium' is a certificate that can be obtained once the car Body Shop under analysis get a compounded average score not lower than 62,5% of the maximum, and is referred to a group of 31 KPIs, of which 15 are related to the organizational quality and 16 to the economic-financial equilibrium of the business: important to specify that these indicators are measured and evaluated for the last three years since the year for the Assertion. Furthermore the improvement or the worsening of these KPIs, together with the possible volatility of each of them may contribute to the scores got by each indicator;
3. during the third phase, named 'Competitive Strength', the KPIs involved in the evaluation amount to 62 and the compounded average score might not be lower than 72,5% of the maximum;

4. the forth phase is characterized by the formal and physical validation of the previous two phases, by a certifying agent, in the car body Shop and with the authorization by the last one for the access to the informatics system, where there are all the data useful for the calculation of the KPIs for Assertion;
5. the last two phases are useful for the monitoring of the business in one and two years respectively for the assertion obtained, in order to evaluate again the 62 KPIs as a maintenance of the certificate.

Each one of these phases, as well as each one of the 62 KPIs have been deeply discussed and shared, at the end of a six-months work, with a group of work made by ten Car Body Shops located in Piedmont, two category organizers and the contribution of some of the greatest supplier of goods and tools for Car Body Shops of the market, in terms of competences and experience in the sector. Such group of work has rised the analytical operating organization of each one of the these ten enterprises involved, starting from the check-in to the delivery of the fixed car to the client, with the aim of underlying the points of strength and weaknesses and identifying the consequent improving paths to follow, also in order to react to the competitiveness' pressure.

4.1 Next steps

Next steps of the Assertion Process for the Sustainability of the Business Model of the Car Body Shop would be made by following four different directions:

1. to collect a total of at least 200 Car Body Shops asserted and then create a cooperation with Accredia (the national unique Entity designated to certify all those activities that would certify at their own pace other businesses, for example Standard & Testing, Spin Off of the Politecnico di Torino, under the control of the Economic and Development Ministry of the Italian Government, and following the European Rule 765/2008, for certify the competence, the independence and the impartiality of all those organizations that would certify, verify and inspect laboratories), with the goal of making the 62 KPIs a public standard of reference;
2. to communicate to all the interlocutors of the Car Body Shops the list of those who have achieved the Assertion after having completed all the cycle, underlying their scores performances and those variables subject to improvement;
3. to update time after time the models of analysis of performances of Car Body Shops referring to both organizational quality and to economic-financial equilibrium;
4. to plan national conferences focussed on Car Body Shops market segment with the aim of exposing the results of all the analysis made by the Research Centre and By the Spin Off of the Politecnico di Torino, with reference to the

economic-financial trend of the Car Body Shops and to the evolution of the supply chain itself.

5 Conclusion and Future aim

In the end, the goal of the Research Centre for competitiveness and Enterprise's Value together with the Spin Off of Politecnico di Torino Standard & Testing, is to build a strong connection between university didactic world with the one social and economic of the workers, paying particular attention to the Car Body Shops' Market segment. The background of automotive competitiveness will cross, in very short term, from the production to the selling and to the repairing, a real change in paradigm; due to this fact all the operators of the chain will have to react promptly to these changes , adapting their own business model on the new organizational set-up, performance parameters, minimal competences' level, investment innovation etc. This might represent an epochal turning point for one of the most relevant pieces of the Italian economic system, when us, as scientific researchers, have the challenge to assure an award for all those main characters of this sector who respect the law and are able to create and share economic value for and with the community.

Different discourses and dialogues emerge from this case:

- An interinstitutional dialogue between the university (Politecnico) and its multi-stakeholder networks of agents
- An endogenous dialogue between local actors in determining the essential features to be monitored, also with competing interests and different point of views
- A micro-foundational dialogue between the Politecnico and each small company involved in the project, especially on the feedback effect on business performances.

As a future development of this research, we will contextualise and better triangulate data collected from the user, developing a more sophisticated interventionist research protocol with reflective analysis**.**

Abstract

Design-based learning is an educational approach grounded in the inquiry and reasoning processes towards generating innovative solutions. The approach is known and proven to be effective in the context of learning natural sciences and engineering education. Thake into account that design cognition is also close to entrepreneurs to create opportunities and innovation, we adapt the design-based learning for entrepreneurship education in co-creation project-based learning. In this paper, we illustrate how we train nascent innovative entrepreneurs using co-design approach to foster innovative thinking (creativity, analyticity, intuition, flexibility of thinking) in the project-based learning format. Our exploratory research has revealed key characteristics of co-design project-based learning approach for nurturing of entrepreneurs in the digital age.

Keywords – design-based learning, digital, prototyping, innovative thinking

Paper type – Academic Research Paper

1 Introduction

Entrepreneurship education (EE) can be taught in different ways by a wide range of approaches (Pittaway and Edwards, 2012; Kuratko, 2005; Hjorth and Johannisson, 2007; Wang and Chugh, 2014). Still we have a lot of discussion about the scope, objectives and methodologies that should be addressed in EE (Fayolle, 2013; Fayolle and Gailly, 2015; Kuckertz, 2013) as well as about its actual impact. EE has evolved over the years due to influence of dynamic business environment and uncertainty, rapid development of technologies and ubiquitous digitalization. Today's entrepreneurs have more resources at their fingertips than ever before. The internet, social media, big data made many tools available to innovative entrepreneurs. It also opened up an entirely new place to do new

products and business. EE moves away from approaches of “about” and “for” to the character of “through”. Entrepreneurial learning needs to reflect the process that entrepreneurs go through by focusing on action, experiences, reflection and generation in an unknown future (Kassean et al. 2015; Neck and Greene, 2011).

Exploratory learning (also experimental learning) often results from the internal transformation through developing new knowledge (Kreiser 2011; Zhao et al. 2011) and deviance-error learning (Bingham and Davis 2012).

Action-based entrepreneurial pedagogy involves getting out of a classroom to get hands-on experience talking to users/customers and regularly present lessons learned (Ries, 2011; Blank, 2013). Over the last decade, innovative entrepreneurs use hypothesis-driven approach for opportunity creation called lean startup (Eisenmann, et al. 2011). Key features of this approach are willingness for experimentation, ability and skills to learn from experiments (Alvarez, 2010). Such learning requires "innovative thinking" competence (creativity, intuition, analyticity, flexibility of thinking), ability to be collaborative, open to feedback, willingness to fail and learn from experience. Analytical reasoning taught in business schools, equips managers with cognitive skills and methods. Innovative entrepreneurs deal with high degrees of uncertainty are still equipped not enough in terms of managerial methods and tools. There is a gap in EE when it comes to addressing complex, ill-defined problems with poorly formalized, scarce or ambiguous facts.

Effectuation suggests that instead of predefining goals in highly uncertain environments, innovative entrepreneurs rely on the means that are available at hand and co-create opportunities (Sarasvathy, 2001). The effectuation logic is based on many features that align with design (Stovang and Nielsen 2015). Design cognition addresses these gaps by identifying specific cognitive acts and structures associated with productive outcomes to open-ended and unstructured cases (Garbuio, et al. 2018). Creativity is an intersection between entrepreneurship and design (Li, 2008; Ko and Butler, 2007). Uncertainty is a major force that drives behaviour in both domains (Sarasvathy, 2009; Buchanan, 1992). Empathy allows entrepreneurs and designers to address explicit or latent needs (Brown, 2009; Chiles et al., 2010). There are many similarities between the front-end of the innovation product design process and the front-end of the entrepreneurial process (Barringer and Gresock, 2014; Mata García et al., 2017). Logically EE calls for user-centered approach (Glen et al., 2014; Fixson and Rao, 2014).

The objective of this paper is to adapt the design-based learning approach for entrepreneurship education with the aim to improve innovative thinking competence of nascent entrepreneurs, operating at fuzzy front end of innovation, and identify key characteristics of co-design project-based learning approach for nurturing of entrepreneurs in the digital age.

This exploratory research is based on qualitative and quantitative analysis. To evaluate the progress in improvement of innovative thinking the pre- and post-codesign workshop surveys of the 54 nascent entrepreneurs were administered with 92,5% response rate. The

data was analyses using statistical method, i.e. calculation of the mean, standard deviation, mean difference and a paired t-test. The research was held in 2019/20 and took 4 months.

The paper is structured as follows. In the coming section, we discuss the background and the underlying principles of design thinking as a user-centered design approach, introduce design-based learning as an educational approach grounded in the processes of inquiry and reasoning towards generating innovative solutions. Next, we introduce CoDesign-based learning approach and its key characteristics to foster innovative thinking as a specific entrepreneurial competence, present specially developed co-creation training workshops for nascent innovative entrepreneurs and the results of statistical analysis of innovative skills development. In conclusion, the results and the direction of further research are formulated.

2 Design approach in entrepreneurial learning

2.1 Design thinking a human-centered, iterative and collaborative process

Over the past two decades, the importance of design and the value of design thinking as a tool for innovation have been recognized by business, entrepreneurial community and government (Gruber, et al. 2015). The concept of Design Thinking (DTh) as a "way of thinking" and a "method of creative action" in the sciences can be traced back to the mid-90s (Simon, 1996) and then has been extended on creation of innovation and organizational change by Tim Brown and Roger Martin (Brown, 2009; Martin, 2009). By DTh we refer to a human-centered approach to problem solving and creation of innovation that puts the observation and discovery of often highly nuanced, even tacit/latent, human "pains"/problem/needs right at the forefront of the innovation process. It considers not just the technological system constraints but also the sociocultural context.

DTh approach starts with an observation of the users/customers/clients and of the system's context and constraints, so-called the discovery phase. Discovery phase involves ethnography, visual anthropology, and the use of design probes and workshops with key stakeholders. The next define phase involves finding and framing the problems/needs and insights. The ideation phase involves brainstorming sessions and exploration, through prototypes and visualizations, alternative potential solutions and how different types of users and stakeholders might interact with those solution concepts. In the final delivery phase, the solution concepts are tested not only in terms of their robustness and effectiveness, but also of their fit with users' needs and the broader context of their lives. The DTh process is highly iterative, as it moves backwards and forwards through the phases. It is highly collaborative, involving users/customers/clients in the framing of the problem, as well as in scoping the new opportunity for design. The DTh process is as well

cross-disciplinary, involving technical, design and business disciplines in each of the phases (Brown, 2009; Gruber, et al. 2015).

Design is the synthesis of creativity, as the ability to imagine a new thing, and innovation, as the ability to bring those new things together (Li, 2008). In entrepreneurship, creativity is required to create opportunity that leads to a new product, business model and ventures (Ko and Butler, 2007). An innovative mindset or thinking is central for designers and innovative entrepreneurs (Koh et al. 2015; Laptev, et al. 2014). Following the logic of common characteristics and similarity, there is a reason to use design cognition (methods and tools) in entrepreneurship, in particular to create new product, opportunities and business model. In addition, universities and business schools acknowledge the design approach as an effective learning approach (Kolodner, 2002; Gómez, et al. 2013; (Dunne and Martin, 2006).

2.2 Design-based learning

Design-based learning (DBL) is an educational approach grounded in the processes of inquiry and reasoning towards generating innovative artefacts and solutions (Gómez, et al. 2013). DBL can be taken as an instructional method, which engages students in solving real-life problems. DBL emphasizes planning and design of activities in which students make decisions in the design cognitive thinking processes. In teams, they go iterating through problems and insights identification, generate ideas, create and test solutions (Doppelt et al. 2008; Doppelt, 2009). As an educational approach DBL is akin to and in part stems from pedagogical principles of problem-alike reasoning and problem-based project-based learning (De Graaff and Kolmos 2003). DBL is a promising instructional method to enhance the learning of the natural sciences and engineering (Kolodner, 2002; Gómez, et al. 2013).

DTh, as the combination of tools, processes, and mindsets that designers utilize to solve problems, has increasingly been added to course curricula in business schools for managers (Dunne and Martin, 2006; Liedtka, 2022; Glen, et al., 2014) and nascent entrepreneurs (Garbuio et al., 2018; Huber, 2016; Sarooghi, et al., 2019; Linton and Klinton, 2019). However, the characteristics of DBL needed to enhance the learning of competencies of entrepreneurs haven't been explored systematically.

During the last decade, we have been developing the laboratory infrastructure and using DBL to improve the competencies of nascent technology entrepreneurs in innovative product development and business models in collaboration with colleagues from European universities in a framework of EC Tempus/Erasmus+ projects. In the last couple of years, we experimented with the co-design approach in DBL workshops to improve the specific competence of nascent innovative entrepreneurs and studied key dimensions relevant to DBL (the project features, the facilities for project activities, the role of the teacher/instructor, the social context and assessment methods). In the next section, we present details of DBL co-creation activity, research methods and results.

3 CoDesign-based learning for innovative entrepreneurs

3.1 CoDesign-based learning in fostering specific entrepreneurial competence

Innovative entrepreneurs can benefit from design approach when looking for new challenges, creating opportunities and process of problem solving. This paper focuses on fostering innovative thinking – the ability to find radically new, innovative ways to solve problems by:

- Creativity – *the ability to generate a large number of ideas and striving for high variability of decisions.*
- Analyticity – *the ability to organize information, identify key inconsistencies, errors or problem areas, identifying cause-and-effect relationships and trends.*
- Intuition – *the ability to instant catching of prospective opportunities.*
- Flexibility of thinking – *the ability to rebuild quickly integrating newly arrived information in their proposals, the ability to offer different solutions to the same task, susceptibility and tolerance for different ideas.*

Co-design with users/customers/clients and entrepreneurial team is a highly collaborative and iterative process that discovers "pains"/problems, frames the key insights, and then rapidly prototypes and trials potential solutions with key stakeholders before moving into the delivery phase (Gruber, et al., 2015; *Frow, et al, 2015; Sandersa and Stappersb, 2008, 2014;* Ali and Liem, 2015). At the heart of co-creation is the primacy of human experience, and that the products and business model should be designed to enable that compelling experience, rather than the other way around.

In the 2019/20 academic year, 57 nascent entrepreneurs with different background (science, engineering and business) were selected to foster innovative thinking competence by CoDesign-based learning (CoDBL) workshops organized by MSU Innovation Business & Entrepreneurship Lab. During each of 4-week CoDBL workshops, three cross-disciplinary entrepreneurial teams of five-six members were immersed into co-design activities with users/customers/clients. They gained experience in our rapid prototyping lab equipped with digital facilities (3D printers, milling and laser machines, scanners, VR/AR, etc.), materials for modelling, and creative spaces in "d.school style" for co-creation team work. CoDBL workshop can be described as a combination of “hard” (a set of equipment for design, rapid prototyping and creative space for team/project work) and “soft” (entrepreneurial management, user-centered and participatory design approaches, customer development, lead product development) components for creating successful innovative products. CoDBL workshop instructors and entrepreneurial team supervisors are both university staff and industry representatives from design, engineering and management. CoDBL workshop teams had to carry their projects through all the steps of the creative problem-solving product co-design process within fuzzy front end (Kim and Wilemon, 2002), i.e identification of customer/market/technology opportunities, co-development product ideas to meet

user/customer demand and co-development of a product concept. The goal of CoDBL workshop teams was to co-develop and validate product concepts, i.e. MVPs- minimum viable products (Ries, 2011; Blank, 2013; *Frow, et al, 2015;* Ali and Liem, 2015).

Carrying out the CoDBL workshops we also studied the improvement of innovative thinking competence of nascent entrepreneurs. To clarify the impact of co-design-based learning and project based learning approaches the statistical analysis was carried out in order to determine the effects of the CoDBL workshop. Two surveys in the form of questionnaire were administered to workshop participants: one at the beginning of CoDBL workshops and another after the completion of the product design project. We asked participants of three CoDBL workshops (54 nascent innovative entrepreneurs) to rate their innovative thinking (creativity, intuition, analyticity, flexibility of thinking) on a scale of 1 to 5 where 1 = poor, 2 = basic, 3 = medium, 4 = advanced and 5 = expert level (see Table 1). The response rate was 92,5%. Tables 1-3 show how the skills/abilities of the CoDBL workshop's participants changed.

Table 1, The results from the pre- and post- CoDBL for participants of the CoDBL workshop#1.

Skills/Abilities	**Pre- CoDBL**		**Post- CoDBL**		**Mean**	**Paired t-test***	
	Mean	SD	Mean	SD	**difference**	**t-value**	**p-value**

Based on the participants' rates for each components of innovative thinking competence before and after the CoDBL workshops, we calculated statistics and the paired sample t-test. Tables 1 – 3 show the results of the experiment data. The results of the paired t-test show that the p-value for each of the category is less the 0.0001, which indicates that there is the difference between pre- and post- values for each category. We observe that the results of the three CoDBL workshops activities are rather successful. The results of the statistical analysis demonstrate an increase in the mean values for all components of innovative thinking competence of the CoDBL workshops participants (nascent innovative entrepreneurs). Based on the change in the standard deviation (SD) we conclude that the group of participants becomes more homogeneous after going through the CoDBL. Following each of the three 4-week CoDBL workshops, one participant from each team was selected and interviewed. The purpose of the interview was to determine perceptions regarding effects of the co-design workshops, accepted value and further personal development this way.

3.2 Characteristic of CoDBL in entrepreneurship

The result of CoDBL workshops revealed, that co-design approach in teaching entrepreneurship enhances innovative thinking, ability to work in team, establish new connections, network and create opportunity by exploring the social, cultural, technological and economic landscape, and also improve the ability to tolerate ambiguity and uncertain situations, make sound decisions in such situations and being able to control own emotions.

Based on these results, we continued the empirical research and devoted it to identification of the key characteristics of CoDBL in entrepreneurship education. As a first step, we administered the surveys in the form of questionnaire to CoDBL workshop graduates. In addition, we selected and interviewed 18 CoDBL workshop graduates, two from each team. To gain additional expertise, in-depth interviews were conducted with 5 professional product designers and organizers of the co-creation sessions.

As a result, we identified key dimensions relevant to CoDBL in entrepreneurial learning: project features, facilities for project activities, role of the teacher/instructor,

social context of learning and result assessment) and found following characteristics (see Tables 4-7).

Table 4. Characteristics of CoDBL pertaining to project features.

Project feature	Examples
Entrepreneurial project	Competitive combination of innovative product/service and/or business model. Competitive value proposition by innovative product/service or/and business/revenue model. Business/sale perspective.
Cross-disciplinary	Project participants are from science, engineering, design, business, etc. Cross-disciplinary team.
Open-ended	No unique solution is given. No specification, questioning help to arrive to a fully developed specification. Incomplete information is provided in beginning of project activities. Case reasoning approach to solve problems.
Management	Project participants in collaboration with stakeholders define the "pain"/problem/need, the goals and design task. Project participants search solutions based on iteration "hypothesis-build-measure-learn-new hypothesis…" feedback loop. Project participants use design (human-centered) approach and methodology. Project participants can use lean and agile approach. Rapid/exploratory prototyping. Prototype is MVP - minimum viable product. Project participants are requested to determine own procedures and solution testing plan. Real life scenario for solution testing. Final business solution is usually a combination of product/service and business/revenue model.
Experience & experimentation	Project participants apply theory in practical schemes. Hands-on experiences. Project participants conduct experiments and learn from iterations and interaction inside and outside the team. Reflection based on experimentation and experiencing.

Table 5. Characteristics of CoDBL pertaining to facilities for project activities.

Facilities for project activities	Examples
Digital equipment for design & rapid prototyping	Digital equipment for collaborative and distant product concept design. Digital equipment for rapid prototyping. Lab equipment for rapid prototyping (3D printers, milling and laser machines, scanners, VR/AR, etc.) always kept clean, smart and within easy reach. Creative spaces in "d.school style" for co-creation team work with vidio-conference connection.
Creative spaces	Creative spaces in "d.school style" for co-creation team work with vidio-conference connection. Creative spaces for individual work and DIY with Wi-Fi.

Table 6. Characteristics of CoDBL pertaining to the teacher's/instructor's role.

Teacher's/Instructor's role	Examples
Coaching	Coaching on task, process and team. Discussions to reflect on process to technical design and business case. Use hands-outs, worksheets, and other forms of representation. Stimulation of evaluation of process and self-reflection Regular online communication to clarify project issues.
Industrial, venture business & academic expertise/consultation	Faculty (teachers) and instructors act as consultants/expert. Industrial representatives act as consultants/expert. Venture business/capital act as consultants/expert. Formative feedback; project plan, progress reports, mock-up/prototype, etc. Regular online communication to clarify project issues.

Table 7. Characteristics of CoDBL pertaining to the social context and result assessment.

Social context and assessment of the results	Examples
Collaborative/open innovation approach for learning	Identification and communication with key stakeholders ("customer discovery & validation" approach). Co-creation/co-design with key stakeholders/lead users. Building and managing cross-disciplinary project teams. Peer-to-peer communication and peer-to-peer feedback. Peer learning processes within and across project teams. Motivation through competitions. Openness to communicate in social networks and professional communities.
Summative assessment	User/customer validated prototype (MVP - minimum viable product) and business model.

4 Conclusions

This paper supports a new look at design that can be effectively applied to entrepreneurship education. We moved from user-centred design to co-designing and thereby involved users/customers and other stakeholder in the educational process. CoDesign-based learning, as a collaborative learning method, allowed significantly expand the social context and embed nascent entrepreneurs in critical thinking peer-to-peer activities and learning. For further research, we plan to provide recommendations on introducing CoDesign-based learning in project based learning of nascent innovative entrepreneurs and discuss the environment, the role of practitioners and external support from design and innovation business community. At next stage of our research, we will have focus on the study of collaborative project features and digital facilities for project activities.

Abstract

The current research is a part of ongoing work aimed to shed light on relationship' value for woman startup in the crowdfunding context. This paper analyses how intangible resources, as relational capital, can contribute to fundraising during the early stage and, especially, which types of these relations female entrepreneurs must or must not growing to fundraise resources from the crowd.
Based on the qualitative approach of the single-case study, the paper, through the CAOS ('characteristics, ambiance, organization, start-up') observe all the relevant relationships (cardinal links in first, second, and third types) that can lead the success of the financial operation.
The findings show that at least for the early-stage, in the crowdfunding operation, the informal configuration of the relationship established by woman start-up can produce a negative effect on fundraising process.
Several implications have been reached. Firstly, for the academic community, this study can contribute to expanding the literature on gender study especially which that focusing its studies on the start-up phase of female company. Secondly for practitioners, because ever more companies, especially in the actual context of the digital age, are oriented toward alternative ways of finance, particularly via internet as crowdfunding. In this way, efficient use of relational capital' resources could be a value driver to overcome the hard stage of the start-up. Also, again concerning managerial aspects, the model applied (CAOS) allows to observe that the misdistribution of the role can involve the failure of the female startup.
The limitation of the research concerns the SMEs (startup) dimension. Analysis of data has been available only through direct interviews with female entrepreneurship. Regard to future perspectives, the present paper represents the second step of "RC and Woman start-up" research mainstream. In the future, the authors will replicate the analysis, by the acquisition of additional data, will investigate which RC factors can promote the success of fundraising operations.

Keywords – Female entrepreneurship, Woman startup, Crowdfunding, Relational capital

Paper type – Academic Research Paper

1 Introduction

The advent of the Digital Age is allowing the startup firms to overcome traditional patterns of SME's typical function. The real change is related to the use by companies of the new channel of finance introduced by a new phenomenon called FinTech Revolution (Blakstad and Allen, 2018). In this landscape, small and medium companies, in accordance with their needs, can choose if utilize new financial instrument oriented by debt channel, as mini-bond, or by equity-channel, as crowdfunding (Paoloni, et al., 2020a; Paoloni, et al. 2019a; Caratelli and Fattobene, 2018).

Crowdfunding, allows small entrepreneurs to raise funds from a large crowd via Internet. It has the potential to help fill the funding gap because it allows nonqualified individuals to also invest in innovative start-ups. (Belleflamme, et al., 2014; Hornuf and Schwienbacher, 2017). This innovative financial tool has significant scope to facilitate investment in emerging economies (Zheng, et al., 2016; Liao et al.,2015),

The main actors involved in a typical crowdfunding operation are (i) project initiator who presents it credit request or idea/project to be funded; (ii) individuals or groups (i.e., the crowd) who support the funding request; and (iii) a moderating organization (i.e., the platform) that brings the parties together to launch the idea or support the borrowing request (Pellizzon, et al.,2016).

However, regarding gender studies, female entrepreneurs still meet barriers to access credit. The main difficulties still discussed in literature about the barriers to financing related to gender factors accessing credit and of their preference to use personal loan more than man (Cesaroni and Sentuti, 2014; Constantinidis et al., 2006), has been found also in the stream of the innovative financial instrument (Coleman and Robb, 2009; Kanze, et al, 2018).

Recent research about crowdfunding and woman start-ups' (Paoloni et al., 2019b) has confirmed a gap in the literature concerning their use of crowdfunding.

Based on previous mainstream on the importance of intangible assets to fundraise (Ahlers, et al., 2015; Vismara, 2016; Brown, et al., 2019), the present research investigated how relational capital (RC) could help the crowdfunding operations of WSUs. To answer this research question, a qualitative research methodology using a multiple case study (Yin, 2014) was utilized, and the CAOS model of micro-entrepreneurship by Paoloni (2011) was also applied.

This paper is organized as follows. Section 2 develops the literature review and highlights some gaps in the literature. Section 3 presents the methodology. Section 4 tackles the case study and findings. The last section summarizes the conclusion, implication for practitioners, limitation and future perspective.

2 Literature Review

The interest for alternative finance channel' topic, as crowdfunding, has grown up into the SMEs dimension in the last decades. Crowdfunding is one of the main actors of the Fintech revolution phenomenon (Arner, et al., 2016; Chen, et al., 2017; Gabor, et al., 2017). Across this new financing tool, the company can give financial resources directly from the "crowd" (Belleflamme, et al., 2014; Fatoki, 2015; Maier, 2016; Block et al., 2018).

During the time, despite the mechanism to give resources from the crowd is still unchanged, crowdfunding has taken various forms. What differentiates each type from the other is the return reserved to the subject that has contributed to the campaign. Actually, the main 4 forms known are donation-based, reward-based, lending-based and equity-based (Cholakova and Clarysse 2015). In the donation-based the donors financing the companies' project without expecting anything in return. In the reward-based, after received funds, the company reserved to backers a specific reward inherent in the project development. This form of financial gathering is the most commonly used in art' projects. (Kuppuswamy and Bayus, 2018)

The lending-based is the crowdfunding form closest to the traditional loan channel. In fact, by the lending model, the company, before that, the crowdfunding campaign was declared open, establishes inter alia the loan repayment condition reserved to the lenders (Bottiglia, 2016). Finally, in the equity model, the investor contributes directly to the number of equity shares of the company. Once that investor subscribes the equity, it shares the risks related to the economic activity of the company (Ahlers, et al., 2015).

This particular form of crowdfunding has been introduced in 2012 in the legal regulation of several countries. Referring to the Italian context, equity crowdfunding has been introduced by Decrees-Law no. 83/2012 and 145/2013.

Focusing on economic data have confirmed that this innovative tool is popular with SMEs. Starteed (2019) reported that, in Italy, the volume of crowdfunding resources has grown from 66 million in 2015 to 442.68 million in 2019 (up 85% in four years). Also, only the equity-model in 2019 generates 128.5 million with 408 campaigns.

However, regarding gender studies, recent research about crowdfunding and woman start-ups' (Paoloni et al., 2019b) has confirmed a gap in the literature concerning WSUs' use of crowdfunding. The main difficulties still discussed for traditional enterprises conducted by woman have also been observed for crowdfunding operations, as the topics of accessing credit (Cesaroni and Sentuti, 2014), the barriers to financing related to gender factors (Constantinidis et al., 2006) or their preference to use personal loan more than man (Coleman and Robb, 2009). For instance, in the crowdfunding context, female entrepreneurs raise significantly less funding than males (Cumming, et al., 2019; Kanze, et al, 2018).

Geiger and Oranburg, (2018) evidence that crowdfunding campaigns that have a female primary signatory (i.e. key founder, president, or CEO of the company) receive less funding. This research also underlines a relation between the offering amount and

funding raised. Female companies receive increasingly less funding than male and their likelihood to give all the resource requests depends on offers amount: the higher the maximum offering, the lower their probability of success.

The reasons for gender differences within business financing remain unclear. Several scholars perceive these inequalities to the different contributions of intangible assets, as human, social and intellectual capital, during crowdfunding operations.

Zheng et al. (2014), through the multidimensional approach, the integration of structural, relational, and cognitive dimensions provides an inseparable view of social capital in an entrepreneur's fundraising efforts. Ahlers, et al., (2015) examine the impact of venture quality (human, social and intellectual capital) and uncertainty on fundraising success. Drawing on signaling theory, the authors show that the main factor that contributes to the success of fundraising operation is human capital, measured by the percentage of board members with MBA degrees. While intellectual capital (as measured by patents) and social capital (as measured by alliance) had little or no significant impact on funding success.

Vismara (2016) shows that the entrepreneurs' social connections help investors to reduce information asymmetries and influence venture finance decisions. Also, this study highlighted that project proponents can effectively rely on their personal connections in the initial stages of campaigns to attract larger numbers of contributions.

Brown, et al., (2019) examine the role of entrepreneurial networks in the equity crowdfunding process. Through a quantitative approach, the authors highlighted a different contribution of the network concerning the different stages of the crowdfunding campaign. In the first stage (pre-crowdfunding), the study demonstrates strong ties between the entrepreneurs and their personal networks. Family, friends and personal colleagues of entrepreneurs encourage it to look into the crowdfunding instrument. Even in the first stage, the second type of network activated by the entrepreneur is that with the crowdfunding' platform. This contact has a crucial role in the success of operations. The platform can promote the campaign with its personal contact, like other firms, bank or investors community. Once the campaign is launched, the second phase can start. In this stage, the company establishes two different types of relationships. The first one with the small investors (i.e. the "crowd") which contributes to share capital with a small contribution, the second one with the professional investors, as venture capital and business angel. The last stage "post-crowdfunding" shows that crowdfunding confers multiple benefits (pecuniary and non-pecuniary) on firms who successfully go through the process. It helps cement weak ties with new business networks such as business angel investors whilst simultaneously strengthening weak ties to small investors in the "crowd", similar to the "fanvestors" noted by others (Brown et al., 2018). The post-crow- funding phase also sees the start-ups become engaged in a form of "network orchestration" which has both positive and negative elements.

The most recent studies investigated how entrepreneurs can build social capital. Larsson Y. et al. (2019), through social capital theory in a mixed-methods case study,

show that entrepreneurs strategically select their limited resources to build their social capital. The development of RC contributes to the community's giving collective resources for ventures.

Eiteneyer et al. (2019) investigated social capital and the digital crowd. The study suggested that reward-based crowdfunding could provide a digital opportunity for the involvement of customers in entrepreneurial ventures and business-to-consumer (B2C) relationships. Through quantitative analysis, the study underscored crowdfunding as a digital platform for market-oriented innovation.

However, no directed treatment related to relational capital and crowdfunding by the qualitative approach was conducted in the above literature. In this stream, this ongoing research (see also Paoloni, et al., 2020b) aim to analyze, through a single case study, what kind of relationship between the two would promote WSUs' successfully fundraising operations.

3 Methodology

To analyze the proposed topic, we will use the case study method with a descriptive single-case design. Case study methodology that includes both quantitative and qualitative data helps explain both the process and the outcome of a phenomenon through thorough observation, reconstruction, and analysis of the case under investigation (Lyons, 2005; Tellis, 1997; Stouffetr, 1941). The case study method allows a close examination of the data within a specific context. Case studies explore and investigate contemporary real-life phenomena through detailed contextual analysis of a limited number of events or conditions, and their relationships (Yin, 2014). To gather information about the case study in accordance with Yin (1981), data collection procedures were followed by face-to-face interviews with key informants and illustrative materials (e.g., presentation and conference materials).

The information required is in regard to specific aspects of the company, its organization, and the environment in which it is inserted. Moreover, to understand the complexity of this case study, it is very important to understand the reason that led the company to conclude the financial operation.

To answer our research question, we will use the CAOS model (Paoloni, 2011). The CAOS (an Italian acronym for 'caratteristiche personali, ambiente, organizzazione, and start-ups') model refers to the personal characteristics of the entrepreneur (C), the environment in which the micro-enterprise operates (A), organizational and managerial aspects (O), and finally, the motivations for starting a new business and the particular stage in which the SME is observed (S).

The determinants of the model are:

Personal characteristics of the entrepreneur (C): Defines distinctive factors of each entrepreneur, how they may affect the role played by the entrepreneur within the firm, and the capability to build networks and take advantage of them. Elements composing these dimensions are the following:

- anagraphic information of the entrepreneur or company (name, age, education, professional experience);
- micro-enterprise information (denomination, legal form, size, location);
- motivation supporting the business;
- business vision;
- management form;
- entrepreneur's role in the firm;
- decision-making process activation.

The environment in which the micro-enterprise operates (A): Describes the socio-economic-cultural context in which the enterprise is positioned. The environment can influence connections that a company creates while interacting with subjects in this context. Thus, the environment also impacts on the relationships deriving from the Italian economic system.

Organizational and managerial aspects (O): Identifies the factors connected to the entrepreneur's objectives, tasks, and responsibilities within the organization to understand how the agri-food system is situated in the Italian economic system and its financial characteristics. These are the elements to consider:

- assignment of roles;
- identification of responsibility;
- operational and management procedures that define how roles and business actions are executed.

The motivations for starting a new business (S): Describes the relevant phase in which the entrepreneur is focused on each of the following actions:

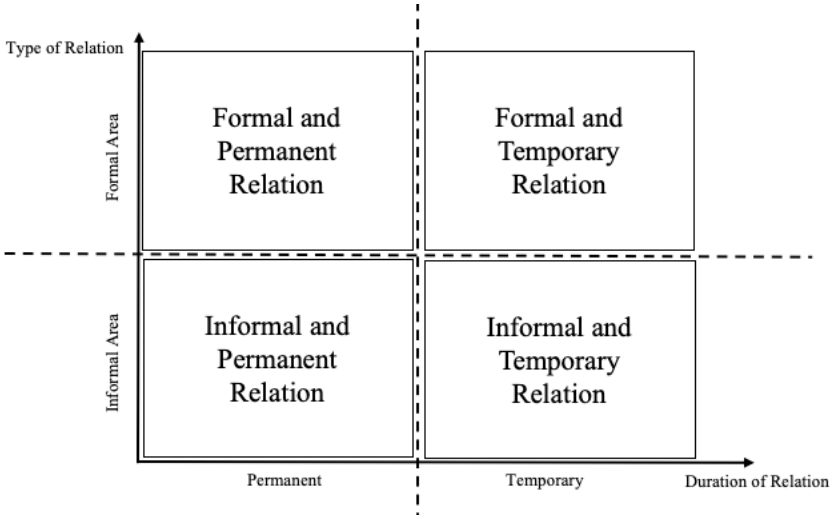
- study of the environment;
- writing a business plan;
- finding financial funds;
- choosing the legal form;
- building up the organizational structure;
- launching the business.

The CAOS model is useful for the aim of this paper, because it facilitates describing all topics that involve the company in a certain context. To this point, this model is also used for evaluation of capital relations.

3.1 The model for analyzing the case study

The model we use to analyze the relations of SMEs in this single-case study is found in the following Paoloni matrix (Paoloni, 2011), based on four types of network relations. The matrix is composed of the intensity of the relations variable—permanent or temporary—and the type of relation variable—formal or informal.

The model identifies four network relations, as shown in Figure 1.



Source: Authors

Figure 1. Relations matrix.

The relations are important in order to understand how the networks support the enterprise in developing a business.

The process identified in the CAOS model (Paoloni, 2011) requires a careful analysis of the four elements. We will call the connections linking Point S with Points C, O, and A the cardinal links, because they represent the cornerstone of all business relationships. Within these connections, there will be different kinds of relationships: formal, informal, temporary, and permanent. The cardinal links are:

- first (S–C/C–S),
- second (S–O/O–S),
- and third (S–A/A–S).

The first cardinal links identify all contacts that the SME activates to start the business; they depend on their characteristics, their needs, and their motivations. The formal relationships present in the start-up stage are, for example, all the contacts that connect the enterprise to the lenders, customers, suppliers, or financial administration and other stakeholders.

The second cardinal links are those relationships that the micro-entrepreneur activates to organize the enterprise and to define roles, tasks, and responsibilities associated with it, as well as the relationships among the various governing bodies (lines of influence).

The third cardinal links during the start-up phase concern the micro-enterprise and the environment into which it is set. These relationships come from outside the micro-enterprise. In these relationships, the environment is the driver of the relational circuit. Often, the use of a certain type of network is not the conclusive solution for the fulfilment of a need, but is necessary at a particular point in time of the business's life. An example in this case study is the need to raise funds in the start-up phase.

4 Case study: Bike ‘n’ Bike

The case study of Bike ‘n’ Bike, an Italian WSU, was analysed through the application of Paoloni’s CAOS framework.

4.1 Personal characteristics of the female entrepreneur (C)

Matilde is 37 years old and lives in Rome (IT). She has a degree in art restoration, but her passion is bike travel. Finding people with which travel by bike is one of the troubles that she faced with her hobby. To fill these difficulties, in 2016 Matilde founded Bike ‘n’ Bike, a start-up with the aim to connect people who organize bike tours with those looking for such an opportunity. Bike ‘n’ Bike portal, thanks to Matilde’s background and her goal of improving the customers’ experience, allows the users to choose many different travel options and bike-tour around the Italy.

Concerning the company’ governance Matilde shares the leadership of the company with her co-founder and marketing manager. Also, Bike ‘n’ Bike employed two other persons with complementary skills. However, the decision-making process is centralized on Matilde, rarely her partners are involved in this crucial role.

4.2 The environment of the micro-enterprise (A)

Bike ‘n’ Bike is an online and multilanguage (Italian and English) platform that connects many people from all over the world. For these reasons, like the most common start-up, Bike ‘n’ Bike has no need for a physical location, in fact, it users can communicate directly on the platform to organize bike travel. Two types of users the platform accepted: the host and the traveler-guests. The host is usually Italian only one is international; currently, there are 32 hosts. The international host, from Croatia, is the result of Matilde’s network.

Traveler-guests, instead, come from all over the world. For the future, Matilde hopes that Bike ‘n’ Bike became an international platform able to organize bike-tour in all Italian territory.

4.3 Organizational and managerial aspects (O)

Bike ‘n’ Bike is an online portal with a light structure. The activities on the Bike ‘n’ Bike portal are coordinated by Matilde, who leads the decision-making process. As mentioned, she only occasionally asks for suggestions from her other partners for relevant questions. Corporate planning is oriented only for the short term; the weakness of financial resources does not allow Matilde to formulate a plan oriented for a long period.

Monitoring activities are performed on the users’ activities on the platform. The business model is constant; the hosts give a percentage fee for all tours organized through the Bike ‘n’ Bike portal. Matilde is aware that the business model does not allow for the

sustainability of the business for a long time, but this is only to attract users. During the interview, she said, "Bike 'n' Bike does not live on its earnings but always needs liquidity injections by owners." This liquidity gap does not allow the company to develop its business.

4.4 The motivations for starting a new business (S)

Bike 'n' Bike born from Matilde's passion for bike travel. The market segment where Bike 'n' Bike is located is highly selective and limited; for these reasons, Bike 'n' Bike could become a relevant operator in the bike economy sector. However, to develop this positive effect will require a significant financial effort, including cost of internationalization, cost of the agreement with international hosts and guests, cost of insurance, cost of bike transport and taxes. In order to starting this expansion process, Matilde has tried to candidate a crowdfunding campaign but with no positive results. Moreover, she has never taken part in a start-up program organized by business incubators, where she could develop a Bike 'n' Bike fundraising project. Thus, the company has a level of undercapitalization that does not allow business development as Matilde hoped.

4.5 The analysis of RC in the start-up phase

Based on the CAOS model, the relationships of Bike 'n' Bike are as follows:

- Cardinal links of the first type (S-C). This phase is characterized by informal and permanent relationships. The Bike 'n' Bike owners are a group of friends with a passion for bike travel. In this phase, there is a lack of relationship between the variables S and C.
- Cardinal links of the second type (S-O). This phase is characterized by informal and permanent relationships. The informality of the relationship is highlighted by the decision-making process; Matilde asks for suggestions from her partners only for relevant questions.
- Cardinal links of the third type (S-A). This phase is characterized by informal and permanent relationships. Many hosts and guests that use the Bike 'n' Bike portal are Matilde's friends who have the same passion.

5 Discussion and Conclusion

In the digital era crowdfunding phenomenon has become international allowing small-medium enterprises to raise funds from a large crowd via internet . (Belleflamme, et al., 2014; Arner, et al., 2016; Chen, et al., 2017). However, female start-ups seem to no have easy access to the operations. In literature, several scholars assert that, in the crowdfunding context, the female entrepreneurship meet the same difficulties to access credit still occurring in the traditional financing channels (Cesaroni and Sentuti, 2014;

Constantinidis et al., 2006; Coleman and Robb, 2009; Cumming, et al., 2019; Kanze, et al, 2018)

A relevant contribution is provided by Brown, et al., (2019). It examines the role of entrepreneurial networks in the equity crowdfunding process, highlighting a different contribution related to the different stages of the operation: pre-crowdfunding, when the campaign is opened and the stage post-crowdfunding.

Starting from these pieces of evidence, our study, structured by the qualitative approach, analyzed through the CAOS model (Paoloni, 2011) the relations that entrepreneurs Matilde has established during the start-up phase of her company.

The evidence highlight a lack of relationship with investors prevented the start-up from finding the financial resources needed to develop the business. The relationships observed with the CAOS model showed an informal and permanent link among all the variables. This relationship involves many relevant aspects of the start-up lifecycle: the relationship with start-up partners, decision-making process, and relationship with the users (guests and hosts) of the online portal.

In this light, it is possible to conclude that this type of relations activated by the entrepreneurs doesn't allow the company to overcome even the first stage of "pre-crowdfunding" described in Brown, et al., (2019).

This research is a prosecution of the qualitative study on crowdfunding and female start-ups. It also contributed to the expansion of gender studies and the role of RC in innovative financial tools.

Regarding managerial implication, the results of the present research, compared to our previous contribution (see Paoloni, et al., 2020b) can give an initial contribution in order to start new activities run by a woman. Especially we refer to the efficient use of relational capital' resources as a driver to overcome the difficulties meet during the start-up phase. Also, again concerning managerial aspects, the model applied (CAOS) allows asserting that the misdistribution of the role, described in the cardinal links (especially into S-O and S-C), involves the failure of the female startup.

Limitations concerned the dimension of the firms. The analysis of data was available only through direct interviews with female entrepreneurs. Concerning future perspectives, the present paper represents the second step of "RC and Woman start-up" research mainstream. In the future, the authors will replicate the analysis, by the acquisition of additional data, will investigate which RC factors can promote the success of fundraising operations.

Abstract

In recent years, several routes have been entered to face the scarcity of financial market liquidity, with the aim of increase access to credit for individuals and micro and medium enterprises (MMEs). In this framework, the application of Islamic banking finance instruments has progressively assumed relevant dimensions, showing to be compatible with the needs of micro entrepreneurs. Moreover, the increasing concentration of wealth of Islamic market is leading western realities to look at the potential arising from collaboration between conventional and alternative markets to decrease inequalities within gender entrepreneurship. Within this context, globalization and digitalization have enlarged market opportunities to empower women financially. Authors examine the socio-economic status of women Shariah compliant financial products to investigate the impact that Islamic micro finance instruments could have to upward mobility of worldwide female entrepreneurship. The objective of this paper is thus to explore viable means for both middle east and western women to manage their wealth from an Islamic perspective.
The applied methodology is grounded in academic publications and reports published by authoritative bodies, also relying on cross-sectional data. It is organized in different steps: first, a proper analysis of Islamic finance instruments is in-depth; then, the comparison between traditional and non-conventional financial instruments is shown; and the assessment of women Islamic-backed status is tackled; moreover, the proficiency of microfinance is analysed; finally, succeeding the finance models evaluation trough the application of a balance scorecard system, a SWOT Analysis is mentioned.
The approach undertaken appears to be innovative in consideration that Islamic Microfinance is still considered a new market. Thus, a concerted action to expand existing knowledge on the possible advantages coming from the study and complementarity of different financial systems is needed.

Indeed, the research represents a deepening in order to assess system potentials. In addition, the high feasibility of such application in different contextual realities would result important for the possible fulfilment of worldwide both Muslim and no-Muslim statused women needs and objectives.
The attractiveness of the application is going to be crucial in order to tackle gender gap in financial inclusion. The possibility to overcome the restrictions related to inadequate collateral, insufficient legal status, high transaction costs and the sensitivity of entrepreneurs, proper of Islamic microfinance would possibly allow to overcome interest-based financing products thus permitting women and MMEs to contribute to the re-launch of economies and financial policies.

Keywords – Microfinance, Alternative Islamic finance, Female entrepreneurship, Emerging countries, Gender and Women's Empowerment Sustainable development.

Paper type – Practical Paper.

1 Introduction

This research practical paper essentially deals with the access to Islamic microcredit for Muslim and no-Muslim statused women. In a broad sense, it concerns a systemic analysis of critical finance different and more inclusive from below than the current and prevailing one. A sort of new "ethics of reciprocity", based on the assumption of the possible opportunities for Muslim women to contribute to developing, in their own territorial realities, and to the increase in the wealth of the community. Ultimately, it represents a positive influence in the economic field with a significant leap beyond the wall of requests for guarantees and commitments by banks. The current credit system, as is known, very often contributes to reinforce social injustice, because it generally offers money to those who already have it. Moreover, the current crisis, even more dramatically widened by the spread of the pandemic worldwide, must be seen as an opportunity to regenerate an unfair and unjust system, to ensure equal dignity of access to credit for all.

In this scenario the role of Islamic finance appears fundamental to ensure the autonomy of Muslim and no-Muslim women, through the microcredit that appears to offers tools and methods of interventions able to fight and get out of poverty, to favour the achievement of the necessary autonomy, to face complicated life situations, both personal that of the family, with greater security to believe in their own abilities and resources, to nurture self-confidence and the possibility of choosing their own future.

The crux of microcredit in Islamic finance, precisely in relation to the evolution of the precepts and constraints imposed, not only of a religious nature, but also political and social, is to verify how much women can contribute, and with what tools, to the growth of the communities to which they belong with the application of Islamic microfinance instruments. In this regard, it should be considered that despite the different interpretations of Qur'anic assumptions, the development of female entrepreneurship for access to microcredit, which may appear negative as a starting point, could instead prefigure and insert itself in the occidens culture, through the recognition and the

strengthening of the undoubted potential of ethical finance. This in consideration of the different modulation of loan conditions, where a capillary network of capital investments, albeit in the short term and without recalculation of interest, could however determine a virtuous circuit of more widespread liquidity, such as to make up for the effects of the lack of the interest rate for credit institutions. This would lead to a significant increase in physiological inputs to the market, such as to ensure potential growth in the most disparate sectors of intervention. These different circumstances of microfinance policy, based on the diffusion of fiduciary credits, may determine new economic and social support policies, involving the main actors (banks) to take up an epochal challenge, which, starting from the bottom, would allow a diffusion of wealth, in economically weaker social strata and for millions of women, otherwise excluded from the credit world and markets.

The paper is divided into three sections. First a theoretical framework and a proper analysis of Islamic finance instruments and tools is in-depth; then, the comparison between conventional and non-conventional financial instruments is shown; and the assessment of women Islamic-backed status is tackled; moreover, the proficiency of microfinance as development financial instruments for local entrepreneurship is analysed; finally, succeeding the first identification of finance models based on the combination of correct Islamic banking tools within microfinance and the following evaluation trough the application of a balance scorecard system, the advantages of the application to female entrepreneurship are assessed and a SWOT Analysis is mentioned.

2 Theoretical framework

In the near future, the implementation of financial and economic cooperation models able to overcome women entrepreneurs existing obstacles, such as gender gap, limited business experience and access to credit is becoming increasingly fundamental for the development of Countries. According to Schumpeter (1934) entrepreneurship stands at the basis of business cycles and of economic development. Similarly, Barretto (1989) stated that economic development is the results of entrepreneurial efforts expressed within new markets and organizations. Successively, Haque (2007) defined the concept of entrepreneurship as “A process of identification and development of innovative ideas and opportunities into business”. Indeed, promoting new business brings employment generation, innovation, high welfare and improvement in living standards. Brush Candida et al., (2007) and similarly, Green, Kirkpatrick, and Murinde (2006), assessed the existence of a causal relationship between the development of enterprises, poverty mitigation and management of the financial policy. Within these assessments and despite the definition of Millennium Development goals (MDGs), economic development still faces challenge to increase employment opportunities for women manly due to international crisis and to difficult living and social conditions. However, it is strongly believed in literature that economic integration and globalization is progressively spreading the idea of women entrepreneurship stream into developing countries

contributing to enrich society and to support local development. Over time, the innovation of new modalities of access to credit increasingly permits to women to acquire a role in societies as a substantial parte of different productivity systems (Ellahi, Awais and Raza., 2018). As pointed by Ghani et al. (2011) and Kalim (2012), women constitute one of major driver to globally overcome economic challenges leading to a modern high tech world with the ability to diversify production services. Stevenson, Onge (2005) and Iaona (2007) conducted the analysis of female entrepreneurship within different countries and region assessing as differences were mainly based on their cultural and ethical beliefs, their access to natural resources and policies pursued at the national level to promote female entrepreneurship. Indeed, the encouragement of female entrepreneurs requires a detailed analysis of environmental and social factors affecting them, accompanied by economic and financial policies pursued by the government aimed at promoting gender equality. Within this scenario, the exploitation of financial market and microfinance institutions, as a source of funding to mitigate poverty and increase gender equality, helping poor and needy people to run their business, can be seen as an eligible field to prevent gender gap and to help women, indeed creating job and life opportunities. Among the different typologies of alternative and non-conventional finance, literature agreed to consider the application of Islamic Finance instruments a possible cure for the ailing of global financial markets and of different living standards (Iqbal., 2008) as evidence exists that it performed much better than their conventional counterparts, even during crises (Farooq et al., 2015). Islamic Finance is defined as a collaborative promising approach capable of establish long term relationship based on trust, responsible participative principles, cost of capital decrease, lower interest rates and easier access to loans (Van Benthem, 2016; Allen, 2013; Zgheib, 2017; Bakar et al., 2011). Similarly, Islamic microfinance can play an important role in the development of the economy, by providing financial services without interest (*riba*), representing a common ground of collaboration between conventional and non-conventional models. The fiduciary and no-speculative element of Islamic microfinance encourages long-term, partnership based, profit and loss-sharing investments at a zero interest rate demonstrating indeed to have substantial potential for supporting local economies and women entrepreneurship. Those existing few studied that have been conducted in order to assess the relationship between women entrepreneurship and microcredit programs have mainly focused on a social service perspective (Akter et al., 2018), showing that utilization of microcredit could help to improve the overall development of regions: lack of credit and less access to financing shows in fact to be the main critical factor affecting the existence of gender gap.

Therefore, the present paper aims at improve existing knowledge on the exploration of the benefits coming from the application of Islamic micro-financing tools for worldwide developing female entrepreneurship.

3 Islamic Microfinance tools and existing models

At the Microcredit Summit in 1997 microfinance was defined as a "program, which extends small loans to very poor people for self employment projects which generate income in allowing them to take care of themselves and their families". However, those poor who are practicing Muslims, and are thus unable to take advantage of traditional microfinance contracts, which involves the payment of interest (ElKommi and Croson., 2012). Islamic microfinance represents in fact the meeting of two rapidly growing industries: microfinance and Islamic finance. Islamic Finance activities, as much as microfinance instruments, have to be compatible with Islamic law that is based on the respect of specific precepts and religious behavioural standards of the Qur'an: prohibition to realize interest on loans (Riba); obligation to make socially responsible/legitimate investments (Halal), injunction to arrange contracts involving unreasonable uncertainties and ambiguities (Gharar); restrictions on speculation (Maysir), prohibition to invest in prohibited activities (alcohol, gambling, weapons etc.) (Haram), and charity obligation for each adult Muslim (Zakat).

Islamic Microfinance has been progressively growing in the world, particularly in poor countries, as credible alternative to traditional financial models with the aim to allow poor populations having access to basic financial services at low cost (Ahmed., 2002). Islamic microfinance products are actually concentrated in a few countries; the top three are Indonesia, Bangladesh, and Afghanistan where the demand is very strong, accounting for 80 per cent of global outreach (Karim, Tarazi, Reille., 2008).

Given the moral and ethical attributes of Islamic financing schemes, while conventional microfinance institutions have expanded their operations in the last two decades, poverty-focused microfinance based on Islamic principles is also growing rapidly showing a feasible application also within no-Islamic contexts. This is due to the inner values of Islamic microfinance were the absence of interests and speculation leads to the promotion of a major ethical finance based on mutual cooperation able to promote socio-economic development (Abdul Rahman., 2007). Islamic banking, that, as investors, are characterized by risk-sharing and provision of loans without collateral, proves to be a good solution for micro-entrepreneurs (Dhumale and Sapcanin., 1999) which are motivated to succeed while feeling supported and empowered by a major trust relationship with credit institutions.

Different tools of Islamic banking prove to be feasible and applicable to develop Islamic microfinance.

The Mudarbah: three parties are involved: rabulMaal (zakat, waqf, or government), mudaarib (Islamic banking institution) and final mudaarib (i.e. women entrepreneur). According to pre-decided ratio, profits are distributed and entrepreneurs have full control over the business, with a monitoring duty from the bank which own all risk;

The Musharkah: the Islamic bank becomes a partner of women entrepreneurs and losses are distributed according to capital contributions and profits according to

predetermined ratios. In this case a third-party guarantee can prove a good solution for risk mitigation;

In the case of Murabaha, Islamic banks purchase and then sell goods and services to entrepreneurs, earning a mark-up. It is most suitable for purchasing business equipment. This method of financing includes continuous monitoring by banks and loans are further initiated to the entrepreneurs with good repute and loans usually given to a group of micro-entrepreneurs to reduce the chances of default;

Within the Ijarah Muntahia Bitamleek, Islamic banks purchases required assets and rent it to entrepreneurs. Entrepreneurs, further pay this rent back after regular intervals and will be responsible for taking care of assets and banks monitors its performance;

Qardhul Hasan or interest-free loans is useful for promoting new entrepreneurs start-up capital. Regular instalments for repayment are settled according to an agreed contract. However, Credit risk is involved in this case (Ellahi, Awais, Raza., 2018).

Those above described main Islamic financial instruments can easily been combined and applied to microfinance trough four different models.

The first one is the Composite model that works as follows: donor (IsMIFI) create zakah fund and waqf fund based in physical and cash is build; the poorest who are economically inactive will get zakah fund as safety net and skills training are delivered for the necessitous utilizing community-held physical assets under waqf; skills improvement will therefore encourage the poorest to graduate from poverty and become economically active; beneficiaries are formed in self help groups with mutual guarantee; allocated fund based on combination for profit debt based and equity based modes; loan repayment, with possibilities of higher loan in the future; zakah fund is used to guarantee against default; saving is encouraged under micro-savings; takaful fund (as insurance) is encouraged to protect against risks and uncertainties (Obaidullah., 2008b: 53-55).

The second one is the Wakalah Agency Model that utilises fund from zakah and NGO donor, distributed to the poor in qardhul hasan, hence, zakah is promoted as self sustaining development tool for the needy, and educate them to be independent (Wilson., 2007-210). The management company act as agency and assesses the eligible credit application. For this duty, a fixed fee, is set up as reward of conducting the operation. The participants could get fund disbursement, but with rationing mechanism and prioritization to prevent mass of capital be taken out. In this case, it is similar to credit union, but with qualified financial administration and protection for clients (Riwajanti., 2013).

The third model is the Mudarabah model that is based on profit and loss sharing contract (Wilson., 2007: 211). In this model, company acts as financier (Rabb al mal), invest the fund to client (mudharib) and get pre-determined ratio of profit share as return, in which similar to joint venture. Hence, due to the fluctuation of actual profit, the amount of share will fluctuate. If there is loss, the bank will liable for not getting the fund back and clients has risk of not obtaining rewards for the works done in running the business. Zakah fund could not be used in this method because the nature is more commercial rather than social (Riwajanti., 2013).

The forth SPV Model is proposed by Dusuki as an alternative, which have the following features: a variety of fund sources with specific microfinance intention are mobilised by Islamic Banks; a bankruptcyremote SPV is created; certain amounts of funds are allocated and forwarded to SPV; the funds are distributed to based on clients' demand (Dusuki., 2008: 61).

From the assessment of the above models it is possible to conclude that Islamic microfinance maintains the basic format of conventional microfinance in terms of weekly/monthly repayments and social development programmes. However, Islamic microfinance presents much more opportunities to use other external funds which based its existence and effectiveness from charities (zakah, waqfs), the mode of financing is more varied to accommodate the different needs of the impoverished, and the approach in dealing with default is softer.

4 Comparison between traditional and non-conventional financial instruments

According to the recent studies, the overall supply of Islamic products is still quite small relative to the conventional microfinance sector ones and customers using Sharia-compliant products still represent less than 1 per cent of total microfinance outreach. However, with the rapid growth of the market, literature has increasingly investigated the performance of Islamic banks (Bashir., 2001), comparing it to conventional banks (Abdul-Majid et al., 2008; Beck et al., 2013) and assessing the existence of a persisting gap in empirical studies deemed to analyse the performance of Islamic MFIs. In general, there are several characteristics that distinguish conventional microfinance from Islamic Microfinance (Ahmed., 2002). While, both of them mobilize external funds and savings as their source of fund, Islamic charity such as *zakat* and *waqf* are major source for funding Islamic microfinance, which instead are not present in traditional microfinance. The second specificity of Islamic microfinance concerns modes of financing that should eliminate interest in their operation whereas conventional microfinance can adapt interest-based financing. The third feature concerns funds transfer by microfinance institutions. In conventional microfinance, the institution can directly give cash to their client as the financing. While Islamic financial services providers are not allowed to give cash to their clients as loan is prohibited in Islam and it is therefore base on good transferred. Moreover, Islamic microfinance may use similar technique of conventional institutions (group lending as a way to alleviate risk in their operation) and they also developed Islamic ethical principles to ensure their clients paying regularly. Within the contract in the conventional micro finance a part of funds is deducted as inception on the contrary within Islamic finance no deduction at inception is foreseen. While conventional microfinance institutions focused mainly in women as their client, advocates of Islamic microfinance argue that Islamic MFI should be extended to the whole family as well (Abdelkader, I. B., and Salem, A. B., 2013).

5 Assessment of women Islamic-backed status

Accordingly to Islamic religion there is nothing against Muslims running out business (Kayed., 2010). The only condition that must be preserved is the realization that every business undertaking is intended firstly to please *The Almighty Allah* (Kayed., 2010). Entrepreneurs (both women and men) embrace positive values in promoting productivity through entrepreneurship (Nayeam., 2006) and positive correlation of women and earnings appear to be a message of the Holy Qur'an which quoted: « *Men shall have a benefit from what they earn, and women shall have a benefit from what they earn*. » (Surah An-Nisa: Ayat 32). Furthermore, the status of women seems to be assessed in the Qur'an as it declares the *creation of opposite genders as a part of divine scheme, a matter of reflection* (51:49, 36:36) and *good deeds of all humans will be rewarded irrespective of their gender* (16:97). To cite some religious sources that corroborate these theses, non-exhaustive passages are indicated: *« O mankind! reverence your Guardian-Lord, who created you from a single person, created, of like nature, His mate, and from them twain scattered (like seeds) countless men and women;- reverence Allah, through whom ye demand your mutual (rights), and (reverence) the wombs (That bore you)* » (4:1). In other verses, the Qur'an says: « *Women have rights similar to the rights against them" (2:228). Women and men possess equal rights for work and compensation*. » and « *Never will I suffer to be lost the work of any of you, be he/she male or female: you are members, one of another* » (3:195) (al-Hibri., 1997).

As a confirmation, Islamic law and jurisprudence does not deprive a woman from the right to work within the limits that protect her honour and dignity, permitting them to conduct financial transactions. Indeed a correct implementation of principles and rules of Islam appears to offer women real possibilities of enhancing various types of businesses, encouraging their participation in socio economic activities, within the respect of the following guidelines: first, Women must take consent, if married, from her guardian or husband, as her actions will may influence the functioning of the family and it is her role ensuring, while running a business, that her home and children are properly cared for. Husband then may contribute to the correct implementation of the business. Secondly, care must be taken to choose the business that cannot deal with forbidden activities, services, or products and has to be appropriate and fits with women skills. Each activity that can prevent women from fulfilling any of her Islamic obligations is not allowed. Thirdly, women has to respect the Women's Dress in Islam as *Allah* has stated in the Qur'an that *women must guard their modesty* (Qur'an : 24.31).

To conclude despite to different interpretation, it is not correct to affirm that Islamic culture does discriminate women economically or socially as often portrayed (Ridley., 2016). The real challenge is to intervene on a social basis to increase recognition of women's capabilities within and across Islamic societies (Ali, 2013; Barlas, 2001; Hassan, 1994).

Therefore it is precisely with the aim of encouraging female participation and exploitation of Islamic microfinance participatory instruments that it was considered

appropriate to develop the following balanced scored card accompanied by a swot analysis of the microfinance scenario with the attempt to enrich present knowledge on the effectiveness of such assessments for the development of women entrepreneurship.

6 The SWOT Analysis of Islamic Microfinance and the Balanced Scorecard Model for Islamic Microfinance Institutions

On the basis of the above authors have deemed it appropriate to conduct a proper analysis of Islamic microfinance through the definition of a swot analysis in order to identify its Strengths-Weaknesses-Opportunities-Threats. The aims is to identify advantages and dominant inhibitors for the development of Islamic Microfinance for women. In particular, the analysis of existing literature shows as strengths of the application of microfinance models are:

1) the high initiative of local community. The existence of microfinance shows to be a major ethical and moral financing method, to whom women get more entrusted and motivated by the absence of interest and by the lack of speculation and moral hazard, as it prevents community from the pressure of return that is very burdensome to them;
2) Islamic finance initiatives do not require large capital showing to be compatible with poorest needs leading to inclusive growth and poverty alleviation;
3) Islamic finance shows to be keener for small and medium micro enterprises segment, which represents the majority of businesses in development countries.
4) Islamic banking has become very popular across the world in a short span of time as it shows to be more stable than conventional banks differently based on debt and on high rates of inflation.
5) Islamic banks are more immune to instability as evidenced during the global financial crisis as the level of sophistication of the technology used is low and does not require high skills to request and obtain access to credit.

Meanwhile, the weaknesses are:

1) Cost of obtaining legal permits and of definition of regulations from governments; Lack of unified benchmarks and standards;
2) Cost of monitoring and communication to reach needed person and general insufficient knowledge, perception and awareness of its potential.
3) Lack of dedicated institutions: Islamic MFIs should adopt the role of such an institution.

On the other hand, factors that regarded as opportunities are:

1) Public interest toward Islamic micro-finance transaction is getting bigger also as a consequence of economic and recent pandemic crisis, as Government needs both for developed and underdeveloped countries to find way to increase access to credit;
2) Finance sector is very flexible – there is no limit of minimum financing;

3) Shifting from a product orientated approach to a client orientated approach.
4) Islamic MFIs should promote and establish community owned and controlled endowment funds to strengthen local capital accumulation while IMFIs itself should adopt a role of observer and regulator so to address any loopholes in the system.
5) Huge market size especially the high concentration of Islamic practicing is big opportunity for Islamic Banks.
6) Growing developing economy has huge potential to attract investments from cash surplus Islamic countries.
7) Large number of Muslims practicing avoids participating in the conventional banking system and as a result large credit is not utilized.
8) The spreading of new technologies and production processes in the field of information and communication technology (ICT) that can really support dynamic business activities, including supporting the ability to access the market quickly

While the threats are:

1) Gap between the ability to save and utilize credit because of first inexperience that need the definition of training and educational procedures;
2) Weak regulation and legality of Islamic microfinance institutions – The absence of sufficient law;
3) Introduction of Islamic banking could be seen as threat to secularism and may result in political turmoil; two parallel banking stream may give rise to communalism.

   Indeed, what emerges from the swot analysis is that the application and development of the Islamic microfinance presents far more strengths and opportunities than threats and weaknesses. The greatest is the lack of institutions made up of those that act as benchmarks for the definition and dissemination of best practices, which is the reason why authors decided to hypothesize a Balanced Scorecard (BSC) of these institutions.

According to the Balanced Scorecard Model (BSC), the different dimensions to be considered in order to improve and emphasize Micro Finance Institutions (MFIs) performance for women entrepreneurs are the following: Financial, Customer, Internal business process and learning, growth & innovation. In learning, growth & innovations perspective, the performance measures to use are:

- *Training* - Defined in terms of the proportion of staff receiving training on different status of worldwide women conditions.

- *Innovations* - Measures the capability of the organisation to develop new products, processes, and services to define new markets for women entrepreneurs.

- *Knowledge sharing* - Accurate and timely information shared among women.

In the internal business processes, the performance measures to use are:

- *Per unit costs* – Define a general framework to which all banks and institutions can refers to apply microfinance instruments to their realities and measure of the resources

used in producing a unit of service. For example, cost per loan issued, and cost per member served by the MFI.

- *Cycle time* – Optimization of the time taken for a project to be completed. This can be a key measure of women satisfaction. This may include; time to get service, time to process a loan application etc.

- *Response time* – Measure of the amount of time taken to respond to a request for service.

- *Backlog* - Measures the amount of work in queue, waiting to be processed. For example, the number of loan applications waiting for processing

In the customer perspective, the performance metrics used were:

Coverage – Measure of the female population served by the MFI, which also included the number of men & women getting the financial services from the MFI.

Accomplishment – Overall outcome or achievement of a program, including poverty reduction or improvement on household income or increased awareness of the services.

Quality - The proportion of services provided without error or complaints.

Satisfaction - Women satisfaction is measured by a pre-defined survey, based on customers' comments on their satisfaction levels and the benefits they have attained.

In the financial perspective, the performance to use are:

Profitability ratio – Measures the net income in relation to its balance sheet.

Financial viability – The ability of an MFI to cover its costs with earned revenue, and not relying on donor funding to subsidize its operations.

Portfolio quality ratios - Provide information on the percentage of non-earning assets, which in turn decrease the revenue and liquidity position of an MFI. For example, repayment rates, portfolio quality ratios and loan loss ratios.

Leverage & capital adequacy – Leverage refers to the extent to which an MFI borrows money relative to its amount of equity. Capital adequacy refers to the amount of capital an MFI has relative to its assets. Capital adequacy relates to leverage in terms of the adequacy of the MFIs funding structure.

Indeed, the proposed Balanced Scorecard Model (BSC) shows as it is possible to contribute to the definition of a comprehensive set of performance measures able to provide a valid framework for strategic recommendations.

7 Conclusions

Microfinance has been identified as an important and increasing potential policy instrument that allows greater financial and social independence even for the weakest by facilitating access to financial services. In order to incentivize such a trend urge the need, with the support of advanced technologies, of providing business education, training, and skills to women entrepreneurs in order to decrease the performance gap between male-owned and female-owned entrepreneurs. Analysis shows as possible resolutions consists in increasing bank participation in microfinance and diversifying their portfolios, provision of education and training program, better coordination and networking and

technical assistance. Moreover, female enterprises result less in number than men mainly because of existing gap in governmental policies for encouraging women and because of the lack of communication that today is very difficult because of poor infrastructural facilities, instabilities in the socio-cultural and political environment and high production cost which are major factors that act as a hindrance to the development of female entrepreneurs. Because of this reason technology and innovation can find a fertile ground to support this development assuring to women of being able to spread encouraging attitude, combine family commitments with business running. The SWOT analysis and the Balanced Scorecard Model (BSC) also reveals that Government in order to open to women business should open its doors to Islamic banking as the strengths and opportunities far out-weigh the weaknesses and threats, along with the definition of correct performance measures for dedicated Institutions. To conclude the present research is hopefully going to lead governments to formulate policies for the implementation and the spreading of Islamic microfinance identifying gaps in policies and social set up with the aim to explore these issues seriously, especially in the context of developing countries.

Towards National Learning Assessment System

Isabel Pinho

Govcopp
University of Aveiro
Campus Santiago, Aveiro, Portugal

Abstract

Improving education quality is crucial for raising human capital. Raising the quality of education system and particularly learning outcomes is useful to know and understanding where we are in terms of learning achievement and what are the action that we need take to improve.
Some questions – who, what, when, how, and why – become of central importance for planning National Learning Assessment System. To answer each question and all of them in a coherent way for the multiple contexts we suggest a knowledge governance approach. Clarifying concepts, understanding the links between data, information and knowledge and making them available to different segments of stakeholders requires this holistic approach.

Keywords – Smart Public Administration, Quality education, Assessment systems, Knowledge Management, Knowledge Governance.

Paper type – Academic Research Paper

1 Introduction

The emergence of an evidence based approach in education are related to the educational effectiveness movement.

Implementation of Evidence-Based Practices in Learning Assessment can brings some barriers. To overcome or minimize these barriers, it is necessary to consider the local characteristics of its main actors: students and teachers.

Planning National Learning Assessment System is a crucial step for the effectiveness of this system. Ask the right questions and reflect and answer those questions, taking into account not only the results you want to achieve but also the characteristics of the population of each country.

To deal with this complexity, we can take a knowledge governance approach in order to build robust and flexible assessment and reporting systems. This is an important tool for discussion, political decision, and educational evaluation policy implementation, for improvement of teaching and learning and evaluation of the educational policy itself.

Linking research, policy, practice, teaching and learning and the diverse stakeholders in data and information is a challenge that will only be successful if everyone participates in an informed way and with increasing literacy on assessment.

2 The role of Evidence

The relevance of information and knowledge has been widely recognised as a resource to capture evidence in education OECD (2007). The use of evidence is more and more the base of an informed decision process at Educational Policymaking (Giebels et al., 2015; Wiseman, 2010). Complex knowledge processes of acquiring, creating, interpreting, sharing and using research evidence can provide solid knowledge and practical steps also for educational research, practice and policy implementation (Finnigan e Daly, 2014; Pinho et al., 2012; Rego et al., 2009).

The role of research for understanding education policy and its implementation is relevant; this role of research is also linked with teaching and learning practice (Fensham, 2009; Scheeler et al., 2016). Information on student context and outcomes can support decisions about strategies and approaches on robust evidence generated by research (Hollands et al., 2019).

Some research-based procedures associated with the implementation of policy reforms and the change of practices must overcome barriers to their implementation. Sometimes there is language difficulties and clear communication between research and practice; other barriers are linked to resistance to change at both the individual and institutional level. Gaps in specific training in assessment may also create problems as well as the fear of sanctions in case of not reaching the goals can cause distrust. Some recommendations for facilitating the implementation can help educational researchers, leaders, and policymakers, such as: (a) utilize local data, (b) incorporate practitioner narratives in the dissemination (c) use scaling-up strategies to reach an institutional tipping point for EBP implementation, and (d) conduct and disseminate use-inspired research that integrally involves practitioners and their perspectives. See Table 1 for an overview of these recommendations Cook et al. (2012).

Table 1 – Recommendations for Facilitating the Implementation of Evidence-Based Practices in Education

Use local data	
	Administrators can present findings showing the positive impact that an evidence-based practice has had for students whose educational needs are similar to those of children in their teachers ' classes; in other classrooms in teachers ' own schools; or in nearby, similar schools and classrooms.
Use practitioner narratives	
	Testimonial accounts from colleagues are important sources of evidence for many practitioners. Careful and conscientious use of teachers' narrative accounts of the implementation and effects of an evidence-based practice can be used as a powerful complement to summaries of research findings
Attain institutional tipping points	
	Initially, considerable effort and resources will be needed to initiate and extend the use of a new evidence-based practice in schools and school systems (e.g., providing extensive training to a small group of carefully selected teachers). However, once implementation of practice is scaled up to approximately 60% of teachers, it will become part of the school culture.
Conduct use-inspired research	

	Researchers should strive to conduct rigorous research that provides practice-based evidence regarding evidence-based practice. That is, in addition to determining the efficacy of an intervention, it is important that research examine whether an intervention has broad reach, can be broadly and readily implemented and adopted, and can be maintained over time.

Source: Cook et al. (2012)

3 Data, information and information systems in education

Education need to use information systems to take change and to monitor the results and the impact (González-Sancho e Vincent-Lancrin, 2016). At schools level we also need to implement Knowledge management to increase the link between tacit and explicit knowledge (Petrides e Guiney, 2002).

There is no "one best way" to do evaluation but we can identify many practices shown by research and bridge the research–practice gap by identifying, promoting, and implementing evidence-based practices (Wrigley e McCusker, 2019).

Knowledge governance can facilitate a flow of multiple services based on data and information (Diagnosis, Review, Dialogue and Implementation), which can be provided separately or in combination.

We also need to link linking administrative data for research and for decision. This have some implications, such as: (i) the data linkage environment and privacy preservation; (ii) the linkage process itself (including data preparation, and deterministic and probabilistic linkage methods) and (iii) linkage quality and potential bias in linked data (Harron et al., 2017).

4 The key questions

Learning Assessment is a complex issue. The debates about the role of evaluation and the classification evaluation types, inside the spectrum formative and summative evaluation, define a field of study with a strong link between theory and practice (Dixson e Worrell, 2016; Leite e Nunes, 2009; Morosini *et al.*, 2016; Pastore *et al.*, 2019; Pedrosa *et al.*, 2019; Wiliam, 2010).

For planning learning assessment system we need clearly answered some key questions:

The first question is: What to evaluate? In the present case the specific question will be: what is learning assessment? By defining the focus of the evaluation we direct and limit the choice data and indicators, such inputs (infrastructures, students and teachers' socio-demographic characteristics), processes (teaching and learning, school leadership, school administration) and of the results.

The second question is: Why evaluate? In answering this question, the objective (s) that may have a greater bias for accountability or improved learning are identified.

The third question is: Who to evaluate? The unit of analysis must be clearly defined. In the present case the focus is the assessment of student learning.

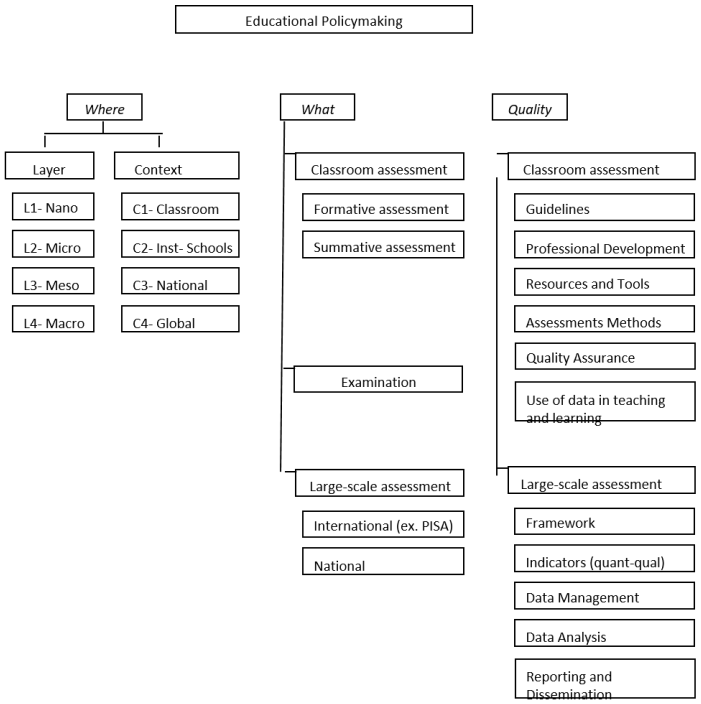
The fourth question is: How to evaluate? The so-called "evaluation technology" includes the evaluation criteria and standards as well as the instruments, indicators and metrics.

The fourth question is: Who evaluates? In addition to the general aspects of evaluators and evaluation agencies, it is important to identify and promote training on the skills and competences needed to evaluate.

The fifth question is: How are evaluation results used? It is interesting to identify who are the users of the results and to what extent this feedback is used.

5 Learning Assessment Knowledge Governance

To provide adequate answers to previous questions in an integrated manner, a knowledge governance approach is useful (see Figure 1). Knowledge governance refers to choosing the structures and mechanisms that can influence the processes of knowledge looking the interrelation between micro, meso and macro levels, with a strategic focus (Foss, 2009; Foss, 2007; Pinho *et al.*, 2019; Pinho e Pinho, 2016).



Source: author

Figure 1 - Learning Assessment Knowledge Governance

We need information of the context because “what works” in education are necessarily local and policymakers must use evidence with critical thinking, without forgetting the context (Goldman, 1976). Each information layer (Nano, Micro, Meso and Macro) and each context (Classroom, Institutional-Schools, National and Global) must be identified to definite the scope of Learning assessment exercise.

This classification is useful for operationalizing learning assessment at each level. We also need to clear identify what kind of Learning Assessment; there are two main types of assessment: formative and summative.

6 National Learning Assessment System

Each country or state have its Education System that can be analysed across some areas such as: accountability, school curriculum, teacher qualifications, early childhood education and care, achievement in basic skills, early leaving from education and training higher education, graduate employability and learning mobility (Clarke, 2017; Eurydice, 2019a, 2019b).

It is not enough to have data, it is necessary to know how to use the data by the various educational stakeholders. At micro level, as Matthew Militello said ” the road to improve teacher pedagogy and equitable student learning may indeed be paved with data” (2013, p. 113). Assessment data is also used at macro national level, such as for evidence-based policy and decision making (Best *et al.*, 2013).

Teachers, school administrators and leadership, educational researchers, and others stakeholders need training and support on data and information, not only by technological data procedures but also on ethical issues to use this soft resource. Classroom assessment (formative and summative), examination and large-scale assessment are different categories of assessment, but there is a need of an effort of integration and coherence to reach the common objective: improving learning

To build a coherent National Learning Assessment system it can be useful to have a knowledge governance approach in order to integrate the different levels of action, the different assessments, the different stakeholders, the different objectives, the different data and the diverse information that are blocks of this “building” of multiservice.

Abstract
This paper focuses on the Italian public administration that, with its more than 10,000 inefficient data centers, employs at least 30,000 people who are tasked with the maintenance and technological updating of these obsolete infrastructure and with the upkeeping applications (often outdated and on which much more people work) that run on these infrastructures. Yet, there is no measure to empower or even hire Chief Information Officers, Chief Technology Officers, Chief Information Security Officers, Cloud Computing Architects, Data Scientists and so on.
In the specific case of the Italian public sector, despite Information and Communication Technology (ICT) is rapidly changing our planet, there is a significant ICT specialists' shortage; the situation is common to other countries but in Italy it is particularly severe due, not only, to the lack of skills but also to the abundance of useless and wrong ones.
The purpose of this paper is to highlight the 'Italian digital emergency' with a specific focus on the public sector and suggest a way to improve the situation in Italy but also in other similar countries through innovative ways of recruiting and training, and with structural reforms, for instance, in the system of education.

Keywords – IT, digital competences, e-competences, public sector

Paper type – Practical Paper

1 Introduction

In Italy we live in a constant state of emergency. Society as a whole is aware of a vast array of emergencies: employment, immigration and emigration (brain drain), healthcare, justice, social security, tax evasion, organized crime, corruption (Dècina, 2016). Yet, there are many others the majority of citizens is totally unaware of, and among these there is the 'digital emergency' (Attias, 2019; Attias and Cerofolini, 2019). At the beginning of 2020, the dramatic consequences of the COVID-19 epidemic, which was unforeseeable when we set to write this paper, have further emphasized the added value of digital technologies as they are proving to be critically important to manage and mitigate one of the world worst health emergencies, in the last 100 years or so.

The 'digital emergency' is pervasive and intersects (Borgonovi and Buccoliero, 2000; Eggers, 2005; Contini and Lanzara, 2009; Barone, 2015; Quintarelli, 2016) all the other emergencies affecting Italy. Therefore, if the problem is not dealt with comprehensively, all the other emergencies could not be effectively addressed and would remain unsolved (De Maio, 2005; Palozzi et al., 2018).

In particular, our analysis is focused on a specific segment of the digital emergency, that is the public sector employees (including those ones of private IT companies that work for public administration) and their digital competences (Ala-Mutka, 2011; Ilomäki et al., 2011; Murawski and Bick, 2017).

Although the IT skills shortage in the public sector is a worldwide phenomenon, we will focus on the Italian public sector not only to underline the critical deficiency of digital competences but also to provide a list – to be regularly updated – of the most significant IT competences that are missing. Such analysis will help to assess the level of digital skills in the public sector, identify priorities, and is conducive to develop a strategy for a stable improvement cycle of digital competences (Attias, 2016).

This paper is organized as follows. Section 2 focuses on the definition of digital competences and digital divide. Section 3 expounds on the IT skills shortage in Italy, with a special attention to the public sector digital emergency. In Section 4 we propose possible solutions to bridge the gap and in Section 5 we will wrap up our main conclusions.

2 e-Competences and digital divide

Digitalization is pervasive: whether we like it or not, sooner or later, we will all be impacted by its effects; it is dynamic/agile: we cannot deal with it occasionally, but with continuity; it is young and society, as a whole, has not yet developed a full awareness of the actual impacts of digital technologies; thus, analysing the implications (as a philosopher) of digitization is still necessary.

Digital technologies are a primary enabling factor, represent a propulsive push towards a process of democratization of our planet and a means against inequalities (Avila et al.,

2014). Actually, the level of civilization of a country is also measured by its degree of digitalization (Attias and Ruggiero, 2017).

Digitalization can make a difference and has already allowed many countries, which have already exploited its full potential properly and knowingly, not only to reach a higher economic growth and higher level of social and civil maturity, but to progress more quickly towards the welfare of all their citizens.

Within this framework, we wish to examine and propose some definitions.

The European "e-Competence Framework" (e-CF) (EN 16234-1, 2019) was developed to answer the need *of supporting mutual understanding and provide transparency of language through the articulation of competences required and deployed by ICT […] practitioners and managers* (Fernández-Sanz et al., 2017); it proposes the following definitions:

- competence: "a demonstrated ability to apply knowledge, skills and attitudes for achieving observable results";
- knowledge: "set of know-what";
- skill: "ability to carry out managerial or technical tasks"; attitude: "cognitive and relational capacity".

In this paper, we focus on e-competence such as the ability to develop and use ICT resources in order to take part in a conscious and critical way in social and economic activities increasingly transformed by digital technologies.

In our opinion, indeed, 'e-competence' plays a fundamental role for the development of a critically conscious and empowered society, a creative and innovative workforce, a dynamic system of higher education that can seize the new opportunities and respond adequately to the changing needs of society and economy.

Attias et al. (2017) recognize three main and different meanings of 'e-competence' which have infinite nuances in continuous and constant evolution:

1. e-competence of those who are ICT professionals and specialists;
2. e-competence of those who use digital technologies in their job;
3. e-competence of those who use digital technologies in their everyday life, unknowingly and without any specific expertise.

This division entails very different forms of digital divide. Today, the 'digitally excluded' is no longer or not only, the one who does not have access to the network, or does not have the technologies to access it, but the one who does not know how to exploit the network and technologies. The 'digitally excluded' is the one who does not have the cultural competence or critical skills to fully enjoy digital citizenship and participate - we use the word with a political undertone - to social life. The 'digitally excluded' is therefore unable to understand the opportunities at hand (Solimine, 2014).

Paradoxically, if in the past an ICT specialist could not be considered at risk of digital divide, this assumption is no longer entirely true.

Accordingly, Attias *et al*. (2017) define the digital divide as *a multidimensional, multidisciplinary and constantly evolving concept, the definition of which must be*

dynamic and flexible, since it should adapt to and absorb the continuous changes and numerous innovative opportunities which are offered by the enabling technologies for the digitisation.

The term "digital divide" refers chiefly to the gap between individuals, social groups, businesses and countries in accessing and having the capability to use digital technologies. Yet, the "digital divide" is a multifaceted concept as it encompasses different inequalities and elements such as lack of access and connection, affordability, retrieval and usability of information, possession of adequate computers and/or other devices, technology adoption and experience i.e. technology-literate end-users, upgrading of working professionals' skills to stay on the cutting edge of innovative technologies, responsible interaction with and use of social networks and social media, ability to retrieve and use the information available on the internet, adaptation of the social, cultural and political context, transformation of the economic and working conditions.

By access, retrieval and usability of information we refer to the availability of network connections, both fixed and mobile, and usage opportunities. The latter includes not only the population's widespread, adequate and satisfactory digital skills - at least in the Internet use- but also the availability of online services. The public sector has a unique role not only in providing access and affordable connectivity but also in promoting the digital literacy among the citizens; on the one hand, useful and easy-to-use public services, support and increase the penetration and citizens' adoption and, on the other hand, spur the digital transformation of the public sector, in a sort of virtuous cycle. Better public digital services lead to a stronger demand for them.

Today, the civilization of a country is also measured in terms of digital civilisation: the country's level of digitalisation and digital awareness.

Everywhere in the world, any "digital divide" inevitably generates geo-historical and geopolitical inequalities and differences, in other words, "digital exclusion", both on an individual and collective level, with negative, more often than not, repercussions on social organization, cultural evolution and the overall progress.

The above definition replaces the most common ones, which are strictly related to the access to the Internet and World Wide Web (w.w.w.) (Anderson et al., 1995; DiMaggio et al., 2001). Unquestionably, this definition takes into account a wider interpretation of the digital divide as a cultural issue that affects more broadly even those who have full and constant access to the net and new technologies (Fuggetta, 2018).

3 Where Italy stands

3.1 Ranking

Numerous studies rank Italy in the last positions in terms of digital skills and recommend to take effective policy measures to improve citizens' digital skills.

The “OECD Skills Strategy - A Diagnostic Report: Italy” (OECD, 2017) shows how Italians lack basic digital skills.

The Digital Scoreboard (European Commission, 2020) points out that Italians (all individuals) between 16 and 74 years old who regularly (at least once a week) use Internet are 73.9%, compared to a European average of 85.3%. The lowest percentage refers to Bulgaria (66.8%) while in Scandinavia, Luxembourg, the Netherlands, the United Kingdom and Germany at least nine out of ten citizens are regular internet users.

If we consider the indicator “individuals aged 16-74 with at least basic digital skills”: Italian males represent 44.9% against a European average of 60.5%, Italian females represent 38.2% against a European average of 56.2% (European Commission, 2020a). The figures are worse for “above basic level of digital skills”: Italians aged 16-74 represents only the 22% against the 61.6% of Icelanders and a European average of 33.3% (European Commission, 2020b).

Finally and sadly, the 2019 data (European Commission, 2020c) reveal that only 23.4% of Italian citizens (all individuals aged 16-74) uses the internet for interaction with public authorities (individuals interacting online with public authorities, last 12 months), against a European average of 54.6%. Only Romania (11.7%) performs worse than Italy.

The Digital Economy and Society Index (DESI) is a composite index, conceived in 2014, that summarises 30 relevant indicators on Europe’s digital performance and tracks the evolution of EU Member States in digital competitiveness, across five main dimensions: “1. Connectivity”, “2. Human Capital/Digital skills”, “3. Use of Internet Services by citizens”, “4. Integration of Digital Technology by businesses”, “5. Digital Public Services”. Figure 1 reports DESI ranking of 2019.

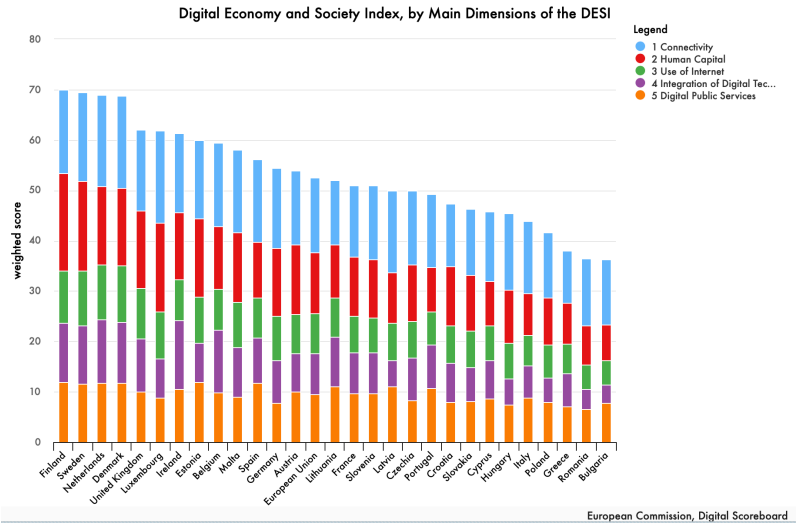

Figure 1 - DESI 2019 Ranking

Since 2014, Italy has always ranked in the last positions in company with other countries such as Bulgaria, Romania and Greece. Italy performs very poorly in spite of the investments in ICT which, historically, have always been significantly higher than in the above-mentioned countries. This proof that the quality of the investments matters more than the absolute value.

Although over the years the European Commission has refined DESI methodology, one of the indicators in which Italy's placement has remained dramatically constant is digital skills. This latter has two sub-dimensions: "internet user skills" and "advanced skills and development" (which we consider one of the most relevant dimension of DESI). The former draws on the European Commission's Digital Skills Indicator, which is computed based on the number and complexity of activities involving the use of digital devices and/or the internet. The second includes indicators on ICT specialist employment and ICT graduates where Italy has major deficiencies as shown in Figure 2 (DESI, 2019).

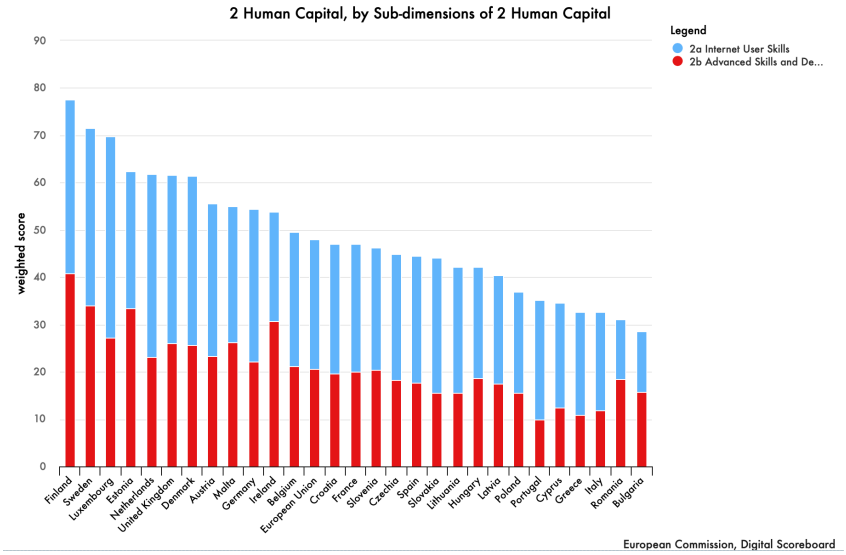

Figure 2 - DESI 2019 Human Capital

Obviously, these poor results, concerning both basic digital skills and those of the ICT specialists, refer also to the hybrid professions, which are currently, and increasingly will be, positively impacted or 'cross-contaminated' by the pervasiveness of ICT.

In our scenario, almost every profession (e.g. lawyers, doctors, accountants, teachers), even if not digital native, will be 'cross-contaminated' by ICT (Rubino et al., 2019). Hence, all workers will have to acquire 'digital proficiency' in a short time, while very few will remain strictly speaking ICT professionals (Butera, 2019). Information Technology is rapidly changing our planet; we cannot afford ignoring the future that is rapidly becoming present (Davenport and Prusak, 1998).

Of course, we do not maintain that everybody should become a digital expert, competent in all the new digital technologies (e.g. cloud computing, blockchain, cybersecurity, artificial intelligence, machine learning) but we cannot ignore that as they spread on a planetary level, these technologies are becoming more and more pervasive and are more and more impacting our daily life.

It will not be an easy cultural change. Currently, many geographical areas and/or social classes are already affected by the digital divide (Norris, 2001; Attias et al., 2017; Longo, 2018). However, we firmly believe that the change should be addressed (Xhaët, 2017).

In Italy, the current state is serious and the country lives in a persistent 'digital emergency'.

3.2 The public sector: a failed story of IT infrastructures and applications

At present, in the Italian public administration, there are about 11,000 data centers (data processing centers) (Meta, 2019), providing services to over 22,000 central and local administrations (de Rosa et al., 2020); approximately, there is a data center for every two public sector entities.

Almost every Italian municipality manages its own server autonomously, sometimes in precarious conditions, without adequate security, without any concern for energy efficiency. The number is definitely out of control and has no equivalent in the rest of Europe. This situation causes significant inefficiencies and diseconomies. Moreover, many data centers are not counted in the official surveys, such as the one that the Agency for Digital Italy (AgID) carried out in 2019 to inventory the "ICT asset of the public administration with the aim of detecting the state of the IT infrastructure and acquire useful information in order to rationalize data centers and adopt the cloud model".

The Italian public sector employs at least 30,000 people (default estimation) who perform maintenance tasks (backup & logging) and technological updating (patching & updating) of these obsolete infrastructures; even more workers are involved in the execution chores relating to the applications that run on these infrastructures.

According to AgID, the applications are more than 200,000 (but the real number, which no one knows, is perhaps more than one million). Over the decades, the public sector has developed a huge number of applications that are not interoperable but perform very similar tasks in slightly different manners and run on at least 160,000 databases – most likely many more. To run these applications, the public sector employs thousands of protocol systems experts, custom document management systems experts, legal treatment management systems experts, management control systems experts, custom HR system experts, custom collaboration system experts etc., instead of improving the hiring number of or reinforcing the role of Chief Information Officers (Lawry et al. 2007), Chief Technology Officers (Adler and Ferdows, 1990; Smith, 2003), Chief Information Security Officers (Whitten, 2016), Cloud Computing Architects (Rhubart, 2012), Data Scientists (Davenport and Patil, 2012) and so on.

Thus, we can easily assert that we have about 11,000 "absolute digital monarchies" both from an infrastructural and applicative point of view (procurement included); the sovereigns are the public sector high-ranking officials who claim ownership of them and strenuously defend their survival.

This difficult situation has negative impacts on the public sector employees (and even more on IT companies employees that work for public sector) who are losing their skills and cross sectoral competences that they have acquired in years of specialist studies, and whose expertise is not easily replaceable. As a result, there is an enormous quantity of pointless and 'damaging' (OECD 2019).

The fragmentation of obsolete IT infrastructures and applications and the 'waste' of human resources could be solved only through an in-depth reorganization that could potentially save at least two billion euros per year (de Rosa et al., 2020) and, thus, free resources for more proficuous investments in innovative areas.

The Italian Government is implementing a strategy to reduce those dreadful numbers, 'shifting' the public sector services from the current obsolete and/or inadequate data centers to safer solutions and/or cloud computing technologies, where applications are delivered (unique by type) in SaaS mode[1], in compliance with regulations and technical guidelines for the benefit of all central and local public administrations (OECD 2018).

4 What the Italian Public Administration needs

4.1 New jobs opportunities

After this review, we wish to focus on the e-competencies that could positively impact the public sector. With this scope, we listed below some of the new jobs' opportunities in the field of ICT: Chief Information Officer, Chief Digital Officer, Chief Technology Officer, Chief Security Information Officer, Chief Data Officer, Digital Architect, Cloud Computing Architect, Cloud Computing Integrator, Data Driven Decision, Business Intelligence, Data Scientist, Open Data Expert, Internet of Things, Big Data Expert, Mobile App Development, e-Commerce Specialist, e-Public Procurement, Digital Marketing Manager, Web Marketing Manager, Online Store Manager, User Experience Manager, Analytics Director, Web Analytics Manager, Digital Copywriter, Digital Designer, Search Engine Optimization, Search Engine Marketing, Community Manager, e-Reputation Manager, Social Media Manager, Artificial Intelligence, Machine Learning, Blockchain, Cyber Security, Industry 4.0.

[1] *Software as a service (SaaS) is a software licensing and delivery model in which software is licensed on a subscription basis and is centrally hosted.*
SaaS applications are also known as web-based software, on-demand software and hosted software. The term SaaS is considered to be part of the nomenclature of cloud computing, along with infrastructure as a service (IaaS) and platform as a service (PaaS).
SaaS apps are typically accessed by users using a thin client, e.g. via a web browser. SaaS has become a common delivery model for many business applications.

In the following sessions, we analyse some of these jobs, highlighting concerning required skills.

4.1.1 C-suite

As known C-suite refers to a cluster of some of the most important corporations' senior executives able to set the company's strategy, make higher-stakes decisions and ensure the day-to-day operations align with fulfilling the company's strategic goals (Rouse and Pratt, 2019). It is obvious that in order to efficiently and effectively pursuit results, C-level managers need to have adequate expertise in order to improve performance through critical organizational outcomes (quality, innovation, profit, and ethics), adopting systems and technical processes required for high performance (Dawson et al., 2015). With particular regard to ICT, C-level management must have a specific and significant technical expertise in their field but also a deep understanding of the business (Curran, 2009), and a business strategic view (Smith, 2003).

In the following paragraph, we want to provide a short description regarding the most common IT C-level roles that, according to us, could help the Italian public sector.

- Chief Information Officers (CIO) guide the evolution of IT resources, adapting the internal infrastructure to the achievement of the strategic objectives. They contribute both to the definition of business and change management process, defining key performance indicators and service level agreement. Furthermore, they manage the IT department budget and resources in order to assure the daily operation of information systems and satisfy the needs of users. CIOs do not only provide the right technology but they also lead the evolution of IT departments with strategic perspective, helping their chief executive officer colleagues to steer companies (Smaczny, 2001); As Babin and Grant (2019) point out, CIOs are increasingly becoming leaders who actively participate in strategic business decisions to develop a business-focused set of skills, in addition to technical ones.
- Chief Digital Officers have the responsibility of implementing and accompanying the digital transformation (Engesmo and Panteli, 2019). They focus on the re-engineering of traditional analogue processes across different types of organisations and industries. The digital transformation of an organization affects both the industrial, productive and administrative areas and the organizational and management areas. Although this process has already been underway for several years, it is not be completed, yet. There are still many challenges, in terms of deploying a common and shared strategy within the company, and implementing organizational models allowing the different departments to communicate effectively and make consistent use of IT resources throughout the company.
- Chief Technology Officers occupy the highest position associated with technology responsibilities (Lohmuller and Petrikhin, 2018); they monitor technological advances (Adler and Ferdows 1990), assess technological aspects of major strategic initiatives (Roberts 2001; Medcof 2007) and select profitable new

technologies to apply within the organization to improve productivity and competitiveness.

- Chief Information Security Officers (CISO) have the responsibility to identify and implement the best organizational model to ensure adequate data and technology security (Karanja, 2017). CISOs are focused on risk minimization and on introducing appropriate controls and standards in compliance with the security regulations. They are responsible for cybersecurity, disaster recovery and business continuity management, identity and access management, privacy, risk management, design of security architectures etc. (Digital4HR, 2017).
- Chief Data Officers (CDO) have the responsibility for data management strategy; through data analysis, they identify new business opportunity (Xu et al., 2016) and help the decision-making process in order to improve the competitiveness (Noh, 2016); as Gellweiler (2020) states: *the CDO is placed between IT and marketing*. Their work is based on two pillars: data science and data analytics.

At this point, it is appropriate to point out that the public sector produces and control an enormous amount of data with an extraordinary added value.

Unfortunately, these data are often stored in vertical silos that are not interoperable with other public sector entities and their potential is not maximized. Government organisations should be able to collect, analyse, process and interpret these data for analytical, predictive and strategic purposes. The information extracted would generate new knowledge useful to citizens, also in terms of the services offered to them. Accordingly, another important role is the Open Data expert that reports to CDO.

4.1.2 Other useful roles

In addition to the above-mentioned C-level roles, the Italian public sector could benefit from the use of the following professional profiles:

- Digital Architects; they make effective decisions and enable rapid solution development by employing modular services and components (Korhonen and Halén, 2017); they would translate the requirements of the public managers into solutions that are sustainable, effective and innovative. Due to their professional background, most of the public sector top management do not have specific knowledge in technologies. Digital Architects can help public managers to better understand the short, medium- and long-term implications. In other words, Digital Architects are one of the technical cornerstones of the digital transformation of the Italian public sector. In particular, it would be beneficial hiring:
  - Enterprise Architects who define processes, information and data to adapt to a very high-level strategy (for example, a national planning for central government);
  - Solutions Architects who define the design and implementation of a single IT system for central and local administrations;

    - Data Architects who deal with information architecture (how to acquire data, where to store them and how to use them) through the existing data and information mapping;
    - Cloud Computing Architects who are expert in cloud technology that will be increasingly adopted by the Italian public sector in compliance with the National Strategic Plan[1];
    - User Experience Architects who help the public sector to design citizen-oriented services that are inclusive and respond to the real needs of people.
- e-Public Procurement Managers who manage a vast and delicate area. Nowadays, managing an administrative procedure could be considered only a good start. The Italian public sector should be the driving force of a dynamic society and should be able to understand the market ruled by global dynamics. The synergic and interdisciplinary skills such as IT, legal and managerial (organizational, strategic, analytical, etc.) should complement the management skills.
- Artificial Intelligence, Machine Learning, Internet of Things;
- Social Media Managers who take care of improving the relationship between PA, private companies and citizens through the communication channels. The effectiveness of the communication model presently adopted in the public institutions could be enhanced by fostering a more inclusive participation of citizens who can express their needs and share their ideas.

4.2 Room for improvement: few suggestions

At the end of this review, we wish to put forward some recommendations that may help the public sector to successfully complete its digital transformation.

The digitalization process has already started; a new governance has been put in place[2]. Much remains to be done. The process is not an easy one and requires a strategic and whole-of-government approach. The actions taken so far are only the necessary prerequisites, but they are not enough to guarantee an effective digital transformation of the Italian public sector and, more generally, of the entire country.

We believe that the major resistance to the digital revolution is a cultural one.

Ask me my three main priorities for government and I will tell you: education, education and education (Tony Blair, 1996[3]).

---

[1] *It is a strategic and economic policy document for all public administrations that oversees the Italian digital transformation. The Plan defines: the operational course of action in the development of public information technology; the strategic model of the evolution of the PA information system; ICT investments in the public sector according to the European and Governmental guidelines.*

[2] *The Digital Transformation Team (established by 2016); the appointment of the minister for technological innovation and digitalization (September 2019); the establishment of the Department for Digital Transformation (September 2019); PagoPA, a state-owned company with the purpose of supporting the use of digital services in Italy.*

[3] *Speech at the Labour Party Conference, 1st October 1996.*

In every country, the system of education is the pivot of the digital transformation. Digital citizenship should part of the school curriculum. Students should understand their digital rights and duties in the digital society, should be taught to acquire a critical approach to the Internet, media, social networks, and should learn how to protect themselves from the dark side of the World Wide Web (cyberbullying, predators, scams, etc.).

Digital literacy should help youth not to be passive users of technology but should help them grow into true digital citizens with the right digital skills and a clear understanding of rights and duties, of do's and don'ts.

Only the school systems digital revolution can assure the creative and innovative workforce of the future. Unfortunately, the Italian school system has not even addressed this topic. Changing the education system is a long-term endeavour. Yet, there is not much time left.

Digital citizenship should be introduced in the school curriculum and should be taught by specialised teachers, properly trained for different age groups. This is the first step to foster the right e-competences.

As for the higher education, the academia should support and facilitate the entry of new IT graduates into the workforce and put in place specific measures to align the number of graduates from particular programs to the market needs.

Another crucial component of the digital transformation is central or regional digital infrastructures - the so-called enabling platforms - that should be supported by substantial investments, right skills, proper organization and state-of-art technology. These infrastructures - some are already in place - would be able to provide advanced digital services not only to the public sector but also to private companies and citizens.

Last but not least, digital literary should remain high in the Italian government political agenda. Consequently, even the media, not only the specialized ones, but also the major ones, those that today deal little and badly with issues related to Information Technology, should assume specific skills to be up to face these new challenges.

5 Conclusions

There is robust evidence that show the dramatic situation of digitalization in Italy. This 'emergency' has manifold implications on the entire population and its impact on the daily life has been emphasized during the lockdown period due to COVID-19. Indeed, digitalization impacts the educational system, work in the public and private sector, civil society.

Its complexity does not make easy finding proper solutions; it takes time to bridge the gap. In this paper, we tried to raise awareness, providing a broad framework, although not exhaustive, of the Italian 'digital emergency'; we focused, in particular, on the inadequate level of competences of the public sector employees who work in the IT. Also, we highlighted the potential usefulness of some job profiles.

Then, we put forward some consistent proposals for improving the current situation in the medium-long run; our suggestions focus on: the introduction of compulsory ICT course starting from the primary school; a better labour market alignment between the number of graduates from particular programs with the demand for workers with these qualifications; a targeted investments to centralize the ICT infrastructures and more efficient management of the public sector workforce with the appropriate skills; last but not least, a renewed and continuous attention to digital skills and culture in the political agenda.

Acknowledgments

We are grateful to Daniela Battisti and Fabio Cristofari for wise and helpful comments on earlier draft.

Abstract

The digitalization of the public sector has been implemented through smart technologies, that is digital processes and tools. At local government level, this allows not only to communicate with citizens and provide digital services, but also to collect information generating new knowledge. Smart data and analytics can improve services, foster transparency, promote accountability, as well as improve decision-making, management, and control.
The study focuses on the digital transformation of municipalities in Italy. It highlights opportunities as well as critical issues and obstacles for local government digitalization within a knowledge management context. In particular, the timeliness, relevance, and selectivity features of information and control systems seem to be overlooked: digitalization has often induced mere bureaucratic obligations, often made even more ineffective by the digital divide.
The paper benefits from national data and the experiences and opinions of managers who generate, manage, and could use digital information at local level. The issues raised by digitalization at local level highlight the need to refine competences about information systems and knowledge management, but also to listen to local requests to avoid fuelling new gaps instead of favouring a homogeneous development at the lower tier of government.

Keywords – control systems, information systems, ITC, knowledge management, public sector

Paper type – Academic Research Paper

1 Introduction

Digitalization has fostered radical changes in government and governance (Dawes, 2009). It is not yet a standard across public administration (Gil-Garcia et al., 2019), even though it is a fundamental knowledge management tool and strategic lever (Criado and Gil-Garcia, 2019; Sandoval-Almazán et al., 2017) as the Covid-19 pandemic has shown. The digital transformation allows not only to benefit from new ways of communicating with citizens through a single access point and the provision of online services, but also to better master administrative processes (Asgarkhani, 2005), by on the one hand simplifying and homogenising them and, on the other, ensuring transparency and improving information systems (Criado and Gil-Garcia, 2019; Velsberg et al., 2020).

This paper explores the role of digital solutions in the public sector by focusing on whether and how smart technologies are influencing local governments in Italy, a mixed bag in Europe for digitalisation. Despite the adoption of the Digital Administration Code since 2005, Italy is in the fifth last place of DESI (Digital Economic Strategy Index - European Commission, 2019) with which the European Union classifies the digitalization process underway in its member states. Italian public administration is suffering from a delay in the adoption of smart technologies due to the slow adoption of ICT (Information and Communications Technology) (Court of Auditors, 2019).

After a brief review of the literature, this contribution focuses on the empirical data collected at national level by the Italian Statistical Office (ISTAT) and at local level through interviews with key respondents. The opinions of a sample of town clerks, financial managers and auditors from local governments will help contextualise results.

2 Theoretical background

The digitalization of the public sector has been implemented through smart technologies, that imply the combination of technology, people and organisations (Velsberg et al., 2020). “E-government” is understood as using advanced technologies to achieve better services as well as improved administration and management (Dawes, 2009). As far as local government is concerned, digitalization is associated in the relevant literature with five key aspects:

- the online delivery of services to citizens and businesses through a single access point (Yildiz, 2007);
- the rationalization of internal operations with the simplification and standardization of processes and procedures using online software and platforms (Asgarkhani, 2005);
- the improvement of management and control information systems (Anthony, 1965; Amigoni, 1978) through the automated and timely collection of accurate data (Bertot et al., 2012; Lourenço, 2015; Cinquini, 2019) which increases knowledge, transparency and accountability;

- the introduction of smart working and remote work practices (Garson, 2003);
- the promotion of citizen participation, the so-called e-democracy through platforms and web-based applications with innovative ways of engaging citizens and of tapping into their knowledge and inputs (Ingrams et al., 2018; Mergel 2018), which not only improves outcomes but contributes to transparency and accountability.

Therefore, at local government level internal and external stakeholders benefit from a greater exchange of information and improved trust and communication (Desouza and Bhagwatwar, 2012). The production and consumption of knowledge has experienced tremendous changes in the last decades in line with technological advancements to collect and share it (Secundo et al., 2017), yet it needs to be managed efficiently and effectively as a key resource of local government. "Smartness in public sector innovation" (Velsber et al., 2020) requires sufficient management capabilities and robust strategies, along with a willingness to explore and adopt new work practices rather than simply implement emerging technologies. Hence, knowledge management can become "a powerful enabler" (McAdam and Reid, 2000, p.328) since the "effective functioning of government rests on effective acquisition and dissemination of knowledge" (Moffett & Walker, 2015, p.68).

Overall digitalization can thus create public value by developing from a facilitation tool into a strategic lever for knowledge management (Criado and Gil-Garcia, 2019). Indeed, it affects the intellectual capital of local authorities in its three components (Dumay et al., 2015), i.e. its human capital with the new skills to be acquired by local government employees, its structural capital with the digitalization of procedures and the development of tools for the collection and sharing of data with a view to transparency, reuse and interoperability, and its relational capital with new ways of dealing and engaging citizens and other stakeholders.

However, the literature reveals that results of public sector reforms, such as digitalization, are often influenced not so much by new tools, but rather by contextual factors (Castelnovo & Sorrentino, 2018). In general, environmental dynamics and system-inherent barriers, such as a high degree of compliance, red-tape and complexity, can hinder achievements (Mergel, 2018). The main challenge is how to overcome these barriers (Massaro et al., 2015).

Furthermore, considering the barriers to the implementation of smart technologies and the failure rates of many digitalization projects (Anthopoulos et al., 2016), e-government channels are often added instead of replacing or being integrated into traditional ones, resulting in additional costs for public sector organizations at the expense of efficiency (Budding et al., 2018; Nam, 2019).

On the other hand, in order to satisfy internal and external knowledge needs in an efficient and effective way, for strategic planning, directional control as well as operational control (Anthony, 1965), information systems must be selective, relevant, timely, reliable, verifiable, flexible and acceptable (Amigoni, 1978), but technology does not always allow it (Lavertu, 2016). While digitalization increases the amount of

information available, its diffusion, flexibility, versatility and timeliness, helping encourage the involvement of internal and external stakeholders and promoting transparency and accountability, it can also cause an excess of information, with a loss of relevance and accuracy, as well as security issues (Mancini et al., 2017). As highlighted earlier, smart technologies can improve public services, internal procedures, information systems, working practices and citizen engagement, yet they need to be managed so as to account for the risks of their misappropriation (Desouza and Bhagwatwar, 2012) and the amplification of real-world biases and discriminatory practices such as the digital divide (Lember, 2018).

Therefore, this paper aims to investigate the impact of digitalization on local government, and in particular on its knowledge management practices and its intellectual capital, considering both positive impacts and liabilities.

3 Methodology

In order to explore the research questions, a case study was analysed through quantitative and qualitative evidence. As mentioned before, Italy provides an extreme case study (Seawright and Gerring, 2008), as it is so far behind with respect to most of Europe in its digitalization process. The Italian public sector is traditionally characterized by a level of organizational inertia favoured by elements of self-regulation that favour stability, which may involve an orientation towards immobility, apathy and slow change (Sancino et al., 2018).

The issues related to the digitalization of Italian local authorities were first framed through a review of the literature and an analysis of the legislation. Secondly, the empirical evidence provided by national statistics and insights from key informants were analysed. Specifically, the data provided by the ISTAT survey "Survey on information and communication technologies in local public administrations - Year 2018" conducted in the summer of 2019, were used to verify the level of local government digitalization and the degree of accomplishment of regulatory requirements. The survey can be considered representative of the universe of Italian local authorities given that 6,117 Municipalities participated out of a total of 7,954, or 77% (ISTAT, 2020).

The national statistics produced by ISTAT were complemented, explained and contextualised through qualitative information collected via unstructured interviews carried out with a selection of town clerks, financial managers and auditors in November 2019 (Table 1). This allowed exploring how smart technologies are perceived on the ground and what impact they are having on the operations, knowledge management practices and intellectual capital of Italian local authorities with different dimensional characteristics.

Table 1. Interviews

	Respondents
Small municipalities with less than 5.000 people	12
Medium municipalities with 5.000 to 9.999 people	8
Large municipalities with 10.000 to 49.999 people	5
Towns and cities with 50.000 people or more	5
Total	30

A qualitative analysis was then performed through "open coding", segmenting the answers to the interviews into meaningful expressions (Kim and Andersen, 2012) to identify more precisely key concepts and their interconnections starting from the raw data.

4 Results

In Italy the informatization of public administration activities began already in the last century (Natalini and Stolfi, 2011) in some fundamental areas, such as the establishment of the tax registry, the integrated public accounting information system and the centres for the payment of public employee salaries. Over time, smart technologies have assumed an increasingly important role shifting gradually from a simple facilitation tool for institutional activities to a strategic lever for change and development (Criado and Gil Garcia, 2019).

In the wake of the initiatives at European level, the fundamental regulatory steps with respect to the digitalization of Italian local authorities have been:

- the adoption of the Digital Administration Code (CAD) in 2005, which was then revised in 2016;
- the approval in 2012 of the Italian Digital Agenda (ADI), which identifies the strategy to achieve the objectives set by the European Digital Agenda in 2010;
- the establishment in 2012 of the Agency for Digital Italy (AgID), which develops three-year plans for public administration informatization, and supports and coordinates digitalization efforts;
- the establishment of the Digital Transformation Team, which between 2016 and 2019 managed all digital transformation projects which were subsequently transferred to the Ministry of Innovation, Technology, and Digitalization and the Department for Digital Transformation which were both established in September 2019.

According to the 2019-2021 three-year plan (AgID, 2019), a digital transformation is to be understood not only as a technological innovation, but also as a simplification and facilitation of administrative processes and of the relationship with citizens and businesses by promoting efficiency and effectiveness at government level. The plan is based on four core principles:

- digital by default: conceiving, designing and implementing digital services as the primary (and, if possible, the only one) delivery method;
- once only: avoiding asking citizens for information the administration already has in its possession in one form or another;
- digital identity only: grounding citizen recognition processes on digital elements;
- cloud first: gradually abandoning proprietary IT infrastructures to convert to cloud technology.

Hence, it is necessary to review processes, procedures, practices, responsibilities and skills to digitalize local government activities. To this end, article 17 of the CAD establishes that local authorities should establish a digital transition office and appoint a Digital Transition Manager (RTD) to coordinate and facilitate such developments.

And yet, the evidence collected for this research reveals that the situation on the ground is far from ideal. The report by ISTAT (2020) finds that the level of digitalization reached by Italian municipalities by the end of 2018 was not that sought by legislators, neither with respect to regulatory requirements nor with respect to improving administrative functionality. The interviews with municipal clerks, financial managers and auditors offer interesting insights into the results of the ISTAT survey, which are explored in the following sections.

4.1 What influences digitalization

The ISTAT report (2020) highlights that the factors that mostly favoured the process of digitalization of local authorities were legal obligations (84.0% of municipalities), directives from central and regional governments (79.6 %) and the need to keep costs down (61.5%). Therefore, mainly coercive isomorphism and efficiency issues. Less than half of the municipalities considered as important reasons to digitalise the need to adapt and improve their processes (39.4%), and user satisfaction (38.5%), which thus seem to remain at the bottom of the list of priorities for local authorities.

All respondents to the qualitative investigation agree that too many innovations make it difficult to keep up with the regulations and directives from the central administration. In particular, obligations are becoming ever more, so much so that functionality improvements and users' requests are perceived not so much as stimuli and objectives, but rather as additional issues to be dealt with.

4.2 Digital equipment

ISTAT data show that almost all municipalities now have desktop PCs (99.6%) available to almost all employees (94.5%), even though 13.5% of employees do not have access to the Internet. Portable PCs are present in 62% of municipalities and are used by 6.6% of employees. Contrary to what one might think, although the percentage of employees who have access to portable systems is higher among larger municipalities

(51.8% among small municipalities versus 85.6% for larger municipalities), the proportion of employees using them is highest in small municipalities at 7.9% versus 6.3% in larger municipalities. Interviews confirmed that in smaller municipalities, laptops are used to guarantee flexibility for employees who work at more than one institution. Despite this, smart working solutions, which facilitate shared access to data, information and documents, and tools for remote participation in meetings and gatherings, are not very widespread, especially among small municipalities. According to ISTAT, only 59.0% of municipalities (58.7% among small municipalities) have an Intranet network, 34.3% (27.9% among small municipalities) make use of cloud computing services and 17.8% (13.6% among small municipalities) have videoconferencing tools.

4.3 Internal structures and processes

According to the national survey, local governments have adopted smart technologies for managing official records (83.3%), for accounting purposes (81.0%), for the population registrar (80.8%), and for managing payslips (78.9%), taxes (75.7%) and administrative documents (74.9%). Very few even large municipalities use artificial intelligence tools (2.4%) and analyse the data collected through IT systems to improve internal processes or services (2.9%), let alone to generate useful information for decision-making.

Furthermore, most municipalities have not implemented many CAD directives: only 26.0% have an IT office (15.1% among small municipalities) and only 21.8% have an RTD (17.2% among small municipalities).

Among technologies aimed at reducing costs, 50.9% of municipalities use open source software, 34.8% use VoIP solutions and 6.7% use software from other local administrations. With respect to the rationalization of purchases, 80.9% of municipalities used e-procurement in 2018. But, 88.1% still use tools such as stamps and signatures on formal paper registrars and 45.2% collect as paper records more than half of their documentation, which often originated in digital form.

The Court of Auditors (2019) found that local authorities have difficulties in modifying their information systems and reorganizing their office working modes. On the other hand, qualitative interviews revealed how often the digital applications proposed by the national and regional governments are not suitable to local situations, because they are too complex or are not compatible with the internal procedures of local authorities and, therefore, are abandoned or not really implemented.

4.4 Staff training

IT training also did not meet the CAD requirements in 2018. Only 16.2% of municipalities took part in ICT training courses, involving 7.3% of employees on average.

The interviewees confirmed deficient technological skills at local authority level and how important it is instead to have employees who understand ICT.

At the same time, however, in 2018 the staff of most municipalities participated in general e-government courses: 58.5% municipalities had staff take part in courses on electronic invoicing, 48.2% on e-procurement, 44.2% on telematic payments, 37.0% on internal process digitalization, 25.6% on digital identity, 20.2% on web, multimedia and social media services, 12.7% on open data and 7.4% on cloud computing.

Nonetheless, according to a survey carried out by AgID on a sample of 60 RTDs, the task perceived as most urgent for public administration training remains the development and dissemination of digital skills, both in terms of basic IT knowledge as well as specific digital processes for the public sector (AgID and CRUI, 2019).

4.5 Citizen and business services

Although the last decade has seen the implementation of various digital initiatives such as the Public Digital Identity System (SPID), the National Register of Resident Population (ANPR), the National Service Card (CNS), the Electronic Identity Card (CIE) , the platform for payments of public services (PagoPA), the electronic health record for each citizen, their adoption has been limited.

The survey by ISTAT shows that, despite the fact that almost all municipalities (98.7%) offer online information about their services, only 69% offer the submission of online forms and 48.3% allow carrying out online the entire procedure relating to at least one of their services. Business related practices can be managed entirely online in a third of municipalities (36.9%), while the percentage of those that have fully digitalised citizen services is much lower: paying for parking 2.0%, processing identity cards 2.4%, registry certificates 3.2%, calculating and paying waste taxes 3.3%, paying fines 4.5%, paying municipal property taxes 5.1%. In the period between 2016 and 2018 only 21.5% of municipalities monitored the use of online services and 10.9% monitored the level of user satisfaction. 38.5% have improved their online services, that is they have reduced waiting times (17.7%), increased the proportion of requests received online (22.9%) or increased the proportion of online procedures (18.1%).

Some respondents to the qualitative investigation call for a simplification and rationalization of digital tools. For example, there could be a single and unique digital identity for citizens and businesses by harmonizing existing individual databases. Similarly, digital recognition systems such as SPID, CNS and CIE could be rationalized into a single solution.

4.6 Information systems

Digitalization allows collecting valuable data in information systems for management control purposes (Anthony, 1965; Amigoni, 1978) and for monitoring the impact of

digitalization on service improvements, simplification and cost reduction (Asgarkhani, 2005). In 2019, at least four initiatives were undertaken in this respect: the ISTAT survey "Survey on information and communication technologies in local public administrations - Year 2018", whose results are used in this research; the "Questionnaire for the assessment of the implementation of the three-year IT plan for public administration" carried out by the Court of Auditors; the "Survey on the training needs of the RTD and its office" conducted by AgID; and the investigation on "Common indicators for public administration support functions" promoted by the Department of Public Administration

Although all surveys could be completed online and had partially different purposes, all respondents noted that they implied additional efforts with detailed requests and no direct benefits. Interviewees complained, on the one hand, about the lack of coordination among central government institutions to run a single investigation, and, on the other, that data collection should be automated as far as possible by exploiting the information that municipalities regularly submit to the central administration, without weighing on local government staff and other resources. Some respondents described how in many cases the answers were copied and pasted from one survey to another at the expense of data accuracy and quality.

4.7 Citizen engagement

This aspect of e-government was not explicitly included in the ISTAT survey. However, the investigation revealed that only that 40.3% of municipalities make open data available regarding different aspects of public life: 30.8% of municipalities share information related to economics and finance, 30.7% to government and public sector, 23.1 % to education, culture and sport, 18.7% to the environment, etc.

Respondents to the qualitative investigation reported sporadic citizen involvement initiatives through online platforms and social media: some municipalities have collected comments and suggestions for updating tools such as the Master Zoning Plan, others engage them in activities such as participatory budgeting or surveys to verify the population sentiment with respect to particular initiatives such as square and street naming, scheduling local cultural activities, and so on. However, these are often improvised solutions, mostly entrusted to social networks and therefore unreliable because they guarantee neither data validity nor participation fairness, representativeness and quality.

5 Discussion

Referring to the five areas identified by the literature, the ISTAT report highlights how e-government is spreading both across services and internal processes within local authorities, less so as far as citizen participation is concerned, as confirmed by the interviews with town clerks, financial managers and auditors. Future surveys carried out regularly could allow monitoring progress and compliance rates. The quantitative survey

has shown how smart technologies are often introduced progressively and in addition rather than to replace traditional systems, against the "digital by default" principle and at additional costs. Further, a more organic approach to the interoperability and management of information across databases is needed so that citizens and businesses have a unique digital identity and need to provide their data only once to public authorities, according to the "once only" principle. Until an effective transition to digital systems takes place and has demonstrated by the Covid-19 emergency, smart working at local government level remains of limited implementation, because the necessary equipment is not widely available, and processes and databases are not yet fully dematerialized.

As far as information systems are concerned, digitalization has often induced mere bureaucratic obligations, often made even more ineffective by the digital divide. The interviews revealed a growing gap between data collection initiatives and databases on the one hand, and the ability of local managers to use such information for management purposes, almost as if data collection was an end in itself, resulting in a huge IT compliance effort to little, if any, avail. Considering information and control systems, the several surveys proposed by central administration units appear to neglect the criteria of relevance, selectivity and timeliness of information (Amigoni, 1978; Mancini et al., 2017). In addition to the excess of information requested several times from local authorities, survey results are published the year following data collection, which already refers to the year preceding the survey and resulting in two-year time delay, effectively hindering any prompt action by both central government institutions and local authorities.

6 Conclusions

The study highlights opportunities as well as critical issues and obstacles for local government digitalization within a knowledge management context, although it does not delve on the strategies adopted by local administrations in pursuing digitalization and overcoming these obstacles. This could be a topic for future research as well as the efforts undertaken during the Covid-19 emergency which exacerbated the need for greater digitalization.

So far evidence from Italian municipalities highlights the need to develop, on the one hand, a unified approach to stakeholder information needs, and on the other, IT systems that can transform in activities performed automatically and autonomously in real time those tasks perceived by local administrations as mere compliance and which take resources away from daily functions. This would allow creating a dynamic sharing system with the development of structural and functional synergies which would curb the exclusion and alienation especially of smaller and less structured local authorities, which are often characterized by widespread shortcomings of digital skills.

Therefore, the difficulties that local authorities are facing with digitalisation risk feeding new divides instead of favouring a homogeneous development both between organisations with different dimensional characteristics, endowments and resources, and between central government and local administrations. On the contrary, digital systems

and data collected through smart technologies could not only allow more and better services, transparency and accountability, but could also provide legislators, local decision-makers and managers with more evidence and knowledge to guide their work on the principle of data based decision making.

Abstract

Aims: This study examines the relationship between the time students spent abroad, personality traits, behavioural patterns as well as the circumstances during this time and the student's intercultural competence. The study uses a correlative cross-sectional design. *Design and sample*: A total of 202 academic subjects were surveyed in a cross-sectional design. The study was conducted between the 01.05. – 01.07.2018 via an online survey tool. The average age was 22 years. *Measurements*: The survey characteristics of stays abroad such as type and length of the longest stay or the integration into the target culture, further, intercultural competence, social competence and work-related attitudes as patterns of behaviour and experience using the "Work-related Behaviour and Experiencing Pattern 44". This scale assesses work related personality traits and sorts participants to one of four patterns, describing their health behaviour at work. *Results*: The motivational competence increased after one to five month, the cognitive and behavioral competence was significantly higher after minimum five month. The personality patterns influenced the motivational and metacognitive competences. Having a pattern A or B lead to a lower motivational competence through occupational stays abroad. Further, a S pattern was connected to lower metacognitive competence after a occupational stay abroad or an Au-pair. The results show that for different types of stays abroad and different characters specific support measures are required from companies or universities.

Keywords – intercultural competence, personality, stay abroad, acculturation, stress

Paper type – Academic Research Paper

1 Introduction

To be long-term successful in today's modern, globalized world, a high level of social competence is needed, both in dealing with one's own culture, as well as with individuals with a different cultural background (Kanning, 2003; Genkova, 2019). Competence can be defined as the handling of interaction that leads to more appropriate or effective results in any context (Spitzberg & Changnon, 2009; Yeke & Semerciöz, 2016).

To prepare students adequately for the demands of working life, universities focus on semesters abroad as "the best way" to train intercultural competence (Brohm, 2009). As a result, the number of semesters abroad rises strongly (Wolff, 2017). Thereby universities often take a limited approach to intercultural competence and assume that the longer a student is sent abroad, the more competent a person is (Brohm, 2009).

This point of view neglects individual characteristics of the students and the contextual factors of the stays abroad. Lasauskiene and Bagdonaviciute (2018) assume that the quality of the contacts abroad influences the gain of competences. This also applies to the way individuals deal with intercultural stress (Berry, 2003). Wolff (2017) showed that competence can be gained in the course of time, but these results are little differentiated. Similarly, it has already been shown that a semester abroad leads to the greatest increase in competence (Watson et al., 2013), but these results do not include the personality dimension either.

The aim of this study is therefore to examine empirically a differentiated approach of stays abroad and their impact on intercultural competence. Personality variables and characteristics of the stays abroad were examined. Furthermore, the focus is on the predictors of intercultural competence and action implications are derived.

2 Theoretical Background

Thomas (2003) describes culture as an orientation-system that defines the affiliation of its members through influencing perception, thinking and acting.

Culture therefore also represents a part of social identity (Brewer & Yuki, 2007). In this way, individuals can identify with different cultures without contradictions (Rosenthal et al., 2015). In intercultural exchange situations, however, the learned orientation system may no longer function as expected. The failure of one's own orientation can cause considerable stress for those involved (Thomas, 2003).

Only through the mutual approach to each other it is possible to overcome problems and to enrich each other's experiences through the different perspectives (Sam & Berry, 2010). This process of adaption is called acculturation (Redfield, Linton, & Herskovits, 1936). It means that cognitive and cultural learning and internalization processes must take place among the interaction partners, which are necessary to participate in social life (Heckmann, 2015).

In research it is still very important to differentiate acculturation from intercultural competence. According to Ng et al. (2017) the acculturation process is a predictor for a successful adaptation, the process of adaptation also leads to more competence.

To date, no generally accepted, theoretically sound and empirically proven overall model for intercultural competence exists in literature (Genkova, 2019). Van Dyne, Ang and Koh (2008) designed a differentiated compositional model of intercultural competence. Intercultural competence was divided into the subdimensions metacognitive, motivational, cognitive and behavioural competences. Metacognitive refers to the process of thinking and reflection and describes the interpretation of behaviour of people from other cultures. People with high metacognitive intercultural competence are more aware of potential misunderstandings in intercultural situations because they observe and try to understand. This enables them to react more appropriately. The cognitive component describes the aspect of learning the rules of a new culture. Individuals are aware of these rules and themselves and can act accordingly. The motivational level refers to the urge to understand new cultures, to adapt or to solve intercultural situations successfully. Behavioural intercultural competence refers to the actual skills, such as adapting language, to successfully deal with individuals from other cultures (Racicot & Ferry, 2016). Racicot and Ferry (2016) considered the four aspects of intercultural competence (based on Ang et al. 2007) as four separate constructs that interact with each other but have different predictors and different effects.

The model of van Dyne et al. (2008) suggests no temporal sequence or hierarchy of the individual components, as is the case with other authors (Deardorff, 2006; Spitzberg & Changnon, 2009) who suggested it but this could not be proven. Nevertheless, a temporal component must exist if competence can be increased in the course of an acculturation process.

According to Berry (2003) adaption takes place as a reaction to more or less drastic experiences that an individual has. Those experiences lead to stress that reduces the well-being, especially if the usual coping mechanisms are not working and there is a lack of social support. The core problem that leads to acculturative stress is that individuals are sometimes unable to change their behaviour or standards so that they can behave appropriately in certain situations. According to Berry, Phinney, Sam, und Vedder (2006), there are several moderation and mediation effects on the experience and handling of acculturation stress, both before and during adaptation. Decisive factors are primarily age, gender, and social support.

Van der Zee and Oudenhoven (2013) describe that especially the way how stress in intercultural situations is perceived is crucial. They showed relations with the personality. People who had low values for emotional stability and flexibility experienced uncontrollable intercultural situations as more frightening compared to people who had high values in these dimensions. Similarly, individuals who showed low levels of cultural empathy and openness experienced the situation as more stressful than those with high values.

There seems to be a connection between the handling of stress and intercultural competence. Concerning intercultural competence, the cognitive intercultural competence and social competence, Wang, Chen, Liu, Barkley and Wu (2020) found out that those competences predict the job satisfaction of Chinese expatriates moderated by the psychological well-being. However, the psychological well-being is strongly conditioned by health-promoting behaviour (Schaarschmidt & Fischer, 2008). This study therefore takes on the concept of work-related behaviour and experience patterns by Schaarschmidt and Fischer (2008). The scale is explained in more detail in the Methods section. The present study postulates that people who deal unhealthily with stress have a lower intercultural competence than people who have a healthy relationship with work.

Watson et al. (2013) showed that semesters abroad offer good conditions for the acquisition of intercultural competence due to the high level of contact and the need to interact with different people. Hanada (2019) examined the intercultural competence of Japanese students with a pre-post-design. The intercultural competence was influenced here by the type of stay abroad and in advance by the intention to go abroad and language skills.

The results of Lasauskiene and Bagdonaviciute (2018), as well as the empirical analysis of Hanada (2019) suggest that this kind of a stay abroad creates specific framework conditions. Furthermore, Wang et al. (2020) suggest that work-related health behaviour is related to intercultural competence. According to Gullahorn and Gullahorn (1963) it is crucial in the course of a stay aboard to overcome a culture shock to develop a positive attitude towards the other culture. Today it is assumed that overcoming so-called "daily hassles" is the acculturation stress that needs to be mastered (Genkova, 2019). These differ according to Watson et al. (2013) between two kinds of stays abroad. It is therefore assumed that there is an interaction effect between the types of stay abroad and job-related personality patterns.

Social competence is regarded as a condition for successful interaction with other individuals, which is necessary for a learning process (Rathje, 2007). However, interpersonal differences should not be attributed to culture-bound social competence (Genkova, 2019), but to the variables of the model, which is why social competence is included as a covariate. Furthermore, the duration abroad was already considered a predictor of intercultural competence. Lasauskiene, and Bagdonaviciute (2018) describe that the subjectively perceived quality of contacts with locals also seems to have had an influence on the students' competence. It is therefore assumed that the quality of contacts also has a linear relationship with intercultural competence.

3 Research Question, Method and Sample Description

The present study therefore assumes that people who have been abroad in the past have a higher intercultural competence and those who have been abroad for a longer period have a higher competence than those who have been abroad for a shorter period of time. Since Wolff's study (2007) only allowed a comparison of the conditions before and after

three months and not beyond that, a less specified hypothesis was chosen here to make differences visible after longer periods of time.

Hypothesis 1: The duration has a positive correlation with intercultural competence

Hypothesis 2: The personality is related to intercultural competence.

Hypothesis 3: The type of stay abroad is related to intercultural competence.

Hypothesis 4: Personality influences the effect of the type of stay abroad on intercultural competence.

3.2 Measurement instruments

The acquisition took place via the social network Facebook. An incentive (20€-Amazon voucher) was raffled. The participation lasted about 30 minutes. At the beginning the participants were instructed to answer spontaneously and honestly. Furthermore, the anonymity of the data processing and the exclusively scientific purpose of the study were also pointed out.

The Work-related Behaviour and Experience Patterns Scale (AVEM-44), the Cultural Intelligence Scale (CQS) and the Bochum Inventory for Job-related Personality Description (BIP-6F) were used. Questions about the conditions of the stay were based on the Socio-Cultural Adaptation Scale (SCAS). The duration of the stays abroad was asked as the duration of the longest stay abroad. The type of stay was queried as predefined categories, with an option for "other". The categories were semester abroad, school stay, professional stay, vacation and work and travel. In addition, it was asked how well one had mastered the language of the host country at the time (none - very good knowledge), how often one had contact with locals (Daily - Never) and how good these contacts were (No contacts - Large circle of local friends).

The AVEM-44 records 11 dimensions of job-related personality which are assigned to the 4 patterns via different clusters. Pattern G (German: Gesundheit = health): high but not extreme values for commitment, resilience, satisfaction and well-being without losing distance, low resignation tendency. A healthy attitude towards work. Pattern S (German: Schonung = Gentle): Low values for commitment, importance of work, ambition and willingness to spend, without losing distance, low resignation tendency. In addition, a high level of inner peace and life satisfaction, which, however, does not derive from work. Pattern A (German: Anstrengung = effort): Very high importance of work, willingness to work hard and strive for perfection, but a low ability to distance oneself from work. High commitment, but low resilience, life satisfaction and experience of social support. Pattern A is characterized by a high level of commitment to work without emotional compensation. Pattern B (burn-out): is characterised by low work commitment combined with a low ability to distance oneself from work. The tendency to resignation is high, and there is no satisfaction or experience of social support (Schaarschmidt & Fischer, 2008).

The Cultural Intelligence Scale (CQS) by Van Dyne et al. (2008) is a self-assessment questionnaire covering the four factors of intercultural competence. Metacognitive (questions 1 - 4; example: "I am aware of the cultural knowledge I use when interacting with people from other cultural backgrounds"), cognitive (questions 5 - 11; example: "I know the legal and economic systems of other cultures"), motivational (questions 12 - 15; example: "I enjoy interacting with people from other cultures") and behavioural (questions 16 - 20; example: "I change my language behaviour (e.g. I have to speak a different language") e.g. accent, tone) when an intercultural action requires it") intercultural competence on a Likert scale from 1 = "I don't agree at all" to 7 = "I fully agree" information about their self-assessment. In this study, the German version of the scale by Zimmermann and Neyer (2013) was used.

Social competence was assessed via the fitting part of the Bochum Business focussed Inventory of personality – 6 factors (BIP-6F) (Hossiep & Krüger, 2012) by an 8 items with Likert-scale. The reliability was $\alpha = .72$.

3.3 Sample

106 of the 202 participants were female, 57 were male. 39 gave no indication. The average age was 22.43 years (17-46 years). 83 % of the participants either had a high school diploma or already had a university degree. The largest proportion of respondents (16 %) came from the field of economics, the second largest from psychology (5.4 %). The patterns of the AVEM-44 test could be calculated for 152 data sets. 40% had the dominant pattern G, 27% had S, 20% had risk pattern A and 12% had risk pattern B.

58 % of the participants stayed abroad in the past. 32% had completed a semester abroad, 6% had been an au pair, 13% had worked and travelled, 11% had spent a school year abroad, 11% had been abroad for work and 28% had simply travelled. 64% of the respondents with a stay abroad stated that they had a good or very good command of the national language. 25 % said that they did not speak the language at all. 80 % of the participants stated that they had daily contact with locals. 11 % stated that they had had a large circle of friends. 25 % had some deeper contacts and some very good acquaintances. 31 % said they had had several superficial contacts. The quality of the contacts and their frequency correlated negatively ($r = -.380$, $p < .001$).

4. Results

Hypothesis 1: The duration of stay has a positive correlation with intercultural competence.

This hypothesis was evaluated based on an analysis of variance with subsequent consideration of the contrasts. None of the dimensions showed a linear relationship in the graphical evaluation of competence as a function of time.

Rather, the data appeared to be tending to accumulate, although the variance in the data means that it is not possible to speak of a sharp increase without further analysis. Wolff

(2017) describes that in a study with a post-hoc design that a competence gain was measured after 3 months. Analogously, a grouping after 5 months was observed here and therefore a grouping was made that distinguished between people without experience abroad, those with up to 5 months and those with more experience. Variance homogeneity was only given for the cognitive CQ. Therefore, the robust Welch-test was carried out for the other dimensions. It was shown that the mean values of the dimensions differed significantly, except for the metacognitive CQ. The results of the Welch test are presented in Table 1, the contrasts calculated afterwards in Table 2. Contrasts were calculated for the differences between the first two levels (Contrast 1) and the second and third levels (Contrast 2). The examination of the contrasts showed that the cognitive CQ differed among the participants who had been abroad for longer than 5 months and for shorter periods. The motivational competence increased across all three levels of the duration factor and the behavioural CQ differed between people who had not been abroad at all and those who had been abroad.

Table 1. *Welch-Test. Dependent variable: Dimensions of the CQS, independent variable: Duration ((0, < 5, > 5 months)*

		Statistics	df1	df2	p
Metacognitive_CQ	Welch-Test	2.60	2	82.36	.080
Cognitive_CQ	Welch-Test	5.69	2	97.91	.005
Motivational_CQ	Welch-Test	6.85	2	83.84	.002
Behavioral CQ	Welch-Test	11.44	2	73.99	.000

Table 2. Contrasts of the three levels of duration

		Contrast	Value of contrast	Std.-error		t	df	p
K_CQ	Equal variances	1	-0.56	0.98	0.57	150	.567	
		2	-2.50	1.01	2.45	150	.015	
Mot_CQ	No equal variances	1	-2.03	0.99	2.03	70.08	.045	
		2	-1.74	0.79	2.19	91.26	.031	
V_CQ	No equal variances	1	-5.45	1.18	4.59	52.76	.000	
		2	-0.11	0.79	0.14	82.05	.884	

Contrasts: 1. Level 1and 2; 2. Level 2 and 3

Hypothesis 2: The personality is related to intercultural competence.

The results show that only the influence on motivational competence is significant. Table 3 shows the results of the analysis of variance. Patterns S (M=5.01, SD=.76) and B (M=4.82, SD=.80) show high levels of motivational CQ, pattern G medium (M=3.50, SD=.99) and pattern A low (M=3.19, SD=.90). The analysis of the contrasts shows that

the patterns S (t(125) = 3.11, p = .002), G (t(125) = 2.11, p = .037) and B (t(125) = -2.06, p = .042) differ significantly from pattern A, but not among themselves.

Table 3.Single-factor ANOVA for AVEM patterns and motivational CQ

		QS	df	MQ	F	p
Mot_CQ	Between groups	8.52	3	2.84	3.36	.021
	Within groups	106.44	126	0.84		
	Total	114.97	129			

Hypothesis 3: The type of stay abroad is related to intercultural competence.
Hypothesis 4: Personality influences the effect of the type of stay abroad on intercultural competence.

To test hypothesis 3 and 4, a two-factor multiple covariance analysis was calculated. Equality of variance matrices and variance homogeneity were given. The dependent variables correlated moderately, but not highly.

The factors were type of stay abroad (6 levels) and AVEM (4 levels). The influence of the quality of contact with locals, social skills and duration, which were expected to be related based on theoretical considerations, were excluded. Table 4 shows the influence of the type of stay abroad and the AVEM, excluding the covariates. The AVEM patterns are significant even when the covariates are excluded. The types of stay abroad differ for metacognitive and motivational CQ. People who have spent a semester, school (half) year or au pair abroad have higher overall competences than those who have travelled, worked and travelled or worked abroad. Furthermore, an interaction effect of the type and AVEM on the motivational CQ can be observed. This model showed a goodness for the metacognitive CQ of $R^2 = .538$, for the cognitive CQ $R^2 = .433$ and for the motivational CQ $R^2 = .658$. The model for the behavioural CQ was not significant.

Table 4. Results of the covariance analysis. Relationship between the AVEM and the type of stay abroad and intercultural competence.

Figure 1 Illustrates the interaction effect on Motivational CQ. It becomes clear that the significant effect results from the differences in professional stays abroad, as well as in work-and-travel and only travel.

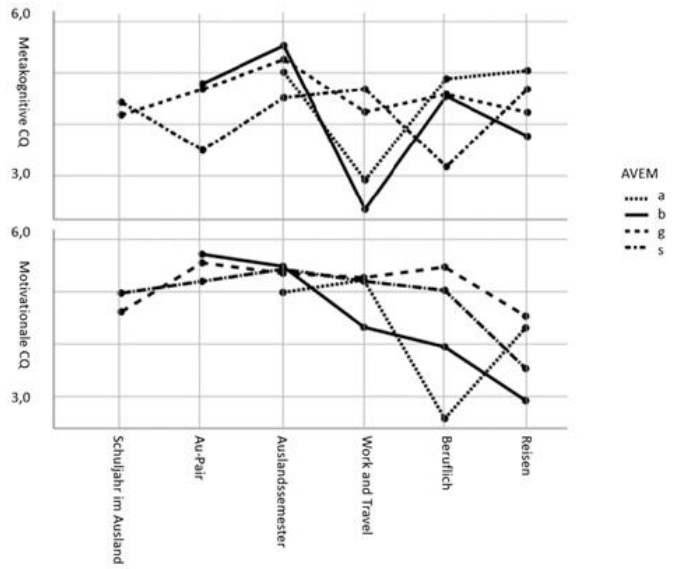

Figure 1. Interaction effects of type of stay abroad and AVEM on metacognitive and motivational CQ

Besides the analysis of the interaction effects, the parameter estimation of the covariates was also considered. Of the variables examined, only the quality of the contacts showed a significant linear influence on the dependent variables. It influenced metacognitive (ß = 0.37, p = .001), cognitive (ß = 0.32, p = .005) and motivational (ß = 0.19, p = .022) competence.

5 Discussion and Summary

Duration affects cognitive, motivational and behavioural CQ. However, significant differences for cognitive and behavioural competence are only observed after more than 5 months. The motivational CQ increases significantly between all three factor levels. The metacognitive CQ does not differ across the three groups.

Significant differences of the cognitive and behavioural competence could be identified after only 5 months contradicts previous theoretical assumptions regarding the gain in competence. In studies that research exclusively from a competence-oriented perspective (cf. Genkova and Ringeisen, 2017), a linear course is predominantly assumed. Rather, it appears that the development of certain competencies only takes place after a certain time. The results do not directly rule out a hierarchical relationship between the

subdimensions of intercultural competence (see Van Dyne et al., 2008). The motivational competence increases earlier in the course of time, however, the sub-dimensions correlate moderately with each other. But, apart from the theoretical assumptions of Van Dyne et al. (2008) and the time sequence, no evidence for this theory could be found. Moreover, metacognitive competence does not appear to be related to time at all, but is rather predisposed by personality. Considering the ambivalent connection between acculturation and intercultural competence that Lee and Sukoco (2010) found, concepts of cultural adaptation should also be included in the discussion.

Gullahorn and Gullahorn (1963) described the psycho-emotional aspects of cultural adaptation as a double U and W curve respectively. Accordingly, at the beginning of the stay abroad, a first honeymoon phase is followed by a culture shock, when the awareness grows that the learned behaviours and standards do not work as usual. As a result, an individual may or may not be able to cope with these problems, as well as daily-hassles (Ward, Bochner and Furnham, 2001). Since the second U-curve of the course refers to the home culture, it can be neglected for this consideration.

A possible culture shock was not shown in the available data. A negative attitude towards the host culture might be revealed by a low level of motivational competence. However, the motivational competence was increased after 1-5 months and even higher after more than 5 months. This suggests that the presumed correlation with duration is exactly the opposite, i.e. a person who is more motivated to interact with other cultures stays abroad longer. Linder (2019) describes that motivation to go abroad is an important factor for exchange students and expatriates. Overall, people who are externally motivated to go abroad (due to pressure, financial incentives, career aspirations) appear to adapt less well and to be less successful.

Regarding the respondents' handling of stress, it was found that subjects with an A pattern had significantly lower motivational competence than the other patterns. Remarkably, respondents with a B pattern differed only slightly from the non-risk patterns. Risk and non-risk patterns differed primarily in satisfaction, resilience and the ability to distance oneself from others (Schaarschmidt & Fischer, 2008). Sam and Berry (2010) describe that affective acculturation is above all also related to psychological well-being. Obviously, the satisfaction that individuals feel in their work or studies also influences the life they lead outside. According to Schaarschmidt and Fischer (2008), dissatisfaction and aversion to others increase from pattern G to pattern B. Lower life satisfaction could result in lower motivational intercultural competence. However, the results at this point do not provide clear evidence of this, as it appears that even people with low satisfaction with a pattern B do not differ significantly from the non-risk patterns. It is therefore concluded that, although satisfaction may result from a progressive acculturation process (Berry, 2013), it is not related to intercultural competence.

Van der Zee and Van Oudenhoven (2013) stress the importance of resilience in dealing with the stress of acculturation. Originally it was assumed that this is a central aspect of

the AVEM patterns for dealing with acculturation stress. However, patterns G and S are not significantly different from pattern B. It can therefore be assumed that resilience cannot be the decisive factor that predicts motivational competence. The difference between patterns A and B should be considered here. The subjects with pattern B had significantly higher levels of motivational intercultural competence than the subjects with pattern A. Both patterns are characterised by low resilience, distance, absence of social support and satisfaction and a high tendency to resignation. The differences are mainly because pattern A is characterised by high work commitment, striving for perfection and importance of the work, whereas these characteristics are low in pattern B (Schaarschmidt & Fischer, 2008). Sample A subjects also had a lower value for the quality of contacts in comparison.

It can be assumed that the sample A respondents did not value the intercultural contact because of their focus on work/study and the intercultural contacts they were able to make. This would correspond to the acculturation strategy isolation according to Berry (1980), which leads to little acculturation success. At the same time there are no significant direct effects on the other competence dimensions. It can be concluded that even people who focus less on their environment and more on work are still able to learn other competence dimensions.

The results for the AVEM samples did not change even when the covariates were excluded. For the type of stay abroad it was shown that metacognitive, cognitive and behavioural competence differed across the types. In this context, persons who have completed a work-and-travel, a professional stay abroad or have travelled have a lower competence than those who have spent an au-pair, a school year or a semester abroad. This confirms hypothesis 3 based on Watson et al. (2013). Furthermore, the assumed interaction effect on metacognitive and motivational competence was confirmed. People with patterns A and B had particularly poor motivational competence after occupational stays, and particularly low metacognitive CQ after work-and-travel. Persons with an S pattern after an au-pair and a work-related stay had particularly low metacognitive competence and low motivational competence after travel. Apparently, certain types can acquire competence to varying degrees under the conditions of the types of stay abroad. Although it was not possible to generate data for every point, it is possible to derive conclusions for the practical organisation of stays abroad. Persons with an S pattern were less metacognitively competent after stays that required a high level of work commitment. If the motivation to interact with others is seen as a basic prerequisite for adaptation and competence acquisition (Sam & Berry, 2010), it could be that less engaged persons are not prepared to achieve the high degree of adaptation under the demanding conditions of working in another culture. Risk patterns A and B had a particularly low motivational CQ after work stays. This specifies the result of hypothesis 2, which shows that resilience and aversion towards others influence the motivational competence when it comes to a professional stay. It can be assumed that under these particularly demanding conditions any risk of burnout is particularly pronounced.

It was shown that semesters abroad are the best way to develop intercultural competence. There is a strong correlation with the quality of contacts with locals. Berry (2003) explains that social support is particularly important in the first period in a new culture. Niehaus, Reading, Nelson, Wegener and Arthur (2018) describe that mentoring programmes for exchange students are particularly well suited to help students make the transition. At the same time, Bolten (2016) showed that intercultural training led to improved competence gains. Regarding higher education and semesters abroad, a mixture of preparation by the home university and support through mentoring seems obvious in order to simplify the acquisition of competencies as much as possible and to prevent negative experiences. Based on theoretical considerations, Genkova (2019) also proposes a mix of methods for preparing and accompanying expatriates.

There are some limitations to this study. The post-hoc view makes it difficult to conclude on interrelationships in the development of intercultural competence. Future studies should take a more differentiated view of students and professionals. Likewise, a possible migration background of the interviewees was not taken into consideration. It must also be noted that the CQS as a self-assessment questionnaire cannot have the same validity as a performance measurement. However, corresponding economic measurement instruments have not yet been developed.

The present study was able to show that the duration of a stay abroad influenced cognitive, motivational and behavioural competence. The motivational competence was already significantly higher after one to five months, the motivational and behavioural competence only after at least five months. The AVEM patterns differed in terms of motivational intercultural competence. During stays at work, A and B patterns led to particularly low motivational competence. In addition, an S pattern had negative effects on metacognitive competence after stays at work and au pairs. The analysis allowed a differentiated examination of individual elements of stays abroad. For future studies, special attention should be paid to the motivation to go abroad, since the motivation to interact was shown to be a central aspect in this study. Also, the importance of intercultural preparatory and accompanying measures is emphasized, especially for professional assignments abroad. Future studies should evaluate these methods under consideration of the job-related personality.

Abstract

The study aims to explore tensions in an inter-organisational knowledge transfer involving key "Quadruple Helix" actors: academia, regulators, industry, and public or civil society, in the emerging FinTech sector of Bahrain. The collaborative initiatives under a Quadruple Helix configuration bring together a group of actors with dissimilar agendas, to work together and solve complex problems despite their differences. The contrasting nature of the various actors, however, makes these collaborations more vulnerable to tension and conflict. This study provides an understanding of the nature of these tensions, of the reasons why they arise, and of some of the strategies deployed by different organisational actors to address them.

In line with the study's exploratory purpose, a qualitative methodological approach was used employing the principles of Grounded Theory. Semi-structured interviews were conducted with key participants.

Initial findings identified a number of collaborative tensions. These involve tensions associated with conflicting interests, incongruent collaboration motives, and the divergent values sought from the collaborative engagements by different stakeholders. While most participants held an espoused discourse of collaboration and collegiality, their descriptions of de facto instances exposed tensions that were in practice recognised by them. The study contributes to the field by further exploring the micro aspects of the collaborative tensions within a Quadruple Helix configuration.

Keywords – Quadruple Helix Innovation Model, FinTech ecosystem, Inter-organisational micro dynamics, Collaborative tensions.

Paper type – Academic Research Paper

1 Introduction

This paper aims to explore the collaborative tensions between key "Quadruple Helix" actors: academia, regulators, industry, and public or civil society, in the FinTech sector of Bahrain.

Few studies attempt to provide an understanding of the dynamic nature of the roles and interactions involved in the helix configurations from a micro perspective. These include an individual actor or stakeholder's level (Alexander et al., 2017; Cunningham & O'Reilly, 2018; Kriz, Bankins, & Molloy, 2018; McAdam et al., 2018), on the level of the relationships (Hasche, Höglund, & Linton, 2019) and joint activities (Höglund & Linton, 2018). The Quadruple Helix framework was found to offer interesting insights into the collaborative tensions that arise between key actors. Studying these tensions further helps understand what shape the interactions take in practice, how the specific collaborations unfold, and what drives the heterogeneous relationships.

The next section presents the theoretical framework, followed by the research methodology, and the analytical framework used to understand the collaborative interactions. Next follows an analysis of interactions. This involves the three tensions associated with conflicting interests, incongruent collaboration motives and the divergent values sought from the collaborative engagements. In the final section of the paper findings are discussed and concluded, exploring the theoretical possibilities for understanding the complex nature of interactions in a Quadruple Helix configuration.

2 Inter-organisational knowledge transfer in a Quadruple Helix ecosystem

In recent years, innovation has been one of the typical features of the financial services sector (Fáykiss, Papp, Sajtos, & Tőrös, 2018), that has been transformed by the wave of financial innovation (Castilla-Rubio, Robins, & Zadek, 2016; Jenik & Lauer, 2017), particularly with the introduction of open banking, robo advisory, and cryptoassets (Laldin & Furqani, 2019). Platforms like FinTech were created to support the financial services industry and cover all aspects of applying technological advancement in delivering, facilitating, or enabling financial services (Laldin & Furqani, 2019). This has given the opportunity to new players, not necessarily financial institutions, to enter the industry and develop innovative solutions (Karagiannaki, Vergados, & Fouskas, 2017). The collaborators come together either in interorganisational knowledge creation networks, according to Holmqvist (1999), or open innovation teams, according to Chesbrough & Schwartz (2007), to develop new products and services using each other's know-how. In the context of the Quadruple Helix, (figure 1), open innovation was seen as "a new and novel strategy, policy-making, and governance approach" (Carayannis & Campbell, 2011, p.328). In fact, one of the core patterns of "Open Innovation 2.0" (OI2) was using the Quadruple Helix, where "government, industry, academia and civil participants work together to co create the future and drive structural changes far beyond the scope of what any one organisation or person could do alone" (Curley, 2015, p.12).

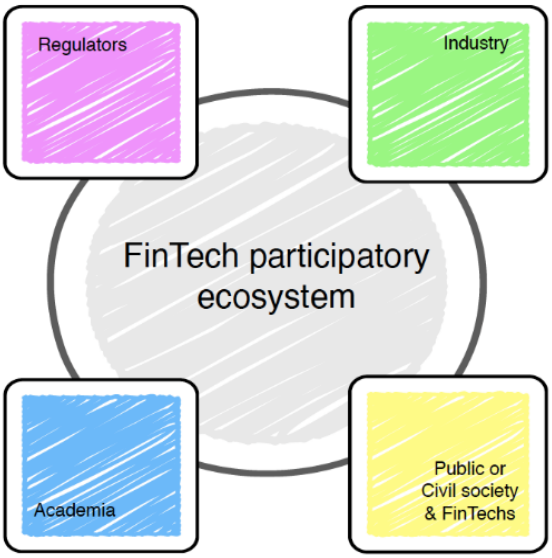

Figure 1 The Quadruple Helix Model. Adapted from: Fitzpatrick & Malmborg (2018).

Theoretically, the Quadruple Helix ecosystem refers to configurations where diverse actors - academia, industry, regulator and public or civil society - are organised into "fluid and heterogeneous innovation networks" (Carayannis & Campbell, 2011, p. 342) where innovation is "driven by increasingly complex, non-linear and dynamic processes of knowledge creation" (Carayannis & Campbell, 2009, p.202). Until recently, theoretical models of the Quadruple Helix innovation model have mostly taken a macro regional point of view (Caetano, 2017; Cavallini, Soldi, Friedl, & Volpe, 2016; Ivanova, 2014; MacGregor, Marques-Gou, & Simon-Villar, 2010). Schoonmaker & Carayannis (2013) and Manniche & Testa (2018) for example have focused on the context of the regional innovation networks, territories and aggregates of actors.

Few studies however attempt to provide an understanding of the Quadruple Helix configurations, the roles and interactions from a micro perspective (McAdam, Miller, & McAdam, 2018). According to Kriz, Bankins & Molloy (2018), it is essential to explore the micro aspects of these relationships to better understand the dynamics within the helix. Research however varied in how the micro aspects of the Quadruple Helix relationships are addressed, and often focused on a variety of levels. These involved individual actor or stakeholder's level (Alexander, Miller, & Fielding, 2017; Cunningham & O'Reilly, 2018; Kriz et al., 2018; McAdam et al., 2018), intra- and inter-organisational relationships levels (Manniche & Testa, 2018), the level of interdependencies (Hasche et al., 2019), joint activities (Höglund & Linton, 2018; McAdam et al., 2018), boundary work (Cunningham, Menter, & O'Kane, 2018), motivations (Cunningham & O'Reilly, 2018) and communications (Plewa et al., 2013). According to McAdam & Debackere (2018) and Kriz, Bankins & Molloy (2018), studying these micro processes further help understand what drives the heterogeneous relationships across the helix spheres.

Because FinTech is an emerging ecosystem and not fully articulated (Still, Huhtala, & Saraniemi, 2016), the Quadruple Helix framework was found to offer interesting insights into the micro aspects of the relationships and the collaborative tensions that arise between key actors (Fitzpatrick & Malmborg, 2018). Tensions were found to be both inherited and unavoidable (Fitzpatrick & Malmborg, 2018), creating a "challenge of balancing the needs of the different actors to achieve societal, economic and environmental value" (Van Horne & Dutot, 2017, p.290). Tensions in the Quadruple Helix literature however were limited to those existing between basic research and commercialisation (Bozeman, 2000; McAdam et al., 2018; Miller, Mcadam, & Mcadam, 2016). On the other hand, tensions that arise from the complexity of the interactions have not been fully investigated (Carayannis & Rakhmatullin, 2014; Hasche, Höglund, & Linton, 2019; McAdam et al., 2018). Exploring these tensions helps better understand what shape the interactions take in practice, how the specific collaborations unfold, and when do specific tensions arise.

3 Methodological approach

A qualitative research strategy was followed to collect and analyse data, adopting the "Glaserian" Grounded Theory principles (Glaser & Strauss, 1967). The methodological approach, depicted in Figure 2 below, is influenced by the three key principles of theoretical sampling, inductively deriving key findings through constant comparison of interview data.

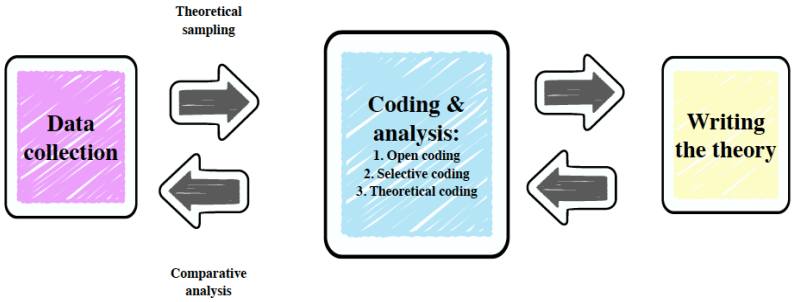

Figure 3 Grounded Theory methodological process.

The principal method for data collection was semi-structured interviews, backed by analysing some internal documentation. Interviews were conducted over a period of around one year with participant actors from all the four helices in the FinTech Ecosystem. The selection of the participants was influenced by an initial exploratory study and the analytical framework that developed with it. They included a Higher Education Institution which was specifically established to cater to the training needs of the financial services sector, representatives from FinTechs, academic regulators; the financial services sector regulator, public/civil society (learners and end users), in

addition to intermediaries. The role of intermediaries has been undertaken by two public entities. The first was a public agency that facilitates the interactions between the government and the other actors above and identify where collaboration and investment opportunities exist. The second intermediary role was undertaken by a public authority, offering consulting, financing, training and entrepreneurship support services to the various actors. Table 1 below displays the codes used through-out this paper to represent participants.

Table 1 Participants' verbatim coding.

Helix dimension	Code
Academia	A1, A2, A3, A4, A5, A6, A7, A8, A9, A10
Intermediary	INT1, INT2, INT3
Industry	IND1, IND2
Regulator	R1, R2, R3, R4
Public/civil society	P1, P2, P3, P4

Constant comparison was the method of analysis following three general guidelines of: (1) open coding, (2) selective coding, and lastly (3) theoretical coding (Glaser & Holton, 2004). Categories and inter-relationships were then developed from the findings which are then delimited, using theoretical saturation to form the basis for the emerging framework (B. G. Glaser & Strauss, 1967). It is important to note that the coding stages used to analyse data, illustrated in figure 2 above, encompass several repetitive cycles, and "are not intended to be distinct and linear" (Heath & Cowley, 2004, 146).

Constant comparison and the iterative process of analysis has enabled developing the characteristics of key categories in the findings as well as to readdressing the relationships between them. Relationships between the categories were established, after observing certain patterns in the data, resulting in one main core category in this study – *Collaborative tensions*. The process involved:

I. Exploring Quadruple Helix context, key actors, the network dynamics and the forms of knowledge transferred.
II. Explaining the impact of sector-specific interests, incongruent motives and values sought from the collaborative engagements on the knowledge transfer process.

4 Collaborative tensions: Conflicting interests, incongruent collaboration motives and divergent perceptions of collaborative value

The study identified three distinct collaborative tensions articulated around the conflicting interests of different stakeholders, their incongruent collaboration motives, and the divergent perceptions developed of the collaboration value.

In what concerns the first tension, *conflicting interests*, one main source of tension was often attributed to the diverse and heterogeneous group of actors involved, with their own interests coming with different objectives, priorities, and foci, as put by this intermediary:

> *"But nobody will have the same interest because the industry has a different focus, a different objective" (INT1, 8:40).*

Tension appeared when partners placed an emphasis on expectations related to their distinct needs. As such, this increased the probability of partners not cooperating. To ensure commitment to the collaboration, participants suggested that stakeholders should be equally engaged and involved in defining common objectives and tasks right from the initial phase of the project. Participants found this helpful in decreasing the likelihood of any misunderstandings, and in helping to avoid divergent expectations and friction as the collaboration progressed. As put by a regulator partner below:

> *"We normally involve our team, our training and development team […] and if they have any concerns they have to raise in the very beginning of the process, to react quickly to bridge the gap" (R1, 12:42).*

The tensions that arise from the conflicting interests however were found entrenched in the collaborators' diverse worlds and mindsets. According to an industry and a public partner, respectively below:

> *"Yes, we are in a different world thinking" (IND2, 5:03).*
>
> *"we see it a different angle and a different perspective" (P2, 8:16).*

Boundaries appeared as a result of the differences in interests between collaborators. Partners may still disagree about a particular solution, no matter how much they appreciate each other's' perspective, because they do not want to change their own practice. Most often partners hold on into their old ways of doing work. As recognised by this public partner:

> *"Just because their legacy structures they have always thought about doing business in a certain way" (P4, 33:11).*

Because the collaborative process usually required accommodating multiple voices, tensions arose as the collaborators tried to envisage and balance the collaboration's internal dynamics with the external demands of the stakeholders regarding the outcomes. Partners were therefore found to either place too much interest to the extent of ignoring their obligations to their broader sphere, or struggle committing to maintaining the collaborative relationship. As a result, some simply avoided the meetings and withdrew from the entire engagement. As put by this intermediary:

> *"One manager in particular said she's been here every year she deliberately didn't go this year and she said to me because I have made extensive contribution, I've seen it as important, first of all my colleagues don't see it as important, and second of all [academia] doesn't listen anyway, why should I come" (INT2, 6:50).*

With so many participants coming from various sectors, responsibility for particular tasks were often found unclear; thus, there was a struggle with those responsible for

taking action. According to the intermediary participant below, many of the ideas discussed were not actually acted upon:

> *"Because nobody wants to own it. It's more talk than solution, so, I think its lack of ownership. Occasionally you'll see someone who says I'll take that, and then you sort of think did anything come out of this, […] it just feels like the action element to these forums, you know agreement might happen, but no action comes from it" (INT2, 9:18).*

Quite often, as the same intermediary continues, partners tended to speak different technical and professional languages inhibiting the ability of the stakeholders to provide substantial input or communicate their needs in a clear manner. Very often, what was actually sought was far from what was actually needed:

> *"You've got lots of people from lots of different industries with different perspectives […] very often what they actually want is quite looks different to what actually they said they wanted […] So, it happened many times there are certain conversations where the academic person uses a whole lot of jargon that the other person doesn't understand or vice versa" (INT2, 18:50).*

To overcome this, participants suggested allocating trainers, experts and specialists from the start, to capture the tacit knowledge that these conversations often involve and make it explicit to others. A participant from the industry suggested involving mediators to translate technical terminology and bridge the gap between the partners' diverse expectations:

> *"So, if there could be someone to translate the technical terms that we use. So, that could be an opportunity for the mediator that we are speaking about" (IND1, 13:07).*

A mediator is thus expected to understand the professional languages spoken by the various partners, be engaged in great deal of inter-institutional negotiation, relationship building and industry research and feedback. This also involves listening to the various partners, translating their needs, and matching the requirements to construct a set of proposals that satisfy the diverse interests. As described by this intermediary:

> *"It is a big gap just between academia and industry, but a lot of my work has been relationship building with people […] scope out needs and flesh them out, that can go around in circles for quite a long time. I need to translate what I'm hearing and try match the two and write the proposal" (INT2, 16:55).*

In terms of the second collaborative tension, *incongruent collaboration motives*, the conflicting interests of the various actors, who eventually prioritised their own interest over their partners, were seen to compel incongruent motives. Partners tended to work together if they perceived their cooperation brought benefits and value for all stakeholders. The motivations driving commitment and interactions were divided between commercialisation or personal gain, and knowledge sharing or altruistic motives. The majority of participants for example, disclosed clear instances of maximising individual utility and self-interests, such as gaining professional recognition or become noteworthy

among peers. The intermediary below mentions that most of the relationships were driven by commercial exchange rather than for knowledge sharing or exchange:

> *"The purpose of the exchange is more for sales than it is for knowledge sharing" (INT2, 16:55).*

While some partners were driven by the well-established names of certain partners according to this academic partner, others felt it was politically good and appealing to collaborate. As put by this intermediary:

> *"A lot of people work with us because its politically good to work with us, because our chairman is on your board or something like that" (INT2, 12:00).*

Few partners, however, were driven by altruistic reasons to the common effort of sharing a quality experience. As shared by this intermediary:

> *"The relationships with the industry were more because of altruistic reasons, the industry was often more genuine about wanting to mentor young people" (INT2, 11:00).*

The intermediary states that quite often the motivations of partners were difficult to align with the realities of the industry, especially with timeline gap between academia and industry:

> *"You have to understand the needs in timelines of industry, there's a really big gap specially the timelines, academia tends to move a lot slower than industry" (INT2, 23:33).*

Therefore, there was an endless need to sustain the motivations of the different partners, teaming them up and ensuring their full engagement which was seen to be quite impossible. According to this academic participant, this was attributed to partners lack of interest which mostly impeded commitment to collaborate:

> *"It's impossible to have a 100% involvement of everybody and sometimes it could be lack of interest" (A6, 39:33).*

This lack of interest was recognised by another intermediary participant, who further recognised the challenge of bringing the different stakeholders together, and ensuring they share the same knowledge to contribute:

> *"Obviously bringing people together has its challenges, and maybe making sure that they are all on the same page" (INT3, 11:27).*

This has further resulted in team members being excluded from the knowledge that the majority of partners withheld. A public participant mentioned that partners have sometimes expressed a lack of understanding of what the project is about and what it constitutes:

> *"People working on that project don't necessarily get what open banking is, or what it has to do" (P4, 24:33).*

In what concerns the third theme of tensions, *the divergent perceptions of collaborative value*, tensions appeared as a result of the incongruent motives that underpinned the interactions. Actors, therefore, according to this intermediary, were not quite persuaded with the benefits of the collaboration, and some felt undervalued, as they were not

listened to. Though aware that their input might not be characterised as technical, partners sought to see their thoughts addressed, welcomed, and positively desired by the rest of partners. the various actors thus expected changes made in response to their extensive contributions. They regarded clear details of the ways their feedback will be integrated as one major reason to join the collaboration meetings. There was an apparent struggle with those responsible for taking action, as many of the ideas discussed were not actually acted upon:

> *"There has been no changes […] because we didn't give or send them a summary of the meeting we didn't send them an action list, we didn't send them any outcome from the meeting, so there is also a communication gap there between us and them" (INT2, 6:50).*

In general, the value sought in these collaborative engagements constituted substantial contribution, in terms of providing the strategic insight and a holistic perspective. Partners however lacked the interest to join the collaborative engagements and the contributions made were described as superficial, fragmented, generic and insufficient to create the expected outcome. This has further impacted the ability of teaming up the different stakeholders, and sustaining their full and equal engagement:

> *"Obviously bringing people together has its challenges, and maybe making sure that they are all on the same page" (INT3, 11:27).*

As the tension associated with divergent values will remain, a public partner suggested engaging in more knowledge transfer activities, and establishing multi-disciplinary teams, instead of departments working in silos:

> *"So, I think there needs to be more transfer of knowledge, and having multi-disciplinary teams, not departments working in silos and not knowing what the other person is doing and they end up having really fragmented strategies" (P4, 24:33).*

To ensure meaningful interactions, participants suggested aligning aims and developing mutual interests by engaging in more dialogic activities. Matching and aligning offerings entirely to the market however were described as a difficult mission. As one public partner puts it, there will always be a gap and mismatch of needs, and as a result, collaboration outcomes may not be satisfactorily to all partners:

> *"We do have gaps and that's normal, we don't sell ice cream, so they might not be always happy with what we provide […] again, to match and speak the language of the market, we can't reach that 100% of course but we are trying to be as close as possible" (P3, 19:18).*

Participants attributed this mainly to the absence of a structured mechanism to assess alignment in the most systematic manner possible and the lack of consensus that the various partners had to establish regarding the changes and improvements to be introduced. The consensus here concerns the direction of the collaboration, and with aligning the collaboration and individual partners with some set of mutual goals:

"The consensus is always yeah we need to change this, but anything beyond that becomes quite difficult" (INT2, 9:18).

To summarise, tensions appeared when partners placed an emphasis on certain expectations related to their distinct needs, and in trying to manage their responsibilities in protecting their interests. Because partners prioritised their own interest over their partners a second theme of tensions appeared, mainly associated with the actors' incongruent collaboration motives and their divergent value perceptions. Participation in the different forms of interaction was underpinned by partners' varying motives, and partners tended to work together if they perceived their cooperation brought benefits and value. Aligning the diverse interests and values in addition to sustaining the various motives for collaboration, however, were found challenging.

5 Discussion and conclusions

Conceptual models of the Quadruple Helix have mostly adopted a macro perspective, focusing on the context of the regional innovation networks, territories, and aggregates of actors (Caetano, 2017; Cavallini et al., 2016; Ivanova, 2014; MacGregor et al., 2010; Manniche & Testa, 2018; Schoonmaker & Carayannis, 2013). Not many studies accounted for understanding the interactions and activities or their complexity on a micro level (McAdam et al., 2018). Research on Quadruple Helix that took a micro perspective, often focused on various levels. These involved the individual actors and stakeholder's levels, the levels of the activities, relationships and their interdependencies, boundary work levels, motivations, and communications (Alexander et al., 2017; Cunningham et al., 2018; Cunningham & O'Reilly, 2018; Hasche et al., 2019; Höglund & Linton, 2018; Kriz et al., 2018; Manniche & Testa, 2018; McAdam et al., 2018; Plewa et al., 2013). Studying the micro aspects of these collaborative tensions were found to help understand what shape the interactions take in practice, how the specific collaborations unfold and what drives the heterogeneous relationships (Kriz et al., 2018; McAdam et al., 2018).

The paper contributes to the emerging body of literature on the Quadruple Helix model in two ways. First, by adopting a micro perspective (Miller, Mcadam, Moffett, Alexander, & Puthusserry, 2016), it uncovers the collaborative tensions that underpin interactions in the helix and shows their interrelations; the study explores the nature of these tensions, the reasons why they arise, and the strategies employed by the various actors to address them. Secondly, this study extends previous research which found tensions were both inherited and unavoidable in helix contexts (Fitzpatrick & Malmborg, 2018; Van Horne & Dutot, 2017), by demonstrating that, beyond that, tensions are constitutive of the Quadruple Helix environment and shaping of its interactions.

Regarding the first area of contribution, initial findings identified three interrelated collaborative tensions as a result of developing a micro perspective. These involve; (1) tensions associated with conflicting interests, (2) incongruent collaboration motives, and (3) divergent perceptions of collaborative value. The first tension, conflicting interests appeared as a result of the diversity and the heterogeneity of the actors involved

(Carayannis & Campbell, 2011), and the boundaries constructed around their diverse worlds, that often focus on their incompatible mind-sets and thus expectations (Muscio & Vallanti, 2014; Van Horne & Dutot, 2017). The conflicting interests further compelled a second type of tension with partners holding and promoting incongruent motives for collaboration (Nielsen & Mengiste, 2014). Examining partners' interests therefore provided an early indication of their motivations according to Austin & Seitanidi (2012) and Seitanidi & Lindgreen (2010). Motivations varied between extrinsic - commercial exchange, advancing career, gaining professional recognition (Battistella & Nonino, 2013; Brabham, 2012)- and intrinsic motivations to contribute to the collaborative effort driven by the opportunity to access complementary knowledge. Iincompatible motives for collaboration further gave rise to a third tension, divergent perceptions of collaborative value. This was found in line with Austin (2010), in how the various motivations that propel partners to collaborate across sectors can generate incompatible values and objectives to collaborate. Moreover, Quadruple Helix participatory projects were often characterised by the presence of diverse values among the individual actors (Arnkil, Järvensivu, Koski, & Piirainen, 2010), and thus participants varied in defining the value of the collaboration (Perkmann et al., 2013), and often espoused different perspectives and expectations of what value is (Hardy, Lawrence, & Phillips, 2006; Seitanidi & Lindgreen, 2010). Individual actors therefore had to confront the tension between balancing their own contribution in comparison to others' fulfilment of responsibilities. According Arnkil et al. (2010), in complex settings such as those of a Quadruple Helix, there is a continuous need for negotiating values among the various participants. Values in this study were viewed in terms of interdependencies partners developed among themselves. This is in line with how perceptions of value increase when the partners appreciate the extent of their interdependence on each other (Clarysse, Wright, Bruneel, & Mahajan, 2014; Gray, 1985). A primary indication of perceived value was thus taking action in response to the individual helix contributions and the ability to influence the agreed action plans. However, tension remained due to the lack of mechanisms that ensure stakeholders are fully informed of the ways their feedback is integrated. Instead actors engaged in internal coordination to partly resolve these tensions (Hansen, 1999).

In what concerns the second area of contribution, the experiences of Quadruple Helix partners demonstrate that the tensions which were identified are constitutive of the Quadruple Helix and shape its interactions. These tensions stem from the collaboration as a forum and the dual position of the actors where they try to pursue the interests of their individual spheres, manage their obligations, and at the same time meet the demands of the collaboration network (Hardy et al., 2006; Kolehmainen et al., 2016; Lawrence & Hardy, 1999). Actors were found to react to this tension in two different ways; however, both reactions impacted the collaboration negatively. The first way partners reacted was by placing an emphasis on the expectations related to their distinct spheres in favour of developing joint collaborative outcomes. Partners were therefore found to be involved only in a superficial manner, showing lack of interest and contribution and ran the risk of

no collaboration (Hardy et al., 2006). The second way was when some partners, specifically academia, eliminated the tension by primarily serving the collaboration purpose, and ignoring their responsibilities to their wider sphere, running again the risk of not drawing on the diverse interests of the various actors (Hardy et al., 2006). With so many potentially diverse participants, and the ambiguity in early stages of the collaboration, individual responsibility and ownership for specific tasks were unclear (Aranguren & Larrea, 2011). Participants expressed the need to structure the initiative and guide actors' individual pursuits (Susman, Gray, Perry, & Blair, 2003).

Intermediaries were therefore introduced to manage tensions arising from conflicting interests, the misalignment between the varied motivations and the realities and timelines of the various actors, and balance the individual helix motives with the collective motives (Cunningham et al., 2018).

To participate in collaborative conversations is therefore to participate in an endless struggle between two roles. The participant is both a collaborator and a sphere representative, and consequently, collaborations are inseparable from these two competing tensions. Further research is needed to investigate how the various actors manage the identified tensions more effectively, helping future Quadruple Helix participants be better aligned and balanced.

Abstract

This paper seeks to open a new avenue in terms of study perspective and investigation methodology to explain the effects that strategic alliances may have on the evolutionary dynamics of an ecosystem. More specifically, we aim to shed light on the importance of developing a new systemic metric and a computational model to predict ecosystems' network dynamics based on the agents' behavior towards cooperation or acquisition practices. Despite existing literature on ecosystems has largely coped with issues related to the structure (closed networks or structural hole theory), the benefit of a network, or actors' behavior, it does not provide contributions or methodological frameworks to investigate ecosystem dynamics trigged by collaboration or merger and acquisition strategies. Nevertheless, the topic is particularly relevant to understand for instance present and future dynamics of modern ecosystems (characterized by a high competitive context) or of nascent ecosystems (such as those in less developed countries), that evolve driven by strategic alliances employed between certain actors (i.e. incumbents and startups or incumbents and service providers). Insofar, authors introduce three new issues in the ecosystems management literature to address this topic: i) the relevance of strategic alliances in the ecosystem evolution; ii) the introduction of a new measure of proximity to evaluate the structure and the characterization of the network - the value chain distance -; iii) an integrated methodology to capture ecosystem evolutions - the agent-based simulation combined with the social network analysis - . Authors propose as the

unit of analysis the industrial ecosystem, an embryonal ecosystem useful to derive general assumptions on the ecosystem configurations and its evolutionary dynamics.
The paper is purely conceptual, its originality concerns the perspective of study and represents the first attempt to propose some direction to better study the evolution of ecosystems as a result of actors' strategic alliances.

Keywords – ecosystem, structure of network, M&A, collaboration, strategic alliance

Paper type – Academic Research Paper

1 Introduction

During the last two decades, academics have gone in-depth by accurately analyzing the realm of alliance strategies and carrying out the uttermost theoretical and practical frameworks. A bit at a time the big picture of the single company features and its context in terms of stakeholders, dynamics or know-how providers became more and more understandable. Therefore, the attention gradually was moving towards the interconnection among actors and resources, and their capacity of jointly generating a greater value-added than a single actor may unleash. This is fundamental at the base of the ecosystem concept. The need to understand the ecosystem as a unique body instead of a sum of different actors is rooted in the possibility of installing a new pattern of relationships in terms of structural configuration. At this point, the strategy of alliances is not only a matter of single actor performance rather seems to be pivotal for the evaluation of the effects on the entire system. In fact, configurations assumed recently by the banking or the healthcare ecosystems are evidence of how is relevant interpret M&A operation in a systemic way. In these high competitive contexts or also in ecosystem nascent in less developed countries, strategic alliances between firms as well as incumbents and new firms (i.e startups) or incumbents and service providers inevitably break the existing balance and create new ecosystem configuration.

The re-modularization of the lens of analysis at the level of the entire system is not full of novelty, although addressing the theme of simultaneous evolution of alliances strategy and structural configuration is a further step towards a fuller understanding ecosystem dynamics. Nevertheless, the existing literature does not provide adequate contributions or methodological tools to investigated some aspect of the phenomenon, focusing on the desirable structure of networks - closed networks or structural hole theory (Burt, 1992; Coleman, 1988, 1990); on the knowledge transfer (Ahuja, 2000); on the speed of innovation and organizational learning (Ahuja 2000; Gulati et al. 2000) for networked firms; despite showing the ecosystem network as the simplest effective organizational form to improve company performance (Fritsch and Kauffeld-Monz, 2010; Ahuja 2000; Gulati et al., 2000). Therefore, issues to address before to carry out an empirical analysis of effects of strategic alliances on the ecosystem evolution are as follows. Firstly, the issue of systemic metrics. In other words, shedding light on which parameters are more useful than others, is necessary for capturing and assessing the impact strategic alliances

may have on the structure and evolution of a network. Authors starting their observation analyzing industrial ecosystems (IE) have identified a new useful parameter, the "value chain distance", a sort of industrial proximity, to measure the distance between the actors – evaluated on the sequential flow of the product or service created in the cluster. The roots of this parameter are tied with the quantification of the structural changes when an actor has re-modulated its strategy. Furthermore, another interesting issue, partially unexplored, concerns the complexity, the heterogeneity, and the dynamism of ecosystems, when they are exposed to the alliances' reconfiguration. In a nutshell, the social network analysis approach (used until now) lacks the predictive ability and it does not deal with the dynamism of an ecosystem. Therefore, for disentangling the complexity of industrial system structure and providing a method for experimentation, we propose a multi-integrated methodology that combines the strictness, the precision and the descriptive capacity of social network analysis along with the forecast ability and complexity suitability of agent-based simulation.

Our research question is stimulated by the above-cited problems, and it is focused on understanding whether some new metrics and new methodologies may be developed starting from the need of clarifying how the ecosystem will evolve along the time in response to the strategic alliances implemented by key actors of an ecosystem. Before experiment and validate our assumptions we start our reflection analyzing dynamic of the industrial ecosystem, an embryonal ecosystem characterized by the M&A alliances led by dominant actors. The originality of this paper concerns the perspective of the study. In other words, we have tried to open a new strain of research by mixing different approaches coming from the innovation ecosystem, the M&A studies and agent-based simulation experimentations. We have proposed a mix between a typical empirical method as the social network analysis with a computational and laboratory method as the agent-based model.

2 Literature background

2.1 Industrial ecosystem and the role of dominant actors

The concept of an industrial ecosystem (IE) arises from the reflections of Frosch and Gallopoulos (1989) regarding the negative effects of industrialization in the late 1980s. Scholars wrote of a necessary change in the traditional industrial paradigm, proposing more integrated models of industrialization that give consideration to industrial effects produced on the natural ecosystem. In fact, their attention focused on aspects related to the environment and on the possibility of reducing the damage produced by industries through an attitude of cooperation between businesses and between businesses and customers. Specifically, the authors considered the IE an analog of the biological one, and therefore it, albeit ideally, should have tended for the infinite recycling of the materials used. Adopting such a policy would have reduced the negative impact of companies on

the environment, encouraging them to develop their economy in harmony with the surrounding ecosystem. This would have been possible through a change of habits of the individual parties, but also through concerted participation by all producers and consumers of a supply chain. Korhonen et al. (2001) re-proposed the concept of industrial ecosystem intended as a system pursuing environmental sustainability, i.e. an ecosystem with the aim of extending the principle of sustainability to all industrial operations. However, their studies were interesting because, in addition to stressing the "cooperation" component, fundamental for the success of an industrial ecosystem, they also stressed that of "diversity". The survival of the ecosystem was based precisely on the diversity in the species, which connotes the system of characteristics such as high flexibility and adaptability. These principles, adapted to the concept of industrial ecosystem intended in the strictest sense of business ecosystem and leaving out the more ecological aspects of the ecosystem, take on a different but more feasible meaning, inviting companies, even if of different nature, to cooperate not only to survive but also to innovate.

In fact, the most recent definitions of IE, inspired by Moore's business ecosystem definitions, introduce a further aspect of the ecosystem which is the capacity for innovation. The industrial ecosystem (IE) is defined by Feng, Wu and He (2018) as a new paradigm for the development of the innovation ecosystem. It refers to "companies that connect through the industrial agglomeration and influence each other to build a network system, sharing information between different participants, disseminating resources and promoting the sustainable development of IE" (Feng, Wu and He, 2018, p.3). Unlike Moore's definition (1996, p.9) on business ecosystems - an economic community supported by a foundation of organizations and individuals interacting in the business world - Feng et al. (2018) maintain the industry meaning of the ecosystem. This meaning refers mainly to an ecosystem based on the supply of products and materials (Tsvetkova and Gustafsson, 2012) or well-defined geography (Boon and Baas, 1997). Although its characteristic may appear as a limit and seems to be overcome by the most modern concepts of networks or of the business ecosystem itself (Iansiti and Levien, 2004), it is very useful for i) the analysis of emerging ecosystems in late-developed countries and for ii) the analysis of very complex ecosystems. Feng, Wu and He (2018) believe that in late-developing countries, the drive for growth and innovation of other businesses can start from an industrial ecosystem led by the leader of an industrial chain. The reconstruction of the bonds and relationships established in the ecosystem help to better manage the levers of development and innovation. Tsvetkova and Gustafsson (2012) use IE to analyze the complexity of some ecosystems. An IE is, in fact, modular and decomposable. Starting from it to analyze ecosystems allows you to isolate the key components and then extend the analysis to the whole. The IE encompasses many of the basic relationships of the ecosystem, which give rise to new flows of relationships over time.

For this reason, it is also crucial to understand the role played by some companies in the ecosystem, in particular, that of the leader companies (Moore, 1996), around which very often the main events of the ecosystem revolve. One thinks of the role of keystones

of Google or Apple in their industrial ecosystem (Yang, Nam and Kim, 2018). Their actions are able of influencing other ecosystem companies in the short or long term and therefore changing the characteristics and configuration of the starting ecosystem.

An ecosystem is in fact made up of groups of companies or sometimes a single company which plays a functional role within the ecosystem. Iansiti and Levien (2004) focus on these aspects and recognize three types of ecosystem roles: the rulers, keystones and niches.

- Dominators tend to dominate a large part of the ecosystem enterprises, especially the smaller ones; they adopt integration strategies, control multiple network nodes to acquire value only to their advantage.
- Keystones are more extended to collaboration and sharing: they redistribute the value within the ecosystem producing benefits for all its members; they control a few nodes, not the whole network.
- Niches are small actors within the ecosystem who try to specialize to differentiate themselves from others, however, they need support to be able to capture more value, they are willing to share in order to grow; they represent a large part of the enterprises of the ecosystem determining their number and variety.

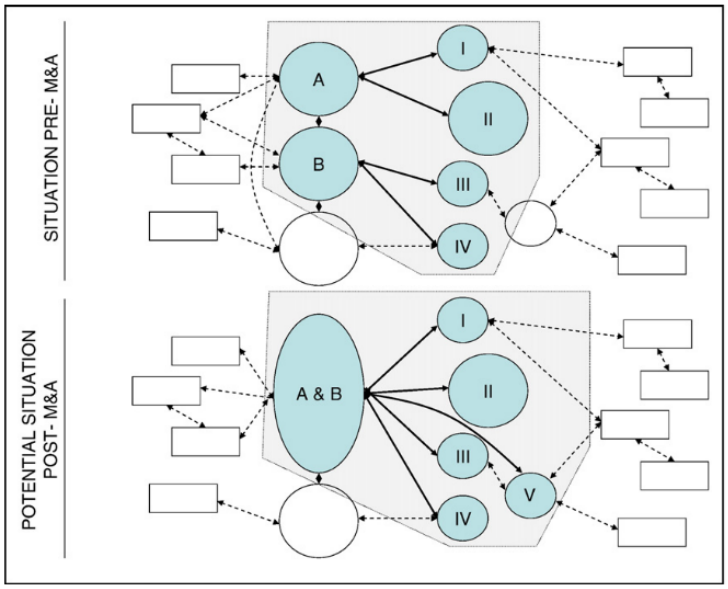
The strategies implemented by some components of the ecosystem inevitably condition it (Iansiti and Levien, 2004), sometimes in the short, sometimes in the long run. Meanwhile, the industrial ecosystem turns out to be a unit of analysis necessary to reconstruct ecosystem dynamics.

2.2 Strategic alliance and ecosystem structure

The behavior of a system emerges from its own structure (Sterman, 2000, p. 107), which in turn is the product of the links between the actors. Analyzing structure and relationships is fundamental to understanding the characteristics and evolution of the ecosystem.

Scholars Yang, Nam and Kim (2018) argue that strategic alliances and collaborations between groups of actors inevitably strengthen or weaken the competitiveness of an ecosystem, consequently also changing its structure (Yang, Nam and Kim, 2018). However, the analysis of the effects of these operations on the structural configuration of the ecosystem is hardly addressed. Yet inevitably mergers, acquisitions and collaboration that result in the consolidation of two companies into a single economic unit respectively (Weston and Weaver, 2001); control of ownership over another company (Hagedoorn and Duysters, 2002); collaborative relationships without compromising the economic unit; they influence the ecosystem in terms of density, number, diversity and therefore flexibility or rigidity. Through these strategic alliances, strong or weak ties are established between the parts that condition survival and innovativeness not only of the single actors. Therefore, although these operations usually concern two or some of the ecosystem companies, the effects produced can also affect other ecosystem companies not directly

involved (Figure 1), transmitting and generating a change indirectly (Hertz, 1998; Havila and Salmi, 2000). Much depends on the strength and character of the relationships through which knowledge, financial resources and the relationships themselves are transferred. For example, very weak links between the parties are indicative of strong independence of the actors but also of reduced flexibility of the ecosystem, which will become more exposed to changes (Simon, 1962; Tsvetkova and Gustafsson, 2012).



Source: Öberg et al.,2007

Figure 1.

The literature analyzes the effects of M&A or even collaborations focusing only on the parties participating in the alliance; few were interested in wider effects. Some such as Havila and Salmi, (2000) discuss the changes brought about by a dyad of businesses that merges or acquires by questioning the radical change that this behavior would cause on the entire network. In fact, through mergers and acquisitions, new relationships appear or old ones disappear, also influencing relatively distant actors in the network. Others, such as Anderson, Havila, and Salmi, (2001) and Öberg and Holtström (2006) analyze the effects of M&A on business relationships and end customers, arguing however that many companies do not act as part of a network, but think in a selfish logic. Öberg and Holtström (2006) became interested in the effects on the network by limiting themselves to the focal network (companies and their customers), but felt the need to invite researchers in an analysis that included a wider network horizon and including in the analysis indirect interactions that can be transferred following an M&A or a collaboration.

3 The value chain distance to investigate industrial ecosystem

This study attempts to extend the management literature by exploring a new measure of industrial proximity to interpret the distance between the actors – evaluated on the sequential flow of the product or service created in the cluster - and to understand links and the centrality of their role within the industrial ecosystem (Frosch and Gallopoulos, 1989; Ehrenfeld, 2000; Basu and van Zyl, 2006).

Porter's study (1991) offers a strategic perspective based on the positioning of the company and its capabilities to provide the best defense against the competitive forces. On the other hand, he also introduces the concept of value-generating activities (or strategically relevant areas) beyond the functional approach, to explore the value chain of a company which represents the building blocks of competitive advantage. The effects of environmental evolution affect the functional areas of the individual company, forcing it to reconsider its structure, the duties and roles of the different actors involved in ecosystem companies. Nowadays, the analysis of the structure of a company's value chain would lead to configure a different subdivision compared to that provided by Porter. Indeed, with the development of outsourcing phenomenon most of the activities that do not belong to the core business are brought outside and most companies close or far from their value chain position, collaborate, or are acquired.

Drawing on the network picture change developed by Öberg et al., (2007), we can develop some theoretical speculation about how a new measure of industrial proximity as the value chain distance may be useful to evaluate the structure and the characterization of the network due to strategic alliances lead by key actors. These considerations on the network open to broad reflections regarding the typology of information, knowledge and resources exchanged between nearby or far off actors from the value chain, which may be conditioning at actors level the intensity of the relationships, at the systemic level the structure (in term of flexibility or rigidity) and the specialization of the ecosystem (i.e. product, service, customer or technology oriented).

We decided to adopt Öberg et al., (2007) study because it is one of the most conceptual frameworks in industrial studies regarding the merger or acquisition causing changes in a business network, especially about the concepts of ‘network pictures’ and ‘networking’. Thus, we validate this model trying to extent adopting a new measure of industrial proximity as value chain distance.

For these reasons, the structural effects on the network based on the concept of value chain distance can be reassumed in two directions. First, it helps to identify the key actors of the networks and their capability to forge the ecosystem. Second, it can improve the external growth process that allows to connect the value chains of different companies and therefore to take advantage of their strengths in carrying out the business. From this perspective, the value chain can be intended as a system of interdependent activities, connected internally and potentially connected to external value chains. Links between actors and the external value chain may affect the structure, the characteristics, and the evolution of the ecosystem.

The links to analyze range from a traditional vertical collaboration between the company's value chain and those of suppliers or channels, to those between firm and buyer, to a horizontal relationship between competing firms, characterized by possible links such as M&A or collaboration.

Therefore, the strategic orientation can change because it passes from the management of the resources controlled by the structure and the internal skills accumulated, to the search for external opportunities (collaboration) and to the possibility of using resources greater than those directly controlled (M&A). These opportunity-driven strategies are based on a specific ability to access common information within the entire ecosystem and effectively use external resources-skills to pursue the best opportunities and long-term competitive advantage. As affirmed by Gummesson and Mele (2010), interaction in the ecosystem strives to enhance services through a better connection between resources, processes, and outcomes.

Thus, the interchange of value among relatively distant actors would be fruitful for the effect of the structure and competencies of the network. Our aim is to simulate an analysis that includes a wider network horizon and including in the analysis of indirect interactions that can be transferred following an M&A or a collaboration.

4 An integrated methodology: social network analysis and simulation model

This paper seeks to open a new avenue in terms of investigation methodology. The aim is enlarging the researcher's toolkit in order to provide a new multi-perspective method in favour of industrial ecosystem scholars. The body of thesis is the outpacing of difficulties related to two main methodology: the static nature of network analysis, and the lack of strictness of the agent-based model. Indeed, the most common structural network analyses, depicting the network in a very thorough way (Wasserman & Faust, 1994). Although this realm of research instruments is not able to provide a forecast or a future projection. At the opposite the agent-based model has its points of strength in the capacity of managing the complexity by running a large spectrum of changes and simulating the evolution of scenario (Macy & Willer, 2002). Although it is common that the agent-based simulation might be affected by a great generalization, by ending to provide just the trajectory of evolution but no more practical and applicable implications.

The expression "computer simulation" is referred to the exploitation of a computational model aimed at enlarging as much as possible the understanding of complex systems (Epstein & Axtell, 1996). The Agent based model is particularly useful when the system complexity is generated by the tally of each individual strategy within a broader body. The matter of fact is tied with the size of the phenomenon and the difficulty of realizing direct observations. In the light of this scenario the possibility to realize " in-machina" experiments, opens the route to in depth examination of complex system (Sallach, 2003). An agent based model fits very well when: the experimentation concerns a representative

and typical agent; the set of agent's strategies is depicted by a finite domain; the numbers of dependent variables is finite; the domain of each dependent variable might be infinite; the choice of a strategy influences the entire set of variables that are interconnected among them. Therefore, the ABM has a great level of suitability in order to shed light on very interconnected and fuzzy mechanisms at the base of industrial ecosystem. Indeed, for the sake of clarity the model may be run by adopting a reasonable degree of generalizability for the agent. The set of agent's strategies might be potentially unlimited, although, we decide to investigate strategies that may impact on the structural configuration of the ecosystem, therefore, for simplicity we restrict the spectrum of analysis to three main strategy: mergers, acquisitions and collaboration. The novelty of an integrated multi-perspective agent-based simulation concerns the set of dependent variables, that our model draws by the network analysis. In other terms we evaluate the impact of agent's strategy choices on the structural configuration of network, more specifically, we have selected as dependent variables the following network measures: density, diversity, flexibility and rigidity.

5 Discussion

Our conceptual remarks represent a first attempt in forecasting the evolution of ecosystems' dynamics, whereas the majority of studies in the field tend to provide a snapshot analysis of the current ecosystem's performance or investigate the determinants of their evolution state. While the study of networks within the ecosystems, especially through quantitative methods, contribute to show the important role of connectivity among the ecosystems' actors, the emphasis on the agent-based theory, allows for more comprehensive modeling of interdependence dynamics. Indeed, by foreseeing the agent's reactions following other agents' behaviours (i.e dominant actors) , the model allows to capture the dynamic evolution of the ecosystem by zooming in on its inner dynamics, instead of generally considering their evolution as the result of external factors at the macrolevel. More specifically, such a model would contribute to measure the ecosystems performance based on indicators that go beyond the conventional measures of economic and innovation performance, including ecosystem's flexibility to respond and adapt to external changes thanks to the observation of actors' behaviour. The possibility to predict the level of ecosystems' flexibility or adaptation would carry relevant implications for policy-making, which could therefore redesign and rethink programs, policies and interventions from an antifragile perspective to build robustness in the concerned ecosystems. However, it has been argued that the ecosystem's flexibility could be constrained by the strong independence of actors. However, the flexibility of the ecosystem should not compromise the independence of each individual actor, as it would make them too vulnerable to change. This is why some scholars still believe it is essential that the ecosystem is made up of a solid core, while surrounding itself with transversal ties that allow it sustainability and flexibility (Simon, 1962; Tsvetkova e Gustafsson, 2012).

Moreover, including the concept of value chain distance as an explanatory variable for agent's behavior would allow integrating a further form of proximity in addition to the well-known ones, i.e. geographical, social, cognitive, organizational, institutional and sectoral (Boshma, 2005). Indeed, while a great body of studies has investigated the implications for collaboration deriving from the above-mentioned types of proximities, none of them has so far contributed to understanding how affiliation to a similar or different value chain can inhibit or stimulate practices of cooperation or M&A. Understanding whereas actors within the same ecosystem would be more or less prone to acquire or collaborate with actors with a short value chain distance would carry interesting implications for the policymaking. In particular, in those cases where the relationship between the value chain distance and cooperation is negative, the government may be encouraged to stimulate the establishment of micro industrial districts within the ecosystem where incentivizing practices of collaboration driven by innovation.

6 Conclusion

This paper seeks to open a new avenue in terms of study perspective and investigation methodology. More specifically, we aim to shed light on the importance of developing a new systemic metric and a computational model to predict ecosystems' network dynamics based on agent's behavior towards cooperation practices. By integrating insights from Social Network Theory and Agent-Based Theory, we suggest that the development of this predictive model would contribute to a greater understanding of the complex nature of ecosystems. Furthermore, by including the concept of value chain distance as a further explanatory variable of agent's behavior would contribute to improving the clarity of the fuzzy mechanisms at the base of the industrial ecosystem, as well as proposing assumption related to the structure (in term of flexibility or rigidity) and the specialization of the ecosystems (i.e. product, service, customer or technology-oriented.

Particularly, the mixed model and the value chain parameter may contribute to better explain the effects that collaboration or merger and acquisition (M&A) strategies may have on the evolutionary and innovative dynamics of an ecosystem. On these bases, we suggest that further advances should be made in this direction.

Abstract

In recent years, the business models of companies have undergone significant changes. These transformations are fueled by the increasingly domineering advent of technological innovation.
New technologies affect most sectors of the economy with significant impacts on industrial processes. The development of devices capable of transmitting and processing huge amounts of data in a timely manner promotes the efficiency of production processes and greater precision. In line with these considerations, the implementation of Industry 4.0 technologies could be considered the tool capable of promoting the sustainability of business processes. The protection of the ecosystem, the satisfaction of the present and future needs of the community, as well as the continuous evolution of the production and industrial process have led to a radical transformation of the competitive business environment.
The issue of pollution and climate change is radically transforming the relationship between businesses and the environment, pushing them towards the implementation of strategies that affect the social, economic and social environmental problems in which they operate. Furthermore, in support of the adoption of sustainable behaviours, there are also new European regulations that increasingly encourage the integration of environmentally friendly policies.
Since environmental sustainability is one of the main drivers of competitiveness and innovation to date, this work aims to study the relationship between technological innovation and sustainability.

In order to achieve our goal, a regression model for the panel data will be estimated considering a time horizon of 5 years. The analysis will be conducted with reference to a sample of listed companies operating in the public services sector in Europe and the United States.
In our document we will use a multiple regression analysis to test the relationship between sustainability and digitalization of processes.
Since there is a productive synergy between Industry 4.0 and environmentally sustainable production, we expect to find greater sustainability in companies that use the digitalization of their industrial processes.
Today many studies focus on sustainability, while there is still little research explaining the relationship between digital innovation and sustainability. This study aims to fill this gap by offering an empirical analysis of the national and international context. The contribution has practical implications, as it provides market operators with information on how environmental sustainability issues will be affected by the adoption of new digital technologies.

Keywords – sustainability, environmental, innovation, digital technologies, business processes

Paper type – Academic Research Paper

1 Introduction

The growing interest in new digital technologies is fuelled by the ability to achieve significant benefits for the business. The implementation of new technologies affects most fields of the economy with significant impacts on industrial processes. The development of devices capable of transmitting and processing huge amounts of data in a timely manner promotes the efficiency of production processes as well as greater accuracy (Rajput and Singh 2019). The data available for companies and the way they use them can help to consolidate a valuable competitive advantage (Pappas et al. 2018). This is essential to survive in a constantly changing market. In this regard the company's ability to identify, assimilate and use the information most useful to the development of its business (Cohen and Levinthal 1990) is crucial and then transforms it into product or process innovations. The implementation of Industry 4.0 technologies is also the tool that can promote the sustainability of business processes. The issue of sustainability, which is extremely topical, is leading the prevalence, if not all of the organizations, to pay more and more attention to the environment (Kotze et al. 2010) and its preservation. In particular companies are increasingly oriented towards the development of a sustainable corporate culture, which is encouraging the optimization of business operations (A. Nowak et al. 2011). In fact the growing focus of companies and their stakeholders on the issues of environmental sustainability and corporate social responsibility has emphasized the adoption of policies and the pursuit of increasingly sustainable goals. The protection of the ecosystem, the satisfaction of the present and future needs of the community (Brundtland 1987), as well as the continuous evolution of the production and industrial process (Savastano et al. 2019) has led to a radical transformation of the competitive business environmental.

For this purpose, Business Process Management (BPM), understood in terms of overseeing the work done in order to achieve consistent results and take advantage of opportunities for improvement (Dumas et al. 2013), needs a transformation. More precisely the conventional view of BPM needs to be extended towards a dimension of environmental sustainability (A. Nowak and Leymann 2013; Reijers and Liman Mansar 2005; Seidel et al. 2011). This new configuration of the BPM, defined as BPM green (Maciel 2017; Seidel et al. 2011; Carl Stolze et al. 2012), is aimed at reducing the environmental impact of business processes, through the use of alternative raw materials, the reduction of electricity consumption (Cappiello et al. 2013), carbon emissions (Recker et al. 2012) or, more generally, through the efficient use of resources (A. Nowak et al. 2011). In this regard in contrast to traditional Key Performance Indicators (KPIs), Nowak (2010) and other authors have identified Key Ecological Indicators (KEIs) as tools useful for assessing environmental performance.

Since environmental sustainability is one of the major drivers of competitiveness and innovation to date, this work aims to investigate the relationship between technological innovation and sustainability. In particular, we intend to investigate the relationship between the digitalization of business processes and sustainability.

The paper is structured as follows: section 2 presents the literature review; section 3 describes the research methodology; section 4 presents the results; section 5 discusses the results and finally section 6 presents the conclusions, the implications and the future research lines.

2 Literature review

2.1 Sustainability and business process management

Sustainability is usually defined as the "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (World Commission on Environment and Development (WCED), 1987). Business process management can be defined as the subject field that provides appropriate concepts, methods, and tools to model, implement, operate, and monitor business processes (Reiter et al. 2014). The importance of implementing environmentally-aware business processes can be observed in several industries. Various organizations have taken in the first steps towards improving the environmental impact of their processes by defining and realizing corresponding business strategies and process adaptations. The execution of a business process has always a certain impact on the environment (Alexander Nowak et al. 2011). Business processes play thus an important role in contributing to the carbon footprint of an organization (Lan 2012). As a business process transforms inputs into outputs, the renewable and non-renewable inputs as well as the type and environmental quality of the outputs determine the sustainability of a business process (Seidel et al. 2011). In this line of thought, the extent of renewable inputs as well

as the extent of emissions (outputs) that can be kept within the assimilative capacity of the environment should be maximized, while the extent of non-renewable inputs and the extent of emissions (outputs) that exceed the assimilative capacity of the environment should be minimized (Seidel et al. 2011). Therefore, a green business process is an environmentally conscious business process that is necessary, efficient, effective, agile, and measured in the context of an organization (Lan 2012) and delivers organizational value with a minimal impact on the natural environment (Seidel et al.,2012, January). Additionally, from a more technological perspective, an energy-aware business process is a service-based business process that considers functional and non-functional requirements, as well as specific annotations for guiding energy assessment (Cappiello et al., 2011).

Different yet similar definitions of Green BPM can be found. They commonly build on the business process lifecycle from "classical" BPM, and add the ecological factor. Examples are the "dedicated consideration paid to the environmental consequences of these business processes" (Seidel et al. 2011), the optimization of business processes considering the ecological dimension (Alexander Nowak et al. 2011), and the aim to support environmental objectives (Lubbecke et al. 2015). Hence, one can understand Green BPM as the discipline that provides appropriate concepts, methods, and tools support business process modeling, implementation, execution, monitoring, and continuous change with dedicated consideration of the environmental impact of these business processes.

Green BPM is not an entirely new way in optimizing organizations' business processes. In fact, existing BPM methodologies and techniques such as discussed in (Hammer and Champy 1994) are leveraged, extended, or refined in order to support the new requirements emerging from environmental concerns. Green BPM deals with the optimization of business processes based on the four common dimensions cost, quality, time, flexibility, and in particular also considers a fifth dimension: the ecological dimension. This dimension covers a variety of aspects like energy consumption, water consumption, or production waste incurring during performance of business processes and activities contained therein, respectively. Although Green BPM is still in an early stage, more and more organizations try to find different ways for improving the environmental impact of their business processes. The motivations for this development are manifold: increasing costs for raw-materials and energy, legislative regulations to reduce emission of carbon, or the public image of an organization, to name some examples. Many institutions and researchers focus on Digitalization and innovation program into utilities firm according to its attributions and responsibilities in society, contributing to growth and delivering goods and services (European Commission 2019a, 2019b).

The main difficulty organizations are faced with is finding a proper solution for green business process improvement considering (a) the particular business process structure,

(b) if and how the process may be changed, and (c) how the process interacts with business partners (A. Nowak and Leymann 2013).

An early approach to capturing green BPM was proposed in (Ghose et al. 2009) and has later been extended and detailed in (Hoesch-Klohe et al. 2010; Hoesch-Klohe and Ghose 2010a, 2010b). The authors provided a first overture for the computation of carbon emissions when modeling business processes. They identified environmental properties, which describe water or energy expenditure, or the impact to the flora and fauna, and resource types that can be annotated to the process model in order to calculate the total environmental impact of a process. They addressed these aspects by proposing a mechanism to aggregate heterogeneous environmental properties of activities (Hoesch-Klohe and Ghose 2010a) as well as a methodology on how to capture and use the relationship between resources and process activities (Hoesch-Klohe et al. 2010). To boot, they introduced an approach to ecologically improve business p0rocesses by redesigning business process models using so-called process fragments. These fragments, usually incorporating a specific functionality, can be exchanged based on their environmental impact. The approaches are mainly focusing on the Design and Analysis phase of the life cycle. Process models are annotated during the modeling time, which allows determining the aggregated resource consumption. This data can also be used as decision support for process model adaptation (Ghose et al. 2009). The information on emissions is taken as granted. Notwithstanding, the approaches support the annotation of this information to the process model and also consider the aggregation of heterogeneous green performance indicators.

Another approach is provided in (Ardagna et al. 2008). The authors developed mechanisms for energy-aware resource allocation and policies for SOA- and process-based applications while ensuring certain QoS requirements. The proposed approach identifies three layers: process layer, infrastructure layer, and control layer, which provide an integrated plan of attack to decrease energy consumption in ICT. The approach comprises both, design time and runtime. Operations are designed considering ecological and economic requirements. The optimization of web service selection is performed within the process layer. The infrastructure layer deals with the trade-off between performance and energy expenditure. So, it uses current runtime information and adapts services if possible, i.e. decrease the energy consumption while not worsen the performance. Additionally, the control layer performs server provisioning and virtual machine placement decisions. The approach focuses entirely on energy consumption and how it can be reduced. Nevertheless, the focus here is on business processes and sensor data as well as the analysis of this data and corresponding adaptation mechanisms. The approach partly considers business related aspects. A basic assumption is to always fulfil customers' requirements and to address the trade-off between performance and energy consumption. This requires proper engineering and services used in the operation. Hence, this approach deals (at least partially) with ecologically optimized Operation, Marketing and Sales, Procurement and Technology Development parts of the Value Chain. The

approach has been further refined in (Cappiello et al. 2013), which focus on models and methods for the analysis and reduction of energy consumption associated with applications which are made energy-aware through annotations and Green Performance Indicators (GPI) in applications. The approach sets a green lifestyle for the development of adaptive, self-healing, and self-managing application systems able to reduce energy consumption. The approach also uses so-called GPIs in order to determine the energy consumption of an application. They are thought to describe the green properties of an application. Hence, this approach deals (at least partially) with ecologically optimized Operation, Marketing and Sales, Procurement and Technology Development parts of the Value Chain.

To sum up, one can understand that an environmentally sustainable (green) business process is a business process that generates business value with minimal impact on the environment, thus without compromising the environmental resource availability for future generations (Maciel 2017).

2. 2 Digitalization of business processes

Companies have always operated in continuously disturbed environments. Not only the presence of competitors, but also and above all the continuous changes affecting the market, generate the need to implement flexible company management policies capable of promptly modifying the products and production processes implemented.

Companies are currently facing a new challenge represented by the fourth industrial revolution. Artificial intelligence, Big Data, Internet of Things are the engine of this revolution (Schwab 2016) and are radically changing every aspect of business life (Jovanović et al. 2018).

In particular, changes are observed at the level of operating processes (Maresova et al. 2018), in the way in which the activities are conducted within the industrial value chains (Parida et al. 2019) and in the promotion and marketing of products. So, the way of doing business is literally changing.

By digital transformation we mean "the application of digital capabilities to processes, products and resources" (Schmarzo 2017) in order to make business processes more efficient, increase value for customers and minimize the risks associated with business.

Furthermore, there are benefits in terms of automation and optimization of processes and the consequent saving of time, costs as well as a reduction of errors and risks (Grubic and Jennions 2018). Through the IoT it is possible to promote the reduction of errors as well as improve their usefulness thanks to information from customers who have already used similar products (Tao et al. 2017).

In fact, the advantages deriving from the use of digital technologies can be different.

Some authors (Neumeier et al. 2017), based on the classification by Frank and Winter and Fischer of an organization in four different intra-organizational layers (Business Model, Business Processes, Application Systems & Services and Infrastructure.), have

identified for each layers some specific benefits deriving from the application of digital technologies.

With reference to the Business Processes, they identified advantages in terms of increased productivity, process flexibility, reduction of product time-to-market, proposal of service speed, operational excellence, process automation, intelligent workflow integration, process improvement, obtaining external network synergies. Such advantages could be obtained, for example, through "using the Internet to conduct marketing or sales activities, to do competitive benchmarking or gather information, to communicate within and outside the organization, or to conduct or support administrative tasks such as purchasing or distribution" (BarNir et al. 2003).

The transition from a traditional business process management system to a digital one requires, however, the development of high skills to correct the processing of the enormous quantities of data and information available to companies. Indeed, it is precisely the way in which these data are provided that can favour the consolidation of a solid competitive advantage (Pappas et al. 2018).

Some authors (BarNir et al. 2003) have shown that the digitalization of business processes depends on the age and size of the company: in the longer-lived and larger companies there is a greater digitalization of the processes.

Many companies, therefore, are changing the objectives of business management, moving towards the development of a digital business strategy (Bharadwaj et al. 2013). However, this is not enough to be competitive on the market.

The digital strategy must be accompanied by the company's ability to be flexible and to adapt continuously to changes in the context in which it operates (Keen and Williams 2013).

The adoption of highly developed strategies by large industrial companies often determines not only an improvement in production processes but also the use of new resources and new business models compared to companies without a digitization strategy (Neligan 2018).

The business model represents the architecture to be implemented to generate a profitable business, both from the point of view of producers and customers (Osterwalder et al. 2005).

In particular, to benefit from the advantages deriving from the use of new technologies, the business model must be built around digital technologies such as artificial intelligence, digital platforms and big data analysis (Parida et al. 2019).

Business models, therefore, are influenced by new digital technologies, determining a new form of communication along the supply chains (Glova et al. 2014).

Furthermore, digitalization also plays a key role in the development of sustainable business models, which make the company more profitable (Maffei et al. 2019).

In fact, we are observing the transition from a traditional business model (BM) to an innovative business model (BMI), which represents the desired business model (Foss and Saebi 2017), focused on digitalization as a tool that promotes sustainability of business

(Maffei et al. 2019). Digital technologies are therefore instrumental to sustainable development (van der Velden 2018).

Digital transformation can create different opportunities to reduce material dependence, improve productivity, increase, the use of renewable energies and synergies between companies (Demartini et al. 2019).

In addition, through digitalization, companies obtain information on energy consumption in real time, promptly viewing the improvements deriving from energy efficiency and thus helping companies better understand the benefits of energy saving (Ringenson et al. 2018).

2.3 Sustainability and digital transformation

It took most parts of the business community some time to recognize the issues and challenges in full. Recently, studies found that managers' started to incorporate sustainability into their core strategic thinking rather than seeing it as being of minor importance (Accenture 2011; Lacy et al. 2010). This is especially true for the generally innovation friendly IS/IT community: the trend of Green IT made sustainability a premiere subject for its decision makers. Although IT consumes resources, its intelligent use offers the major opportunity to transform organisations and societies towards more sustainable and energy-saving behaviour (Boehm et al. 2011; Ozturk et al. 2011; Carl Stolze et al. 2012). Nonetheless, it took IS researchers some time to follow their counterparts from other disciplines. Even these days the IS perspective is still not reflected as it should be within the research activities regarding sustainability (Melville 2010). Having in mind that the quality of the environment is not immediately affected by technological artifacts per-se but by human behaviour (Elliot 2011), technology is a means to an end that can facilitate and support changed behaviour. It should go hand in hand with on-the-job training towards sustainability (Stolze et al. 2011) and the thoughtful design of the chained activities performed by humans and machines (Ozturk et al. 2011) – also known as BPM. Thereby, BPM could be a tool to help managers around the globe to tackle questions of sustainability by changing the way activities are performed. Therefore, researchers should not only solve (theoretical) knowledge problems but offer innovative, relevant solutions to those practical problems (Wieringa 2010) at the intersection of BPM and sustainability.

BPM is a holistic management practice for making out and transforming organizational operations (Hammer 2010). In their efforts to oversee and improve business processes to enable business benefits in terms of costs, flexibility, time savings, quality, or, indeed, sustainable practices, BPM also involves the use of IT and IT-based systems. Past years have discovered the emergence of holistic enterprise resource planning systems (Davenport 2000), automated workflow systems (van der Aalst and ter Hofstede 2005; van der Velden 2018), CASE and other process design systems (Orlikowski 1993), expert systems (Markus et al. 2002), and business rules systems (von Halle 2001) as IT enabled

systems that enable process change management and thereby lead to business value generation.

It is at this intersection of IT-system enablement and process change that we believe the potential for sustainability initiatives lies. Our key premise is that business and IT managers need to engage in a process-focused discussion to enable a common, comprehensive understanding of process, and the process-centered opportunities for making these processes, and ultimately the organization as a process-centric entity, 'green.' It is impossible today to think of undertaking a major sustainability change initiative (involving the re-design of major business processes) without considering what IT can do to that effect. Still, it is equally impossible to think about any major redesign that does not call for major changes in how employees perform their jobs (Kotter 1996). Employees and the management of employees are just as important as IT in the transformation to sustainable practices and solutions, and BPM provides just the perspective that enables an integrated, holistic approach to the management of sustainability change (Seidel et al. 2011).

In line with the previous literature, the following hypothesis is suggested:

H1) Is there a positive relationship between the digitalization of business processes and sustainability?

3 Research methodology

3.1 Sample selection

The analysis focuses on the 575 listed firms operated in the utilities sector in Europe and the USA, for which data on digitalization and innovation was available on the date of analysis (final sample: 118 firms). We constructed a five-year panel dataset (from 2014 to 2018, the last year available in our data sources). These longitudinal data have "observations on the same units in several different time periods" (Kennedy, 2008). A panel data set has multiple entities, each of which has repeated measurements at different time periods. Panel data may have individual (group) effect, time effect, or both, which are analyzed by fixed effect and/or random effect models. Among the reasons for selecting these firms is, above all, the importance of this sector.

In fact, many institutions and researchers focus on Digitalization and innovation program into utilities firm according to its attributions and responsibilities in society, contributing to growth and delivering goods and services (European Commission 2019a, 2019b).

Data on the relationship between digitization and sustainability come from the Refinitiv database (previously called Thomson Reuters Asset4).

3.2 Model and variables

The next section will test the hypotheses regarding the effect of digitalization on sustainability, using panel data analysis to control for omitted/unobserved variable bias.

The significance of our analysis can be tested using panel data technique. In this way, we can control for some omitted variables without observing them by observing changes in the dependent variable over time. This controls for omitted variables that differ between cases but which are constant over time (fixed effects). We can also control for omitted variables that may be constant over time but which vary between cases, and others may be fixed between cases but can vary over time (random effects). More specifically, estimation model is the follow:

$$Y_{i,t} = \beta_0 + \beta_1 X_{i,t} + \alpha_i + u_{i,t}$$

In the model, the subscripts i and t represent ID company and period (year), respectively. The dependent variable ($Y_{i,t}$) is the *ESG Score*; β_0 is the constant and $X_{i,t}$ refers to a vector of independent variables.

Dependent Variable

In order to test our hypotheses, we used data on ESG performance (ESG SCORE) from Refinitiv. ESG score considers three dimensions: environmental, social and corporate governance.

Environmental performance measures a company's ability to minimize environmental emissions and efficiently utilise natural resources in their processes. In addition, environmental performance also considers a company's ability to support the research and development of eco-efficient products and services.

The second area (social performance) measures a company's ability to promote ethical values and generate confidence in its workforce, respect human rights, respect business ethics, and create value-added products and services.

The third area concerns corporate governance performance. It refers to company's ability to act in the interests of its shareholders through business management systems and processes (structure, functions, roles and responsibilities of the board and firm's committees, compensation policy, CSR policies etc...)

The overall ESG SCORE is expressed as he arithmetic mean of the three scores: social, environmental and corporate governance. It is a percentage ranging from 0 to 100 percent.

Independent Variables

To test our hypotheses, we used data on Environmental Innovation performance (Environmental Innovation SCORE) from Asset4 (Explanatory Variable). Environmental innovation category score reflects a company's capacity to reduce the environmental costs and burdens for its customers, and thereby creating new market opportunities through new environmental technologies and processes or eco-designed products. Environmental performance measures a company’s capacity to reduce environmental emissions, to

efficiently use natural resources in the production processes and to support the research and development of eco-efficient products and services.

The independent variables included in our econometric models are the Environmental Innovation score, CSR strategy and GRI report guidelines.

To avoid model misspecification, we control for additional variables that could influence ESG SCORE. In line with existing literature, we used Size as a control variable.

Table 1 shows a summary of the measurement of all variables.

Table 1- Variable description

Independent variable	**Variable code**	**Variable description**
Environmental Innovation Score	Env_Inn_Sco	Environmental innovation category score reflects a company's capacity to reduce the environmental costs and burdens for its customers, and thereby creating new market opportunities through new environmental technologies and processes or eco-designed products.
CSR Strategy Score	CSR_Strategy	CSR Strategy Score reflects a company's practices to communicate that it incorporates the economic (financial), social and environmental dimensions in its day-to-day decision-making processes.
GRI Report Guidelines	GRI_Guid	Is the company's CSR report published in accordance with the GRI guidelines?
Control variable	**Variable code**	**Variable description**
Total Assets	TA	Total Assets represent the sum of total current assets, long term receivables, investment in unconsolidated subsidiaries, other investments, net property plant and equipment and other assets.

4 Results

The following table shows descriptive statistics for dependent and independent variables. The descriptive statistics table includes the minimum, maximum, average and standard deviation.

The average level of ESG performance (ESG SCORE) of the companies analyzed is 57.67%, with a maximum of 92.76%. This reveals that the sustainability performance of companies for the 2014-2018 period has been very satisfactory by the standards of the definition of the score.

Similarly, the level of the environmental innovation score reaches an average value (52.63%) and the maximum value is 99.4%, suggesting that many companies analyzed use technologies to increase their level of sustainability.

In addition, the CSR strategy also has an average value of 70%, just as the orientation of the GRI ratios has an average value of 0.99% (on a maximum score of 1).

Table 2 - Descriptive statistics

Variable	Obs	Mean	Std. Dev.	Min	Max
Id	590	59.5	34,09	1	118
N_of_year	590	5	0	5	5
CSR_Strategy	488	70,279	24,2704	0,5	99,76
ESG	488	57,67424	17,85806	14,01	92,76
Env_Inn_Sco	488	52,63314	27,44755	0,26	99,44
GRI_Guid	261	0,9961686	0,0618984	0	1
LnTA	586	16,38456	1,749009	11,64702	21,64297

The correlation matrix (Table 3) highlights very important relationships between the main variables of the study. More specifically, firm's sustainability performance (ESG SCORE) is found to be positively associated with Environmental Innovation Score, CSR strategy, GRI Report Guidelines and firm's size. These relationships show that more sustainable firms tend to implement digitalization into their business processes and more frequently adopt CSR strategies and/or GRI guidelines. Interestingly, the ESG score is negatively associated with firm's size which suggests that the business dimension doesn't influence corporate sustainability decisions.

Table 3 - Correlation matrix

	ESG	Env_Inn_Score	GRI_Guid	CSR_Strategy	LnTA
ESG	1.0000				
Env_Inn_Score	0.3093	1.0000			
GRI_Guid	0.0981	-0.0645	1.0000		
CSR_Strategy	0.3420	-0.1313	-0.0028	1.0000	
LnTA	-0.1260	-0.2353	0.1200	0.0085	1.0000

The comments that will follow the estimates reported in tabular form will only concern the model identified by the Hausman test. Pooled, fixed and random regressions were initially launched, considering the independent variables present in the dataset and entering robustness for both heteroskedasticity and correlation. To choose between fixed effects and random effects, we run the Housman test, which checks a more efficient model against a less efficient but consistent model, and indeed we need to know that the more efficient model also gives consistent results.

Subsequently, to perform the Hausman test and the Breusch-Pagan test, the same regressions were launched without robustness. First the Hausman test was launched to understand whether the fixed effects model or the random effects model should be used of

specification 2; the test, presenting a p-value of the chi-square greater than 10%, tells us to use the random effects model. Subsequently, the Breusch-Pagan test was carried out which, also presenting a p-value lower than 10%, confirms that it must use the second specification (if the p-value had been greater than 10%, then the specification would have been used 1, i.e. the pooled model). Ultimately, from the results obtained from the Breusch-Pagan test, the second specification must be used and, given that the p-value of the Hausman test is greater than 10%, the random effects model must be used.

Unlike the fixed effects model, the random effects model assumes that the variation between entities is random and unrelated to the predictor or independent variables included in the model (Green, 2008, p.183).

To test the joint statistical significance of the temporal effects, for each regression performed the test $ yeardum was launched from which, in relation to the resulting p-values (prob> F), it is possible to affirm that the null hypothesis cannot be accepted and therefore the temporal effects are always, in the regressions performed, jointly statistically significant at 1%, 5% or 10% as appropriate.

Table 4 - Regression results

Model	**(A) Pooled OLS**	**(B) Fixed Effects**	**(C) Random Effects**
	Coefficient (Robust SE)	**Coefficient (Robust SE)**	**Coefficient (Robust SE)**
Env_Inn_Sco	0.185*** (0.043)	0.124*** (0.024)	0.135*** (0.022)
CSR_Strategy	0.299*** (0.073)	0.185*** (0.042)	0.212*** (0.034)
GRI_Guid	27.950*** (3.637)	7.11*** (1.599)	9.372*** (1.428)
LnTA	- 0.051*** (0.014)	0.99* (1.514)	0.562* (1.010)
Hausman test	6.39 (p-value = 0.1721)		
Breusch and Pagan test	347.62 (p-value = 0.000)		
Years	2014 - 2018	2014 - 2018	2014 - 2018
Temporal effects	Yes	Yes	Yes
Standard errors - grouped data	Yes	Yes	Yes
R-square	26,70%	20,47%	23,53%
F test for temporal effects		Chi-sq 4.97***	17.64***
*** = significant at 1% ** = significant at 5% * = significant at 10%			

Using the random effects model, all the coefficients are statistically significant at 1%, with the exception of the natural logarithm of the total assets which is significant at 10%.

Consequently, it can be said that all the variables considered affect the dependent variable (Y) which, in our case, represents the ESG score.

In line with other studies (van der Velden 2018), there is a positive impact of the environmental Innovation Score on the ESG scores. In fact, one percentage point more than the environmental innovation score causes an increase of 0.135% in the ESG score. Reading the data, we can positively find the theory that, as the adoption of CSR policies increases, the sensitivity of the company to sustainability issues increases by 0.212%.

The GRI Report Guidelines regressor is a dummy variable and therefore, if it assumes value one it is assumed that the company adopts the GRI guidelines, vice versa if it assumes value 0.

In line with this consideration, it is possible to affirm that the adoption of the GRI guidelines positively affects the ESG score, resulting in an increase of the same by 9.37%. The chi-square in our model has a p-value of 0.000 and consequently it is possible to say that the regressors are all jointly significant at 1% and therefore have an effect on the ESG score.

In order for a regression model to be satisfactory, the theory reminds us that R-sq must assume values greater than 50%. Using the random effect model, although the regressors are all statistically significant, both individually and jointly, the R-sq overall, i.e. the average between the R-sq in the groups and the R-sq in the groups, is equal to 23.53%. Finally, analyzing the temporal effects, they were jointly statistically significant at 1% (p-value: 0.0014) and consequently it is possible to affirm that they also affect the dependent variable.

5 Conclusion

This work, starting from the limited number of contributions that explain the relationship between digital innovation and sustainability, tries to partially fill this gap. The issue of pollution and climate change has radically transformed the relationship between businesses and the environment, favouring the adoption of more sustainable production policies (Kotze et al. 2010). At the same time, new technologies have also influenced business processes. In fact, today many companies are transforming their policies, moving towards the development of a digital business strategy (Bharadwaj et al. 2013), aware of their importance to compete in an ever dynamic market (Keen and Williams 2013). Digital technologies are also instrumental to sustainable development (van der Velden 2018). In this regard, the new configuration of Business Process Management (BPM), called BPM green (Maciel 2017; Seidel et al. 2011; Carl Stolze et al. 2012) is very relevant, proposing the reduction of the environmental impact of business processes through the efficient use of resources (Cappiello et al. 2013; Recker et al. 2012).

Based on prior literature demonstrating that innovation play a key role in firm's sustainability performance, this study investigates the relationship between sustainability (ESG Score) and innovation in a large sample of 118 European and U.S. listed firms for

the period 2014–2018. The main results reveal that innovation and digitalization of business processes positively affect a company's ESG performance. For this reason, the hypothesis that a company that is more innovative and open to the challenges of digitalization is also an ethically sustainable and environmentally friendly company is considered likely.

The relationship between ESG performance and company size is negative. This underlines that the adoption of sustainable policies and green business models does not depend on the size of the company, but on other variables, such as decisions of the board of directors or group policies.

The contribution has practical implications, as it provides market operators with information on how environmental sustainability issues will be affected by the adoption of new digital technologies. From a management perspective, our work suggests that managers and CEOs should pay more attention to digitization and innovation. To improve performance in terms of sustainability, it is important to digitize processes, reducing the use of renewable resources and producing eco-sustainable products.

Furthermore, our study suggests the importance of adopting CSR and / or GRI guidelines policies, which are very strategic tools that demonstrate the company's strong commitment to sustainability.

Our study has not studied the managerial and technological aspect (in terms of potentially adoptable new technologies), but future research could go in this direction. In addition, it would be interesting to use a larger sample of companies (expanding the sectors of analysis) and a longer time window.

Abstract

Nowadays, the development of data management technologies has deeply contributed to make immediate and effective the activity of gathering and processing large amounts of data with reference to specific process or performance indicators. The Big Data phenomenon along with Artificial Intelligence (AI) techniques represent a new era in information exploration and utilization, by offering new perspectives in the decision-making processes, especially in complex and fragmented situation. In this way, the emerging knowledge derived pushes toward new models of collective intelligence which can help to face the challenges that are affecting the current social context. In this direction, the paper, by adopting the interpretative lens offered by the Viable Systems Approach (vSa), proposes a conceptual model for managing collective knowledge based on big data and AI and for supporting decision-makers in complex contexts. The work is organized in four main sections. First of all, it opens with the analysis of the theoretical background of reference, highlighting the scientific evidence emerging from the literature dedicated to big data, artificial and the collective knowledge approaches. By adopting the concepts provided by the vSa, a new possible interpretative path is defined concerning managing knowledge in the digital era. In this regard, the Chinese case in facing up the COVID-19 pandemic thanks to collective intelligence approaches is presented. Finally, the potential implications of the work, both from a theoretical-scientific and a practical-managerial point of view, are highlighted.

Keywords - Big Data; Artificial Intelligence; Collective Intelligence; Viable Systems Approach; COVID-19

1 Introduction

The last decade has seen increasing attention to the digital revolution, which has opened the doors for many opportunities and has changed organizations boundaries. Interconnection, smartness and information value are progressively and deeply affecting the world and offering new solutions during always more complex challenges (French and Shim, 2016). For instance, the approaches based on Big Data (Zikopoulos and Eaton, 2011) and Artificial Intelligence (AI) (Nilsson, 2014) techniques can support human beings in the shift from a lower level of the rationality to "objective rationality" (Simon, 1955), by increasing the available information in a very short time. In this way, the emerging knowledge which enables the shift from individual to *collective intelligence* can help to face the challenges that are influencing the worldwide social development (Lévy and Bononno, 1997).

However, from a systems perspective, smart and data-driven approaches require to extend the

viewpoint to the (potential) relationships among different actors that can favour fruitful learning interactions. Consequently, since very few organizations can internally develop a wide range of knowledge, the focus is moved on their ability in formalizing frameworks which aim to build relationships which potentially can provide a new and broader knowledge-based source thanks to innovative information technology (Tsai and Ghoshal, 1998).

Therefore, the paper, by adopting the interpretative lens offered by the Viable Systems Approach (vSa) (Golinelli, 2000; 2010; Barile, 2008; 2009), proposes a conceptual model for managing collective knowledge based on big data and AI and for supporting decision-makers in complex contexts.

The work is organized in four main sections. First of all, it opens with the analysis of the theoretical background of reference, highlighting the scientific evidence emerging from the literature dedicated to big data, artificial and the collective knowledge approaches for managing knowledge and supporting the decision-making process. Continuing, the research path adopts the concepts provided by the vSa, for defining a new possible interpretative path concerning managing knowledge in the digital era. In this regard, the Chinese case in facing up the COVID-19 pandemic thanks to collective intelligence approaches is presented. Finally, the potential implications of the work, both from a theoretical-scientific and a practical-managerial point of view, are highlighted and the limitations are commented.

2 Literature review

2.1 Big data and artificial intelligence for extracting knowledge and supporting the decision-making process

Nowadays, innovative technologies made cheaper and faster the gathering and processing of large amounts of data, concerning specific processes and performance indicators. This new phenomenon, called Big Data, is blowing up, representing a new era in data exploration and utilization (Chen et al., 2012). The "*mass digitization*" (Coyle, 2006) along with "Internet of Things" interconnection (Ashton, 2009) have led to a rapid expansion of large amounts of data, characterized by three dimensions: *volume*, *speed* and *variety*, as reported by the "3Vs" model of Laney (Zikopoulos and Eaton, 2011; Beyer and Laney, 2012; Zaslavsky et al., 2013). Furthermore, additional concepts like *veracity* and *value* have been attributed to this model, to highlight respectively the quality across datasets and the capacity to generate useful output for industry challenges and issues (Uddin & Gupta, 2014).

Big data analytics follow an approach based on Artificial Intelligence (AI), which can be defined as the way of training computers to mimic thinking patterns and can even be done to simulate human behaviours (Nilsson, 2014). The subfields of AI include several techniques of machine learning (Qiu et al., 2016; Zhou et al., 2017), a set of algorithms able to build a computer system that improves automatically through experience; these can be applied to a large data set for identifying non-obvious and hidden patterns of information and building predictive models.

In this direction, big data, thanks to smart analytics, can be considered as an additional valuable knowledge asset (Erickson and Rothberg, 2015): the huge volumes of data are processed for extracting valuable knowledge, which can be used for enhancing the performance of many different processes in organizations. Thus, the adoption of these innovative information technologies determines the capacity to absorb untapped knowledge in big data and combine them with the existing knowledge for improve performance. The combination of tacit knowledge of experienced employees (Ball and Gotsill, 2011) with the knowledge obtained from big data (Feblowitz, 2013) can be a valuable resource for the organizations. In this way, it is possible to analyse the information from different perspectives for valuable decision-making (Lamont, 2012). Moreover, the data, consistent and integrated, make easier to extract knowledge from themself (LaValle et al., 2011). Especially, this new knowledge for organizations can be evaluated to generate new predictive knowledge (Bose, 2009; Pauleen and Wang, 2017).

Therefore, the decision-making process can be improved by data' transmission, capture, storage, analysis, visualization, and interpretation (LaValle et al., 2010; Chen and Zhang, 2014). The algorithms approach permit to extract useful information from large datasets or streams of data (Fan and Bifet, 2013) and can reveal valuable insights:

decisions will be increasingly based on data and sophisticated analysis, rather than on experience and intuition (McAfee et al., 2012).

In the following paragraph, frameworks and approaches for managing knowledge in the digital era are discussed.

2.2 Towards the collective intelligence: the collective knowledge approaches

Organizations should invest in frameworks able to conceptually and operationally integrate smart technologies with knowledge management for a better decision-making process and organizational value creation.

Starting from web 2.0 era, characterized by blogs, Twitter, wikis, photo sharing, collaborative tagging and social networking sites, which enable the creation and dissemination of content in a relatively simple way, Gruber (2008) proposes the Collective Knowledge System (CSK). This framework aims to reveal the potential of the Social Web thanks to the Semantic Web. The first one is intended as the web sites in which user participation is the primary driver of value, for instance, Facebook and YouTube. On the other hand, the Semantic Web can be considered as an ecosystem of structured data, where value is created by data integration from many sources. These systems can provide answers to small-groups of people by elaborating the user-generated contents in the websites, through knowledge extraction approaches. The information obtained, which cannot be found explicitly in web sites, represents emerging knowledge which enables the shift from individual intelligence to *collective intelligence*; this last concept can be defined as the enhancement of the collective pool of social knowledge thanks to networked ICTs (Information communication technologies) which simultaneously and constantly expand the extent of human interactions (Lèvy and Bononno, 1997).

The CKS consists of three subsystems:

1. A *social system* which generates problem-solving discussions (questions and answers) on the web sites;
2. A *search engine* which is capable to find questions and answers in the contents generated by the social system;
3. *Users in a complex situation* which, through a search engine, generate queries for scoring the online question/answer contents. Besides, users can provide feedback about which query/document pairs were effective at addressing their problems.

In such human-machine interactions, both humans and machines actively contribute to the resulting intelligence and can solve user problems thanks to ICT tools (analytics and research engine, etc.) (Gaeta et al., 2019).

Especially, in the field of emergency response, a framework based on the collective intelligence approach can aggregate body of knowledge at an accelerated rate and improve the process of decision-making. Vivacqua and Borges (2012) define a framework which underlines the interaction between environmental information (the

context of the emergency) and the multiple individuals who perceive it (the population and the respondents). The aim is to enable the participation of the population and emergency respondents to support the decision-making process of the latter. The framework is composed of two modules:

I. *CI module* consists of other submodules:
   - the *interface* (for instance web and mobile interfaces) which permits the population to provide data on its perception of the environment;
   - *data collection* which receives and stores the raw data sent in by the population for processing;
   - *data processing* through different algorithms for aggregation, organization, classification, consolidation and verification of the data provided.

II. *Decision Support module* receives CI data, processes it, adds it with data from external sources and provides it to emergency respondents to support their decision-making process.

Also, the metaphor of the black swan proposed by Taleb (2007), which refers to events not expected and with an extreme impact, draws attention to the challenge of creating a link between relevant information from different individuals and groups to face up an unforeseen scenario. A collective knowledge framework can provide a useful way to conceptualize knowledge management for prevention of black swans, and encourages us to think differently about how we view existing practices. However, there is still an open question regarding how to configure a conscious managerial action regarding the collective knowledge frameworks (Hecker, 2012): this pushes to adopt a systemic approach for modelling the problem.

3 A viable systems perspective for managing knowledge in the digital era

The theoretical approach adopted in this paper is the Viable Systems Approach (vSa), based on systems theories (Beer, 1984; Capra, 1997, 2002; Checkland, 1981; Laszlo, 1996; Meadows, 2008; Von Bertalanffy, 1968; Weinberg, 1975), which could be particularly useful for the analysis and interpretation of systems and social organizations. In particular, according to vSa (Golinelli, 2000; 2010; Barile, 2008; 2009), each entity can be described as a viable system, whose ultimate purpose is to survive within its specific context of reference. Focusing on the relationship between environment and system (Ashby, 1968), vSa concludes that a system can remain in balance - with the possibility of self-regulation and research of the homeostasis- and therefore to survive if it can understand and respond to the complexity and turbulence of the external environment. Furthermore, each viable system is seen always from the perspective of its governing body, which is defined as the top decision-making entity (e.g. the leader or the board), composed by one or more individuals (Golinelli 2010). It comes out that the destiny (i.e. system's survival) of every viable system depends on the decisions made by the

governing body. Therefore, the concept of decision is strictly connected with that of survival (Barile and Canfora, 2008).

From the above and as also reported in the previous paragraph, derives that the decision-maker has to face several problem areas that require different resolution paths and various levels of knowledge. Since the decision-making is a cognitive course of action, the maintenance of viability implies a continuous decisional process that can be represented as a knowledge itinerary (the 4Cs), as shown in Table 1.

Table 1. The knowledge itinerary (4Cs)

Chaos	A situation in which the viable system has an unconscious fastidious sensation but it is no aware of the origin/cause, the effect, and the solution. Both problem and resolution scheme are incognita.
Complexity	A problematical area characterized by the viable system's consciousness about the problem Although the problem is known the viable system is convinced that there is no way how t solve it.
Complication	A context in which the viable system increases the optimistic percentage thinking that th problem has a solution, but the formula (i.e. interpretation scheme) is not yet in its hands; it i just a matter of time.
Certainty	It is the last area characterized by the type of problems that seems to be very easy to solv (99% certain) to because a method already exists. These are repeated problems, such a organizational routines.

Source: Authors' elaboration from Barile (2009)

As noticed previously, each informational stage can be associated with a different type of reasoning that decision-maker should implement to foster the transition from chaos to certainty.

In particular, in the transition from chaos to complexity, there is a moment when the decision-maker isn't endowed with adequate knowledge to face the problem and carry out a conscious decision-making process. Therefore, it is necessary to stop the confusional growth, upon the entry of new information, triggering a process that could lead to a resolving hypothesis.

Furthermore, the key notion of *information variety* should be necessarily introduced introduce to explore how the theory can provide to the governing body the strategic drivers for proper utilization of data to acquire knowledge. In particular, the information variety is a representation of knowledge that a viable system possesses in a specific time point and is defined through three dimensions, that can be expressed as follows:

- The *information units* consist of the number of single units of data detained by a system (the structural knowledge of the system). Specifically, the information unit is an incoming signal from the external context or/and from the internal brain's memory centre, subjectively perceived and interpreted by the observer. In the digital era, the information units can be assimilated to the large amount of data generated online and by sensors;

- The *interpretative schemes* permit to assembled and understood the information units (the knowledge "shape" of the system). Indeed, it is precisely the interpretative schemes that determine the transformation of non-specific data into information relating to a given context. They serve as filters acting on information units through particular elaborations. These are organizational patterns because have the primary task to rationally organize the information. In the new technological and informative context, Artificial Intelligence (AI) and, in particular, machine learning techniques allow to interpret data sets and to identify precious information and predictive models;
- The third factor concerns the *value categories*, which are the basic values and strong beliefs of the system (the resistance to change) that influence how the interpretative schemes are used. The value categories characterize the context ethics for the generic moral, inspire and allow the activation of the criteria through which it is possible to express an opinion on events and facts and orientate and derive interpretative schemes. Therefore, the value categories are connected to the emotional sphere of the decision-maker and are independent of the computational capabilities of the new technologies.

In this direction, the paper proposes a framework that supports the decision-maker in the transition from the area of chaos to that of complexity, expanding his information variety thanks to the use of new technologies.

4 A viable framework based on collective knowledge in complex contexts

Based on the previous considerations, the proposed framework, as reported in Figure 1, aims to manage the collective knowledge thanks to big data and AI approaches and to support decision-makers during the transition from chaos to complexity.

The model, shaped by human-machine interactions which actively contribute to the resulting intelligence, is composed of two sections (Gruber, 2008):

1. "*Humans users*" which includes the reference context and focuses on human-human interactions;
2. "*Machine processes*", concerning the automated activities carried out by software and hardware components for enabling the smart technologies processes. This section, in turn, is composed by the *Collective Intelligence (CI) module*, which aims to collect and process the user-generated data, and the *Decision Support module*, that elaborates through AI algorithms the information units gathered.

An open and dynamic view of the context pushes to consider the environmental dynamism as a source of opportunity to improve the decision-makers' awareness of the context. In this direction, the aim of the framework is to interpret effectively the multiple entities which compose the context, by exploiting new forms of interaction (Saviano and Caputo, 2013).

Thus, the framework is based on the following fundamental steps:

i. Firstly, the population, by interacting on the internet with activities of blogging, tagging and discussion through web and mobile interfaces, produces data (Lastowka, 2007); user-generated data concern their perception on the context and personal content.

ii. Subsequently, the *CI module* allows to receive and stores the raw data originated by the population; after the processing and the clustering, the data collected compose semi-structured data which can be managed in a repository (Vivacqua and Borges, 2012; Fan and Bifet, 2013). Therefore, this module outputs *information units* which should be interpreted in the next step.

iii. Next, the *Decision Support module* receives the CI information units and processes these by AI algorithms which provide *interpretative schemes*. Furthermore, this module adds external sources and selects relevant information to support the decision-making process. In particular, a search engine can find data of interest (Gruber, 2008) according to the decision-makers request. The machine learning algorithms, following an AI approach, can identify non-obvious and hidden patterns of information in data for creating knowledge.

iv. Then, the decision-makers, by evaluating the knowledge acquired, carry out the definitive choices. This knowledge of experienced people is tacit (Nonaka and Takeuchi, 1995) and it is strongly connected to their categorical values (Barile, 2009). Thus, this existing concept of tacit knowledge is combined with the new concept of predictive knowledge (Pauleen and Wang, 2017). Therefore, human insights are fundamental to understand, revise and confirm or reject the relationships emerged from the data (Hair, 2007).

v. Finally, the implemented decisions that depend on the decision maker's cognitive processes carry out a behaviour change in the population. This means that, in pursuing survival, each decision-maker can lead to different behaviours, that vary according to the information variety of himself (Carrubbo et al., 2017).

4.1. Computational collective intelligence against the COVID-19: the Chinese case

What has been said so far is reflected in the latest events involving the Chinese government in dealing with the pandemic caused by the COVID-19.

During the annual Lunar New Year holiday, the infectious disease COVID-19 has started to spread in China. In this period, the people returned to their family homes and several billion people have travelled on crowded planes, trains, and buses. Knowing this meant each infected person could have numerous close contacts over a protracted time and across long distances, the government needed to quickly act: China focused on traditional public health outbreak response tactics—isolation, quarantine, social distancing, and community containment (Wu and McGoogan, 2020). However, other approaches based on sophisticated computational methods have been applied by the Chinese government.

China government used data from hundreds of millions of smartphones to contain the spread of Covid-19. All smartphones with enabled GPS offered to telecom providers a precise record of the user's itinerary. Furthermore, Chinese government algorithms can estimate the probability that a given neighbourhood or even an individual has exposure to Covid-19 by matching the location of smartphones to known locations of infected individuals or groups. The authorities used this information to manage limited medical resources more efficiently by, for example, directing tests for the virus to high-risk subjects identified by the artificial intelligence algorithm. China, also, used electronic records of medicine purchases to identify sick individuals who may have attempted to flee quarantine (Goldman, 2020).

In this regard, the Chinese culture, with particular reference to their categorical values, has enabled this approach: in fact, China has no such privacy constraints, and telecom providers have used locational data for years for advertising. Instead, smartphone users in the United States and Europe can access their data, but privacy laws prevent the government from collecting this data.

Therefore, big data and AI analytics helped Chinese authorities to establish the chain of transmission of the virus. On the 2nd March, China reported only 126 new cases, compared to 851 in South Korea and 835 in Iran, out of a total of 1,969 new cases worldwide (Goldman, 2020).

Furthermore, Hu et al. (2020) developed a modified stacked auto-encoder for modelling the transmission dynamics of the epidemics. They used the latent variables in the auto-encoder and clustering algorithms to group the provinces/cities for investigating the transmission structure.

The work aimed to model the real-time forecasting the confirmed cases of Covid-19 across China. The data were collected from January 11 to February 27, 2020, by WHO. They predicted that the epidemics of Covid-19 will be over by the middle of April. If the data are reliable and there are no second transmissions, this model can forecast the transmission dynamics of the Covid-19 across the provinces/cities in China. The AI-

inspired methods are a powerful tool for helping public health planning and policymaking.

By concluding, the accuracy of the AI-based methods for forecasting the trajectory of Covid-19 was high (Hu et al., 2020). In this direction, there is the need to increase the data sharing in the event of outbreaks or disasters, leading to better global understanding and management of the same (Allam and Jones, 2020).

5 Managerial implications, limitations and future research

Nowadays, the digital tools along with big data and AI-oriented approaches can help to achieve the viability of the social system by pointing out a plurality of information that cannot be found such rapidly in other ways. In this direction, the proposed approach highlights the relevance of user-generated content which, through knowledge extraction approaches, enables the shift from individual to collective intelligence. Accordingly, the paper shows that effective management of the external knowledge in a social organization requires a holistic perspective, able also to clarify the role and the contributions of smart technologies, especially in complex contexts.

Reflecting upon these research streams, some implications can be discussed both from theoretical and practical points of view. From a theoretical point of view, the paper merges the collective knowledge approaches with vSa concepts, to combine the perspectives related to new trends in information technology with an interpretative lens of reality. In this way, a holistic approach can provide a clear picture to systemically consider the external information and the social organizations' characteristics by integrating a plurality of contributions into a unique identity of collective knowledge. On the other hand, from the managerial point of view, the work shows a model which aims to manage collective knowledge to support the decision-makers during the transition from chaos to complexity, by leveraging on big data and AI approaches. In particular, it emerges that the tacit knowledge is combined with the new concept of predictive knowledge (Pauleen and Wang, 2017) and the human insights are fundamental to understand, revise and confirm or reject the relationships emerged from the data (Hair, 2007).

Recognising the validity of the proposed concept, some possible future lines of research can be tracked to enrich the framework proposed and deepen it through a possible quantitative approach. Therefore, the reflections herein are only directed towards outlining a possible conceptual path which requires a better definition because of the multiple connections that can be traced among the identified concepts. Furthermore, more studies should be developed to effectively understand collective knowledge approaches correlated to the concept of resilience and how this connection can affect the viability of social systems.

Abstract

Nowadays, all organizations face increased global competition in a knowledge-based economy. Consequently, they need to continually learn and convert their project-derived knowledge into enhanced and innovative products and services in order to remain competitive in an increasingly aggressive market. Knowledge is not merely widely regarded as a key asset in companies, but it is becoming the most critical strategic determinant of economic growth.
This study investigates possible correlations between the adoption of knowledge management systems, complexity of the working environment and digitalization. It investigates any correlation between complex working environments and systems of knowledge management, between specific organizational context and level of digitalization.
The study has been developed with the start of a structured online survey sent via e-mail to a selected target working in companies located in Switzerland and Northern Italy and operating in different sectors, whose size range from small, to mid-size to large, including both local and global organizations. It consisted of 19 closed questions grouped in 4 main KPI (Complexity, Digitalisation, KMS, Organisational Context) aimed to gain a relevant insight on knowledge management practices and digital transformation topics.
The overall picture that emerged shows that organizations with high KPI for digitalization, knowledge management systems and organizational context are tendentially young, small, from tertiary sector and with national customer base. Moreover, the survey demonstrates a strong interconnection between the 3 KPIs organisational context, digitalisation and adoption of knowledge management systems.
Organizations should therefore encourage the creation of knowledge and endeavour to invest in tools and technologies necessary to support processes involved in knowledge management

Keywords – Knowledge Integration, Technological change, Project Knowledge, Digital Transformation

Paper type – Academic Research Paper

1 Introduction

1.1 Purpose / Value

The accelerating technological change imposes organizations an extra effort to become digitally proficient in order to improve attractiveness and efficiency. This is reflected by the effective management of project knowledge using information technology tools, which improve overall organizational performance and contribute to the achievement of business benefits: the ability to integrate the appropriate knowledge for the management of new technologies and, consequently manage the intellectual capital of qualified employees plays therefore a crucial role.

Project knowledge management may be widely applied, also through a lesson learned register, where "any lessons learned that will improve performance for current or future projects is recorded as it is learned (PMBOK, 2017 – p. 97), however the tools used and the levels of digitalization vary a lot.

While there exists a rich literature strand on knowledge management itself, this study, started in March 2020 by the faculty of Project Management of the University of Applied Science and Arts of Southern Switzerland (SUPSI), aims to investigate possible correlations between the adoption of knowledge management systems, complexity of the working environment and digitalization. Following the lacks of a globally recognized practices, the study focuses on the following objectives, evaluated between Switzerland, Northern and Central Italy:

- Correlation between complex working environments and systems of knowledge management.
- Correlation between specific organizational context and level of digitalization.

1.2 Knowledge Management and Digital Transformation

It is widely recognized that knowledge management is a key factor that ensures the success of the organizations and the continuity of their businesses.

As reported by PMBOK, 2017 (p. 100), "it is a common misconception that managing knowledge involves just documenting it so it can be shared".

Actually, knowledge management is meant to be not just the ability to manage (capture, share and re-use) the knowledge gained during the projects, in the way that the "knowledge is shared using a mixture of knowledge management tools and techniques (interaction between people)" (PMBOK, 2017). It also involves the aptitude to change and adapt behaviour according to new assumptions/expertise as well as the competence to arise awareness about the importance of this activity.

With the help of innovation, it enables the organizations to perform business processes in more creative ways, which improves effectiveness, efficiency and at least

marketability. The organizations are able to solve the problems through innovative solutions, which rely on knowledge shared among individuals. It is therefore important to understand how knowledge is created and shared and not only referred to as a standard business operation.

However, there is no one-size-fits-all solution and organizations are being creative looking for different combinations of practices and methods for knowledge management. We expect this study to investigate further if the different approaches adopted by organizations do have an impact on level of digitalization.

There are many activities, which are formed to carry out key elements of an organization's KM strategy and operations. For instance, an organization must first identify and capture knowledge, and then organize it in order to bring knowledge within the organizational boundaries. Knowledge is also transferred and shared throughout the members of the organization using both human and technological means.

The fundamental objective of organizing knowledge is to allow for its retrieval. The consequences of not organizing knowledge in a manner that leads to retrieval and use can be severe. It is therefore important for organizations to spend resources and efforts in managing and organizing the knowledge that exists within the boundaries of the organization. However, literature shows that "processes and technology alone are not enough to drive an organization, but its people (staff) and the knowledge that reside in the people are a very integral pivot in organization's success" (cfr Omotayo, F. O. (2015), Knowledge management as an important tool in organizational management).

Therefore, in order for an organization to be successful, attention must be paid, not only on the processes and technology, but on knowledge and its workforce which are people who are the sources of knowledge.

With this study, we expect to identify a correlation between specific skills of the workforce, organizational context and implementation of successful knowledge management systems.

1.3 Definition of Complex Working Environment

The concept of complexity is related to variety and to the number of entities operating in an organization. However, there does not seem to be a unique definition of complexity.

According to J.R. SanCristóbal (Complexity in Project Management, Procedia Computer Science, Volume 121, 2017, Pages 762-766), as well as a general lack of consensus when defining complexity, complexity models do not take into account critical aspects of complexity. Requirements of a good project complexity model must consider not only the number of elements and their interdependencies, but also the social and political context, and project manager's skills such as shared leadership, emotional intelligence, vision, values and beliefs, etc.

McElroy (Integrating Complexity Theory, Knowledge Management, and Organizational Learning, Journal of Knowledge Management. 4, Pages 195-203) claims

that complexity is strictly related to the concepts of knowledge management and organizational learning: "Complex systems are, by any other definition, learning organizations." Complexity Theory, KM, and OL are all complementary and co-dependent. “KM and OL each lack a theory of how cognition happens in human social systems – complexity theory offers this missing piece.

All the above definitions suggest that the word "complexity" is not necessarily a characteristic of large and mature companies, but can also identify younger companies. We expect our study to confirm this assumption.

A study carried out by Kenney and Gudergan (Knowledge integration in organizations: An empirical assessment. J. Knowledge Management. 10, Pages 43-58) suggests that combinative capabilities and organizational forms affect the efficiency, scope and flexibility of knowledge integration simultaneously; given the above framework our study aims to investigate further if a complex working environment necessary involves a higher level of digitalization and if a firm knowledge integration capacity is determined by the employment of particular organizational forms.

2 Methodology

The study has been developed with the start of a survey in two versions in Italian and English languages, with specific questions aimed to gain a relevant insight on knowledge management practices and digital transformation topics.

The survey was developed through the free tool “Google Forms” and it was submitted by email to a pool of 500 organizations operating in the three sectors (primary, secondary and tertiary) and employing a varying number of employees.

The survey consisted of 19 closed questions grouped in 5 main KPI (see table 1).

- 3 questions on General Information

These questions aim to collect general information like foundation date or location of the organization.

- 4 questions on Complexity

These questions aim to investigate the complexity of the organization by evaluating some criteria like number of employees, customers location or self-evaluation on their experience in managing projects.

- 4 question on Digitalization

These questions aim to understand the use of digital tools for managing projects, sharing and communicating information between employees. They also investigate if cross-functional projects are well connected to each other via digital platform.

- 3 Questions on Knowledge Management Systems

These questions aim to gather insights on the usage of knowledge management systems by asking information on the specific tools, if the knowledge acquired during project management is correctly integrated into business and if it is properly shared through digital tools.

- 5 questions on Organizational Framework

These last questions aim to collect information on the organizational framework, the respondent is asked if the organization encourages new ideas or if it allows experimentation of new tool for managing project knowledge.

Before analysis the gathered data have been exported from Google Forms as .csv file and arranged into a MS Excel spreadsheet. Answers to parameters belonging to the organizational complexity KPI, i.e. “number of employees” and “customer location”, were numerically converted to a 1 - 5 scale as follows:

Number of employees

1-50 = 1;

50-250 = 2;

250-500 = 3;

500+ = 5

Customer location

Regional = 1;

National = 3;

International = 5;

All other answers were either used as their numerical value on a “strongly agree” (= 5) to “strongly disagree” scale (= 1).

All the data collected have been classified following the KPI’s Table, the data were then analysed for KPI’s by two-way ANOVA with Geisser-Greenhouse correction, correcting for multiple comparison using statistical hypothesis testing (Tukey).

The standard error of the mean was calculated for each mean KPI value and correlation analysis was performed calculating Pearson’s correlation coefficient for each pair of KPI’s, with two-tailed 95% confidence interval.

Table 1: Parameters (i.e. answers) were allocated to KPI categories

KPI	Organization Information	Complexity	Digitalization	KMS	Organizational context
Questions	Foundation year	How many employees are currently employed at your organization?	Your organization uses digital tools to gather data on operational activities	Please select the main tools used in your organization to grant an efficient system for managing project knowledge (Paper, digital, KNS)	Your corporate strategy implements practices of knowledge management and provides a guiding framework
	Head Quarter	Self-assessed complexity degree	Employees communicate and share information on digital platforms	The knowledge acquired during project management is integrated into business processes (e.g. lesson learned, return of experience)	Your organization allows for experimentation of new tools
	Sector	How do you evaluate your organization's experience in managing projects?	Employees are fully supported with efficient training in digital technologies	Your organization project knowledge is adequately shared through specific digital tools	Your organization encourages new ideas for managing project knowledge
		Where are your customers located?	Cross-functional project teams are well connected to each other via digital platforms		Your team trusts the source of project knowledge and sees the benefits of using it
					Your team is motivated to share their project knowledge with other team members
Amount of parameters	3	4	4	3	5

KPI values were calculated as average mean value of the corresponding parameters (i.e. answers), where these were converted into numerical values.

3 Results

3.1 Statistical Distribution of participants to the survey

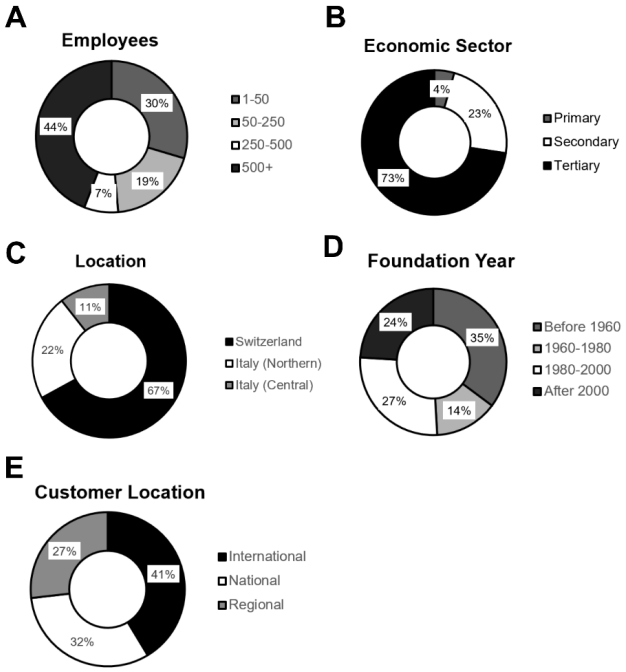

Figure 4 Statistical distribution of survey participants. Percentage distribution for organization's employees (A), economic sector (B), head quarter location (C). foundation year (D), and customer's portfolio network (E) for all invited participants to the survey that provided a feedback. Pie charts show percentage distribution among all category parameters. N=179.

Participation to the survey was relatively low: 179 organizations out of 500 survey invitees answered to the survey (6% of invited participants).

Almost half of the organizations (44%) have more than 500 employees, while one third (30%) have less than 50 employees; the remaining was divided into a range of 50 to 500 employees (Figure 1A).

With regards to the economic sector, the majority belongs to the tertiary sector (73%), while just 4% of the participants belong to the primary sector (Figure 1B).

As a result for the majority of invites to the survey being sent to Swiss organizations, two thirds of the answers came from organizations located in Switzerland (67%), while 22% came from North-Italian and 11% from Central-Italian participants (Figure 1C).

Out of all organizations, one third was relatively old, being founded before 1960 (35%), while young companies founded after 2000 are 24%. The remaining was either founded between 1960 and 1980 (4%) or between 1980 and 2000 (27%) (Figure 1D).

Customer location of the participants was equally distributed between regional (27%), national (32%) and international (41%) (Figure 1E).

3.2 KPI Analysis

The influence of each organizational parameter not related to organization's complexity (i.e. foundation year, economic sector, location) over each study's KPI - created based on the survey questions - was investigated by statistical analysis using Tukey's 2-way ANOVA multiple comparison test. Aim of this analysis was to investigate for statistically significant influences of each parameters over the KPI's.

In detail, KPIs are: complexity, digitization level, maturity of KMS, organizational context with regards to knowledge management and digitalization, including both organization's and employees' attitude.

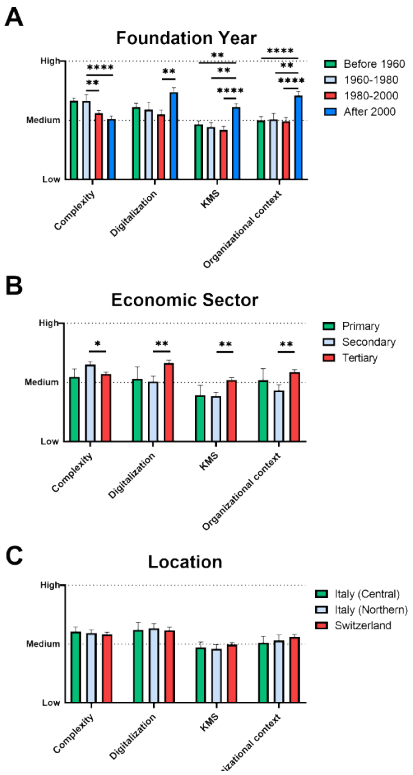

*Figure 5 KPI analysis for complexity-independent organizational parameters. Shown are KPI for complexity, digitalization, knowledge management system (KMS) and organizational context for each organizational parameter, i.e. foundations year period (A), economic sector (B) and head quarter location (C). Bars represent average KPI value (low=1 to high=5), error bars represent standard error of the mean. Tukey's 2-way ANOVA multiple comparison test p values: *<0.05; **<0.001; ****<0.00001.*

Organizational age had influence on each KPI (Figure 2A).

Younger companies showed a medium complexity compared to a medium-high degree in older companies (founded before 1980), this being statistically significant between companies founded in the 1960-1980 towards those founded in 1980-2000 ($p>0.001$) and after 2000 ($p>0.00001$).

The degree of digitalization was higher for organizations founded after 2000 (mid-high) compared to older organizations, with statistical significance towards those founded between 1980 and 2000 ($p>0.001$).

The maturity of the KMS showed to be higher in organizations founded in the 21th century. The difference was significant towards all categories ($p<0.00001$ vs 1980-2000, $p<0.001$ vs 1960-1980 and before 1960). Of note, only organizations founded after 2000 had a KMS maturity above medium level.

In line with both digitalization and KMS performance, the organizational context was shown to be medium-high for young organizations with less than 20 years of history compared to older ones, which sowed a medium-level KPI value ($p<0.00001$ vs 1980-2000, $p<0.001$ vs 1960-1980, $p<0.00001$ vs before 1960).

We then investigated the impact of the economic sector over the KPI's (Figure 2B).

Complexity was slightly above a medium level for organizations belonging to the secondary sector, while those belonging to the primary and tertiary sector showed a medium level of complexity. The higher complexity of the secondary sector was statistically significant only towards the tertiary sector ($p>0.05$).

As expected, the degree of digitalization almost reached a medium-high level only in the tertiary sector, while the other sectors reached a medium level. This difference was significant between tertiary and secondary sector ($p<0.001$).

With regards to KMS maturity, only organizations belonging to the tertiary sector demonstrate a medium maturity level, while those belonging to the other sectors show a low-to-medium degree of maturity.

The difference was significant in particular between the tertiary and secondary sector ($p<0.001$). Similar difference between secondary and tertiary sector was found with regards to organizational context.

While the primary sector reached a medium level, the only statistical difference was observed for the secondary sector being lower that the tertiary sector ($p<0.001$).

On the contrary, the location of the organizations that participated to the survey had no influence on the KPI's (Figure 2C). All KPI levels were found the be around medium level with no statistical differences.

Altogether, this analysis shows that digitization is more developed in both small and medium/large companies. Knowledge management and organizational context are more pronounced with small companies. Location has nor influence on the KPI's.

Besides analyzing parameters not considered in the calculation for organizational complexity, we also looked into the influence of complexity factors – i.e. customers location and numbers of employees - on each individual KPI.

Aim of this, was to understand if these individual complexity factors have any influence on digitalization, KMS and organizational context. Their influence on complexity KPI was not investigated, since customer location and number of employees are parameters used for the calculation of this KPI.

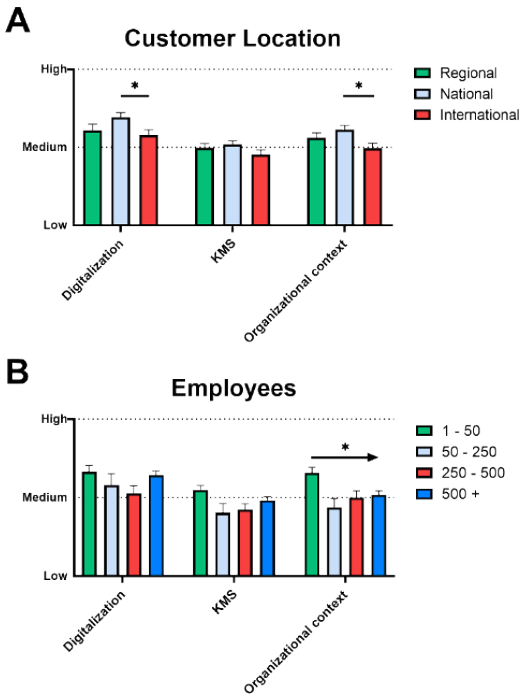

*Figure 6 KPI analysis for complexity-dependent organizational parameters. Shown are KPI for, digitalization, knowledge management system (KMS) and organizational context for each organizational variable that have been included in the calculation for the complexity KPI, i.e. customer location (A), and employees (B). Bars represent average KPI value (low=1 to high=5), error bars represent standard error of the mean. Tukey's 2-way ANOVA multiple comparison test p values: *<0.05*

Organizations with a national customer portfolio showed both a digitalization and organizational context KPI above the one observed for organizations with a regional or – higher and with statistical significance ($p<0.05$) – the ones with an international customer basis. No significant differences were observed with regards to KMS (Fig. 3A).

The dimension of the organization reflected by the number of employees did not have a statistically significant influence on digitalization and KMS.

This is spite of non-significant lower digitalization level in companies with 250-500 employees compared to companies with less than 50 or more than 500 employees.

On the contrary, the organizational context supporting knowledge management was found to be statistically significantly higher (medium-high) in small organizations with

less than 50 employees compared to organizations with more than 50 employees ($p<0.05$) (Fig. 3B).

3.3 Correlations between KPI's

We asked ourselves if there are positive or negative correlations between study KPI's, e.g. if a better organizational context favours digitization and if it can also favour a more effective knowledge management.

KPI performance value for each individual organization participating to the survey was taken into consideration.

To investigate this, we performed Pearson's correlation analysis, for which r value equal to 0 represent lack of correlation, values between 0 and 1 show positive correlations, and values between 0 and -1 show a negative correlation.

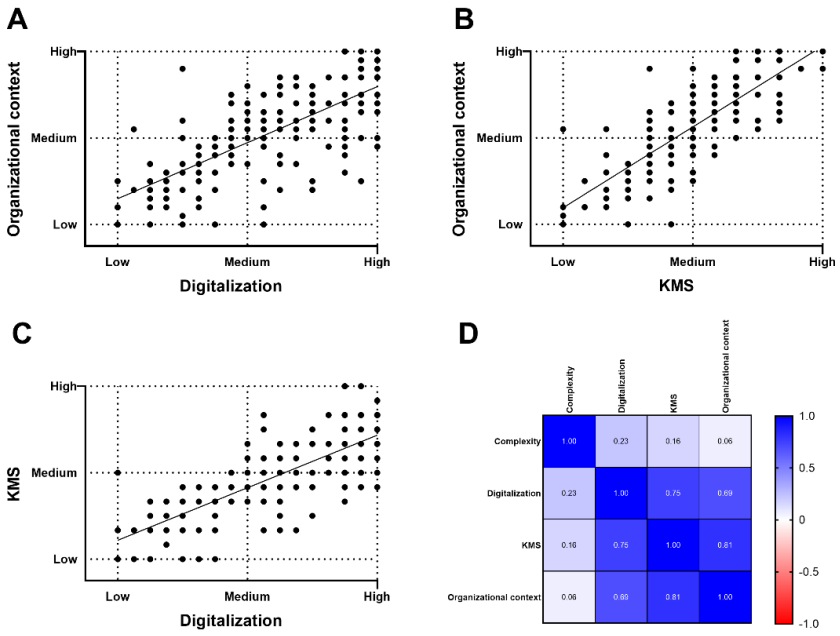

Figure 7 KPI correlation analysis. Shown are 2D plots comparing KPI values for organizational context vs. digitalization (A), knowledge management system (KMS) vs. organizational context (B), KMS vs. digitalization (C). Correlation trendline is depicted on each graph. Pearson's correlation coefficient r (D) between all KPI's is presented, including color-coding ranging from blue (positive correlation) to red (negative correlation). N=179

Based on the results in our survey, a Pearson's correlation matrix highlighted relatively high positive correlation between the following KPI pairs: digitalization vs. organizational context r = 0.69 (p = 4 x 10-27), digitalization vs. KMS r = 0.75 (p = 7 x 10-34), and KMS vs. organizational context r = 0.81 (p = 8 x 10-43).

The p values for all these correlations highlighted a high statistical significance.

The matrix also highlighted a positive correlation (i.e. r > 1) between complexity and other KPI's: digitalization (r = 0.23, p < 0.02), KMS (r = 0.16, p < 0.029).

The correlations with complexity, even if statistically significant, were not as high as observed for the pairs mentioned above.

The positive correlation between digitalization, KMS and organizational context was not only observed among pairs, but also among all three KPI in 3-axis representations (Fig 5).

This analysis showed that the performance and maturity of digitalization, KMS and organizational context are interdependent.

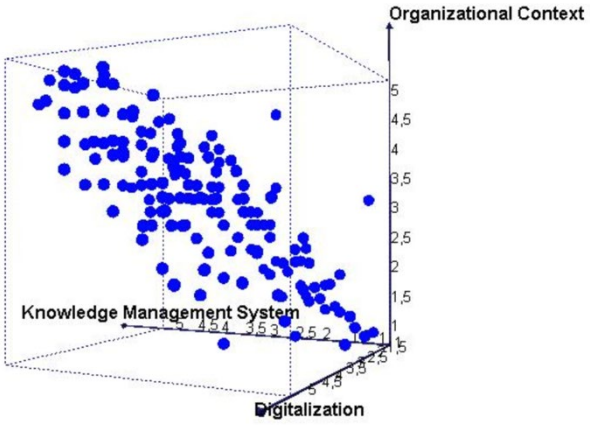

Figure 8 Correlation between knowledge management system, organizational context and digitalization. Shown are values for KPI's for organizational context, knowledge management system (KMS) and digitalization for each participants of the survey represented on a 3-dimensional scatter plot. N=179.

4 Discussion and Conclusions

In the beginning, we have analysed the answers to parameters belonging to the organizational complexity KPI. The first area of the survey proves that digitization is more developed in both small and medium/large companies whereas it has been clearly shown that knowledge management and organizational context are more pronounced with small companies. Is has been also highlighted a positive correlation between complexity

and digitalization confirming our hypothesis that a complex working environment most probably involves a higher level of digitalization.

Digitalisation and the adoption of knowledge management system was found to be statistically significantly higher in companies founded recently which shows that young companies are more aware of the importance of becoming digitally proficient in order to improve attractiveness and efficiency.

The overall picture that emerged has shown that organizations with high KPI for digitalization, knowledge management systems and organizational context are tendentially young, small, from tertiary sector and with national customer base.

Secondly, we found out that there is a strong interconnection between the 3 KPIs organisational context, digitalisation and adoption of knowledge management systems which reflects that a better organizational context favours digitization and a more effective knowledge management. The interconnection was observed among pairs as well with a varying degree of correlation.

Finally, the survey reinforces the idea that managing knowledge does not only involve mere documenting but it also strictly correlates on the ability of the company to keep up with advancements in digitalisation processes and promote favourable organisational context. In this challenging new economy, organizations should therefore encourage the creation of knowledge and endeavour to invest in tools and technologies necessary to support processes involved in knowledge management in order to gain competitive advantage.

Abstract

The paper focuses on Community of Practice (CoP) in the public sector as a lever for the development of learning processes and organizational change. While existing literature suggests that CoPs may be considered as a tool for knowledge sharing and learning process, previous contributions have rarely analysed organizations in the public sector. We deal with an experience promoted by SNA (Italian School of Public Administration) to establish a community of managers specialized in staff training and belonging to different Italian public administrations. The community involved managers from all central administrations and government agencies (about forty organizations) that have cooperated for the rationalization, digitization and innovation of the programming processes of training activities for two years. Our results show that the community has facilitated learning and knowledge exchange and has helped SNA to define needs in terms of training of public servants. Our empirical study contributes to the understanding of the theoretical relationship between CoP and learning processes in the public sector, which has been neglected in knowledge management research.

Keywords – Community of practice, public administration, knowledge exchange, learning

Paper type – Academic Research Paper / Practical Paper

1 Introduction

The concept of Community of Practice (CoP) has been widely adopted in the private sector, representing a phenomenon under scrutiny in the academic literature for almost 30 years. CoPs are often considered as a mechanism to manage knowledge (Bolisani and Scarso, 2014; Kimble and Hildreth, 2005), a way to facilitate learning process inside the organization (Brown and Duguid, 1991; Wenger, 1998). In the public sector domain, instantiations of CoPs are not common and have been rarely investigated in managerial and administrative literature (Smith, 2016).

The aim of this paper is to analyse a peculiar public sector experience in which the introduction of a CoP has been carried out to foster the training process in the Italian Public Administration System. In the last thirty years Italian Public Administration has experienced several reforms clearly inspired by the New Public Management. The effects of these changes are still debated and no clear evaluation has been conducted, but according to public management scholars, they have been generally unsuccessful (Cepiku and Meneguzzo, 2011).

Notwithstanding, the implications of these reforms for public managers are the need of being involved in a long-life learning process in which building up new skills that should be improved over time. Reforms have emphasized the need to reach ambitious goals through a new management approach with continuous improvement of performance, the adoption of the benchmarking method and the measurement of customer satisfaction. Public sector managers operate effectively in a more and more complex and dynamic environment. They have to develop new skills to manage people and to satisfy stakeholder expectations in time of austerity and declining staff morale.

As argued by Larat (2017:89): "*In this sense, training the elite who will be in charge of public administration in the future must go further than merely teaching administrative rules and management techniques".* In this context, the role of training in the public sector could not anymore interpreted as a marginal topic or, at least, one of only narrow, technical interest. As argued by Pollitt (2015: IX) "*the nature of such training is closely linked to some of the most crucial questions in contemporary liberal democracy, and its implications go far beyond the technical".*

Training in the context of capacity development is the way to assure the quality of individual knowledge, skills or attitudes: it is a way to affect managers' behaviours and provide benefits to their organizations. "*In fact, some researchers share the view the training of civil servants can be regarded as a condition, which ensures the viability of public organizations. Thus it is necessary to establish a training system, which will maintain the ability to respond effectively to the challenges of the environment"* (Dolidze, 2017: 156).

Our paper analyses a peculiar case of defining training policies through the adoption of a CoP.

In Italy the National School of Administration (Scuola Nazionale dell'Amministrazione, SNA) provides training courses to all central public administrations. Before 2015, Italian Public Administration experienced a critical situation as reported by Van Wart and Hondeghem (2015:18): "*…the SCS training provided primarily narrowly focused on agency-oriented legal and technical issues such as in the Italian case…".*

The challenge has thus been to overcome the limitations of this model, trying to identify in an original way training needs and programs for Italian civil servants. This attempt was put in place also thanks to the creation of a CoP in which discussing and sharing training issues and policies.

The paper is developed as follows: in the next paragraph, we discuss the role of training policies in the public sector, in paragraph three, the role of the CoP in the public context. Finally, the methodology and the case are presented and the main results are discussed.

2 Defining training policies in the public sector

Training is a traditional topic in management studies (Moore and Dutton, 1978), and it still represents an interesting issue to discuss in the scientific and practical domain. In particular, public sector literature has discussed mainly: 1) the role of competences (with a specific interest to behavioural ones), 2) the governance of public training, with reference to the actors in charge of offering training programs for civil servants and to the methods to be adopted in the training process.

As far as it concerns the role of competences, the general argument is to move from technical programs to behavioural ones. This is mainly due to the fact of considering key administrative personnel as managers. As stated by Larat (2017:89): "*what is at stake is on the one hand the ability of administrative managers to carry out their mission of public service to the full and to meet the expectations of the citizens and, on the other hand, due to the training they receive, to determine the values and benchmarks for public action they will refer to*".

Several studies have examined and documented competencies needed by public administrators. Nordegraff (2000) identify three groups of key competences of public managers: interpretative competencies, institutional competencies, and textual competencies. The author underlines that the specificity of the competent public sector manager lies in the ability to operate effectively in an environment that is unstable due to the political situation. Bowman et al. (2004) argue that successful public manager must possess "skills triangle", which comprises three different types of competences: technical, leadership and ethical.

A variety of public reports have also attempted to study the civil servants competencies in specific countries. The Australian Public Service Commission identified skills like leading people, leading change, strategic thinking, decision-making and judgement, people and organizational development (Australian Public Service Commission, 2015).

The United States Office of Personnel Management developed executive core qualifications for the senior executive service that include leading change, leading people, results driven, business acumen and building coalitions (United States Office of Personnel Management, 2012).

More recently, Darling and Cunningham (2016) have suggested a range of distinct public sector competencies (very different than those identified as critical for the private sector environment) including: managing competing interests, managing the political environment, communicating in a political environment, interpersonal motivational skills, adding value for clients, and impact assessment in decision-making. According to these authors, private sector competencies reflect business environments where goals need to be specifically defined and implemented in a timely manner related to making a profit and surviving in a competitive environment. Public sector competencies instead are driven by environments exhibiting more complex and unresolvable problems and the need to respond to conflicting publics and serving the public good while surviving in a political environment.

In this context, as argued by Larat (2017:89): "*there is a need for modern public administrations to develop a dynamic, adaptive and differentiated system of selection and training of their senior civil servants in order to ensure that not only all public sector executives do possess the skills and competences required for their present position, but also that for those who are capable, they can be promoted to higher positions and then be prepared for this*".

This holds especially true in the so-called career based system (opposite to the position based system), characterised by competitive selections held at early stages in public servants' careers with higher-level posts open to public servants only. Career-based systems aim to put together a group of civil servants who should be well selected and trained. These two policies are a key issue in public human resource management.

As far as it concerns instead the governance of public training, with reference to the actors in charge of offering training programs for civil servants and to the method to adopt in the training process, literature offers insights related to the different actors who can be engaged and how they perform. For example, according to Pacheco and Franzese (2017:39): "*in Brazil, education for public managers is inspired by two main models: on the one hand, the academic model of theoretical education and research, achieving a University degree as MSc or PhD; on the other, the French model, based in Ecole Nationale d'Administration (ENA), to form permanent high staff for the state".*

Another way to approach this issue is to reflect on the governance of the training process and policies' definition. According to Dolidze (2017:155-156) it is possible to identify three different models: "*the centralized model is mostly used in the states with strong bureaucratic institutions and implies that the development of civil servants, including training and qualifications, as well as career promotion, is controlled by the government, and, in some cases, by a concrete state agency, ... The decentralized scheme is advocated by the NPM model and is based on the contractual delivery of training by*

non-governmental providers. Training and capacity building needs are determined by particular agencies or employees, and training providers selected on the basis of a free market – the best quality at the best price. The semi-centralized scheme is based on the cooperation between the government and private actors".

Literature has mainly debated how the education system can support training programs for civil servants, with a specific focus on public managers. Reichard (2017) described the most important European experiences in terms of executive academic programs for professionals. According to Reichard (2017): "*consequently, we observe a growing attractiveness of executive PA/PM degree programs offered by universities which results in an increase of supplying institutions at least in some countries (e.g. Germany, Italy, The Netherlands and the UK)".*

The provision of managerial education to civil servants is thus common all over Europe, with a strong base in the UK. What is not clearly debated in the literature is the way in which training needs are defined in the public sector. This is a slippery issue, because there are many differences in the public context. Every country has a different model, and even in the same country, public administrations (central or local) have different characteristics. If there is a centralized model, a single authority is in charge of defining the public training. In the decentralized model, public administrations have more freedom to define and satisfy their educational needs. The point is to understand how actors (universities, national public schools or other players) define their training programs. Actually, on this topic there is no a specific debate in the literature, even if this represents a sensitive issue in the practitioners' world.

The content of the most important programs (both in Europe or in other countries) are mainly based on general management (Reichard, 2017) and on behavioural competences, and the training needs are typically defined following a top-down approach. More specifically, in the centralized model, the central authority defines generic needs and offers directly or through private educational players specific programs. What are the methods to identify training needs? How do central governments or national agencies proceed to define them?

Our argument is to consider CoPs as a locus to share training experiences and to collect and define specific training needs for the central administrations. In the next paragraph, we will analyse the CoP concept and discuss ideas related to its adoption in the public sector context.

3 Community of practice in a public sector context

The idea of adopting the concept of communities of practice (CoP) within the public administration is not particularly widespread and it is related to specific issues. As argued by Smith (2016): "*Yet, existing research on communities of practice has a largely private-sector orientation with few studies applied to the public sector".*

One way to look at this phenomenon inside public administration is to adopt a social construction approach: public organization could be interpreted as dynamic and context

specific. In a general sense, according to Rooney and Mckenna (2008: 713): "*What this means for managers wishing to create the space for wise practice in public administration is that they must apprehend their organization from a phenomenological perspective — that is, as discourse communities and communities of practice".*

Following a social construction approach for understanding organizations in the public sector is a way to interpret them as a process where continuous interaction among different members and in a specific context takes place, with the aim of establishing practices. CoP is a way to facilitate the adoption of this perspective in the organization.

According to Pyrko et al. (2017: 390) "… *CoPs refer to groups of people who genuinely care about the same real-life problems or hot topics, and who on that basis interact regularly to learn together and from each other (Wenger et al., 2002)".* Koliba and Gajda (2009:100) argued that "*communities of practices can be understood phenomenologically, as relational structures that are mediated by and through the social construction of knowledge (Buysse et al., 2003; Nicolini et al., 2003). As such, they are spaces through which "communicative action" can take place (Polanyi, 2002; O'Donnell et al., 2003)".*

Even if it is not easy to provide a precise definition of community of practice, it is possible to identify several of its features (Wenger, 1998):

- it claims mutual relationships;
- it favours the sharing of the ways of doing things;
- it provides a shared language and gives the possibility of conversing without preambles as part of a continuous process;
- it sees to it that everyone knows what the others are able to do;
- it thrives on the sharing of symbolic elements or play content.

According to Wenger, in order to define CoP structurally it is necessary to reflect on three main themes (Wenger, 1998: 52). The first relates to the creation of meaning, which is connected to a definite process of negotiation. The second theme is that the process of negotiation of meaning is connected to the two dimensions of participation and depersonalisation. The last theme is that interaction between these two dimensions is fundamental in the process of establishing meaning at the level of single individuals.

The process of negotiation of meaning is activated through continuous interaction between the historical dimension, that coincides with the individual experience and the current/dynamic dimension which is associated with the practice that is being experienced. In other words, the interpretation of the practice depends on its content and on its past history. In order to interpret the content of the practice it is necessary to implement logics of participation and depersonalization. Participation represents a process of construction of relationships with other individuals which determines activation- as well as connection phenomena. The depersonalization dimension implies a process of formalization of individual and collective experience within the CoP. This

brings about that the symbolical manifestations of the CoP in terms of objects, artefacts, stories, sagas, refer to certain shared concepts and meanings.

The two dimensions of participation and depersonalization are characterized by relationship of duality, which implies complementariness and interaction. A process of reciprocal reinforcement is grafted whereby participation increasingly strengthens as common and shared meanings within the community are gradually elaborated, which in turn allow participation to be fostered. The concept of CoP is, moreover, linked to the theme of doing, and assumes a temporal dimension as well as a social one. The temporal dimension identifies the CoP's course of shared development. The construction of a common meaning is the outcome of a members' joint course. It needs to be emphasised how in the construction of a CoP, both "history" and the individual and collective stages of development are extremely relevant.

The social dimension refers to the interaction existing among the CoP members. In this sense practice may be interpreted as a process of social interaction and cannot be considered as a resource that may be coded and transferred from one individual to another.

Among the factors which facilitate the creation of community most relevant is the role of the construction of interpersonal relationships through carrying out activities of social interaction that endure through time.

Even if communities of practice are not a typical issue in the public literature, there are some exceptions. For example, Hatmaker et al (2011) studied the introduction of a CoP to integrate newcomers inside the organization, in order to facilitate the process of organizational socialization. In this sense CoP may augment formal socialization tactics such as training because they can offer participants the opportunity to engage in the practice of the profession or craft, rather than just learning about it in the abstract (Hatmaker et al., 2011: 399). The organization could foster CoP as a sort of socialization tactic, a way to create a space where newcomers could learn values, behaviours, language and technical issues.

In a recent study on knowledge sharing and communities of practise in a public organization, Smith (2016) reveals the structures, behaviours, and processes embedded in communities of practice that offer public managers a gateway to informal communication, build community through communication within and across groups, provide access to "know how" information from a diverse set of perspectives, and encourage peer comparisons.

In coherence with the call by Smith to go further in the study on communities of practice in public sector settings, our aim is to analyse a case of the adoption of a CoP within a public organization finalized to make the educational and training process more effective. In fact there is a gap in the literature on this issue as attempts to study communities of practice in a public sector context are related to educational more than to training policies. For example, Neubauer et al. (2011) studied the use of emerging technologies to connect students to practitioners in selected communities of practice.

What about public managers and their training? How is it possible for a public organization to deliver better standards in terms of training policies?

4 Methodolgy

We analysed empirical material collected within the Italian National School of Administration (*Scuola Nazionale dell'Amministrazione*, SNA) to identify actual experiences of a CoP, in which HRM managers from forty-three different Italian public administrations participated (see Table 1). In particular, our analysis was based on an interpretative and qualitative investigation (Birkinshaw et al., 2011) as data and information collected cannot be explained or illustrated without being familiar with the study material. This led us to the crucial problem of distance between observing subject and observed object (Van Maanen, 1979) necessary to obtain an accurate analysis of the phenomenon under investigation (Strauss and Corbin, 1998). We started collecting, elaborating and analysing conversation and practice in order to bring out the "viewpoint" of the researcher in the process of interpretation of the empirical material (Glaser and Strauss, 1967). This method is rooted in social constructivism (Berger and Luckmann, 1996; Gergen, 1989). Issues then emerged naturally from the data (Caven et al., 2012), rather than the data being fitted to predetermined categories. Fieldwork was carried out between September 2017 and early November 2019. The collection of data were carried out using a variety of methods, including participant observations, semi-structured interviews, and document analysis.

Participant observation

Participant observation is the primary source of data for this study. Participant observation is an approach that allows researchers to gain intimate knowledge of a social setting in a naturalistic way (Smith, 2017).Two of the authors of this paper have been part of the project team as Head of Department and External Consultant. During the period of participant observation, they acquired an initial familiarity with the "lexical territory" of the community (Van Maanen, 1979). During their fieldwork, the two authors spent two to three days a month in the community from 9 a.m. to 1 p.m. or from 2 p.m. to 4 p.m. Having free access to the community premises, they could establish formal and informal contacts and become relatively familiar with the managers. They recorded on a data sheet the activities of each shift, reporting verbal and non-verbal expressions, discussions and conversations.

Semi-structured interviews

These interviews were used as a way to cross check information and conclusions reached through participant observation and gain insider understandings of phenomena emerging from the participant observation data (Lofland & Lofland, 1995). We conducted 20 interviews with 20 of the forty-three HRM managers involved in the CoPs designed by SNA. The interviews were guided by a wide-ranging questionnaire. Interviews took

place at SNA headquarter. They were conducted in Italian, lasted one to two hours, and were taped and roughly analysed. We wrote memos to coordinate, developing and sharing a common view among the five authors. In the second step, all authors listened to the recordings. We compared raw materials and written notes taken during the interviews with the recordings. We first listened to all the interviews to recollect the general ideas expressed. We then reviewed the recordings, transcribing the interviews verbatim, stopping the recording after every sentence, to be sure that the meaning was clear. We did this immediately after recording and read the transcripts several times. This reminded us of the events, words and gazes, and helped us to remember what happened in each interview.

In translating and editing the excerpts, we tried to preserve their original meaning within the context of the whole interview. We are aware that the way in which subjects describe and discuss their work and relationships often reveals multiple senses of self, hence the complexity of unlocking individual and/or collective identities (Harding, 2008). We adopted the viewpoint of Ricoeur (1986) in seeing the organizational actors as readers confronted by a text. They are actively involved in creating the language of the context surrounding them, consisting of both organizational and narrative phenomena.

Internal documentation

Finally, we reviewed a series of formal sources, including SNA informative material, planning documents, internal reports and internal communications.

5 The community of practices

SNA was established in 1957 with the aim of creating a system of recruitment and training similar to the French ÉNA (Cepiku et al., 2017). SNA focuses its training offer on three main activities, the first two being multidisciplinary training programs (Cepiku et al., 2014):

- selection and training of public managers (similar to the French ÉNA selection procedure);
- compulsory training for middle managers appointed by their respective administrations after a selection procedure, with a relatively high level of enforcement;
- lifelong executive education on managerial, legal, and policy issues for all civil servants (through bilateral agreements either with single administrations or through voluntary participation by single civil servants).

SNA is responsible for the use of resources allocated by the government for the training of central public administration managers. In addition, SNA can stipulate agreements for the implementation of training projects with central and local administrations. The activities are coordinated by the President and from 2018 are structured as follows:

- five Departments specialised by type of users (Ministries and National Agencies) and by policy areas in which they are more directly involved;
- five didactic and scientific areas;
- two offices responsible for support services (Design, Information System).

In the wake of the 2009 reform, the governance and mission of SNA have been redefined to support the reform implementation process (Strategic Plan 2010–2012, Draft Strategic Plan 2013–2015). This priority has led to a comprehensive effort to redesign the training offered, starting with the initial training for appointed managers, previously centred around legal, economic, and, marginally, organizational skills and delivered through classical lecture teaching. In tandem, the debate on training methods has developed around four main elements: the use of cases, exercises and simulations, interaction with practitioners, and the consolidation of a comprehensive evaluation scheme (Cepiku et al., 2017).

5.1 The training planning and evaluation process

From 2013, the programming of the training provided by SNA for managers of central government administrations was divided into three steps:

(a) strategic programming developed by the political bodies of the central government;

b) the construction of the annual Catalogue of the School's training offer;

c) the actual composition of the classrooms for the courses in the Catalogue.

The first phase coincides with the drafting of the three-year training plan that the Administrations must, by law, transfer to SNA.

In the second phase SNA selects topics and projects considered as priorities and autonomously designs the Catalogue that contains the annual offer of the training courses.

In the third phase the Administrations, on the basis of the survey of their training needs request for their employees participation to the single courses allowing SNA to define the classrooms for each course.

At the end of the courses, an evaluation of the training process takes place through the administration of questionnaires to the participants, whose results are aggregated and represented in a four-monthly monitoring report.

In 2018, in parallel with its organizational redesign, SNA decided to systematically address some critical issues that had been identified over the years regarding the effectiveness, efficiency and sustainability of its training planning and evaluation model.

In particular, the following criticalities were found:

- a certain misalignment between the programming times of the administrations and those of the School;
- a worrying de-responsibility of the management of the administrations in the selection of course participants;

- a significant rate of absenteeism from courses with consequent loss of economic resources that cannot be reused for other courses and/or for other (perhaps more motivated) participants.

5.2 The Trainers' CLUB Project

The redesign of rules concerning the definition of training needs for central administrations has led SNA to promote a multi-annual project focusing on developing the capability of both Administrations and SNA to identify training needs and develop a coherent training offer (Cepiku et al., 2014).

SNA launched a project entitled "CLUB of Trainers" aimed at the creation of a "community" composed of the training managers of all Italian central public administrations. SNA, with the development of the project, intended to entrust the community with the objective of analysing and mapping, in a systematic way, problems related to the management of employee training and to propose improvement initiatives. A project team worked for three months with the Presidency of the School to set up the community (the Club) and for the definition of the working methodology to be adopted in the next implementation phase.

The Project Team was composed by the Head of SNA Department "Management and Innovation", the Head of SNA Information Systems, a contact person from SNA Presidency, three external HRM consultants and three tutors.

Starting from the analysis carried out by the Project Team on the main critical issues, the Club was asked to provide:

- shared analysis of the critical factors related to the planning and management processes of the training services;
- proposals for common solutions for all or some clusters of participating administrations.

During the three months of the project's life, the team also worked on the construction of an IT platform dedicated to the future activities of the community. This virtual space was used to manage the activities of community building and to present and discuss the tasks and objectives of the community. In terms of work methodology, SNA promoted bi-monthly collegial meetings at the School's headquarters and included in the community a contact person for the Presidency, two training experts appointed by the School and a contact person for SNA information systems.

The Project Team also proposed to the Club a section of themes, graphically represented in Figure 1, to be developed in the analysis of the problems and in the elaboration of guidelines or problem solutions.

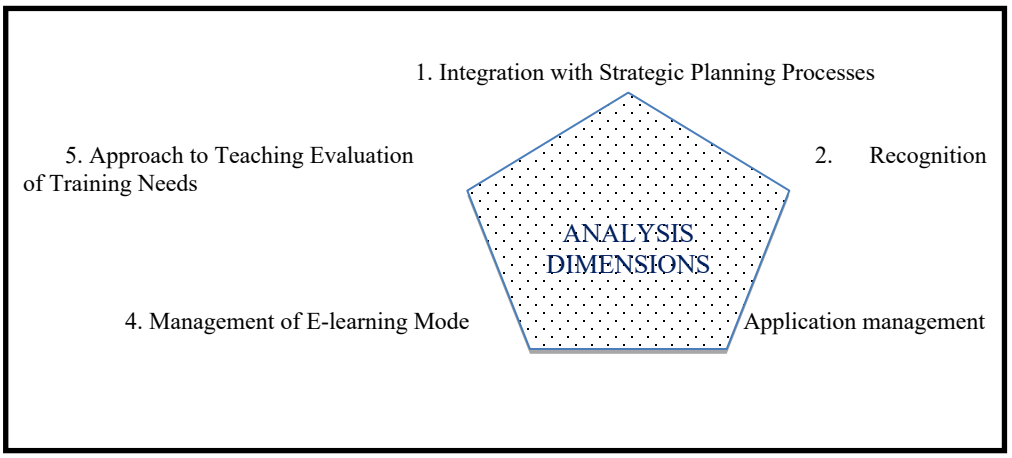

Figure 1 - The analysis model developed by the project team

The Community worked autonomously during the following two years, benefiting from the support of some members of the initial Project Team. SNA has issued invitations to participate to the community to all the HR Directorates of the administrations, specifying the usefulness of involving the subjects who were more directly involved in the management of the training processes.

In the maturity phase, 30 administrations (Ministries and Agencies) participated in the Club. The subjects participating in the Club were managers of complex units entrusted with the direct management of training.

The participants had very heterogeneous personal, professional and experience profiles: the administrations of origin were very different, in terms of the size, the presence of peripheral operational offices, the size of the team of professionals dedicated to training and the hierarchical position of the training office they coordinated. Public administrations involved in the "Trainers' Club" are listed in Table 1.

Table 1 - The public administrations involved in the "Trainers' Club"

1	Ministero dell'Economia e delle Finanze	21	Agenzia italiana del farmaco
2	Ministero dell'Interno	22	Agenzia Nazionale per le Politiche Attive del Lavoro
3	Ministero dell'Istruzione dell'Università e della Ricerca	23	ICE - Agenzia per la promozione all'estero e l'internazionalizzazione delle imprese italiane
4	Ministero della Giustizia	24	Agenzia delle Entrate
5	Ministero del Lavoro e Politiche sociali	25	Consiglio Nazionale dell'Economia e del Lavoro
6	Ministero della salute	26	Garante per la protezione dei dati personali
7	Ministero dell'Ambiente e tutela del Territorio e del mare	27	Agenzia Nazionale per la Valutazione del sistema Universitario e della Ricerca
8	Ministero degli affari Esteri e cooperazione internazionale	28	Ispettorato nazionale del lavoro
9	Ministero delle Infrastrutture e dei Trasporti	29	Istituto Nazionale Assicurazione Infortuni sul Lavoro

10	Ministero per i Beni e le Attività Culturali e Turismo	30	Agenzia nazionale per le nuove tecnologie, l'energia e lo sviluppo economico sostenibile
11	Ministero dello Sviluppo Economico	31	Istituto Nazionale della Previdenza Sociale
12	Ministero politiche agricole, Alimentari e Forestali	32	Fondazione Scuola dei Beni e delle Attività Culturali
13	Ministero della Difesa	33	Agenzia Nazionale per i Servizi Sanitari Regionali
14	Presidenza del Consiglio dei Ministri	34	Agenzia per la Coesione territoriale
15	Avvocatura Generale dello Stato	35	Agenzia italiana per la Cooperazione allo Sviluppo
16	Corte dei conti	36	Agenzia per le Dogane e i Monopoli
17	Banca d'Italia	37	Istituto Superiore per la Protezione e la Ricerca Ambientale
18	Autorità Garante per la Concorrenza e per il Mercato	38	Agenzia per l'Italia Digitale
19	Istituto Poligrafico e Zecca dello Stato	39	Istituto nazionale di STATistica
20	Autorità nazionale anticorruzione	40	Consip

5.3 How the community works

The practice community of the Trainers' Club, during the two years of activity, has met ten times for formal meetings at SNA headquarters and has developed other modes of interaction such as informal and self-managed contacts between participants, in-presence and chat meetings.

Already from the first formal meeting, the CoPs requested to SNA the possibility to modify the assigned objectives and the model of interaction with the School.

Participant observation and interview data reveal roles that communities of practice play in facilitating shared learning across public sector organizations:

1. Opportunity for peer comparisons;
2. Platform to channels for informal communication;
3. Source for shared "know how" and development of best practices.

The following description of the practices adopted by the community develops in relation to these three roles.

Opportunity for peer comparisons

Already at the first meeting the participants asked to be divided into four sub-groups whose composition best reflected the heterogeneity of the administrations represented. Such heterogeneity took shape not only in the size of the organizations (from a minimum of 150 units up to administrations with about 40000 employees), but also in the hierarchical position of the Training Office, the level of contractual classification of the training referents present in the Club, the presence or absence of regional administration structures, and the budget allocated annually for training. The groups met in different rooms of SNA headquarters and spent about three hours getting to know each other and discussing the definition of the basic conditions that would allow the community to operate effectively.

After this first moment of self-analysis within the four sub-groups, during the subsequent collegial discussion, Club participants discussed the role they played within

the Club with respect to the organizational position they held in their administration. Except for a few rare exceptions, participants were not HRM's top managers, but second-tier managers who were actually involved in training management. This was immediately declared a limit to the degree of autonomy with respect to the initiatives that the community would propose, but at the same time it was also considered an essential condition for analysing the problems in a concrete way.

On the basis of this first consideration on the roles of the participants and the diversity of the administrations, the community immediately expressed a request to SNA concerning the assigned objectives: the community would have considered the different organisational models used by the administrations as "configurations" placed along a continuum. Consequently, the Club would have worked to discuss the problems as they presented themselves in the different organizational models, considering specificities and proposing solutions. During an interview conducted by one of the experts of the Project Team at the end of the first formal meeting of the Club, the training contact from AGID (Italian Digital Agency, one of the public administrations involved in the community) declared: "*We are very interested in the Club's experience; it is the first time that people operationally involved in the training processes of my administration are called by the School to contribute to organizational development, as "experienced" and "informed of the facts".... but the only way to be really effective is for colleagues in the larger administrations to strive to develop a common vision of the problems, working on solutions that can be applied, even in a modular way, to all of us!".*

In the course of the sub-groups' work, a participant from another public organization (Ministry of Infrastructures) asked colleagues: *"For some of us from administrations who do not invest adequately in employee training and who do not have an organizational culture sensitive to this issue, being here could mean exposing ourselves to very discouraging comparisons... but if we are all willing to listen and work on proposals that can be practiced flexibly and with the support of the School, then I will gladly make my professional contribution".*

It was also common to see participants exchange business cards, phone numbers, and e-mail addresses and make plans to connect in the weeks after the meeting.

Platform to channels for informal communication

CoP members communicated and shared knowledge either via face-to-face OR person-to-person interactions or virtual ones.

From the earliest stages of the community life cycle, participants took advantage of the opportunity to make informal contact with each other. In many cases, the administrations to which the club participants belonged had already worked together in carrying out functions, providing services or implementing organizational development projects. However, these experiences had not allowed the establishment of stable collaborative relationships between managers and officials in the same sector. In previous occasions of cooperation between administrations, a hierarchical-institutional approach had prevailed,

whereby the structures interacted mainly in a formal way through communications and structured meetings between top managers.

The collection, analysis, and presentation of pre-meeting data able to trigger the discussions is highlighted as a valuable part of the meeting by participants. In the Club, on the other hand, a dense network of informal relationships was immediately established, facilitated by the possibility of direct and personal contacts between managers who shared similar issues.

In addition to the more structured conversations in the chat dedicated to the Club's activities, there were numerous examples of direct contacts and comparisons between individuals and sub-groups to exchange detailed information on a problem or examples of procedures and tools in use in their organizations for planning and managing training processes.

The familiarity among the participants, the recurring stories of individual experiences and the progressive building of relationships of esteem and trust stimulated the sharing of practices.

"*In a short time we were able to perceive a sense of community ... Having the possibility to contact directly and informally colleagues from other administrations was useful to deal in depth with the analysis of common problems and to suggest possible ways out"* - said one of the participants - "*Getting to know each other without interference has created the conditions to stimulate a form of mutual knowledge between professionals; this will certainly be useful in many other collaboration initiatives. Moreover, my feeling is that the sense of loneliness typical of our professionalism has been filled! For example, it seemed to me very useful to be able to talk to the Agenzia delle Entrate's manager [Agenzia delle Entrate is the Italian Tax Agency, one of the administrations involved] when we had to launch for the first time an e-learning training intervention on security issues. The Agency has a very important experience in this kind of initiatives and in the Club, the manager gave detailed testimonials and made available very clear materials to understand the steps of the design process of those courses*".

Evidence of inter-organizational exchange is seen during both structured and unstructured exchanges, but particularly in the informal interactions during meetings. Participants were in contact prior to, during, and after the meeting to connect on issues that they have in common or find out more details on what a community is doing in response to a particular challenge. When asked about the biggest benefits from meetings, participants responded with, "*the mixture of various experience together in one room. An honest and good exchange among participants*".

Source for shared "know how" and development of best practices

During meetings, participants from different public administration stood up and explained to the group why they had done so well or so poorly on specific issues. The discussion together with the sharing of anecdotes, informal comparisons, and confidentiality allowed participants to get ideas and brainstorm with each other.

One of the issues on the Club's agenda was the quality of strategic planning of training policies. Through discussion, the participants in the first meetings identified the critical factors that adversely affect the training performance achieved. In particular, the issue of the time lag between the strategic planning processes of the administrations and its effects on the management of relations between the administrations and SNA in the definition of the annual plan of educational activities was debated. The delays in the delivery to the School of the Training Plans by the Administrations and the strong variety of the methods with which they arrived at the definition of their training needs and at the formulation of the intervention requests of SNA had a strong impact on the capacity of the School to receive all the requests in the best way and to harmonise them in a balanced didactic Plan. In addition, the uncertainty produced by the delays and the differences in behaviour in formulating the training needs generated a high rate of abandonment or non-participation of the employees or evaluations of inadequacy of the courses with respect to the expectations of departure.

Therefore, several Club meetings were dedicated to the analysis of these topics, and to understand the factors that had slowed down or made those processes uncertain. Issues such as lack of connection between internal processes of the individual administrations and the ineffective link between the Administrations and the School were found reliant on countless operational and behavioural factors.

The community compared methods and tools used by the single Administrations to manage the connection between the Strategic Plan of the Minister and the annual Training Plan, and generated proposals that radically modified the process with which SNA manages the requests of the Administrations and composes the annual Catalogue of the courses offered.

A process reengineering intervention that engaged the Club for about six months was established:

- that the School would carry out preliminary activities of listening to the needs of skills by supporting the training referents in the interpretation of the Minister's Strategic Plans. The Club has dedicated two specific workshops to this activity in order to define the tool for the needs assessment;
- that the School would present its training offer six months in advance, trying in this way to direct the planning activities of the Administrations with greater clarity and certainty of time;
- that all the administrations would have adopted the same instrument for the representation of training needs and communication with SNA (the Annual Training Plan), whose characteristics have been defined by the community itself.

After two years of implementation of these changes, the rate of absenteeism of the participants, measured with specific quality indicators, also designed and tested in the Club, showed ample room for improvement, allowing SNA to recover economic resources and increase the number of courses provided.

From this point of view, a salient benefit of the CoP is to bridge formal and informal organizational boundaries in order to increase the collective knowledge, skills, and reciprocity of practitioners who serve in these organizations, as issues are inherently boundary-crossing (Snyder et al., 2004).

6 Discussion and conclusions

6.1 Managerial issues

The study reveals the organizational models, behaviours, and practices embedded in community that offer public managers a gateway to informal communication, build community through communication within and across groups, provide access to shared "know how", and encourage peer comparisons.

Mutual engagement between community members helped provide advice, solutions and acquisition of a collective learning process. The sense of community led to a common perspective of knowledge as a shared good, owned and maintained by the community. The possibility to discuss in depth, among experts and in a recurring and structured way, operational aspects related to the management of the training services provided by SNA, has allowed the creation of a common knowledge base on the strategic choices made by the public administrations, on the methodological options proposed by SNA, on the nature and dimensions of the sources of financing of the training activities promoted by the government for the training of the public senior management. In some cases, such as the definition of a methodology for the design of courses in e-learning, the pooling of experiences and best practices by some "more experienced" participants was the starting point to start up paths for the design of tools that up to that point had seemed very difficult to the administrations.

The CoP also had significant effects in terms of increasing the legitimacy of the actors involved in the system of institutional relations between public bodies.

With regard to legitimisation from organisations, Corso et al. (2009) argue that, if CoPs want to be recognised by the organization, they should demonstrate themselves to be active entities with their own structures. In line with this view, we showed that the participants, although not the top managers of HRM in their administrations, have acquired legitimacy and strength to propose changes, thanks to the legitimacy in the CoP of their professional profile and specific skills. The mutual recognition of that profile and the "institutional" support guaranteed by SNA contributed to increase the legitimacy of those subjects who held the effective governance of the training processes. Moreover, the results achieved by the CoP have also contributed to improve the image and reputation of SNA in the administrations, raising also its legitimacy profile as process owner of the national programming of the training policies in the public sector.

The experience of the CoP has had a direct implication in accelerating the digitisation process, both in terms of programming and training delivery processes. The IT platform

made available to CoP by SNA and dedicated to the collection of applications, the management of courses and the evaluation of activities, has contributed to a more significant orientation towards the computerization of work processes and communication flows between SNA and public administrations.

From the point of view of managerial implications, the case study shows how much the CoP has been a leverage for the participatory design of the training processes of senior public management.

The CoP was conceived by SNA, as said, to address some critical issues that had a negative impact on its performance.

The solutions developed within the CoP concerned:

- the temporal misalignment between the processes of planning and delivery of the training: the reengineering of the processes elaborated by the CoP introduced a phase of "listening" of the training needs of the different administrations and the standardisation of the process of elaboration of the Catalogue of the training offer, characterised by certain times and contents;
- the homogeneity of the profiles in the composition of the classes: the CoP has elaborated criteria and tools for the definition of standard training courses for specific managerial figures (Project manager, Security Manager, Manager of the economic-financial area, etc.). This has made it possible to inaugurate a phase in which, on the one hand, the individual administrations continue to carry out autonomously the survey of training needs and the identification of participants in individual courses, and on the other hand they contribute to composing classes with more homogeneous profiles, with positive effects on the climate and the quality of teaching;
- the communication flows between SNA and the administrations: the CoP has elaborated a single Template for the definition of the three-year training plan that the administrations have the obligation to transmit to SNA. The administrations, moreover, following the accurate discussions conducted in the Club on the theme of mutual interdependencies in the course planning process, have radically changed their behaviour, starting to respect the new deadlines regularly;
- the organization and control of the teaching activities: the CoP has outlined the new responsibilities of the "Training Referent", decentralizing part of the tasks of didactic organization to the administrations. The Referent, in fact, by definitively and formally codifying the list of participants in the individual courses, has become the person in charge of the training requests coming from the internal structures of the administrations and the person in charge of reconciling the different pressures exerted by the managers.

The innovations introduced have, among other things, led to a clear reduction in the absenteeism rate of course participants and to an increase in the number of hours of teaching and courses held during CoP's two years of activity.

6.2 Theoretical issues

The paper focuses on CoP in the public sector as a lever for the development of learning processes and organizational change. While existing literature suggests implementing CoPs as a tool for fostering knowledge sharing and learning process (Jeon et al., 2011; Zboralski, 2009), these topics have rarely been analysed in the public sector. From this point of view, our empirical study could contribute to the theoretical knowledge on the relationship between CoP and learning processes in the public sector, which has been neglected in knowledge management research.

In particular, the case analysed allows an in-depth examination of the role that CoP can play as part of process management models and training policies in support of broader strategic approaches to change in public administration.

The case study shows, in fact, how the use of the CoP as a tool to support the re-design of training service management processes, by the main Italian governmental training agency (SNA), appears effective with respect to the change needs of a heterogeneous set of public administrations.

In order to overcome the significant critical issues in the management of resources (financial and human) allocated for the training of senior public managers, the School set up a permanent working group, still active at the time the paper was drafted, which developed working methods typical of a CoP and proposed organizational solutions that have significantly improved the performance of the School in the design and delivery of training processes.

The changes proposed (and implemented) thanks to the interaction between the administrations participating in the CoP with the support of SNA project team, concerned both operational aspects related to the processes of organization and management of the School's training services, and the more general model of managing relationships between SNA and the administrations.

The case study shows how the CoP can support, also in the public sector, processes of collective learning and organizational change thanks to the enrichment of communication flows between participants, the transfer of specialist knowledge, the development of common languages useful for the interpretation of problems and the strengthening of professional identities.

Finally, the case makes clear that the CoP can contribute to a greater decentralization of the models of interaction between public actors, without affecting the institutional logic underlying the relationships between different administrations, and can thus undermine more formal and bureaucratic approaches to the management of key HRM processes.

Abstract

Service literature suggests that identifying the motivations of tourists is fundamental (e.g., Woosnam et al., 2016; Pomfret & Bramwell, 2016) to be able to adapt marketing strategies according to the different users' needs. However, today digital technologies and more generally service innovations have profoundly changed the decision-making of the tourists photographers. Some contributions (Lo *et al.,* 2011; Ozansoy Çardici *et al*., 2019) agree that the motivation that drives users to take photos is no longer linked just to memory but to the communication of personal identity, especially for the new generations. These changes depend on the use of digital tools such as the introduction of mobile with camera, social networks, and AI. Indeed, Huyn *et al* (2009) conceptualized the tourism in the mobile context, recognizing the use of mobile to search travel information through photo of other visitors; then, Prideaux & Coghlan (2010) investigated the photographic habits, using mobile phones or cameras as a tool of memory.

Several recent contributions (Munar & Jacobsen, 2014; Kozinets, 2017; Trinanda & Sari, 2019) focus on the evolution of tourist's motivation photo due to the development of social networks. Indeed, Munar & Jacobsen (2014) examined the reasons that drive tourists to share their photos on social networks, showing that the findings provide insights into motivational factors such as personal and community-related benefits, as well as social capital that influences the sharing of user-generated content. Besides, according to Kozinets (2017) the visitor became part of art domain with the selfie, not only for narcissistic reasons, as exposed by Fox and Rooney (2015), Sorokowski et al. (2015), and Lee and Sung (2016), but to express aspects of themselves through the art.

Findings show that AI is actually a tool able to influence and add new motivations for tourist photographer: in particular, AI improve the game and curiosity motivations, with the consequent rise of a different and new interaction with art. Future research could use a customer survey (Hulland *et al.,* 2018) to better understand which features of AI are the most appreciated by tourist photographers.

The purpose of the research is to verify, through a content analysis, what emerged in the literature on the first two steps of the tourist photographer motivations. Furthermore, after investigating through the observation, the theoretical framework, we will proceed to define a theoretical framework inherent in the emerging phenomenon of AI implementation also in tourism which at the moment is little treated in managerial literature.

1 Introduction

Susan Sontag has noted: [Photography's] main effect is to convert the world into a department store ora museum-without-walls in which every subject is depreciated into an article of consumption, promoted into an item for aesthetic appreciation (1977, p.110). Photography has always been linked to the world of tourism; on the other hand, who would imagine a trip without photos?

Most of the literature on service (Woosnam et al., 2016; Pomfret & Bramwell, 2016) focuses on the motivations that drive tourists to photograph, considering this fundamental action to be able to adapt marketing strategies according to the different users' needs .

However, today digital technologies have had a significant impact on the motivation of tourist photographers and on photography that has become more 'social': some scholars agree that the motivation that drives users to take photos is no longer linked just to memory but to present an image of themselves 'ideal', (Lo et al., 2011; Stylianou-Lambert, 2012; Ozansoy Çardici et al., 2019).

According to one of the recent contributions in the field, Carbon (2017) stated selfies "reveal something about the creator in particular, but also something about humans in general", in the same vein Larsen and Sanbye (2014) had wondered if selfies are public projection of imagine/idea of ourselves, or better, the desirable image to share within the network, but, depending on the field of research, the literature provides numerous other definitions for 'selfie' (Hess, 2015; Senft & Baym, 2015).

However, unlike mobile e social network, the impact of AI on the motivations of tourist photographer is still poorly addressed. The present study addresses this gap in the literature, exploring the evolution of tourist's motivation to take a photo with the advent of AI through a qualitative research, due to the newness of the topic (Lee, 1999). In particular, we analyze a single case study to develop the conceptual framework of the relationship between evolution of new technologies and tourist's motivations. Indeed, we have chosen an exploratory case study, Google ArtSelfie, and we connected it to the three technologies examined respectively: mobile with camera, social networks and their connections, and finally, Artificial Intelligence.

Then, we carried out a qualitative cluster analysis with concrete examples through quotes on the social network sites – as proposed by Croidieu et al. (2016) – to favour a more complete understanding of the ongoing changes. Data selection was made jointly by all three authors (Silver and Lewins, 2014) to decrease subjectivity (Krippendorff, 2013), and to give more reliability to both dataset and results.

The paper develops as follows. The next section offers a review of tourism motivation and tourism motivation photo. Then, an overview of tourism motivation photo in digital era. The remainder of the paper describes the research process, leading to an analysis of a single case study, Google ArtSelfie.. The conclusions offer insights into how evolution of technologies and, above of all, AI affect the tourism motivation photo.

2 Tourism motivation

According to Crompton (1979), most of the discussions about tourism-motivation tend to revolve around the concepts of `` pull '' and `` push ''. The first motives are used to explain the choice of destination; the second ones are useful for explaining the desire to go on vacation. In general, motivation arises when an individual needs to satisfy a need. According to the theories of motivations (Herzberg et al., 1959; Maslow, 1970; Lunenburg, 2011), the presence of a goal is necessary so that individuals can be motivated to satisfy a need; moreover, they must perceive the purchase of a product or service as a positive effect on the satisfaction of that specific need. In this perspective, the role of the marketing process is fundamental to satisfy needs of users (Mill & Morrison, 1985).

In this regard, tourism managers should know the implications of their marketing strategies on the target audience, in order to better determine the success of the marketing policies adopted (Goossens, 2000).

The recognition of tourist motivation is the basis for the development of the offer and the competitiveness of tourist promotions. In particular, in a highly competitive market such as tourism where the heterogeneity of tourism products is increasingly high, it is essential to understand in depth the driver of the motivation of tourists.In the studies on tourist behavior (Heitmann, 2011), in addition to the demographic and social structure of tourist, the most relevant question is 'why people travel?'. To answer this question, several scholars (Plog, 1974; Crompton, 1979; Dann,1981; Mannel & Iso-Ahola, 1987; Pearce, 1988; Plog, 2001) have proposed different classifications of the factors that influence the travel decision (Figure 1).

Table 1. Tourism motivation-based on literature

Authors	**Tourism motivation**
Dann, G.M.S., Tourist Motivation: An Appraisal, 1981, *Annals of Tourism Research*, vol.3 no.2, page 187 – 219.	Dann proposed seven approach: ● Travel as a response to what is lacking yet desired; ● Destination 'pull' in a response to motivational

	'push'; ● motivation as fantasy; ● motivation as classified purpose; ● motivational typologies; ● motivation and tourist experiences; ● motivation as auto-definition and meaning.
Crompton, J. L. (1979). Motivations for pleasure vacation. *Annals of tourism research*, *6*(4), 408-424.	Crompton distinguishes 7 socio-psychological motives: ● escape from a perceived mundane environment, ● exploration and evaluation of self, relaxation, ● prestige, ● regression, ● enhancement of kinship relationships and facilitation of social interaction; ● and 2 cultural motives: novelty and education.
Mannell, R.C. & Iso-Ahola, S. 1987. The Psychological Nature of Leisure and Tourism Experience. *Annals of Tourism Research.* Vol. 14, 314-331.	Mannell & Iso-Ahola proposed two dimensional tourism motivation model: approach (seeking) and avoidance (escape). They suggest that people are motivated to travel to: ● Escaping personal environment ● Escaping interpersonal environments ● Seeking personal rewards (self-determination, a sense of competence or mastery,challenge, learning, exploration and relaxation. ● Seeking interpersonal rewards (social interaction)
Plog, S.C. (1974), "Why destination areas rise and fall in popularity". *Cornell Hotel and Restaurant Administration Quarterly*, Vol. 14 No. 4, pp. 55-58. Plog, S.C. (2001), "Why destination areas rise and fall in popularity: an update of a Cornell quarterly classic. *Cornell", Hotel and Restaurant Administration Quarterly*, Vol. 42 No. 3, pp. 13-24.	According to Plog, tourists may be classified along two dimensions: ● allocentrism/psychocentrism, who seek adventure and the experiences of new cultural and environmental challenges ● energy, which describes the level of activity desire by tourist
Pearce, P. (1988), The Ulysses Factor: Evaluating Visitors in Tourist Settings, Springer-Verlag: New York, NY.	Pearce developed the TCL model: it demonstrates how tourists can change their motivations over time; motivation levels are influenced by past experiences. This model has strengths in terms of considering dynamic factors influenced by experiences obtained from career history.

Therefore, the variety of models and factors adopted and discussed by scholars show that there is no single criterion that can generalize all types of tourists to fully understand their destination choice.In particular, in this article we focus on a particular type of tourist and aspect of his motivation to travel: tourist photographer.

2.1 Tourism motivation photo in pre-digital era

Photography has always been an important tool for historical documentation and memory preservation; capable of immortalizing a moment, making it tangible (Stylianou-Lambert, 2017).

The ability of photography to organize the world as an exhibition is underlined by Sontag:

[Photography's] main effect is to convert the world into a department store ora museum-without-walls in which every subject is depreciated into an article of consumption, promoted into an item for aesthetic appreciation (1977, p.110)

Photography has for long been tied to tourism and travel activities. It seems impossible to imagine traveling without taking photos.

Many scholars have reflected on the fundamental role of photography in the tourism sector (Cohen et al., 1992; Hillman, 2007; Scarles, 2012; Höckert et al., 2018). Travelers entering a new environment are attentive to local life and other objects and try to capture in their photos those characteristics of local life that are most affected (Cohen et al., 1992); sometimes oblivious to the rules or restrictions required by law (Chalfen, 1979).

Susan Sontag (1973) supported that the tourist's compulsion to take snapshots of foreign places reveals how taking photos can become essential to live an event; at the same time, to communicate experiences with the help of tourist photographs.

According to Sontag (1977), tourists use photography as a tool to appropriate the place they are visiting temporarily; almost as if they wanted to appease the fear of being in an unknown situation.

Tourists build their travel memories through photographs; they are considered as directors of theatrical performances in which the places and destinations photographed are the stage and the traveling companions or the local elements are the actors (Edensor, 2000).

However, the question that scholars have asked is 'why and what is the tourist eye attracted to? (Figure 2).

Urry (1990) initiated the literature on this topic in 1990: he states that when we go away and become tourists, "we look at the environment…we gaze at what we encounter…and the gaze is socially constructed" (p. 1). With the notion 'tourist gaze', Urry argues that the tourist gaze identifies what is out of the ordinary and what is other. According to Urry, individuals travel to the same, specific shot that they saw in a brochure or on a postcard in order to take the same pictures. For the study of the circulation of objects and cameras it reflects the hegemony of vision in modern tourism (Urry, 2002). Following Urry's thought, Cohen et al. (1992) shifted attention from the tourist gaze to the interactions between photographers and locals. Scholars believe that "outsiders" enter a new environment as momentary visitors find themselves in an ambiguous situation that has an impact on their motivation. Everything that leads them to look for photos of this unknown environment for which they are most affected. According to Garlick (2002), photographs are not only constructed for representation to those who did not travel but

also for the tourist himself or herself who may be convinced by the pictures that the holiday was better than it actually was. Later, Schroeder (2002) declares that the superficiality of tourist experiences brings a banal photograph and that the camera is only a barrier to obtaining an authentic and pure experience. In contrast, Gillet et al. (2016) connected travel photography and a process by which tourists must create original and creative images that have meaning for themselves. In their study, Gillet et al. (2016) found that some tourists felt almost obliged to take photos and that there is a positive connection between photography and the happiness of tourists. According to Chalfen (1979), tourist photography contains two general types of photographic images: first, photographs taken by tourists and, second photographs created for tourists by members of a host community. In both cases, Chalfen (1979) states that the tourist is not free in the act of photographing different destination.

Table 2. Tourist motivation photo-based on literature

Gillet, S., Schmitz, P., & Mitas, O. (2016). The snap-happy tourist: The effects of photographing behavior on tourists' happiness. *Journal of Hospitality & Tourism Research*, *40*(1), 1-21.	*We also found evidence of positive relationships between the frequency of photographing on holiday and life satisfaction as well as between the importance of photographing and positive emotions. It can be concluded that a combination of taking many pictures and finding this activity important contribute, respectively, to positive emotions and life satisfaction, two substantive components of happiness. Accordingly, our evidence suggests that photographing on holiday does make people happier.(p.18)*
Garlick, S. (2002). Revealing the unseen: Tourism and photography. *Cultural Studies*, 16, 289-305	*tourists can perhaps promote a new way of seeing, one in which we draw nearer to what remains unseen in the photographic images that dominate our lives today (p.303).*
Sontag, S. (1977) *On Photography*. London: Penguin Books	Tourists use photography as a tool to appropriate the place they are visiting temporarily; almost as if they wanted to appease the fear of being in an unknown situation. *to photograph is to appropriate the thing photographed. . . . It means putting oneself into a certain relation to the world that feels like knowledge – and, therefore, like power (p.4)*

Garrod, B. (2009). Understanding the relationship between tourism destination imagery and tourist photography. *Journal of Travel Research*, 47(3), 346–358.	*the fundamental motivation of tourists traveling to a destination, is to gaze on the panoramas, landscapes, buildings, people, and other manifestations of place they have been led to expect to find there through exposure to visual representations carried in tourism advertisements, television broadcasts, movies, brochures, travel books, and picture postcards* (p.347).

Recent contributions (e.g. Höckert *et al*., 2018; Mostafanezhad and Norum, 2018) shift the attention towards selfie-taking as a new way of looking at tourism. Scholars argue that the 'tourist gaze' has been turned towards ourselves, reaching a new level of self-centeredness in which the 'tourist self' plays a leading role in most of the holiday photos.The development of digital technologies and the explosion of social networks has stimulated this change in the tourist gaze and has impacted on the motivation of the tourist photographer (Nikjoo & Bakhshi,2019) as shown below.

3 Tourism motivation photo in digital era

Photography no longer seems to be a tool used to keep memories but it is increasingly becoming a tool for communicating the identity of the individual. Digital cameras, mobile, photo blogs and other devices have become tools for a new generation of users (Van Dijck, 2008). The act of photographing has become more 'social': sharing one's travel experiences contributes to providing added value to these tourist experiences making them particularly significant (Wang et al. 2012). Through photography, tourists intend to present an "ideal" image of themselves (Stylianou-Lambert, 2012). According to Trinanda & Sari (2019), in the tourist context, selfies are the consequence of technological developments: when the cameras were still in celluloid, tourists took a limited number of photos and moments are expected; now with smartphones and huge digital memory it is possible to take an almost unlimited number of photos. Selfie tourism is a new way of looking at tourism: the camera has become an extension of oneself. Bugeja *et al.* (2018) agree that:

> *"portraits and self-photography is conceptually not new, but, new technology has enabled the ease of capturing photos in larger quantities. Rather it acts as a mirror at which tourists look to take their pictures prior to, as well as when they are taking photos. Tourists are thus not looking through the screen at the destination, but at the screen to see themselves (p.114)".*

So now it has gotten higher on "Look, I'm here!" rather than "This place is beautiful". Below we show the evolution of photography and the corresponding impact on the motivation of the tourist photographer.

3.1 Mobile phone to search information and record memory

Smartphones, advanced mobile phones with software applications play an important role in people's lives and this evolution has opened up and innumerable possibilities in different industry.

Most of the literature (Xiang *et al.*, 2015; Dinhop & Gretze, 2015; Wang *et al.,* 2016; Petrescu & Bran, 2020) links the use of smartphones to the tourist experience and how these new tools influence the travel experience that has become highly 'mobile'. According to Xiang et al. (2015) we have seen two phases of the implementation of the Internet in the tourism industry: the first (1990-2002) in which the Internet has been adopted by the whole sector and the second (2001 to date) in which the attention has been moved from the website to mobile systems (which incorporate the Internet, communication technologies, GPS and photography) which have transformed the tourism sector even more and impacted on consumer behavior. Anja Dinhopl (2015) agree that we are witnessing a moment in the transition of photography, one of the main practices of the tourist context: in particular, the social practices and technological tools that users use to photograph are changing. The results of these changes can be summarized as follows:

1. connectivity and immediate sharing (Dinhopl, 2015);
2. interest of the digital screen that invites socializing and playful shooting (Haldrup and Larsen 2009);
3. the boundaries between everyday life and holidays are blurred (Wang *et al*. 2016).

Globally, the number of smartphone users estimated for 2020 is 2.87 billion (Statista, 2019) and over half of the world's web traffic is now achieved via mobile phones. All this shows how the use of these devices has enormous influence both on the supply and on the tourist demand.

Smartphones manage to guarantee the iteration between the physical and the virtual world and this is particularly important for tourists who in this way can get in touch with the environments they visit at all stages of their journey.

Today smartphones and tablets have GPS systems through which it is possible to store information (e.g. latitude and longitude) of each photo taken by a user. The motivation of tourists to record photos with their mobile phone is also driven by the possibilities offered by some online services (eg Flickr.com) that allow one to share and upload photographs with precise geographical data. The use of the mobile phone offers tourists what Urry has called "imaginative mobility" (2000). So people photographed to photograph what they 'consumed' already in the form of an image: "*Mobile reproductions are more important than life itself (Larsen, 2006, p.249).*

Therefore, smartphones and mobile devices are used for different reasons during the tourist experience. However, a large part of the literature (Wang & Fesenmaier, 2013; Wang *et al.,* 2016) shows that the main uses concern the search for information on the places you intend to visit, as a facilitating tool for planning travel and user travel. A second use concerns photography: tourists have developed routines and habits that carry

on the travel experience. For these reasons, they use the smartphone to take photos in order to keep travel memories and, subsequently, share the images on their social networks because it is now a consolidated habit in daily life and is a way to occupy periods of inactivity of the journey itself (Wang *et al*., 2016).

3.2 Social network to sharing experience

Since the advent of social networks, the increasing propensity of tourists to share content that previously was limited to restricted circles of friends has emerged.

According to McKercher (2016), at least 500 million photographs shared via social networks every day, while already twelve years ago, in a work by De Bruyne, Instagram reached no less than 100 million shared media volumes, 349 million instagram posts with hashtag #selfie are posted on Instagram in 2016 (Wang 2017).

Therefore, Lambert (2012) agree that one of the reasons that push tourists to photograph themselves in the places they visit and publish them on social media, is to demonstrate that they have actually been there. According to Suonpaa (2008) this demonstration of presence ends up becoming a game thanks to the bi-dimensionality of the photographs thanks to the combinations of lights, shadows and perspectives. Again Lambert, in a previous work (2010), recognizes how tourists play with the prospects by simulating climbing the Eiffel tower or straightening the tower of Pisa or kissing the Rock of Aphrodite in Cyprus.

In a 2008 study by Vazire *et al*., it is observed that the publication of travel photos, intended as a comparison with others and in need of self-affirmation and attention, is peculiar to narcissistic individuals who seek a comparison from top to bottom. Being more specific, two different types of comparison are observed: the narcissistic one of "I am better than you" and the envious one of "you are not better than me".

The "envious" approach is generally associated with the massive use of social networks (Krasnova, Wenninger, Widjaja, & Buxmann, 2013), however other authors associate the habit of publishing selfies on social networks with narcissistic visions of self-celebration, (Buffardi & Campbell, 2008; Mehdizadeh, 2010), promoting projections of themselves outside (Fox, Bacile, Nakhata, & Weible, 2018; Lee & Sung, 2016).

The growing importance of the world relating to social networks, as demonstrated by Sigala (2018), allows us to affirm that the real success of a trip does not depend only on experience, but rather on the positive comments and "likes" obtained on the diaries of travel published on social networks. In fact, as in Kozinetz (2010) it is highlighted that one of the main attractions of sharing photographic contents on social networks is the immediacy of publication and related comments and feedbacks.

Based on Wang's work, a subsequent elaborate by Munar et Jacobsen (2013) demonstrates how in the case of tourist photographers the sharing of the travel experience takes place through audio-video content, mainly from photographs, which can be considered the new postcards.

In addition to the evident narcissistic-envy reason, there is an additional motivation for sharing through their social networks their own travel photographs: selflessly supporting others in the pre-trip experience and in its planning. (Von Hippel, 2005; Baym, 2010).

However, in a subsequent Qu and Lee study in 2011, the mainly narcissistic purpose of sharing is confirmed as support for other people is also seen as a moment of self-affirmation. Not surprisingly, by suggesting and reviewing their trip, the tourist considers himself/herself useful and his/her opinion relevant to the choices of others. Finally, to definitively sanction how the sharing of photos online is mainly animated by narcissism, in some studies it is observed that both the photographic profiles, and specific applications for mobile phones, allow to manipulate, even deeply, the photos taken before they are posted online, in order to reach as many positive comments as possible (Toma & Hancock, 2010; Fox & Rooney, 2015).

Based on previous literature, mobile and social networks seem to provide only a partial explanation of the impact on the motivation of the tourist photographer. In light of new technological developments, further efforts are needed to understand how technological evolution and in particular the advent of Artificial Intelligence has had an impact on the motivation that drives tourists to photograph. In this regards, we elaborate a theoretical framework for investigation: in particular, we have identified six blocks in the literature which represent the motivations of tourists to photograph (Figure 1).

Figure 1. The framework for investigation-building blocks of tourism motivation photo based on the literature.

4 Research methodology

4.1 Research aim and framework for investigation

Based on the overview of the above literature, we aimed to better understand the evolutionary process of the motivations that push tourists to photograph with the advent of artificial intelligence, and problems to the debate on the motivations of the tourist photographer present in the literature. This exploratory study was developed to provide theoretical and empirical insights.

First, it uses a theoretical framework to investigate the phenomenon. Second, empirically examine the various theoretical hypotheses. In particular, we studied the potential of artificial intelligence as a driver for the development of new motivations that push the tourist to photograph.

We have described the reasons that emerge from the literature in our literature review above. We have decided to use a theoretical model to guide the results to limit the scope of relevant data by focusing on specific variables identified on the basis of the literature (Tavallaei & Talib, 2010). In this way it will be possible to analyze the differences / similarities between the results obtained and the specific categories.

4.2 Research method and data collection

The research adopted a qualitative approach due to the exploratory nature of the investigation (Halinen and Törnroos, 2005). As a research context we have chosen an evidence from the cultural world: ArtSelfie of Google Art Project. It is generally agreed (Yin, 2002) that the case study method is suitable for examining multiple features of a phenomenon and the interrelationships between them. The choice of the research context on this case study is justified because of its being an explanatory case of the evolution of tourists' motivations in the same way as the evolution of technology. Art Selfie is characterized on an artificial vision technology based on machine learning. In particular, it is an initiative that combines the popularity of the self-timer on the mobile phone with the passion for paintings and, to some extent, wants to make art more accessible for everyone. We chose to analyze the Google ArtSelfie Instagram profile. Instagram, as a context of analysis, has already been used in research on tourism (Fatanti & Suyadnya, 2015). Our dataset, consisted of 460 entries posted, counting about 2,000 words.

4.3 Data analysis

A content analysis (Weber, 1990) was conducted for data analysis. In this regard, the TextSTAT software is used, which offers the options we need to update (eg Word Frequency, the use of concordance). The use of this software has already been proposed

by service scholars (e.g., Jani and Hwang, 2011). Data analysis took place following the following two steps:

1) word frequency (articles, prepositions, conjunctions, proper names);
2) concordance analysis to highlight the most frequent and relevant links between words;
3) The coupling of words and examples promoted an understanding of the underlying meanings of the content of the tourist's communication by tracking back single quotes; this third step revealed latent contents (Borkowski *et al.,* 2012).

The information collected has been analyzed in relation to each categories of the theoretical framework and is discussed in connection with the evidence that has emerged.

5 Findings

In the analysis of tourists' comments, one of the most quoted words, which represents an expected result, is app. The term is associated with words that express a sensation / feeling (e.g. cool and love) and with words that express an action (download and playing). Table 3 summarizes the most significant evidence.

Funny 'and' game 'are two more common words in tourist quotes. Both terms are associated with the infinitive verb 'see' as if to underline the fun of observing the use of the app.Furthermore, the agreement between 'funny' and the adjective 'very' highlights the fun and joyful feeling of using the app.

Among the most quoted verbs are the perception verbs 'feel' and 'love''. These verbs express a state rather than an action and are most often associated with the verb 'like' indicating a feeling / desire. Indeed, the verb 'look' associated with 'like' and 'alike' indicates similarity.

Finally, the verb 'try', placed among the ten most quoted words, is associated with the demonstrative adjectives 'that' and 'this', almost as an expression of the spatial relationship between the individual who speaks and an object.

Table 3. Quotes ArtSelfie

Most frequent words	**Concordant word**	**Exemplifying Quotes**
App	Cool Love Download Playing	**"This app is cool"** **"Still love this app"** **"Download app!"** **"Been playing with the Google app that matches your selfie with museum portraits"**
Game	See Changer	**" In addition to this little game to see what painting your selfie looks like, you can review masterpieces in detail and find out about art news"** **"Omg I didn't realize they bypass your face and go straight to your soul. Game changer."**

Funny	Too very See	**“Hahaha is too funny! What !is the name of the app? Will you show it to me?”** **“It is very funny to see how successful the program is, I recommend it a thousand just tried out the Google doppelganger Arts & Culture challenge”**
Feel	Like Good Dapper	**“70% similarity! Feel like a heroine with paintings or a face on a pendant, like me”.** **“Feeling real good about this”** **“How do I feel about this? Feel dapper”**
Look	alike like much	**“Beautiful! we almost look alike”** **“It looks like a person”** **“Ha, looks so much like you! I know that look. Hope you are well.”**
Love	This Photo My	**“I love this early example of Baroukh's transition from classical figuration to more abstract portraiture”.** **“lovely photo”** **“Google Arts & Culture has a artist selfie section, where you can discover your #doppelganger and I think that I loved my two comparisons!!”**
Try	That This	**“i’ll have to try that! Perfect pic btw! Looks just like you and it is a great painting”** **“I have wanted to try this so badly!”.**

6 Discussion/Implications

Findings show how tourist photographers' motivation change with technological evolution. Indeed, technological innovation stimulates the birth of a more 'social' photograph helping to provide added value to tourist experiences (Wang et al. 2012).

The ArtSelfie case offers adequate results as motivations that push tourists to photograph have changed with the advent of new technologies and, above all, of artificial intelligence. Advancing on the results emerged in literature, we show how AI affects the categories of the tourist photographers’ motivation (figure 1).

6.1 Discussion

6.1.1 Record Memory

This category was the main motivation for tourists to take photos. Tourists have captured the magical moments of their holidays to jealousy preserve travel memories or show them to their friends. From the analysis, it would seem that AI has obscured this category in view of "stronger" motivations. We believe it is a 'hidden' motivation: on the other hand it is important to consider that first of all, with the advent of the smartphone and a huge digital memory, amd online storing capacity, it is possible to take photos at any time almost without consideration. Furthermore, we have studied the comments and

reviews present only on Instagram and it is clear that even if it has not been explicitly stated, having potentially preserved the combination that most has impressed them in the gallery of their mobile phone.

6.1.2 Emotion

The 'emotions' category was associated with the motivation of tourists to capture the shots from which they were most affected and attracted. Even today we continue to talk about emotions but in a different way: in particular, the analysis shows that people have feelings of pleasure in seeing their faces compared to the great characters of the time. For these reasons the word 'love' used both as a noun and as a verb of feeling is among the top ten most frequent words of the analysis.

6.1.3 Curiosity

This category contemplated the curiosity of photographing places that tourists had imagined and desired through brochures and travel books. Curiosity is a motivation that still drives tourists to photograph, albeit with a greater focus on 'themselves'. The verb 'try' that is present in the first ten most used words is significant of the propensity of tourists to photograph or better photograph themselves. In the quotes we read the curiosity of tourists to 'try' the application to find out which character their face would have been associated with.

6.1.4 Happiness

The act of photographing contributes to the happiness and satisfaction of the travel of tourists. The words 'game' and 'funny' show the propensity of tourists to photograph for fun. The correlation with the verb 'see' demonstrates the link between the ArtSelfie application and the game and fun emotions of tourists.

6.1.5 Narcissism

This motivation emerged in the literature on the use of social networks in the tourism sector. On the other hand, with the advent of social media, photography has become more 'social' and there is a transition to the era of selfies. In the analysis of the case, the motivation linked to the promotion of oneself and the sharing of one's photos still emerges. In particular, the verb 'look' associated with the verbs 'like' and 'alike' underlines the willingness of tourists to 'show other social users' which historical character they have been associated with, thus promoting a 'different self'.

6.1.6 Culture, Knowledge

The motivations related to 'culture, knowledge' still drive tourists to photograph today. In particular, the verbs of perception 'feel' and 'love' associated respectively with adjectives like 'good' or 'this / that' show that tourists feel good to see their face associated

with heroines or knights of art history. It is no coincidence that many tourists share their photos by posting a review of their 'doppelganger'. In fact, once the match is found, Google Art Selfie will give you a lot of information on your famous "look-alike", from the author of the portrait to the museum that houses it.

Therefore, applications such as ArtSelfie could be a solution to stimulate not only fun and play but to make art accessible to everyone.

6.2 Implications

Our study contributes to the conceptualization of the motivation of tourist photographers in a highly technological context. The work proves useful to serve research by providing more details of previous scholars on the link between technological evolution and the motivation that drives tourists to take photographs.

As demonstrated by our results, the evolution of technology and especially AI and facial recognition algorithms have had a potential impact on the motivation of photographing tourists.

Our analysis in a practical context can be of help to scholars and professionals who have made great efforts to analyze and understand what are the reasons that drive tourists to take photographs of their journey (Urry, 1992; Schroeder, J. 2002; Gillet *et al.*, 2016). From a theoretical point of view and consistent with the contribution of Vazire et al. (2008), our findings also contribute to opening the debate on the possibility of combining the motivation that drives tourists to take photography and to use social media to share their experiences with the birth of an era characterized by narcissistic individuals who have need self-assertion and attention.

Combining the motivation of tourists with the evolution of technology and in particular AI, also allows to extend the debate on the 'curiosity' that drives users to take photos during their trip (Garrod, 2009). In the same way, we stressed that curiosity is a strong motivation that drives tourists to take photos. However, in addition to the curiosity of photographing unknown places (Garrod, 2009), we show that tourists have a greater focus on 'themselves' and on the propensity to photograph their faces.

So, we are at a time when photography has become more 'social' and users are driven to take photos out of the desire for curiosity to see themselves in a different way or simply for fun. Unlike the previous contributions (Urry, 1992; Wang et al., 2016) in this way it would seem that the main motivation that in the past pushed tourists to photograph - that is to say record memory and search information - no longer exists. Adding to the previous contributions, we emphasize that with the development of technology and especially AI, taking photos has become a daily gesture and in all probability we conclude that the motivation for record memory is still present but “hidden”.

7 Limitation and future research

Some limitations of present study may address the planning of future research. In particular, the choice of content analysis as our methodology leads to some limitations deriving from the difficulty of comparing what the content affirms with what reality reveals. Furthermore, conducting interviews with tourist photographers would be useful to integrate and compare the results and improve the reliability of the study. In terms of the context of analysis, a wider range of evidence from projects of further tourist realities would have been useful to improve the evidence. So new investigations are possible and encouraged.

Abstract

The present research aims at analysing the level of IC disclosure provided by a sample of knowledge-intensive Italian companies through an innovative tool - the web - considered as the most used vehicle to collecting, managing, conveying and sharing BD to investors and other stakeholders. From a methodological point of view, the research adopts a manual content analysis conducted on the websites of a sample of listed Italian companies belonging to the ICT sector. Results show that Italian companies operating in the knowledge-intensive sectors are aware of the importance of providing information on IC to the audience of investors and stakeholders and are exploiting the potential and opportunities offered by the web 2.0 and BD partnership.

Keywords – Intellectual capital; Big Data; Web sites; disclosure; Italian companies.

Paper type – Academic Research Paper

1 Introduction

In recent years, the globalization, the diffusion of the new technologies, the change in consumption processes and the deregulation of many industrial sectors have marked the transition from the industrial economy to the knowledge economy (Lev et al., 2005). In the knowledge economy, intangible resources have acquired greater importance than tangible business models, imposing themselves as key factors for the achievement of competitive advantages sustainable and greater economic-financial performance (Lev et al., 2005; Smriti and Das, 2018). In this scenario, the importance of *Intellectual Capital* (IC) emerged as a set of intangible resources related to knowledge (skills, skills and abilities of employees, databases, routines, reputation, image and relationships established between the company and the ecosystem in which it operates) which allow companies to create value for themselves as well as wealth for the socio-economic environment in which they operate (Dumay and Guthrie, 2017). Given its relevance, reliable and timely information on the IC of companies has become fundamental both for managers to enhance internal decision-making processes and for investors and various stakeholders to refine their company evaluation and, therefore, allocation processes of financial resources. As highlighted by Goebel (2018, p. 2), the IC "plays a key role in corporate communication"; therefore, it becomes necessary for companies to provide all its stakeholders with an adequate flow of information capable of signalling the economic value of IC-related resources as well as their contribution to the creation of value. However, both national and international current accounting systems are inadequate to provide exhaustive information to investors and other stakeholders on the real value of the intangible resources of the companies and the value of the real drivers of the its performance. This has led academics and practitioners to reflect on the opportunity to develop alternative tools to provide more detailed information on IC. In the last twenty years several approaches have been implemented for the measurement and reporting of the IC; however, none of them has become a universal reference (Joshi et al., 2010; Dumay, 2016). Moreover, the introduction of new technologies such as the *Internet of Things (IoT), 3d printing, Cloud computing, Artificial Intelligence, Blockchain* and *Big Data* (BD) has led to a further transformation in the processes of creating value for companies and in business models, leading to decisive changes also in the accounting and reporting practices of information (Dumay and Guthrie, 2017; Al-Htaybat et al., 2019; D'Ippolito et al., 2019). In particular, the BD were received as a tool finally able to overcome the limitations of traditional financial statements by allowing companies to provide more comprehensive information, able to support investors and other stakeholders in understanding and estimating the real economic value of the intangibles

and therefore of the IC (Warren et al., 2015; La Torre et al., 2018). This is particularly useful for companies that can be defined as knowledge-intensive, that is, those in which the role of investments in the management and development of knowledge resources (such as research and development, human resources, knowledge, brands, digital technologies etc.) it is predominant compared to that of physical resources. In fact, these companies tend to report a widely reduced operating value compared to their real economic potential and consequently experience greater difficulties in finding capital and financial resources, given the information asymmetry and the strong uncertainty that is created in the market (Bukh et al., 2005; Oliveira et al., 2006; Sonnier et al., 2009). Some studies on the topic (eg Bozzolan et al., 2003; Oliveira et al., 2006) show that, as a consequence, these companies tend to provide greater voluntary disclosure of the IC to make up for the limitations of traditional financial statements and favour the investor resource allocation process; therefore, it can be assumed that they can represent valid best practices in the field of IC communication (especially via the web, given their core business). The present study intends to contribute to the literature by proposing an analysis of the websites, intended as the main sources of BD, of a sample of 13 listed Italian companies belonging to the Information and Communications Technology (ICT) sectors and therefore considered as best practices in the field of web communication. The ultimate goal is therefore to analyse the level of disclosure on the IC provided by knowledge-intensive Italian companies through the web, considered as the source and the vehicle most used for BD communication. In addition to this paragraph, which represents its introduction, the paper is composed by five paragraphs. The second paragraph is dedicated to a brief review of the literature; paying particular attention to the definition of IC and BD and to the main points of contact between them, as well as to the main studies conducted on IC disclosure. In the third paragraph the methodology used is illustrated, the fourth illustrates and proposes a discussion of the results of the study and the fifth is dedicated to the final considerations.

2 Literature review

2.1 Intellectual Capital e Big Data

Over the past twenty years, numerous scholars (Dumay and Garanina, 2013; Secundo et al., 2017; Ndou et al., 2018) have dedicated their studies to the concept of IC and its main dimensions, proposing different definitions of it. Considering also the value of IC as strategic factor not only for the competitiveness and financial performance of the company but also for the ecosystem of stakeholders in which it operates, the European Commission defines the IC as the "intellectual material, knowledge, experience, intellectual property and information that can be put to use to create value" (Stewart, 1997; European Commission, 2006; Dumay, 2016, p. 169).

The IC company is usually broken down into three traditional capitals (Guthrie and Petty, 2000; Bozzolan et al., 2003): 1) human capital; 2) structural capital and 3) relational capital. *Human capital* is defined as the sum of the skills, knowledge, capabilities, creativity, motivations and attitudes of employees acquired through experience or specific training programs. (Bontis, 2001; Joshi et al., 2010; Smriti and Das, 2018). *Structural capital* represents coded and rooted knowledge within the company in the form of consolidated processes, routines, copyrights, patents, hardware, databases and information systems. It can be considered as the structure that supports the company's human resources in the processes of creating value. (Bontis, 2001). *Relationship capital* represents the company's external IC projection in terms of relationships established with stakeholders such as suppliers, partners, customers, etc. It represents the knowledge that flows from the outside to the inside of the organization and that is transformed into the economic value of the company through the implementation of strategic partnerships and alliances, customer satisfaction and loyalty, the development of an image and a positive reputation on the market and the creation of a strong brand (Bontis, 2001; Joshi et al., 2010).

Therefore, IC must be see not as a static concept but as a set of interconnected capitals which, when properly managed and valued, contribute systemically to the process of creating value, allowing the company to obtain a lasting competitive advantage and – consequently - to obtain economic and financial performances higher to the competition.

In the last few years, the advent of the fourth industrial revolution has led to a progressive digitization of the internal processes for creating the value of companies as well as accounting and reporting of information, envisaging an evolutionary scenario in the communication between companies and stakeholders (Dumay and Guthrie, 2017 ; Al-Htaybat et al., 2019; D'Ippolito et al., 2019). In particular, big data have given new impetus to corporate reporting by designing an innovative context for the sharing of information between company and stakeholders based on the use of *hypertexts, hyperlinks* and multimedia files such as audio and video which have increased interactivity , and the accessibility of information, promoting the timely and instantaneous sharing of financial and non-financial data through digital platforms (Al-Htaybat and von Alberti-Alhtaybat, 2017; Al-Htaybat et al., 2019).

Big data are in fact considered as huge volumes of digital data, which can be found in various sources, which when properly processed can generate structured knowledge and tangible benefits for organizations (Secundo et al., 2017). They possess six fundamental qualities: volume, variety, speed, truthfulness, variability and value that make them a unique tool capable of supporting managers, investors and other external stakeholders in making better estimates of the value of the company, supporting the creation of the value, solve potential problems related to internal processes and improve the reporting processes of financial and non-financial information (Al-Htaybat and von Alberti-Alhtaybat, 2017). The latter aspect is fundamental because it highlights how BD can mark an evolution in corporate reporting by ensuring a multiple and continuous exchange, through different

information sources and platforms, and in various formats, of timely and relevant data (Al-Htaybat et al., 2019). However, in order to be useful, BD need to be adequately refined, treated and managed and above all to be conveyed through dynamic channels suitable for capturing their value (Al-Htaybat and von Alberti-Alhtaybat, 2017) such as the internet and technologies web 2.0 (Al-Htaybat et al., 2019). The web has become the main channel through which companies can collect, manage and share BD through hypertexts and hyperlinks, audio, video and data analytics software, increasing the accessibility, interactivity, timeliness and usability of information and therefore, overcoming the static nature and the delay with which information is transmitted in traditional financial statements (Htaybat and von Alberti-Alhtaybat, 2017).

The big data and web 2.0 connubial, revolutionizing the accounting and reporting practices of companies, has given new life to IC research because BD has been accepted as a new tool capable of providing a satisfactory level of disclosure on IC (La Torre et al. , 2018; Ndou et al., 2018). The big data can be considered as the company's structural capital and therefore as an intangible asset which can improve the value creation process and guarantee a competitive advantage (Secundo et al., 2017). The big data and web 2.0 allow to increase information transparency decreasing the information asymmetry with investors and stakeholders (Secundo et al., 2017); in fact, they allow to overcome the limitations of traditional financial statements by providing better information on the intangibles owned and developed by the company (La Torre et al., 2018).

This especially in the context of knowledge-intensive high-tech companies that make substantial investments in the acquisition and development of intangible resources, which are systematically excluded or undervalued from the financial statements (Bukh et al., 2005). Furthermore, these companies are characterized by a significant level of complexity and management decentralization, by a high rate of renewal of the resources and technologies used and above all by a conspicuous volume of tacit knowledge which constitutes a core element of the IC (Palazzi et al., 2019). Furthermore, knowledge-intensive companies operate in environments characterized by strong competition and high future variability of market conditions which make forecasting analyses of economic results very complex (Bozzolan et al., 2003). In these companies the BD represent an important input and output of their production processes as well as a key element of their IC; hence, knowledge-intensive companies can be considered best practices in the use of BD both in support of management processes and in support of external communication processes.

2.2 Prior research on IC disclosure

IC research has evolved through four main stages (Dumay and Garanina, 2013; Secundo et al., 2017; Ndou et al., 2018). In the first stage of the research, academics and practitioners focused mainly on studies and analyses aimed at acquiring awareness and recognizing the potential of IC; in the second stage, research on IC began to consolidate

and spread like wildfire with the development of additional methods to identify, measure and report of IC companies (Dumay e Garanina, 2013); the third stage focuses on the concrete analysis of the practical implications deriving from the use of IC-related resources in business management processes (Dumay and Garanina, 2013). The fourth and final stage expands the investigation perspective by considering the relationships between the company, stakeholders and the wider socio-economic environment in which it operates. This study intends to be placed in the fourth stage of IC research, proposing an analysis of the websites, intended as main sources of BD, of a sample of 13 Knowledge-Intensive Italian Companies with the aim of analysing the level of disclosure provided on the IC.

The previous researches that investigated the quantity of voluntary disclosure of the IC are mainly located in the second and third stages and are focused on the analysis of the annual reports as a possible source of information. Many studies have also shown a strong influence exerted by the industrial sector of belonging on the level of disclosure of the IC provided (Bozzolan et al., 2006; Oliveira et al., 2006; Bruggen et al., 2009; Sonnier et al., 2009; Goebel, 2018). Specifically, companies considered as knowledge-intensive, belonging to sectors characterized by a high rate of innovation and renewal of the resources and technologies used, as well as based mainly on the acquisition, management and exploitation of intangible resources in their processes of creation of the value, tend to provide a greater quantity of IC disclosure to: (1) reduce information asymmetry with investors and other stakeholders; (2) decrease uncertainty and risk perception (3) improve the allocation of investors' financial resources and stakeholder decision-making processes; and, (4) reducing the cost of capital (Bozzolan et al., 2003; Oliveira et al., 2006; Bruggen et al., 2009).

The limitations of the annual reports has stimulated researchers to analyse new sources and more dynamic vehicles able to satisfy the information expectations of stakeholders on the IC (Cuozzo et al., 2017). Pisano et al. (2017) analysed the level of disclosure on human capital provided by a sample of European companies through a web 2.0 social network - LinkedIn; Lardo et al. (2017) used a sample of 40 European football clubs to evaluate the level of disclosure on the IC provided through social media (Facebook, Twitter, Google Plus, Instagram) and the relationships between the disclosure itself and the market value, the volume of revenues and price of players; Duff (2018) examined the level and quality of voluntary disclosure on the IC conveyed by a sample of professional accounting consultancy companies in Great Britain through a multiplicity of tools such as: annual reports; Corporate Social Responsibility - CSR reports and websites; Terblanche and de Villiers (2019) analysed the level of disclosure on the IC provided through Integrated Reporting - IR by a sample of companies listed on the South African market; Manes Rossi et al. (2018) focused on the university context, analysing the websites of Italian public universities to examine the level of IC disclosure provided as well as the characteristics of the websites in terms of accessibility and usability; e, Ndou et al. (2018) conducted a case study on an Albanian university to verify how BD

generated through different online platforms such as websites and social media are influencing the IC disclosure.

These studies mark the transition from the third to the fourth stage of IC research and highlight how other means made available by the new industrial revolution such as the new digital technologies (BD and web 2.0) are marking an evolution in corporate reporting, representing a new path for transmitting to investors and other stakeholders useful information excluded or underestimated by traditional reporting tools.

3 Research methodology

The study focuses on a specific sample of companies listed on the Italian stock exchange. Using the "super sector" classification for industrial sectors reported on the Borsa Italiana website, only companies belonging to one of the sectors classifiable as knowledge-intensive and therefore operating in ICT were selected. Therefore, the selected sector is the Media, including 13 companies. These companies make high investments in the acquisition but above all in the production and internal development of intangible resources related to knowledge and innovation and are characterized by a high technological rate of their production processes and information systems (Sonnier et al., 2009). As such, on the one hand, they adopt innovative business models made available by the digital revolution such as BD and web 2.0 applications that allow improving the effectiveness and efficiency of internal processes. On the other hand, they exploit these innovative resources to improve the process of external communication with investors and other stakeholders, overcoming the limitations of traditional financial statements. This allows it to decrease the perception of risk by possible capital bearers and to guarantee a greater flow of financial resources from the markets (Bozzolan et al., 2003, 2006). Thus, these companies can be considered as best practices in the field of IC communication through innovative digital tools such as the web and BD.

The analysis of the voluntary disclosure of the IC focuses on the official websites of the companies considering only the web pages in digital format (HTML) with annexed hyperlinks and hypertexts, thus excluding the files conveyed in other formats such as pdf , word or power point (Striukova et al., 2008; Cormier et al., 2009). This allows capturing only the information that can be transmitted via the web and not in classic formats and which, as such, constitute a distinct source of information (Striukova et al., 2008; Cormier et al., 2009). The method used to conduct research on websites is content analysis. Content analysis has been defined as a "search technique for obtaining replicable and valid inferences from data based on their context" (Krippendorf, 1980, p. 31). It is the most used method in the works that examined the IC disclosure and is considered reliable, objective and empirically valid (Guthrie et al., 2006; Cuozzo et al., 2017). The content analysis has been conducted referring to the framework most used by the majority of active literature on the topic (Guthrie and Petty, 2000; Bozzolan et al., 2003; Guthrie et al ., 2006; Striukova et al., 2008; Duff, 2018). It derives from the initial framework developed by Sveiby in 1997 and subsequently modified by the aforementioned authors

based on the peculiarities of the geographical contexts, industrial sectors and information vehicles used.

Table 1 provides a list of all the elements (24) examined grouped in the 3 categories.

Table 1 - Framework for the IC voluntary disclosure analysis

	Item	Description
	Internal capital (structural)	
1	Patents	Information on patents acquired or developed.
2	Copyrights	Information on the copyrights held.
3	Trademarks	Information on the company's trademarks.
4	Corporate culture	Information on the company's social, psychological and cultural environment.
5	Management processes	Information on management processes.
6	Information systems	Information on the internal and external information systems used by the company in its processes.
7	Communication systems	Information on the communication systems used both inside and outside the company.
8	Financial relations	Information on relations between the company and investors and lenders.
	External capital (customer/relational)	
1	Brands	Information about the brand or corporate brands and their value.
2	Customers	General customers' information.
3	Customer satisfaction and loyalty	Information on programs developed for customer satisfaction and consolidation.
4	Company reputation	Information on the perception of the company by stakeholders.
5	Distribution channels	Information on the main distribution channels used.
6	Business collaborations	Information on strategic alliances, partnerships and agreements entered into with other companies
7	Favourable contracts/licensing	Information on signed contracts or licenses obtained by the company.
8	Public relations	Information on stakeholder engagement: events, meetings, fairs, conferences organized to promote the company.
	Human capital	
1	Employee	Information on employees, company profiles and tasks.
2	Education and professional qualifications	Information on employee education and professional qualifications.
3	Training	Information on training programs developed for different categories of employees.
4	Human resource management	Information on human resource management.
5	**E**mployee / partner innovation	Information on creativity and technological inventions developed by its employees or partners
6	Recruitment policies	Information on the recruitment and turnover policies adopted.

7	Career opportunities	Information on career opportunities offered to aspiring candidates.
8	Diversity	Information on the equal opportunities policies adopted.

The information collected through the manual content analysis of the websites was coded following a fundamentally dichotomous approach, that is based on verifying the presence or absence of the information contained in the framework described above (Pisano et al., 2017; Manes Rossi et al., 2018).

4 Result and discussion

The data contained in table 2 illustrates the general results of the content analysis conducted on the websites of the 13 selected companies operating in the ICT macro-sector.

Table 2 - Results of the content analysis for each category

	Tot.	Average	%	Var.	Min.	Max.
Internal capital (structural)	8	6.31	79%	0.73	6	8
External capital (relational)	8	7.15	89%	1.14	5	8
Human capital	8	5.8	63%	6.91	1	8
Total	24	18.58	78%	15.77	12	24

In line with previous studies (Striukova et al., 2008; Lardo et al., 2017; La Torre et al., 2018; Manes-Rossi et al., 2018; Ndou et al., 2018), the results show that Italian Media companies operating in the knowledge-intensive sectors, are aware of the importance of providing information on IC to the audience of investors and stakeholders and are exploiting the potential and opportunities offered by the web 2.0 and BD partnership.

In fact, each company in the sample provides on its website, on average, about 18.54 items out of the 24 analyzed, representing about 78% of the total, with a minimum of 12 and a maximum of 24 items. This allows us to confirm the hypotheses previously made on knowledge intensive companies (Bruggen et al., 2009; Sonnier et al., 2009; Goebel, 2018) and to confirm how they can be considered best practices in the use of BD in external communication processes with stakeholders. These companies operate in highly competitive environments characterized by rapid technological progress and therefore invest heavily in the acquisition and internal production of intangible resources such as digital information systems, innovations, development and training of human resources, research and development to obtain sustainable competitive advantages compared to the competition (Bozzolan et al., 2003,2006; Bukh et al., 2005; Sonnier et al., 2009).

About 89% of the items in the relational capital category have been reported on the websites of Italian ICT companies. This result is in line with what has been observed by the prevalent literature on the subject (Guthrie and Petty, 2000; Bozzolan et al., 2003;

Guthrie et al., 2006; Bruggen et al., 2009; Goebel, 2018). It allows us to confirm how, in the context of the knowledge economy, characterized by the globalization of markets and by strong competition existing no longer on the product in the strict sense but on related services and on marketing, relational capital has taken on a fundamental importance for companies. Therefore, the information on this capital is of great importance for communicating to stakeholders how the company is able to create value from the inside out by focusing on the development of medium and long-term relationships with suppliers, partners and customers. On the contrary, the less attention paid to human capital, although it contrasts with the fact that knowledge-intensive companies rely heavily on the development and training of human resources in their value creation processes, in some way can be explained by the desire to such companies not to reveal much information on strategic resources to which the know-how and the tacit knowledge assets of the company is linked. In fact, such information could create damage to the company because it could be exploited by current and potential competitors to imitate the company or take away strategic resources, eroding market share (Bozzolan et al., 2003).

These considerations can also be extended to the analysis of the individual elements of the three capitals whose results are shown in table 3.

Table 3 - Content analysis results for single elements

Intellectual capital elements	N. of company	% of company
Internal capital		
Patents	2	15%
Copyrights	3	23%
Trademarks	13	100%
Corporate culture	12	92%
Management processes	13	100%
Information systems	13	100%
Communication systems	13	100%
Financial relations	13	100%
External capital		
Brands	12	92%
Customers	9	69%
Customer satisfaction and loyalty	9	69%
Company reputation	11	85%
Distribution channels	13	100%
Business collaborations	13	100%
Favorabile contracts/licensing	13	100%

Public relations	13	100%
Human capital		
Employee	7	54%
Education and professional qualifications	10	77%
Training	9	69%
Human resource management	7	54%
Employee / partner innovation	11	85%
Recruitment policies	7	54%
Career opportunities	9	69%
Diversity	6	46%

In particular, from the analysis of the individual elements of the framework, it emerges that the majority of the information of internal capital (trademarks, management processes, information systems, communication systems and financial relations) and some information of relational capital (distribution channels, business collaborations, favorable contracts/licensing, public relations) are reported by all the companies in the sample, as well as information on corporate culture and brands are reported by almost all of the sample (92%). These data confirm the results of other studies (Guthrie and Petty, 2000; Bozzolan et al., 2003; Guthrie et al., 2006; Oliveira et al., 2006). As for human capital, information on: employee / partner innovation (85%); education and professional qualifications (77%); and career opportunities (77%) and training (77%) are the most reported. This testifies to the centrality of the elements of human capital in ICT companies and the possibility offered by the web 2.0 and BD partnership to offer information that is excluded or only partially reported in traditional financial statements (Bozzolan et al., 2006; Bruggen et al. , 2009; La Torre et al., 2018). Particular attention should be devoted to the information on gender policies that is reported only by 46% of the sample. This result could be explained by the fact that, in compliance with the European directive 95/2014 on non-financial information, the companies in the sample may have opted for other tools (e.g. Sustainability Report or IR) to transmit this information or have prepared a specific gender balance.

Finally, as regards internal or structural capital, in line with previous studies (Guthrie and Petty, 2000; Bozzolan et al., 2006; Guthrie et al., 2006; Oliveira et al., 2006; Duff, 2018), the items most present on the websites of the companies analyzed are: management processes; Informative system; communication systems; e, financial relations. This result testifies how in the knowledge-intensive Italian companies the need to meet the information expectations of the stakeholders emerges regarding the internal structure of the IC and all that is at the basis of the creation of value (management processes); moreover, it is also indicative of the fact that for these companies the BD are

considered part of the structural capital in the proper form of information systems and communication systems.

5 Conclusions

This study contributes to the debate on IC disclosure in the fourth stage of IC research, exploring an innovative vehicle through which companies can transmit information to stakeholders on IC. Specifically, an analysis of the websites, intended as the main sources of BD, of a sample of 13 listed Italian companies belonging to ICT sectors was proposed to analyze the level of disclosure on the IC provided.

The analysis has shown that the Italian knowledge-intensive companies have acquired a marked awareness about the importance of providing information on IC and, for this purpose, are exploiting the potential and opportunities offered by the web 2.0 and BD union. In fact, the results showed that the companies analyzed provide a high level of disclosure on the IC via websites. This result can be traced back to the attempt to reduce the uncertainty and risk perceived by investors regarding the economic-profit prospects of companies, improve the decision-making process of the stakeholders and create positive effects on the market in terms of decrease in the cost of equity (Bozzolan et al., 2003,2006; Bukh et al., 2005; Sonnier et al., 2009). Therefore, this study, although conducted on a limited sample, demonstrates how the BD on the IC conveyed via the web allow overcoming the limitations of traditional financial statements, providing a high level of disclosure to all interested parties. Particular attention is paid to external capital which incorporates information relating to collaborations, distribution channels and relations with stakeholders to emphasize the contribution given by the IC to the creation of value for the outside while limited attention is dedicated to certain aspects of capital human as training and management of human resources, whose data are particularly sensitive and their diffusion can create negative consequences in competitive terms.

From the point of view of the practical implications, the research will be useful for standard-setters and practitioners: the former will be able to draw methodological indications useful for the elaboration of guidelines for the external communication of the IC that contemplate the use of BD and the web; the latter will have useful information to improve the IC disclosure of companies by using communication tools other than traditional annual reports. Academics will also be able to benefit from this research, which can be used as a reference for developing similar analyzes in different geographical and / or product contexts.

However, the study has limitations that can also be considered as ideas for future research. In particular, the analysis was conducted on a small sample of companies belonging to specific industrial sectors and was conducted over a single year. Therefore, future research could be conducted on larger samples including companies belonging to other sectors and could also include qualitative analysis of the information on the IC conveyed by the companies.

Abstract

Healthcare decision making process is a cognitive process included a choice between option as categories and diagnosis; its complexity is due to the involvement of more peoples and the gap between information availability and necessity. It could be affected by several factors including cognitive shortcut of decision makers. To identify these biases of decision-making process and improve its quality Kahneman identified a tool: the checklist.
This study aims to analyse firstly the clinical decision process of orthopaedic surgeons, secondly it aims to understand if and how the more information availability derived by the use of an accounting tool (Time Driven Activity based Costing) can modify the decision-making process.
Both goals regarding the decision making process about management of follow-up of patient undergoing a knee and hip arthroplasty surgery.
To achieve its goals semi-structured interviews with three orthopaedic surgeons from three different working contexts were conducted.
Several biases affected the decision-making process of orthopaedic surgeons choosing follow-up path of their patients; in particular, physicians are mainly influenced by consolidated practice and by the decisions of other departments or opinion leaders.
The information derived using an accounting tool might be helpful to improve or modify decision process, although further empirical studies are required to test the feasibility and utility of the tool.
This study fosters the debate between practitioners and scholars about the use of tools to improve quality decision process in healthcare sector.

Keywords – Decision making process, Clinical Decision making, Healthcare organization, Time Driven Activity Based Costing, Big data.

Paper type - Academic Research Paper

1 Introduction

Decision making is a complex and progressively unpredictable process which relies upon precise information availability (Sousa et al, 2019)

In healthcare the decision-making process, called "clinical decision process" (Higgs et al, 2008), is a part of more complex process named "clinical reasoning". The topic of a clinical reasoning has been studied for more than thirty years, three fields of research have characterized it and they are related to:

- Understand the process of clinical reasoning
- Knowledge and memory related to clinical reasoning
- Mental representation of clinical reasoning (Norman, 2005).

Although, up to now there are no unique definition of this concept; moreover, there are several definitions of it and they are very different from each other (Durning et al, 2013).

For clearness, in healthcare literature often clinical reasoning and clinical decision making have been used as synonymous to define "*the process by which a healthcare practitioner decide what to think and do with a patient"* (Christensen et al, 2017), but During provides a precise definition of clinical reasoning "*the mental process and behaviours that are shared (or evolve) between the patient, physician, and the environment"*. In this article, according to Higgs et al. (2008), we refer to clinical reasoning as the whole process of physician thinking during his practice within clinical decision making is a step of it, made to emphasize the outputs or decisions. In particular, clinical decision process is defined as a *complex dynamic and under pressure* (Hausmann et al, 2016) process included a choice between option as categories and diagnosis (Higgs et al. 2008); its complexity is due to the involvement of more peoples and the gap between information availability and necessity. Moreover, in healthcare organizations decision making process became even more heavy in terms of information necessity. Accordingly, given that the goal of a healthcare institution is creating higher value for patients at lower costs (Porter, 2010), information availability about effectiveness and efficiency of treatments among patient value-chain becomes fundamental to address this challenge. For these reasons, managers of healthcare organizations need solutions would allow them to improve decision-making and business processes together with communication among doctors, patients, and administration, as well as an effective access to different data (Olszak, Batko, 2012).

It should also be noted that within clinical decision process the state and the action spaces of physician (decision maker) are strictly influenced by the patient, there is a sort of interdependence between the two actors that can lead the entire process and its results

(Lippa et al, 2017). Hence, clinical decision process could be influenced by several factors like external context (Robinson et al, 2020), environment, complexity of the task (Higgs et al, 2008) and by the capabilities, confidence, and emotions of practitioner (Smith et al, 2007). According to Kahneman et al (2011) the human process of decision making can be affected by several bias due to the human mode of thinking. In Author's opinion there are two modes or systems of thinking: the system one, or intuitive system is characterized by quick thinking, unawareness and little effort; as a contrast, the system two, or reflective system is characterized by slow thinking, awareness, deductive reasoning and more concentration. By using the system one, peoples incur in cognitive shortcut that can affected decision making process (Cristofaro, 2017). To help decision makers to avoid this bias and improve the decision making process Kahneman et al (2011) identified the checklist: a tool to improve the quality of decisions finding defects in the process.

Furthermore, this work focuses on the lack of data availability and the above-mentioned gap of information necessity and availability for practitioner. In the era of "datafication" (Lycett, 2013), big data may represent the solution to provide information: increasingly analytic insights are employed within top-performing organizations to guide both future strategies and day-to-day operations (Lycett 2013). This change is already progressing into financial processes but has not yet been substantively impounded into accounting and auditing (Moffit and Vasarhelyi, 2013). However, according with Wang et al. (2018), healthcare sector is characterized by a beginning low and slow adoption rate of big data, compared to other sectors (like media and retail sectors such as commerce and finance). Thus, it would be appropriated the employment of tools aimed at obtaining useful information for the whole operation of healthcare organizations. To this aim, managerial accounting tools can be considered effective also for information collecting within the healthcare context. Especially within the accounting field applied to healthcare, several authors have identified the Time Driven Activity Based Costing (TD-ABC) as a managerial tool (Kaplan and Porter, 2011) which fosters collaboration between clinicians and clerical workers by mapping the whole value-creation process (Dombrée et al, 2014; Baratti, 2010; Demeere et al., 2009). Moreover, TD-ABC is particularly suitable for the surgery field (Akhavan 2015) due to the higher process standardization.

TD-ABC could bring more, and better information related to times, processes and costs. It can probably overcome the leading obstacle to a widespread adoption of analytics (LaValle et al., 2011), which is identified with the lack of knowledge about the use of analytics as support of business and value improvement. In accordance with Moffit and Vasarhelyi (2013), the accounting models should evolve and change in order to focus more on data content, atomicity, data linkages; as a consequence, information gathering should be switched from a periodic aggregation of data to a real-time flow. In healthcare providing, this improvement would be considerable useful for clinical management (both clinicians and administrative staff) in order to quickly understand the efficacy of a treatment and its resource consumption.

To achieve its goals the paper has the following outlines after this introduction, including the main theoretical background the second one focuses on the research problem addressed by this work. The third section reports the methodology of the study, while the fourth section presents the research findings. Section five, the last one, discusses the results obtained and provide some considerations about the contribution of accounting tool in clinical decision process.

2 Research Problem

The study focuses on follow-up of knee and arthroplasty surgery due to the high frequency and demand that characterize these surgery procedures (SDO - Hospital Discharge Report 2016).

Accordingly, it is fundamental to specify the concept of follow-up to which we refer: *"a check on someone who has been examined before in order to assess the process of a disease or the results of treatment"* as reported by Dictionary of medical terms.

As reported by some estimates provided by Bcc Research, the world market relating to joint reconstructions should reach a value of 26.81 billion dollars by 2025, with a number of interventions equal to 5,198.38 million.[1] The moment of follow-up decision was chose to analyse a different aspect of clinical decision making, studies tended to focus of clinical decision making within the hospital on in emergency situation (Flynn et al, 2012; Lo and Katz, 2005; Hess et al, 2015) but we want analyse the process related to the long management of the patients.

Given the above, this work has a twofold aim: firstly, it aims to analyse the clinical decision process of orthopaedic surgeons about the management of follow-up of their patients after a knee and hip arthroplasty surgery implementing the checklist to three different surgeons in three different healthcare contexts.

The second goal of this paper is understand if and how the more information availability derived by the use of an accounting tool (Time Driven Activity based Costing) can modify the decision-making process about the management of follow-up of patient undergoing an knee and hip arthroplasty surgery.

3 Method

To analyse different scenarios of orthopaedic surgery world, three semi-structured interviews with three different orthopaedic surgeons from three different working contexts were conducted. In particular, have been interviewed an orthopaedic surgeon working in a public trauma centre hospital, a university professor director of "Scuola di specializzazione" and an orthopaedic surgeon working in several private hospitals. All the respondent work in Italy, in different regions and have at least five years of experience.

[1] *Global Joint Reconstruction Market: Focus on Procedure Number, Type, and Country - Analysis and Forecast, 2018-2025*

Firstly, to contextualize and define the topic a definition of follow up was required to all respondents.

To achieve the first goal, Kahneman's checklist was submitted to the three respondents. According to Cristofaro (2017) the checklist was adjusted to make it suitable for the healthcare context and in particular it was focused on the follow up after knee or hip arthroplasty. To reach the second goal of this paper other three additional questions were performed. They aim at understanding how physicians' decision making process is expected to be modified after the introduction of a data sheet which collect information about clinical and organizational data on patients' management (healthcare processes, staff involvement, bed occupancy, pharmaceutical treatment, kind of therapies, examinations after surgery, functional improvements, relapses). It is important to underline that this data sheet is due to the application of TD-ABC.

These questions intend to highlight changes about the following dimensions of decision-making:

1. Effectiveness of information availability.
2. Improvements in decision-process.
3. Perceptions of physicians about usefulness of a managerial tool in patients' management.

4 Results

To facilitate the reading of findings it's important to specify that in this section, and in the following one, the surgeon working in a public hospital is reported as "SH", the surgeon director of "Scuola di Specializzazione" is reported as "SD" and the surgeon reported as "SP" is the one working in several private hospitals.

The three respondents define the term "follow up" as following:

SH: "The whole phase of clinical and instrumental control to which the patient undergoes after discharge."

SD: "An assessment in steps, decided by the operator, of a patient's post-operative conditions."

SP: "It is a path of scheduled visits to check the patient's condition over time"

The table 1 summarizes the responses to the Kahneman's checklist (2011). The biases reported are those defined by Kahneman (2011), they concern the possibility that decision can be led by:

1. own interest of decision maker (Self-interested);
2. preference of decision maker about one alternative (Affect heuristic);
3. team communication or absence of communication among team members (Groupthink);
4. past success (Saliency bias);
5. no fully evaluation of other alternatives (Confirmation bias);
6. information availability (Availability bias);
7. information base (Anchoring bias);

8. connection between alternatives or situation and decision maker (Halo effect);
9. history or past events (Sunk Cost);
10. excessive optimistic (Overconfidence);
11. excessive pessimistic (Disaster neglect)
12. excessive conservative (Loss aversion);

All the respondents showed the possibility that the *affect heuristic* influencing their clinical decision making as *halo effect* led their process. The *Saliency bias* it is another distortion came out by the interviews, even whit a little impact in the SD's opinion.

Table1: Application of Kahneman's checklist

Questions	**Bias/Code**	***Content Example***	**Respondent(s)**
In your choice of the patient's follow-up path, do you think there is any reason to think that the personal motivations of the clinical operator (orthopaedic doctor) influenced the prescription (number and frequency of checks)?	Self-interest	*"No, because the prosthetic follow-up is completely standardized"*	SH
		"Most likely yes"	SD
		"systematically not, however there is a percentage of variability linked to the patient"	SP
Is it possible that the choice of a specific follow-up path has been made on the basis of consolidated practice, rather than on the specific analysis from the context in reference to the specific contingencies of the patient?	Affect heuristic	*"Customizable follow-ups are rare. We do what the scientific literature reported"*	SH
		"Probably yes"	SD
		"Yes, it is possible"	SP
Are decisions regarding follow-up made at the operating team / ward level or at the individual doctor's (orthopedic patient's) level?	Groupthink	*"Decisions are made due to standardization of ward."*	SH
		"Decisions are made by operating team"	SD
		"In my working reality, the individual doctor decides because often the surgeons make follow up in their private clinics"	SP
a. If conflicting opinions emerge, are they sufficiently examined? How are any "conflicts" resolved?		*"Yes. Conflicts are resolved by ward director"*	SH
		"Conflicts are resolved by team leader and/or the oldest one"	SD
In your opinion, how much the choice of a specific follow-up path is influenced by the experience of the clinical operator regarding similar past situations?	Saliency	*"It Influences, because in addition to scientific bases, orthopaedic surgery also relies heavily on personal experience."*	SH
		"A little, because it is probably connected also with what you want to evaluate and with what literature reported"	SD
		Above all. The choice is influenced almost exclusively by similar past situations.	SP

When choosing a follow-up path, are different credible and reliable alternatives considered?	Confirmation	*"There are not many alternatives to standard follow-up"*	SH
		"Yes, they are"	SD
		"Not much. Alternatives exist but we don't consider them enough"	SP
What clinical information is used to make decisions about patient follow-up process? If you could have other information (non-clinical) which would you need?	Availability	*"Mainly comorbidities and type of surgery are used to make decision about follow-up. If I could have other information, I would like to know the patient's lifestyle habits and where he/she lives"*	SH
		"The ones reported by the literature"	SD
		"Patient's pain, functional skills, lifestyle habits and job"	SP
Which source provides you with the data referred to in the previous question?	Anchoring	*"A deeply patient's anamnesis"*	SH
		"The several international score that you want apply"	SD
		"Medical examination and patient itself"	SP
When choosing a follow-up path, is it possible that the decision was made (or influenced) on the basis of similar decisions made by other departments or other clinical contexts?	Halo effect	*"Yes. Scientific literature gives us many things"*	SH
		"Certainly yes"	SD
		"Yes. Opinion leaders and their modus operandi matter a lot"	
When choosing a follow-up path, how does the patient's medical history influence your decision?	Sunk-cost fallacy	*"It conditions a lot, for example in an epileptic or Parkinsonian patient it is known that a more frequent follow-up is necessary"*	SH
		"As far as the case of the clinical sphere is concerned, probably the embedding parameters make the difference"	SD
		"It could make follow-up more frequent"	
When choosing a follow-up path, do you usually consider extremely positive implication scenarios regarding the patient's specific contingencies?	Overconfidence optimistic	*"When choosing a follow-up path, I usually consider always positive scenarios"*	SH
		"I determine the extent of the follow-up both for what I have read in literature and because I think that is the right period to detect the progress of that situation"	SD
		"I define the period according to time for patient to can slowly start to have a normal life, without aids, without particular foreclosures"	SP
		"The choice is always ideal as	SH

		it should be"	
When choosing a follow-up path, always consider a realistic scenario regarding the patient's specific contingencies?	Disaster neglect	*"Actually, the period is defined because at that point I should have a data that tells me if that path is a positive or negative path."*	SD
		"That period has logic behind. It is the healing time of the tissues from the intervention. I can imagine them repaired in a month and for this I set that date for the medical examination."	SP
When choosing a follow-up path, do you usually consider extremely negative implication scenarios regarding the patient's specific contingencies?	Loss aversion	*"When choosing a follow-up path, I usually consider always positive scenarios because complications are infrequent in this kind of surgery"*	SH
		"Actually, the period is defined because at that point I should have a data that tells me if that path is a positive or negative path."	SD
		"The guideline is the same logic that I said before"	SP

Source: Authors' elaboration from Cristofaro (2017)

Concerning the impact of the TD-ABC data sheet on clinical decision making, the results are shown in Table 2, it reports the three additional questions and the responders' answers in brief.

Very different opinions raised up from the interviews, SH believes that the data sheet can be suitable for specific patients that require more information, e.g. patients undergoing hip and knee revision, while SD stressed the relevance of analysing data resulting from the data sheet to compare them with other departments practise; in contrast to this SP didn't recognize the utility of the tool due to the high number of information recorded making confusion for the decision maker.

Table 2: Interview regarding TD-ABC data sheet

Questions	Content Example	Respondent(s)
Do you believe that the shown data sheet, filled in with all the information requested, could somehow direct, modify or influence your choices regarding the patient's follow-up path?	*"It could in some cases such as revisions, first implantation in dysplastic patients or young patients"*	SH
	"Yes, perhaps the analysis of a substantial number of sheet collected allows me to change the patient's follow up path."	SD
	"I honestly don't know. In my opinion, it helps you to ask yourself more about what you are doing than about follow-up"	SP
Do you think it is a useful tool for your decision-making process?	*"Yes. It would be necessary to always make a qualitative assessment especially of the post-operative period"*	SH

	"Yes, the analysis of data derived by the use of data sheet can be an useful tool for my decision-making process"	SD
	"No. I don't think so"	SP
Why could this tool be useful??	*"Because analysing the organization we can improve it. In this way we can do the prosthetic Fast track that establishes, after 2-3 days from the operation, with a stable clinical picture, the going of patients directly in rehabilitation structures to free the surgical department allowing the entry of new patients"*	SH
	"Because it could somehow change what other surgeons say and verify what I do"	SD
	"Because it is too detailed, full of information, very specific. To make it useful for that purpose I would probably save 5/6 information no more and I would provide only that to no confusing the decision maker"	SP

Source: Authors' elaboration

5 Discussion and Conclusion

The analysis of the interviews discloses a high impact of consolidated practice on clinical decision making about follow-up. This might be to have a two reasons: firstly it might be caused by a "standardization process" of this kind of healthcare pathway (Healy et al, 1998; Scranton, 1999). The other reason is due to a "cultural issue" related to the physician's training, which makes practitioners feel more confident in doing what they have always done (as reported by SP during his interview); such behaviour can bring decision makers to minimize the risks of their practice and exacerbate its benefits (Kahneman 2011).

According to all respondents, another variable that certainly influences the decision-making is the practice of other department decisions. Several reasons might explain this result and they are related to the scientific nature of medical science (based on scientific literature), as emerging by evidence based medicine (based on best practice) (Timmermans and Angell, 2001) or by the impact of "opinion leader" (Locock et al, 2001) in healthcare disciplines; in particular, this aspect came to light during two interviews. In respondents' opinion surgeons are more conducive to changing their practice based on the experience of those they deem most competent in the field.

It is important to highlight that answers (and the clinical decision making too) are influenced by work environment. This is especially evident from disagreement in team member consideration during follow-up choice; while in public structure as university department or hospital decisions are shared in team, the surgeons working in private structures makes its decisions on his/her patients by itself. This result is line with Smith et al (2007) and Eisenberg (1979) that identified external factors, features of clinician, clinician's interaction with his profession and the health care system, as the factors that can modify the decision process.

No direct evidence of self-interest bias is arisen by interviews; but regarding the decision about frequency of follow-up a particular consideration came out. According to all respondents the frequency of follow-up is established in line with literature, practice and in some rare cases according to patient's peculiarity. Nevertheless, another reason that can modify the follow-up frequency is the interest of physician in recording some data (clinical or not) to report them in a scientific study. In this case the period between one check and another might be not related at all with a patient condition or safety, but it related to a scientific interest of physician.

Moreover, with regard to the impact of TD-ABC data sheet on clinical decision making, according to all respondents some information within the "documents" can surely modify (probably improve) their decision process. The respondents could not declare with certainty the usefulness of the tool because maybe because they could only analyse it on theoretical level.

At the moment, however, for practitioners this tool is overfull of information and in respondents' opinion this can compromise its feasibility and utility.

This study shows several biases that can affect clinical decision process regarding follow-up after knee and hip arthroplasty. Checklists could potentially help physician to avoid these errors, but it needs to be integrated in daily practice.

Furthermore, the accounting data can affect the clinical decision process but further research on the empirical application of TD-ABC data sheet are required to test its utility and feasibility.

The study presents several limitations related to the use of qualitative method which implies interpretive role of researchers and limited extension of data. Moreover, only three physicians are interviewed. Nevertheless, the difference in terms of work environment of our interviewees reduces such a limit giving a good representation of Italian orthopaedic environment.

Another limitation regarding the topic addressed by this study, its specific literature background is on cognitive process that prevalently belonging to the psychological and healthcare fields, with few strong interconnections with managerial ones.

In conclusion, this study highlights the linkage between accounting data and decision-making process in healthcare context, by fostering debate among scholars in these fields. For practitioners, this study shows an experience of a quality decision making process tool employment that brings out some cognitive shortcut that can led the clinical decision process. Particularly with this regard, the study can contribute to debate by both scholars and practitioners about the application of tools that can improve quality of clinical decision process.

Abstract

This conceptual paper investigates the role of cooperatives for social innovation and local sustainable development in the context of the Region Lombardy, which is the Italian most populated and most economically relevant region, as well as the region with the largest number of employees in cooperative enterprises. The discussion is based on an exploratory study involving 9 cooperatives through semi-structured interviews with members of the boards and managers with the aim of exploring subjective viewpoints and gather in-depth accounts on cooperatives as central actors within the Social and Solidarity Economy ecosystem. In the paper the results of the interviews are presented, some implications are derived from them and some problems are identified that could limit the cooperatives' capacity to unfold their full potential as natural carriers of social and sustainable innovation.

Keywords – cooperatives, social innovation, sustainability, Social and Solidarity Economy, local development.

Paper type – Academic Research Paper

1 Introduction

According to International Labour Organization, the Social and Solidarity Economy (SSE) includes "enterprises and organizations, in particular cooperatives, mutual benefit societies, associations, foundations and social enterprises, which specifically produce goods, services and knowledge while pursuing economic and social aims and fostering solidarity" (ILO 2019, 66). Despite the differences in the legal forms, what is common to all these organizations is their "collective ownership and governance structures, which ensure that they respond to the needs of stakeholders that are different from investors" (ibidem).

Among the SSE organisations, a special role is played by cooperatives that in Europe "have been active since the early nineteenth century, helping various groups of people (consumers, producers, workers) to gain access to basic goods and services ranging from groceries to healthcare" (Borzaga, Salvatori, and Bodini 2019, 45). According to the 2019 report of the International Cooperative Alliance (ICA), more than 12% of humanity is part of any of the 3 million cooperatives in the world as members/consumers or employees/participants. Moreover, cooperatives contribute to the sustainable economic growth and stable, quality employment, employing 280 million people across the globe, i.e. about 10% of the world's employed population.

In Italy, cooperatives play a fundamental role within the SSE, if not in the total number of organizations (about 15% of the SSE organizations) certainly in the total number of employees (more than 75% of the employees of the SSE organizations). According to (ISTAT 2019), in 2015 (which is the last year for which official statistical data is available), 59.027 cooperatives were active in Italy, with 1.151.34 employees, producing a value added of more than 28,6 billion euros. In Lombardy, which the most populated and most economically relevant region in Italy, 8.314 cooperatives were active in the same year with 219.332 employees.

Social innovation and sustainable development are two core principles of the cooperative movement since, as value-based and principle driven organizations, cooperative enterprises are by nature a sustainable and participatory form of business (ILO-ICA 2014). Indeed, principle 7 of (ICA 2015) places the primary emphasis for cooperatives on concern for the sustainable development of their immediate local communities, with the goal of benefitting both the cooperatives members - who democratically own and control them – and the communities within which they operate. From this point of view, cooperatives can play a fundamental role for local sustainable development and social innovation, while maintaining a strong business orientation that makes cooperatives a relevant economic actor.

While the role of cooperative for local sustainable development and social innovation has been widely discussed within the literature (both academic and grey), how cooperatives frame their activities strategically as local development and social innovation initiatives is still a quite underexplored topic. In this conceptual paper, we

explore this topic in the context of the Region Lombardy, which is the Italian region with the largest number of employees in cooperative enterprises, with a specific focus on cooperatives that can be considered as small and medium-sized enterprises. More specifically, the paper presents the result of an exploratory study based on qualitative semi-structured interviews conducted with members of the boards and managers of 9 cooperatives with the aim of exploring subjective viewpoints and gather in-depth accounts on the role of cooperatives for social innovation and local sustainable development.

The paper proceeds as follows. In the next section some arguments are presented that support the claim that cooperatives are fundamental actors for social innovation and local sustainable development. Then the methodology of the exploratory study is described, and the main evidences emerged from the qualitative semi-structured interviews are presented and discussed. Finally, some conclusions are drawn from the discussion and the limitation of the study and some further research directions are indicated.

2 Hybridity as a source for social innovation and local sustainable development

According to (UNIDO 2017, 13) social innovation "refers to a novel solution to a social problem that is more effective, efficient, sustainable, or just than current solutions. The value of social innovations accrues primarily to society rather than to individuals" (UNIDO, 2017, p. 13). Mulgan, Ali, Halkett e Sanders (2007, 9) define social innovation as "the development and implementation of new ideas (products, services and models) to meet social needs". Social innovation amounts to a "complex process of introducing new products, processes or programs that profoundly change the basic routines, resource and authority flows, or beliefs of the social system in which the innovation occurs" (Westley and Antadze 2010, 2). In more general terms, (Moulaert and MacCallum 2019) defines social innovation as innovation in social relations based on values of solidarity, reciprocity and association and ethical practice for meeting needs, transforming social relations, and collectively empowering communities to shape the future.

At the local level, social innovation rests on two pillars: "institutional innovation (innovation in social relations, innovations in governance including empowerment dynamics) and innovation in the sense of the social economy – i.e. satisfaction of various needs in local communities" (Moulaert and Nussbaumer 2005, 2071). To achieve these goals, social innovation implies new organizational modalities and new socio-economic principles based on the development of collaborative relationships among a plurality of actors, including the direct beneficiaries of innovation (Bernardoni and Picciotti 2014, Pestoff 2012b). This gives cooperatives, and other SSE organizations, a central role among the actors of social innovation. Indeed, scholars, policy-makers and other stakeholders more and more refer to social innovation as the most valuable outcome of SSE (Tortia, Degavre, and Poledrini 2020, Moulaert and MacCallum 2019).

SSE organizations are characterized by "collective ownership of institutions which aim to transform labor relations, promote participative democracy, and design new wealth-sharing arrangements" (ILO 2019, 8). They are organizations that "follow social solidarity principles of pursuing social, environmental and redistributive justice through cooperative, associative and solidarity relations" (ibidem). Cooperatives share these principles with the SSE organizations, which is what makes cooperative different from typical profit-oriented organizations. However, cooperatives are enterprises and, as such, besides pursuing social goals, focusing on democratic values and principles such as solidarity, equality and inclusion (Kerlin 2010), cooperatives also pursue business goals. This is what makes cooperative different from other SSE organizations, such as the non-for-profit organizations. By combining the social orientation of the SSE organizations and the business orientation of enterprises, cooperatives are hybrid organizations and this property of cooperatives has relevant implications for their role as actors of social innovation.

In organizational studies, hybridity refers to the coexistence within the same organization of different (sometimes even conflicting) institutional logics, typically related to the public, private or third-sector domain (Brandsen, van de Donk, and Putters 2005, Evers 2008, Ebrahim, Battilana, and Mair 2014). Organizational hybridity is one of the main characteristics of cooperatives that "pursue multiple goals rather than having a single purpose. In fact, their very raison d'être is to pursue both economic and social goals" (Pestoff 2012a, 85). For cooperatives, the coexistence of plural logics is a permanent phenomenon (Besharov and Smith 2014, Mair, Mayer, and Lutz 2015, Battilana 2018). It represents a positive aspect (Kraatz and Block 2008), since "operating in institutional interstices and combining multiple logics (i.e. considering and adhering to multiple prescriptions) might open up opportunities, as organizations can access broader sets of resources and expand their practices, which allows them to be innovative, to create new products and services and to pioneer new ways of organizing" (Mair, Mayer, and Lutz 2015, 715).

In discussing innovation in third sector organizations, Osborne (1998) observes that their innovation capability depends more on their interactions with the local political context than on their organizational properties (such as the organizational structure and culture). In other words, the innovation capability is not one of their intrinsic characteristics. Vice versa, as for all enterprises, the innovation capability represents for cooperatives a survival condition (at least in principle) that should be pursued as a fundamental aspect of the organizational development strategy. The capacity of combining a business-oriented perspective with a social and solidarity-based perspective is what that can make cooperatives, as hybrid organizations, natural carriers of social and sustainable innovation.

Although the role that cooperatives as hybrid organizations can play for social innovation and local sustainable development has been discussed quite widely within the academic and grey literature, how cooperatives can play this role 'on the ground' at the

local level is still a quite underexplored topic. This leads to the research question this paper intends to address, i.e. "how small and medium-sized cooperatives can frame their activities strategically as local development and social innovation initiatives?".

3 Methodological approach

The paper is based on an exploratory study that involved 9 cooperatives based in different provinces of Lombardy and covering different areas of activity. The main characteristics of the selected cooperatives are summarized in the following table:

	Typology of the cooperative	**Dimension** (Number of employees)	**Role of the interviewed**
C1	Workers buy-out	medium	President of the board
C2	Work integration social cooperative	medium	President of the board
C3	Community cooperative	medium	CEO
C4	Work integration social cooperative	small	Executive director
C5	Work integration social cooperative	medium	President of the board
C6	Work integration social cooperative	medium	Executive director
C7	Community cooperative	medium	President of the board
C8	Community cooperative	medium	Head of administration
C9	Community cooperative	medium	President of the board

The interviews have been based on the methodology for semi-structured interviews described in (Adams 2015) and have been designed with the aim of exploring subjective viewpoints and gather in-depth accounts from the interviewed (Flick 2009). The interviews, that lasted about one hour each, took place between January 2020 and March 2020 and have been made by phone by two researchers. At the end of the interviews, the two researchers jointly codified the answers, made them anonymous and analysed them to elaborate an aggregated synthesis. The researchers then complemented the interviews with the analysis of documents published on the cooperative websites, e.g. the statute of the cooperative and the social responsibility report (where available).

To answer the paper research question, the semi-structured interviews have been designed to investigate issues related to the social and solidarity economy and the cooperative' attitude toward social innovation and local sustainable development. Moreover, given the role that, according to the literature, the cooperatives' hybridity can play to enable and support social innovation initiatives, in the interviews also questions related to the organizational and the governance structure of the cooperative have been included.

4 Major evidences from the interviews

The strict interaction with the local context, as an important stock of cultural and relational capital, is considered strategic by all the interviewed that consider the cooperative form as the best suited to understand local emerging needs, to answer them rapidly, and to give creative solution to problems that cannot be solved with more traditional public or private interventions. Moreover, all the interviewed stressed the cooperatives' central role in the SSE, as they contribute to the local development and, at the same time, can provide an answer to the economic and social challenges related to the ongoing transformation of work in the digital age. This confirms the importance of cooperative for social innovation and local development as described in the academic and grey literature. However, when asked what social innovation and local development mean for their organizations, the interviewed gave quite different answers, also depending on the field of activity of their cooperatives.

Most of the interviewed related social innovation to social justice, as equity and social inclusion, and to the cooperatives' capacity to satisfy social needs on behalf of public administrations according to the subsidiary principle. These interviewed consider the cooperative model as alternative to more traditional organizational paradigms and acknowledge the peculiar role of cooperatives within the SSE. However, how their cooperatives implement social innovation in their activities is more related to the development and implementation of new ideas (products, services and models) to meet traditional social challenges (poverty, exclusion, marginalization, etc.) than to the capacity to contribute to change the social system in which the innovation occurs. Therefore, these interviewed showed a reduced interest in wider challenges emerging from the ongoing transformation in the social systems, such as sustainability, quality of life, societal impact of new technologies, transformation of work in the 4th industrial revolution, etc. This result is unsurprising since most of the cooperatives considered operate in the welfare sector.

When asked about sustainable development and how sustainability can impact their activities, most of the interviewed refer, first of all, to economic sustainability, as the condition that will guarantee the cooperatives' survival in the long period and the possibility to achieve their social objectives. The strong focus on the internal economic sustainability is a direct consequence of the organizational hybridity of the cooperatives that, as enterprises, are expected to generate income from their activities in order to survive and develop. Actually, for 8 cooperatives in our sample at least 70% of their income derives from business activities (all the interviewed described their cooperatives as hybrid organizations pursuing, with different intensity, business, mutual and public values).

Only one of the interviewed explicitly describes sustainability as the foundation for a different economic development model. This is the case of the workers buy-out cooperative that, unlike the other cooperatives, is a production cooperative operating in an industrial context. In this cooperative, the adoption of a sustainability-oriented

perspective led to redefine the internal processes to make them more environmentally sustainable.

In some of the interviews the topic of decent work has been touched upon as a relevant aspect of social innovation. In the case of the workers buy-out cooperative, the interviewed explicitly relates the reasons that led to the establishment of the cooperative to the necessity of guaranteeing to its members a decent work after the closure of the company that employed them. Other cooperatives mention delivering quality jobs along with social protection and respect for rights at work among their objectives. The focus of those cooperatives is on three elements. The employment of older workers who had lost their work during the economic crisis and would have difficulties in finding new jobs due to their age. The female's employment, with the necessity of guaranteeing a better work-life balance. The need to assure contractual forms that can guarantee the workers' rights, as opposed to low-pay, low-benefit and low-protection jobs.

Quite interestingly, most of the interviewed do not relate (social) innovation to modernization, digitization or, more generally, to technology-driven innovation. All the cooperatives declare to use basic ICT tools, mainly for administrative purposes. Most of them (6 out of 9), consider digital innovation as a relevant aspect of their strategic vision. However, almost all the cooperatives in the sample (8 out of 9) declare low levels of implementation of digital tools, thus highlighting a relevant implementation gap.

Although some of the interviewed (especially those belonging to the work integration social cooperatives) relate the low technological level of their organizations to the typical human-labor intensive activities of the cooperatives, what emerges with evidence from most of the interviews is the lack of internal technological and managerial competences and skills.

5 Discussion

The small number of cooperatives that have been involved in the exploratory study does not allow to draw general conclusions. However, some elements emerge from the interviews that are relevant to answer the research question, i.e. "how small and medium-sized cooperatives can frame their activities strategically as local development and social innovation initiatives?".

First, the interviews confirmed the cooperatives' strict interaction with their local context, which allows them to re-embed "in progressive societal norms and creating or strengthening institutions that can mitigate or counteract perverse effects of 'business as usual'" (Utting 2015, 2).

According to the academic and grey literature, the cooperatives' embeddedness allows them to provide better and more adequate answers to the systemic challenges of the contemporary world by fostering an economic development model that contests the tenets, instruments and outcomes of the neoliberal agenda (Utting 2015). The interviews confirmed the re-embedding of economic practice as one of the

elements that differentiate cooperatives from other enterprises and that make them a central actor for the local economic and social development. However, considering how the interviewed described it, the role of their cooperatives for local development can be characterized more in terms of social entrepreneurship than of social innovation. They all mentioned the development and implementation of new ideas to meet social needs that can impact the broader context through a process that, in the words of (Westley et al. 2014), can be defined as 'scaling out', i.e. "the organization attempting to affect *more* people and cover a larger geographic area" (237). This is different from social innovation that "not only introduce innovation, but also manage the broader context, in such a way that the innovation has a chance to flourish, widening the circle of its impact" (254) through a 'scaling up' process that identifies "opportunities and barriers at broad institutional scales, with the goal of changing the system that created the social problem in the first place" (237).

For the interviewed, social innovation processes should be considered as the product of the interaction between the business subsystem and the wider political, economic, and social system. Based on this interaction, innovation mechanisms capable of prospering and affecting the local systems could be triggered. For most of the interviewed a greater formal recognition by the local institutions of the cooperatives as active parties in the definition of the interventions that affect the social system is an enabling element for the role of cooperatives as actors of social innovation.

With respect to the cooperatives' local embeddedness, a critical problem emerged from the interviews concerning the still scarce institutionalization of the relationship between the cooperatives and the local context. The interviewed reported that the relation is often only episodic and left to the individual managers and members of the board attitudes and interests without being formalized in the cooperative governance system. This is an aspect of the cooperatives' difficulties in implementing participatory governance systems, which can limit the cooperatives' social innovation capabilities. In fact, as it is well known from the literature, the inclusion of local stakeholders in the governance system would encourage the development of new organizational methods and new collaborative relationships between the actors of the local system. A more participatory governance would increase the cooperatives' capability to actively contributing to shaping the social system, thus going beyond the sphere of social entrepreneurship.

Second, all the cooperatives involved in the study are aware of the role that, according to the academic and grey literature, cooperatives can play to cope with global challenges, such as sustainability, climate changes, rising of social inequalities, deregulation, state retrenchment, financialization and commodification. However, beyond a general cultural commitment, also due to their local reach, the cooperatives did not implement specific measures geared to those topics.

What instead emerged quite clearly from the interviews is the cooperatives' commitment to employment creation and decent work as opposed to the tendency toward the commodification of work in the neoliberal agenda. This confirms the role that in the

contemporary debate is assigned to cooperative values, such as self-help, self-responsibility, democracy, equality, equity and solidarity, to prevent a 'self-employed precariat' from developing and to oppose neo-liberalism by offering alternative approaches (Ridley-Duff 2019).

Third, all the interviews confirmed the strong value-orientation of the cooperative model. This is a defining characteristic of cooperatives that in the literature has been related also to the resilience of the cooperative business model in times of crisis and downturn (Utting 2015, Birchall and Ketilson 2009, Roelants et al. 2012). The resilience of cooperatives has been confirmed by the interviews. After the Italian Government approved the Covid19 lockdown on March 9, the researchers contacted again the cooperatives by phone to ask them whether and to what extent they expect the anti-Covid19 measures to affect their activities. Whereas the Covid19 pandemic is estimated to impact negatively on the Italian economy with a 51% turnover reduction (SVIMEZ 2020), the interviewed cooperatives reported a reduction up to 30%. This data, as well as data concerning the performances of the Italian cooperatives during the financial crisis from 2008 to 2013 (Carini, Borzaga, and Fontanari 2015), confirms the peculiar role of cooperatives in time of crisis, also with respect to the creation of new and good employment.

Fourth, it is quite surprising that, despite their strong commitment to the creation of good employment, neither of the cooperatives involved in the study mentioned the potentially critical impacts of the 4.0 revolution on human employment. As observed above, this can be partly explained by considering that most of them operate in the welfare sector. However, considered together with their quite low level of implementation of digital tools and their general lack of technological and managerial competences and skills, this observation points to a critical aspects that can reduce the small and medium-sized cooperatives capability to contribute to the development of the Social and Solidarity Economy.

In most of the cooperatives involved in the study, including the largest ones, the distinction between the competences of the board and the managerial activities is not clear, with members of the board also performing typical managerial functions (e.g. the management of the human resources). This can be considered as an index of the scarce penetration of a managerial culture within the cooperatives studied. Although all the interviewed agreed on considering their cooperatives as hybrid organizations, the preponderant role of the board clearly indicates that in those cooperatives the logic of enterprise has not been fully developed yet.

This is the most critical element that emerged from our exploratory study, since hybridity is the condition that would allow cooperatives to unfold their full potential as natural carriers of social and sustainable innovation. As (Sapelli 2015, 110-111) points out, this requires cooperatives to develop an 'organizing ability' through the development of a managerial culture different from both the 'logic of belonging', typical of the cooperative world, and the logic of profit, typical of enterprises. According to (Ebrahim,

Battilana, and Mair 2014), the development of the organizing ability within cooperatives presupposes a "growing shift toward the hiring of professional managers, and the adoption of formalized practices such as strategic planning, independent financial auditing, and quantitative evaluation and performance measurement". However, to avoid the risk of mission drift that can derive from the managerialization of cooperatives, the need arises for "the selection and training of managers in tune with core social enterprise values" (Shaw 2006, 12). This is what the cooperatives in our study still lack and that represents the major skill gap that should be addressed to strengthen the cooperatives' role in the Social and Solidarity Economy.

6 Conclusions, limitations and further research directions

In this conceptual paper, we discuss the role of cooperatives for social innovation and local sustainable development based on an exploratory study conducted on 9 cooperatives in Lombardy. The results of the qualitative semi-structured interviews conducted with members of the boards and managers of those cooperatives confirmed the role of cooperatives as the natural carriers of social and sustainable innovation. The embedded nature of cooperatives and the strong value-orientation of the cooperative business model have been confirmed as important drivers for cooperatives as central actors for local sustainable development, even in times of crisis and downturn. At the same time, the interviews evidenced a lack of managerial culture and skills within the cooperatives, which can limit their capacity, as hybrid organizations, to contribute to the local sustainable development based on the principles of the Social and Solidarity Economy.

The study has been based on a small number of cases and this is its main limitation that does not allow to draw general conclusions. However, the aim of the study was not a systematic study of the cooperatives of Lombardy. Rather, based on evidences from the literature, and coherently with its exploratory nature, the study was intended to identify what aspects should be investigated with further researches to better understand the role of cooperatives for social innovation and sustainable local development within the social and economic context of the most populated and economic relevant region in Italy.

Abstract

This paper aims to investigate and understand existing knowledge and paradigm of community issues to shift towards new knowledge management models, where open innovation could improve communities' health with rightly managed to validate knowledge creation and integration.
The article is conceptual in nature and adopts a systematic literature review approach, based on the concepts of knowledge management and open innovation in the healthcare sector. It analyses the most relevant studies. The paper's contribution consists of how it connects open innovation in healthcare to knowledge management. The aim is to build a conceptual framework defining the main objectives of the article: (1) knowledge transfer and co-creation both inside and between health communities; (2) valid knowledge transfer through open innovation. So this paper aims to identify main definitions, concepts, and background theories.
The analysis showed that 66 articles (22 in PubMed and 44 in Web of Science) are related to the topics of knowledge management and health ecosystems; open innovation and health; knowledge co-creation and community; knowledge transfer and open innovation, during the past ten years period (2011-2020). All articles were analysed in detail and divided to categories. This paper aims to investigate and understand existing knowledge and paradigm of community issues to shift towards new knowledge management models, where open innovation could improve health communities to validate knowledge co-creation and integration.
This study proposes knowledge management approach and managerial paradigm shift from ecosystems to health communities. Identified the main articles and definitions in the field of knowledge transfer and health communities, proposed perspective of open innovation

Keywords – health communities; knowledge transfer; knowledge management; open innovation; co-creation

Paper type – Academic Research Paper

1 Introduction

Managerial practices aim to grasp understanding the health ecosystem as a whole (Laihonen, 2012). But paradigm changes and medical professionals still often have a too poor understanding of patients and their needs, and poorly represent real views of the smaller communities (Bullinger et al., 2012). It should thus be attempted to integrate the community and use of 'experiential' knowledge, like the personal experience with the particular health issue. That kind of integration to health care research should contrast formal, clinical knowledge and enroll innovations right to the problem-solving (Bullinger et al., 2012; Steininger et al., 2010; Serrano-Aguilar et al., 2009) Such communities could be initiated by patients themselves or by external stakeholders, but it necessarily should include stakeholders and professionals from the biomedical value chain to extend processes and control validation and using the created knowledge to seek the best results. The patient role changes from the listener and knowledge taker, into collaborative, involved in their health knowledge creation and integration as an equal partner (Allarkhia, 2015). This is how the healthcare sector is evolving into a knowledge-based community with diverse stakeholders: patients, their relatives, hospitals, pharmaceutical companies, the media and more (Bose, 2003), who share a wealth of information on health issues, thus affecting to the quality of health care. The main problem is still active that different actors of health communities have different informational sources, where information is not censored, safe or valid (May et al., 2007). Also there are many examples when the situation became harmful - how uncontrolled information really harmed not just a few persons but all public health: anti-vaccine movement (Stein, 2017; Hussain et al., 2018) which led to measles breakthroughs (Stanley, 2019; Mavragani&Ochoa, 2017) or increasing of other diseases. The main goals of health-generating communities should be to make more effective use of both face-to-face or online, positive-influencing knowledge and practices; collect, create, share and use them to empower learning communities to build health; the management of an existing knowledge network to fulfill the desired knowledge flow (Tang, 2017). People want to get health information fast (here-and-now) and from sources that can trust (Quintana et al., 2001; Petraite et al., 2018; Mazenyte&Petraite, 2019), where patients could find validate personalized information. Of course, digital technology should drive communities to sustain efforts for developing collaboration that enables social, economic and public value creation (Romanelli, 2018). But each community faces different challenges in addressing a variety of health issues, so it is important to identify them and find the most appropriate solutions.

Community members are motivated to exchange information and share their knowledge; actors are useful in the process of innovation because they are self-interested, contribute to the activity and work to meet the needs of the community (von Hippel, 2016). With the help of this knowledge, new pathways are being developed that can facilitate access to healthcare, change attitudes from clinical solutions to health problems, and help people find the right answers to their health concerns.. There we can find the right place to apply OI and get the best results both in knowledge transfer inside

community (outside-in) and also in knowledge transfer between different, separate communities (inside-out). Community members became creators who co-creates innovation and contribute to value creation (Kohler & Chesbrough, 2019). Open innovation (OI) is becoming one of the most important tools to address complex problems in the research of health sciences. Different solutions, platforms are available to the community and also to domain experts as to particular problem solvers (Hill et al., 2017).

For this study, we define communities as social networks instead approach of ecosystems to understand how to transfer knowledge inside the community and between different communities. We using a transdisciplinary approach to explore both, medical and managerial contexts to find out a variety of articles and relevant needs.

2 Material and Methods

The article is conceptual in nature and adopts a systematic literature review approach, based on the concepts of knowledge management and open innovation in the healthcare sector. Papers have been selected to search for our research domain to find the most important scientific articles for selected topics. Articles have been explored via the PubMed and Web of Science platforms, published in the past 10 years (2011-2020) (see Figure 1).

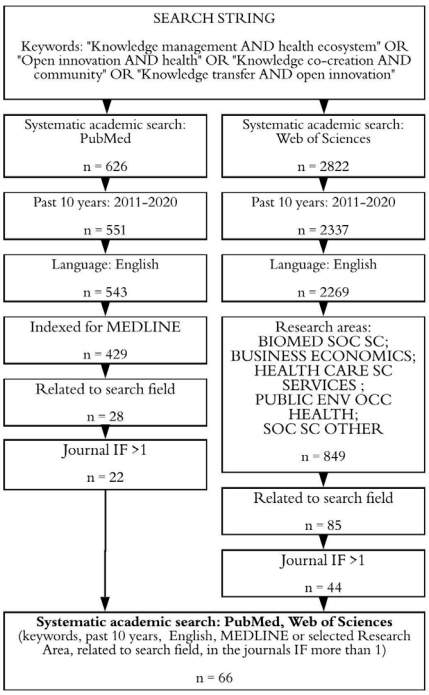

Figure 1. Analysis of PubMed and Web of Science platforms

The analysis showed that 626 papers in PubMed and 2822 papers in Web of Science are related to the topics of knowledge management and health ecosystems; open innovation and health; knowledge co-creation and community; knowledge transfer and open innovation. Keywords were paired by the groups of interest. During the past ten years period (2011-2020) PubMed showed 551 and Web of Science showed 2337 papers related to the research topic. Papers that were in other languages than English or didn't fit into research areas or searching fields or were in very low indexed journals (Impact Factor less than 1) were excluded from results. There are 66 articles related to chosen topics in the field. All articles were analysed in detail (see Annex 1): title and authors, keywords, publishing year, Impact Factor (IF), subject of paper (in 3 categories) and DOI.

The paper's contribution consists of how open innovation in healthcare connects to knowledge management. The aim is to build a conceptual framework defining the main objectives of the article: 1) knowledge transfer and co-creation both inside and between health communities; (2) valid knowledge transfer through open innovation. So this paper aims to identify main definitions, concepts, and background theories.

This paper aims to investigate and understand existing knowledge and paradigm of community issues to shift towards new knowledge management models, where open innovation could improve communities' health with rightly managed to validate knowledge creation and integration.

3 Results of literature review

There was selected to analyze 66 articles in total from the platforms: PubMed and Web of Science. Articles were revised and the first-order category assigned for each article based on the subject of the article, individual categories consisted of such categories as Disease Management; Digital Health; Ecosystems; Community Empowerment; Precision Medicine; Software Development; Diffusion Of Innovation; Drug Management; Open Innovation; Patient Empowerment; Maternal Health; Health Platforms; Community Management; Online Communities; Co-Creation; Know-Do; Entrepreneurship; Community Health; Health Systems; Health Services; Environment Health; Business-Model Transformation; Public Health; Patient-Centered Care; Health Literacy, Value Creation; Collaboration; Society and others. First-order categories were revised once again to assign more generalized subjects, eight categories were formed: Knowledge Management; Knowledge Translation; Open Innovation; Innovation; Health Management; Health Ecosystems; Co-creation; Value Creation. Categories were discussed once again and agreed that the most common subjects of articles were two: knowledge transfer and health community. See Annex 1 for detailed results.

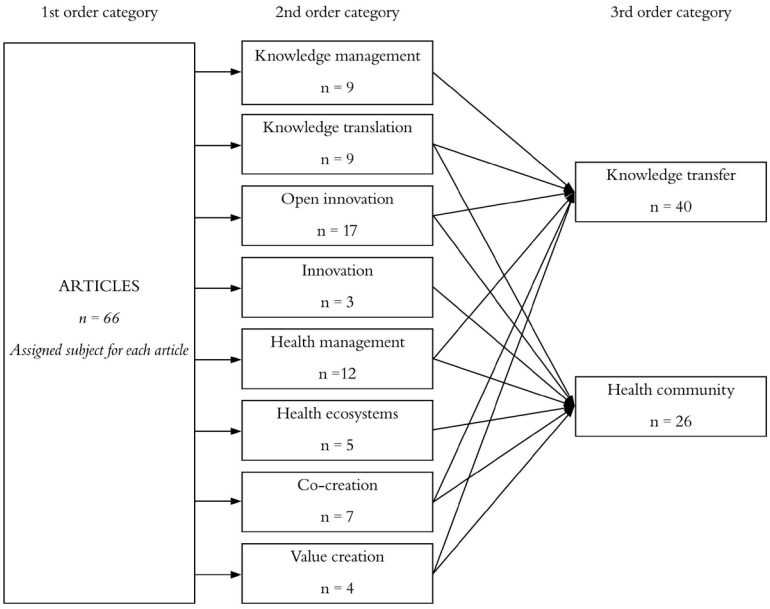

Figure 2. Results of literature review: categories

A literature review has brought attention that the two most discussed topics in analyzed articles: knowledge transfer and health community (see Figure 2). 3rd order category was developed during the systematic literature review process, it has shown that all articles were talking about knowledge transfer and/or health communities in one or another way. It was direct interfaces or indirect matches that could be applied to those categories. For example, an article talking about healthy ecosystems were signed into the category of health community in order that we could adapt relevant theories, methods or approaches to our research.

Our literature review suggests to raise new models of knowledge transfer inside and between smaller health communities instead of wide ecosystems approach which is usually in the center of attention. New models would create additional value both to healthcare and managerial research ant practices. Term of an ecosystem is borrowed from biology and in designed ecosystems, organizations come together by co-specializing with each other, creating bonds that engender collaboration, without excluding competition (Jacobides et al., 2018). While the term health community still doesn't have the static definition in managerial sciences. It is noted that there are differences between the usual "community health" and the health community. The concept of the health community remains poorly defined despite relevant literature. Various terms such as the community of practice, patient collaboration, active patient, patient empowerment, or participation are used (Greenhalgh et al., 2011; Vallentin-Holbech et al., 2020). But still, it is not exactly the right example for our approach. Literature suggests more definitions and

approaches to online health communities. But online communities face challenges such as knowledge co-creation to develop valid knowledge, knowledge integration, and sharing between different communities, personal data issues, and also - face-to-face communities lack the right definition – the need of comparing different categories has a high demand. Health communities could be divided in different categories such as online health communities (OHCs) "are an increasingly popular source of health information and peer-to-peer support, particularly for patients with chronic health conditions" (Magnezi et al., 2015) or direct, face-to-face health communities "Direct face to face user and provider collaboration to co-design products or services, and includes a focus on the aesthetics of a service" (Robert et al., 2015) (see Table 1).

Table 1. Indicators of direct health communities and online health communities (OHCs)

Type	Indicators	Authors
Direct health community (face-to-face)	Direct contacts; Clear goals; Societal focus; Patient safety and health care quality; Co-production, co-design, co-creation; Measured results; Rejection of paternalism; Active patient in the treatment process; Quality of services; Health care system improvement; Small, coordinated groups; Aims for every actor; Clear decisions; Inbetween sharing; Challenge that patients to not participates in decision making; Obstacles as low health literacy and lack of knowledge; Previous experinces of poor care; Lack of confidence; Inconvienient place or time scheduling	Gustavsson, 2016; Levinson et al., 2005; Greenhagh et al., 2011; Longtin, 2010; Bergerum et al., 2019; Robert et al., 2015
Online health communities (OHCs)	Source of health information for community members; Peer-to-peer support (especially for patients with chronic diseases; Allows to connect on convienient time to exchange personal experiences, treat plans, indications and self-management; Public sharing; Support each other in need; Foster collaboration and knowledge co-creation between patients, researchers, health care professionals, and other stakeholders; Multilateral exchange of knowledge and ideas to create new knowledge; Differences between "online health support groups, that typically include patients only" and OHCs, that not only encompass participation from patients but also includes health professionals as discussion moderators"; Tensions among users; Providing ethics and data protection; Dealing with too lot information, which is not usually valid; No clear goal; Daily sharing without results; Professional conflicts between actors.	Amann, J., & Rubinelli, S., 2017; Amann, 2017 Magnezi et al., 2015; Colineau & Paris, 2010; Josefsson, 2005; Hilliard et al., 2015; Maloney-Krichmar & Preece, 2005; Bullinger et al., 2012;

Thus, there is no agreed definition of the health community and too little examples of it. Such limitations on literature confuse all stakeholders and raise indifferencies because no agreed model is proposed. We facing the complex issue: to define the health community in managerial sciences and to design an appropriate model for transfer knowledge (via open innovation perspective: both inside and between health communities). Even OI is classically applied and defined to business models „Open

innovation is the use of purposive inflows and outflows of knowledge to accelerate internal innovation, and expand the markets for external use of innovation, respectively. [This paradigm] assumes that firms can and should use external ideas as well as internal ideas, and internal and external paths to market, as they look to advance their technology" (Chesbrough, 2006), „Open innovation described as a distributed innovation process that is based on purposefully managed knowledge flows across enterprise boundaries" (Chesbrough, Vanhaverbeke & West, 2014), „The boundaries between a firm and its environment have become more permeable; innovations can easily transfer inward and outward between firms and other firms and between firms and creative consumers, resulting in impacts at the level of the consumer, the firm, an industry, and society" (Bogers et al., 2017), yet open innovation perspective in healthcare is starting to discuss more and more in various approaches (see Table 2).

Table 2. Definitions of Open Innovation in healthcare

Definition	Authors
"OI used to investigate the adoption of an open health platform by patients, care givers, physicians, family members, and the interested public. OI practices in health care lead to interesting innovation outcomes and are well accepted by participants"	Bullinger et al., 2012
„The OI concept, therefore, postulates that ideas and knowledge should be used as both inputs and outputs for the innovation process. In contrast to other industries, the healthcare industry holds peculiarities that influence and restrict the OI concept. Differences in organizations, norms, regulations and data protection, intellectual property protection culture as well as innovation complexity and information asymmetry"	Reinhardt et al., 2014
„OI in health, as we define it, refers to new forms of collaboration between different actors involved in the health innovation process. Notably, it refers to new kinds of collaboration between public sector (health service and/or research organisations) and private sector organisations; health service/research organisations and their employees (practitioners and researchers); health service/research organisations and the patients and citizens they serve."	Gabriel, Stanley& Saunders, 2017
"A fundamental premise of open innovation is that inter-firm knowledge transfer can accelerate R&D. In industries where complexity and a diversity of capabilities, and specialized infrastructure are required to bring a solution to market, open innovation is touted as a business method where channels of external cooperation can be synergistic. Healthcare is such an industry"	Silva, Schaibley & Ramos, 2018

The main goal of knowledge transfer is to identify, (co-)create, integrate, share, distribute existing and new knowledge, and unsuccessful process of it will have negative impacts for future value creation (Ng et al., 2012). Knowledge transfer also could be considered as adopting accessible knowledge to new contexts for the generation of new ideas and improving innovation processes (Christensen, 2003). Most scholars are using online communities definition for describing knowledge collaboration or transferring

(Faraj et al., 2011), but they're also noted, that context of OI in the context of health communities is still lacking (Secundo et al., 2019; West and Lakhani, 2008; Dahlander et al., 2008). Noted, that there is a growing need for effective community knowledge transfer and knowledge boundaries investigation. OI mechanisms would help for users or actors of communities to achieve valid knowledge transfer (Secundo et al., 2019, Randhava et al., 2017). There are some literature, that proposes the main dimensions of knowledge transfer in OI, describes roles and relations between involved actors, talks about objects and mechanisms of knowledge transfer (Battistella et al., 2016; Secundo et al., 2019), but still, we do not have enough understanding what are the main differences and challenges in the healthcare system, we reach a gap, where the sensitivity of topic is must discussed and models of knowledge transfer in healthcare through OI perspective proposed. There is the main need to focus on described gap exploration and got in-depth analyses with proposals of checked, adapted, and valuable models.

4 Conclusions

Our findings contribute to existing research with the highlights of health communities as potential knowledge creators and integrators. In general – health communities should work as co-creation between various stakeholders (patients, medical professionals, researchers etc.) and valid knowledge transfer through open innovation between other communities. By taking health communities in the agreed model, it is necessary to highlight the potential to the innovation processes. This article explored the existing relevant literature related to the topics of knowledge management and health ecosystems; open innovation and health; knowledge co-creation and community; knowledge transfer and open innovation. Paper has identified two main 3rd order categories: health communities and knowledge transfer. Findings showed that OI is approachable to the healthcare sector and has wide possibilities of using, but yet – health communities lack definitions and models to find out valid knowledge transfer model from existing literature. So this article lays as a background and present opportunities for the further research of health communities, defining it and creating models of informational flows, knowledge co-creation, and integration aka knowledge transfer, inside and between those communities, what forms an interesting avenue for future research.

Abstract

Museums as social and cultural institutions should drive innovation to strengthen the relationship with the audience, contribute to social value creation and develop community-oriented processes within cultural ecosystems. The study investigates to what extent Romanian and Italian museums are perceived as innovative by their audiences to understand how a museum could better meet the expectations of the audiences. As social value-oriented institutions, museums should involve their communities to contribute to cultural knowledge creation fostering audience participation by involving the users to co-create public value and shape the museum as an innovation-driven community. In driving innovation, museums are involving their audiences and stakeholders to contribute to cultural heritage knowledge within cultural ecosystems. Museums as community-oriented organizations should drive audience-centered innovation for cultural knowledge creation.

Keywords – museums, innovation, community, innovativeness perception.

Paper type – Academic Research Paper

1 Introduction

In the past few decades, museums have experienced impressive changes in the way they perceive and assume a cultural and educational role in society (Emery, 2001; Long, 2013), the way they develop and implement educational and public programs (Hooper-Greenhill, 2007), as well as how they perceive and cooperate with their communities by strengthening continuous involvement and engagement of the audience and driving users to contribute to sustaining museum knowledge and information sources for cultural value creation (Kadoyama, 2018; Simon, 2010; Holden, 2006).

In the twenty-first century museums should behave as engaging institutions that place the visitor at the center of museum experience in order to support the visitor to engage with objects and collections, and learn. The engaging museums helps strengthen diversity, social inclusion and cohesion, becoming a community meeting place (Black, 2012). The changes in museums are of such a large extent and profound that the definition of museums supported by the International Council of Museums is changing, but the process is so complicated, the stakeholders to be considered so various, that an agreement has not been met yet. Part of the challenges to be overcome is to understand the wide diversity of museum activities and their impact on societies and communities, including the social innovation that they could achieve. Thereby, Vicente, Camarero and Garrido (2015) have defined innovation within museums as tendency that enables the museum to better present its exhibits to the visitors and incorporate systems, processes, organizational and technological infrastructures in order to better contribute to cultural knowledge and value by interacting with audience. Thereby, innovation in cultural organization as well as museums has been interpreted as a means to react to inefficiency and organizational crisis as a way to repair and arrange the structure and policies (Vicente, Camarero and Garrido, 2015). Moreover, innovation should help museums to develop as organizations, evolve as institutions working in the service of society, and communities that contribute to sustaining value co-creation interacting with audiences (Minkiewicz, Evans and Bridson, 2014). As embracing both technological and organization innovation as a strategy, museums contribute to achieving social and economic performances promoting learning and development within cultural ecosystems (Camarero and Garrido, 2008; Borin and Donato, 2015).

Museums should select a change management strategy in order to face all contemporary challenges by dealing with complexity and creativity management (Janes and Sandell, 2007), leading the museum as an effective agent of social innovation, a community space and audience-oriented organization able to rethink how to promote future and sustainable development engaging the public within communities (Watson, 2007; Crooke, 2007).

All these transformations are tightly related to transformation within society and the changing expectations of the wider public, as well as with the evolving practices in the museum world and of the curatorial practices. This latter aspect is connected to

technological innovations, as well as innovative practices adopted by museums when designing exhibitions or various public programs. This innovative practice leads to a more appealing public offer, as well as to increased impact. We observe a direct link between the image of a museum and the amount of innovation associated with its name.

The motivations of the study rely on the need to relate visitors' perception about museum's innovativeness to communication and organizational arrangements and policies museums have to build in order to be perceived as innovative, social and value-driven organizations living within cultural ecosystems to build a sense of community involving the public. The present paper investigates to what extent Romanian and Italian museums are perceived as innovative by their audiences. To reach this aim we developed an online survey. The results help museum managers better understanding their audience and how they perceive museums from an innovation point of view.

This is both theoretical and empirical. Museums are driving innovation by involving the audience and constructing a meaning of their communities in the cultural heritage content definition. The paper is structured in six sections. Following the introduction, in the second section, the theoretical background relies on rediscovering museums as innovation-enabled and community-oriented organizations living within cultural ecosystems. In the third section, a study on the perception of museums' innovativeness is presented. The fourth section elucidates the discussion. Finally, conclusions are set out.

2 Museums as innovation-enabled and community-oriented organizations living within cultural ecosystems

Museums as memory, cultural and educational institutions are information-driven and information utilities, knowledge-based and learning-driven and community-oriented organizations that contribute to cultural value creation (Bagdadly, 2007; Freedman, 2000; Hein, 1998; MacDonald and Alsford 2001; Marty, 2007; Davies, Paton and O'Sullivan, 2013; Sheppard, 2000; Holden, 2006).

Museums should embrace an innovation-oriented view developing new systems, process, organizational and technological arrangement to contribute to cultural value by interacting with audience and better presenting cultural services to the visitor (Vicente, Camarero and Garrido, 2015).

As community-oriented organizations, museums contribute to local and urban development by strengthening educational mission (Tuffs and Milne, 1999) and proceed towards sustainable development by achieving economic and social issues in terms of cultural development and quality of life in the community (Pop and Borza, 2014). Museums should rethink a community vision (Baumann, 2001) to benefit society providing its educational, learning and cultural mission (Hein, 1998) and to develop innovation for social change and value creation processes to achieve cultural sustainability (Castells, 2001; Burton and Scott, 2007; Pop and Borza, 2016). Museums should open up to flexible and multiple interpretations of knowledge, rediscovering

constantly meanings when the truth is dependent on context (Davies, Paton and O'Sullivan, 2013). As working with and for communities, museums should define how to engage with their audiences, to deal with knowledge, how to control and share knowledge on cultural contents, and behave as an institution serving the purposes of society (Watson, 2007).

Museums should strategically promote interaction between museum staff, collections and the public, engaging with a working and active audience in an interactive process (Balogoun, Best and Lê, 2015) building social capital within a community whereas museums and users share same the interests and goals (Rounds, 2012), and the audience is an active agent that influences how museums act and represent what a museum examines (Karp, 1992). As engaging the audience, museums become a community meeting place in order to contribute to cultural diversity and social capital (Black, 2012). As involving local communities, museums are leading institutions of cultural and social growth by fostering and deepening community relationships by involving the members and representatives of local community in museum work and building long-term relationships (Kadoyama, 2018). As a community space and relevant institution to diverse audiences, the museum should continuously learn how to meet new needs and desires understanding the communities outside the museum to engage more successfully with a broader audience (Crooke, 2007).

Museums are seeking to contribute to public value by involving the public. Increasingly, museums have to enable the public to act as producer and creator of social and cultural value by making a contribution and becoming involved (Scott, 2010). As fostering social engagement and visitor's participation and building social capital by following an audience-centric view as a way to develop social innovation in cultural context (Consiglio, Cicellin, Scuotto and Ricchezza, 2017), the museum community as a whole should rethink how to define, establish, evaluate and measure their work, worth and results in the public eye (Sheppard, 2000) developing interaction between museum staff and users as a source for cultural value creation (Romanelli, 2017). In particular, museums should exert favorable influence on visitor's behaviors by developing relational, services and digital capabilities and policies in order to attract new audience and involve visitors to be part of cultural heritage and knowledge content definition (Manna and Palumbo, 2018).

Museums as cultural connectors and meeting places of social innovation (Castells, 2001) contribute to promoting social value and action democratizing knowledge about cultural heritage in a changing world (Burton and Scott, 2007; Bautista, 2014) becoming audience-driven organizations (Gilmore and Rentschler, 2002) that select a visitor-oriented strategy for innovation and change. Museum foster technological and organizational innovation developing both market and service orientation (Camarero and Garrido, 2012). Museums as participatory institutions promote users' engagement and enable audience involvement in cultural knowledge processes (Simon, 2010) by involving visitors to take part in the production and value creation about cultural heritage enhancing

the opportunity for collaboration and networks between staff and communities (Kelly, 2010), developing interactive and collaborative forms between the museum and the public (Bonacini, 2012). Museums should involve the audience as a source for enabling value-oriented relationships. In particular, museums should shape and strengthen the visitor's experience as value co-creation process (Antòn, Camarero and Garrido, 2018).

As agents of social change, museums «are exploring the potential for greater community activism, believing that their own institutional sustainability is closely tied to community sustainability» (Sheppard, 2000, p. 64). Museums should engage with the public as social institutions working for sustaining, and maintaining public value (Holden, 2006). Museums as providers of authentic cultural knowledge (Russo and Watkins, 2007) are redefining cultural authority adapting to changing society (Bautista, 2014), maintaining a legitimizing role as a symbol of the community (Burton and Scott, 2007). Museums contribute to value creation making available and sharing their knowledge with audiences within a cultural ecosystem (Borin and Donato, 2015).

As social and cultural (instrumental, institutional and intrinsic) value-driven organizations (Holden, 2006), museums should proceed beyond a visitor-centered approach to build relationships with the public to create public value (Scott, 2010) and support the legitimacy of cultural value that museums contribute to create for society and within communities (Holden, 2006). Museums should develop the capacity to innovate from a social perspective. Innovative discourse and ways to interact with visitors and communities could determine museums to be active actors in society and their communities, to contribute to social inclusion, to participatory citizenship, to understanding various phenomena influencing the present world, such as migration, climate change or stigmatization (Antos, Fromm, and Golding, 2017). Applying an innovative approach, museums could better reach their mission and become more sustainable institutions (Pop and Borza, 2016) promoting social value (Burton and Scott, 2007). As driving innovation, museums contribute to economic, social, and environmental sustainability, appealing to a general public attracting more revenues from visitors. As innovative institutions, museums are attracting sponsors and other partners in order to promote joint collaboration and partnership. The relationships improve and this leads to development and efficiency. At the same time, an innovative museum becomes a sustainable institution also from a cultural perspective, which is essential for such an organization (Errichiello and Micera, 2018). Museums should create an environment that supports visitor engagement with collections (Black, 2012). Museums are increasingly involving visitors and communities in many ways fostering participation and involvement in cultural project (Simon, 2010). Switching from information to provocation could be based on technology and the creative use of technology. This enables museums not only to better communicate, therefore, convincingly transmit information and educate but also to engage with their communities (Buletić, 2017).

Technologies do not exist *per se* being socially constructed and shaped (Williams and Edge, 1996). Technology helps museums for change by moving from a collections-driven

approach to an audience-driven orientation (Bonacini, 2012). Technology helps museums to attract new audiences and enhance visitor's experience of exhibits (Vom Lehn and Heath, 2005). As becoming hybrid places, museums tend to recombine leisure and learning using entertainment as a means to support learning opportunities and attract new and wider public (McPherson, 2006). Technology could help museums in many ways. Firstly, it facilitates the delivery of information in a more appealing manner considering the changing preferences of the public. It could also help show artifacts and elements of the intangible heritage that would be otherwise out of reach (for instance lost heritage or which exists in some other place). Digitization could help museum visitors travel in time and space. A stimulating way to engage with visitors, in an innovative way, is using chatbots (Tzouganatou, 2018). They could be simply used as information-providing robots, or through gamification, they could enrich the museum experience, not only the knowledge gained during the visit. Another relatively novel technology that could be valorized by museums is 3D printing. It allows museums to offer visitors exact replicas to handle, enriching the museum experience, and allowing for a better understanding of the heritage (Cooper, 2019). Creative 3D food printing also offers many forms of engaging in a fun and educational way with the museum's public (Antlej, Leen, and Russo, 2017).

Virtual and digital technology enhance the museum as an institution serving the society providing cultural meaning, knowledge, legitimation of educational and learning mission. As embracing technology, museums tend to develop the virtual museum as a powerful metaphor for creativity as well as knowledge repositories (Carp, 2004). Virtual reality and artificial intelligence help drive innovation within museums. They offer a stage for visitors engaging and learning, contributing also to a rewarding museum experience. For instance, the type of narration and engagement leads to better or smaller educational outcomes (Moesgaard *et al.*, 2015). Digital innovation comes with specific challenges. For instance, too much gamification might lead to a shift of the attention from content to the game experience itself. Some general challenges are related to the difficulty to design a proper and effective digital strategy, the resistance and lack of digital knowledge and competencies of the museum's staff, or various privacy /legal concerns. 3D printing raises concerns with copyright and funding distribution (Cooper, 2019). As developing smart open innovation museums should select a strategy both to ensure economic funding and also enhance social performances enriching collaborative networks and long-term sustainability (Pop and Borza, 2016).

3 A study on the perception of museums' innovativeness

It is important to elucidate how people perceive museums' innovativeness. In the following subsections, the aim and method, the sample and respondents profile, and findings are presented in order to understand how museums are perceived as innovative and social institutions engaging visitors and meeting the needs of their audiences. Gathering information about how people perceive museum's innovativeness helps museums to plan innovation policies to better meet the needs of visitors and users of

museum information and knowledge sources. As innovative organizations, museums develop an innovation-oriented view to social and cultural growth that enables value creation processes within cultural ecosystems.

3.1 Aim and method

Understanding the perception of museums in the mind of the wider public would help museums managers better design their offer and communication strategies. One of the image-dimensions increasingly relevant is how innovative and creative museums should be. Therefore, the present research maps the perception of the Romanian and Italian museums from an innovation standpoint. To benchmark the results, the public was asked to compare the museums in their country with museums abroad.

A self-administered online survey was distributed online during March and April 2020. Considering various contextual limits, the questionnaire was kept to a minimum number of questions. The results allow us to identify how various types of museum visitors perceive the innovativeness of museums in general, and in their country specifically.

3.2 Sample and respondents profile

We used a convenience sample and administrating the survey online (via Facebook) during the same time (10 days). Due to a higher completion rate, the number of respondents in Romania is almost double (N=406) as compared with the one in Italy (N=207). There are noticeable differences also between the respondents' profile: 67% of Romanian respondents are female and 33% male, meanwhile in Italy the ratio is closer to 50% - 50% (50.2% female respondents and 49.8% male respondents).

3.3 Findings

Given the recent developments in tourism and travel and the increasing access of Romanian and Italian public to museums abroad, we intended to investigate perceptions related to the extent in which museums are considered innovative as well as to assess whether there are noticeable differences between how people perceived museums at home and abroad.

Therefore, we devised the questionnaire in a manner allowing us to differentiate between museums from the country of residence and museums from abroad as well as to distinguish, within each type of museums between main exhibition and temporary exhibitions and educational program for children and other, more general public programs.

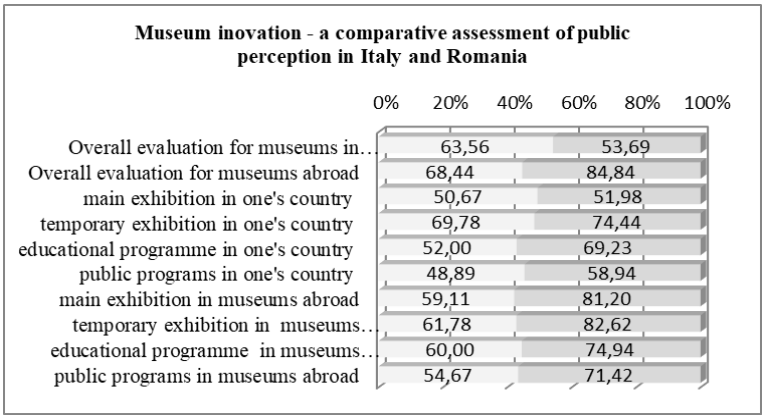

Fig. 1 – Museum innovation – a visitor perception

As shown by the chart above, there is a constant tendency for the Romanian public to rate museums abroad as being significantly innovative compared to museums at home across all categories (overall assessment, temporary exhibition, etc.) with the highest difference being registered for the overall assessment: 31.15%. The same happens for the Italian public, with the gap being less obvious: only 4.92% and a noticeable exception when it comes to temporary exhibitions: those at home are perceived as being more innovative than those abroad (69.78% as opposed to 61.78%).

Looking into data from respondents that have attributed a higher level of innovation to museums from their own country, findings indicate a systemic difference regarding respondents' perceptions over their cultural consumption and familiarity with museums.

As data indicates, the Italian respondents do not see themselves as particularly familiarized with museums, despite considering themselves as generally interested in cultural activities (90.29% of them attributed scores from 3 to 5 on a five points scale when asked to assess the affirmation: I see myself as a person generally interested in culture). On the other hand, Romanian respondents are scoring lower for the general interest in culture (66% reporting a moderate to high interest in culture) but see themselves as quite involved in activities related to museum visiting both at home and abroad.

scores from 3 to 5 on a five points scale	**Italy**	**Romania**
frequent museum visitor	55.3%	71.42%
familiar with museums from their own country	64.53%	80.78%
regular museum visitor abroad	69.41%	75.61%
general interest in culture	90.29%	66%

Fig. 2 – Public's perceptions of cultural consumption and museum visiting

To better emphasize how different are the perceptions of museum innovation, a profile of the most enthusiast respondent was constructed. We took into consideration the socio-demographic characteristics of respondents who attributed the highest level of innovation to museums from home. In Italy, the most appreciative respondent on museum innovation is likely to be a male, aged between 35 to 50, having a top management position and a university degree and living in a city with over 1 million inhabitants. Meanwhile, in Romania, museums are likely to be seen as highly innovative by a respondent having the profile of a female, under 25, with a university degree and no management position, living in a city of over 1 million inhabitants and working in business/economics.

4 Discussion

Understanding how visitors as users of museum information and knowledge sources perceive a museum as an innovative institution helps redefine and arrange strategies and policies for communication, organizational design, and new services infrastructure by rethinking organizational processes and human resources policies. Museums as communities contribute to promoting cultural value co-creation processes sustaining the interaction and dialogue between museum professionals and users as proactive co-producers of cultural knowledge contents, dialogue, and supporting cooperation among private and public actors as a relevant issue of multilateral relationships, social exchanges, and shared values.

The research issues elucidate the need for museums to rethink a strategic and organizational approach in order to build relational and social ties with audience to develop loyalty and trust-based linkages with audience as proactive actor that contributes both to economic and social sustainability of museums and cultural and educational mission of a museum as a value-driven and innovation-oriented community. In coping with increasing environmental complexity and uncertainty, museums should contribute to facilitating value (co-)creation processes, proceeding towards sustainability as a vision for action and change to drive the audience to learn and contribute to enhancing cultural heritage value and advance the progress of society.

5 Conclusions

Today, museums need to drive and anticipate changes by promoting innovation and building social relationships within cultural ecosystem to develop the museum as a community-oriented organization living within a cultural and social ecosystem for engendering collaboration and fostering communication with audience and the public to become an innovative institution that serves for society and within communities. As proceeding towards sustainability, museums should develop organizational, technological and human resources in order to promote continuous innovation as a key driver for change and action in order to contribute to cultural and social value within society. As

community-oriented organizations, museums should build strong ties and relationships with all the stakeholders of museum community enabling them as proactive co-producers of cultural heritage and knowledge as source that lead to public value creation.

In this study, there are theoretical, managerial, and organizational implications. Museums increasingly tend to emerge as innovation-driven organizations strengthening the relationship with their audiences to contribute to building the museum as a community within social and cultural ecosystems. In driving innovation, museums should intervene in organizational design and human resource management policies to re-plan how to better use and enhance knowledge, information, and technological sources. Museums more and more should pay attention to supporting the relationship with users and co-producers of museum knowledge and value.

In this study, there are some limitations. This study is the starting and preliminary section of a wider research project aiming at investigating the relationship between museums and audience on the capability to drive and appreciate innovation as a source for change within the cultural ecosystem and identify how innovativeness has a successful impact and issues on audiences' needs and experiences.

Further research perspectives imply to extend the investigation and consider the point of view of museum employees as professionals and managers within several European museums and compare with Romanian and Italian museums' strategies and policies aiming to exploit in turbulent times of environmental and external changes as the pandemic crisis has recently shown.

Abstract

The aim of this paper is to examine the state of researches on the knowledge management subject related to the supply chain, and its possible innovation based on the integration with blockchain technologies.
Knowledge management (KM) is the process of identification, organizing, storage, sharing and management of knowledge and information towards value creation. Organisations try to apply and embed it into their primary activities as supply chain processes (Akhavan, Philsoophian, Rajabion and Namvar, 2018).
Supply chains are configurations of firms working together in a network that constantly need to upgrade their operations and capabilities, both upstream and downstream, from raw material to end-use consumption. The information flows that lie at the heart of network members ' communication and collaboration are not only diverse sources of information, they also provide an opportunity to build knowledge-based resources that are an important part of the capabilities of the extended firm. Performance can be improved by sharing updated knowledge among the supply chain process and functioning through knowledge management tools (Jha and Karn, 2019).
Knowledge management is based on trust management. The Blockchain technology can be used as a method for managing trust in generating, storing, sharing, protecting and applying a variety knowledge. Blockchain can potentially improve knowledge management, in order to share successfully relevant data and information about the product and services included in the "chain". Despite to other initiatives to employ other technologies to share knowledge across the chain (such as "social manufacturing" or "cloud manufacturing" in the manufacturing industry (Zhi Li et al., 2017), the DLT (Distributed Ledger Technology) era introduces many opportunities like, "provenance certification" of stored information because of tamper-proof transaction history maintained in the distributed ledger, "knowledge automation" capabilities (Ziyuan Wang et al.

2018). The adoption of blockchain in the supply chain could create a new governance model for creating public value for a specific business process. This research aims to answer how to create the best connection between the business environment knowledge base and the supply chain management processes integrating blockchain technology.

Keywords – Blockchain, Supply Chain, Knowledge Management

Paper type – Academic Research Paper

1 Introduction

Knowledge management (KM) in supply chains is one of the most critical challenges faced by supply chain executives as they seek to establish collaborative projects in the supply chain. The need for the organizations to establish close relations with partners in the business and supply chain requires coordination, transfer and exchange of knowledge and best practices (Mariano, Dogan, Mogre, and Perego, 2010). Knowledge management can be viewed as a leverage mechanism for supply chain integration; the enhancement of intra and inter-relations across the supply chain; supply chain strategy alignment; and the reinforcement of knowledge transfer in product development (Perez-Salazar, Alfonso Cedillo-Campos and Hernandez Gonzalez 2017). Companies exchange information resulting in a potential for knowledge sharing and create value. Sharing and transferring knowledge in a supply chain increases the competitive advantage of the whole chain and guarantees the continuity of its operations (Scholz-Reiter, Delhoum and Stoll, 2007). Thus, knowledge exploitation plays an important role within each organization and between organizations integrating the supply chain, especially in the business relations between suppliers and customers. However, extending internal knowledge management programs to external sources is a demanding task because of some typical barriers (Barson et al. 2000) classified these barriers in four categories: technology barriers, organisation barriers; people barriers and finally cross category barriers which are featured by technology, organisation and/or people (Scholz-Reiter, Delhoum and Stoll 2007).

Since the efficient use of knowledge is critical to the survival and success of companies in competitive globalized markets, knowledge management systems (KMS) have become an essential tool for supply chain management (SCM) (Rodríguez-Enríquez, Alor-Hernández, Mejia-Miranda, Rodríguez-Mazahua and Sánchez-Ramírez, 2016). Organizations work in a global market climate that is marked by rapid developments, innovations in technology, increasing consumer demands and intensified competition. For organizations to survive in such a turbulent environment, they must promote their capacity to learn new practices and technologies and consistently improve their performance and long-term organizational success (Attia and Essam Eldin, 2018). The rapid digitisation of industry, or Industry 4.0, is trending in supply chain management. The opportunities surrounding digitisation have made it possible for supply chains to

access, store and process a large amount of data both from within a firm and externally (Schniederjans, Curado and Khalajhedayati, 2020). Information management is based on trust management and blockchain can be used as a confidence building tool to create, store, exchange, secure and apply a variety of information. The blockchain is a modern decentralized technology that can theoretically overcome the above problems and enhance the management of information.

This investigation seeks to answer the following research: Is Blockchain the technology for future improve trust and governance of Data, Information and knowledge in the Supply Chain Management?

2 Research Methodology

In this research study, we have used the systematic literature review methodology in the field of knowledge management, supply chain and blockchain. The list of papers was downloaded using Scopus (www.scopus.com), which is the largest abstract and citation database for academic reputed scientific research journals, books and conference proceedings. The literature review presented in this paper examines early views of the important investigations and developments within the areas of knowledge management and blockchain within the context of supply chains environments. For the research the authors have used follows keywords:

- supply chain and knowledge management
- supply chain and blockchain

The search results of the article are shown in the tables below:

Table I - Keywords “Supply chain and Knowledge management”

3 Framework - Theoretical background

3.1 Knowledge management

Knowledge management can be defined as the set of activities which allow organizations to create, store , distribute and apply knowledge. Knowledge management is an enterprise process. It is the process through which firms create and use their institutional or collective knowledge (Gunasekaran and Ngaic, 2007).

Knowledge has turned out to be one of the key motivating forces for business success. Thus, information management within an enterprise has become the central focus for all businesses. In general KM is "a process cycle for defining, transmitting, storing and disseminating information for reuse, understanding, and sharing and learning around the organization" (Chong, Ooi, Bao and Lin, 2014).

The aim of knowledge management is to develop approaches that will make it easier to get the right knowledge to the right person at the right time and in the right format (Halawi et al., 2006). Knowledge management would also help organizations to remain competitive by sharing information with external partners and knowing the products , services, strategies and best practices of their competitors (Attia, and Salama, 2018).

The importance of knowledge and knowledge-related capabilities as a competitive advantage is derived from the Resource Based View Theory (RBV). The resource-based view theory suggests that firms compete on the basis of their resources and capabilities. The resource refers to anything tangible or intangible possessed or acquired by a firm, while the capacity is to use resources to carry out tasks or activities (Attia and Essam Eldin, 2018). According to RBV, the theory assumes that resources are the source of a company's capabilities and that its capabilities are the foundation of its competitive advantage (Samuel, Goury, Gunasekaran and Spalanzani, 2011). The Resource Based View Theory (RBV) explains strategic resources that are valuable, rare , inimitable and non-replaceable and can make a massive contribution to social, economic and technological benefits.Knowledge is considered to be the most significant resource in knowledge-based view (KBV) theory. KBV's theory focuses specifically on the nature and role of knowledge in achieving new innovations. Developing superior knowledge resources that are embedded in products, processes and services provides a long-term solution; enhancing performance and competitive advantage (Jali, Abas, and Ariffin, 2017). Knowledge management (KM) bridges information demand and supply on behalf of learning processes and, consequently, organisational performance improvement. Knowledge assumes tacit and explicit forms. Tacit knowledge is deeply rooted in action, commitment, and involvement and, thus, it is hard to formalize and communicate. Explicit knowledge is codified and transmittable in formal, systematic language and thus it is captured in libraries, archives, and databases. There is a permanent interaction between tacit and explicit knowledge that moves across individuals, groups,

organisations, and back to individuals again (Schniederjans, Curado and Khalajhedayati, 2020).

3.2 Blockchain

Between 2007 and 2008, the world was shocked by the financial turmoil caused by the chain of financial collapses built on bad debt which triggered a crisis that had not occurred since the Great Depression. During this period, the world has witnessed the fragility and instability of a tightly interconnected and highly indebted global financial system. In response to these events, in October 2008, Satoshi Nakamoto published a white paper on a mailing list (Nakamoto, 2008). introducing the topic of blockchains to the world, outlining the benefits of a currency exchange system called bitcoin. To date, bitcoins and other cryptocurrencies are probably the most commonly recognized use case of the blockchain and as such are an adequate basis with which to explain the operating principles of the technology (Hughes, Park, Kietzman & Brown, 2019). The blockchain has been defined in several ways: the mainly accepted definition is that it is a distributed ledger. Distributed ledger technology (DLT) is a generic term that describes all the technologies that distribute information on multiple sites, countries or institutions and that includes the blockchain. A blockchain refers to an open, shared, de-centralized and distributed ledger in which transactions are recorded and added in chronological order with the aim of creating tamper-proof permanent records (Nakamoto, 2008). Blockchains are made up of nodes located on a communication network that uses some common communication protocols: each node on the network stores a copy of the blockchain and a consensus function is implemented to verify transactions to preserve the immutability of the chain (transactions they cannot be changed). Blockchain technology is unique in that it does not require a central server to store and retain data. As long as the network reaches consensus on what transactions have taken place in the past, it acts collectively as a server to host data. If a dishonest participant decides to change the previous data, the majority of the network quickly excludes it (Hughes, Park, Kietzman and Brown, 2019). Blockchain technology differs from most existing information systems projects by including four key features; non-localization (decentralization), security, verifiability, intelligent execution (Saberi, Kouhizadeh, Sarkis and Shen, 2018). A blockchain is an encoded digital accounting that is stored on multiple computers on a public or private network. As each transaction occurs, it is put in a block. Each block is connected to the one before and after it. Each block is added to the next in an irreversible chain and transactions are blocked together, hence the term "blockchain". The current blockchain could be compared to the internet adoption for commerce of several years ago which emerged disruptively in many established companies and heavily influencing supply chains (Treiblmaier, 2018). The advent of the blockchain is considered a digital revolution but at the same time it is a natural consequence of the development of the Internet (Firica, 2017). Similar to the Internet, blockchain is not a single technology, but operates on a number of technologies

that include the Internet as an infrastructure and uses the blockchain protocol to store transaction records and establish consensus rules (Treiblmaier, 2018). A big difference between the current Internet design and blockchain technology is that the Internet was designed to move information (not value) and to move copies of files (not original information). In blockchains, the value is represented in transactions recorded in a shared and protected ledger by providing a verifiable and secure transaction record with timestamp. These transactions are viewed through a verification process that is consistent with the network's consent rules. Once the new record is verified and added to the blockchain, multiple copies are created in a decentralized way to create a chain of trust. (Saberi, Kouhizadeh, Sarkis & Shen 2018). Two main types of blockchain stand out in terms of access control: the blockchain can be public or private (bitcoin uses a public version). Within a public blockchain, each transaction is public ("without authorization") and users can remain anonymous. Each user can join without requesting the authorization of other members. The network typically has an incentive mechanism to encourage participants to join the network. Bitcoin and Ethereum are examples of public blockchains. Within authorized blockchains, participants must obtain an invitation or permission to join. Access is controlled by a consortium of members (consortium blockchain) or by a single organization (private blockchain) (Wang, Hugh Han & Beynon-Davies 2018). In addition to being used in the financial sector, blockchain technology has found application and is also being developed in the logistics and supply chain activities. Blockchain is potentially a disruptive technology for the design, organization, operations and general management of supply chains.

4 Findings

4.1 knowledge management and supply chain practices

A supply chain is a network of collaborative firms that transforms raw materials into distributed products. Supply chain management is one of the practice used by companies to improve their business performance as well as to retain their competitive advantage, as competition is among supply chains and not between individual organizations (Attia and Essam Eldin, 2018). The advantages of supply chain management derive from the ability of a company to quickly exploit the entire network of suppliers, suppliers, buyers and customers. The information flows that lie at the heart of coordination and collaboration between network members are not only disparate sources of information, they also provide an opportunity to build knowledge-based tools that are an important part of the capabilities of the extended firm (Samuel, Goury, Gunasekaran and Spalanzani, 2011).

Supply Chain Knowledge can take on different formats such as forecasting, product design, competitor analysis, demand analysis, customer analysis and specific problem solutions.

Supply chain knowledge flows can be categorized into two categories. Formally structured (explicit) knowledge flows include transaction related information such as purchase orders, invoices and delivery schedules. The flow of tacit knowledge in the supply chain is more context-specific, largely unstructured and embedded in the relationship between supply chain partners. It consists of two components: the technological know-how and the cognitive component (Li, Tarafdar and Rao, 2012).

Explicit knowledge is discrete and digital, and can be easily transmitted through formal and systematic means. Examples include past records, such as archives or databases. Tacit knowledge, on the other hand, represents a higher level of abstraction than explicit knowledge. Tacit knowledge is difficult to codify, to transmit, It contains data that are processed, organized and useful, but the logic of its organization is often complex, implicit, and ambiguous (Shih, Hsu, Zhu, and Balasubramanian 2012).

Today, knowledge management (KM) is recognised as a way to improve SC performance (Ruel, Shaaban, Ducros, 2019) and information management is considered crucial to achieving sustainable competitive advantage in supply chain management. Knowledge management (KM) transforms information, data and intellectual assets to firms' perdurable value through recognising useful knowledge for running and managing operations (Lim, Tseng, Tan and Bui, 2017).

The resources of a firm are capital equipment, patents, individual skills, brands and reputations, financial resources, physical resources, technological resources or organizational resources. Knowledge could adds value to an organization through its contribution to products, processes and people, while knowledge management (KM) transforms information, data and intellectual assets into lasting value by identifying useful knowledge for management actions. KM tools support the organization in exploring, innovating, disseminating and automating corporate knowledge (Samuel, Goury, Gunasekaran and Spalanzani, 2011)

As a result, many partner companies in an integrated supply chain network cooperate with their suppliers and customers and share information and knowledge with a view to creating a collaborative network capable of competing effectively on the marketplace (Cai, Goh, De Souza, and Li, 2013). Members of the supply chain are expected to realize mutual benefits through collaboration, mutual trust, long-term commitment, partnership, frequent communication and sharing of information (Attia, and Salama, 2018). Knowledge sharing refers to the use of information assets across different business partners to focus on supply chain activities, identify market opportunities and/or capture business value. Inter-organizational knowledge sharing is a complex issue based on inter-organizational relationships. Inter-organizational knowledge sharing is a critical factor in the coordination, allocation and integration of collaborative resources across the supply chain (Cai, Goh, De Souza, and Li, 2013). Compared to sharing information, knowledge sharing contributes more to effective and efficient decision-making. The greatest challenge is to establish a trusting relationship between the parties (Shih, Hsu, Zhu, and Balasubramanian 2012). Knowledge sharing often implies the need to release certain

protected information, e.g. intellectual property, financial , strategic and operational information, to partners who may or may become competitors. Knowledge sharing involves some level of risk as one partner can not fully dictate how the other partner can use shared knowledge (Cai, Goh, De Souza, and Li, 2013). With respect to supply chain management, trust is essential to cultivating a successful relationship and promoting cooperation and sharing of expertise across the supply chain. Inter-organizational trust not only influences the nature of a business relationship, but also, more importantly, impacts strategic alliance outcomes in terms of information exchange and knowledge sharing (Chen, Lin, and Yen, 2014).

4.2 Blockchain and supply chain management

The supply chain consists of a series of activities and states that the products cross in their path from the initial suppliers to the final customers. When the parties actively and collaboratively manage the activities and relationships in the supply chain to maximize customer value and obtain a sustainable competitive advantage, we can speak of supply chain management (SCM). It represents a conscious effort by supply chain companies to develop and manage in the most effective and efficient way possible (Dujak, Sajter, 2018). A supply chain often intersects business functions and national borders with a large network of business partners. These interactions increase the vulnerability of the supply chain and can lead to its disruption. To reduce these vulnerabilities, supply chain professionals need to identify potentially vulnerable links and assess their level of risk (Min, 2019). Blockchain is potentially a disruptive technology for the design, organization, operations and general management of supply chains. The ability of the blockchain is to ensure the reliability, traceability and authenticity of information, together with intelligent contractual relationships in a trustless environment, all leading to an important re-design of supply chains and supply chain management (Saberi, Kouhizadeh, Sarkis & Shen 2019). According to Chang, Chen and Lu, (2019), with the blockchain there is a "business tracking reengineering in supply chain" (BPR). “The BPR refers to the "radical rethinking and redesign of business processes to achieve significant improvements in contemporary critical performance measures, such as costs, quality, service and speed". As we saw earlier, several scholars have described the main benefits of using blockchain in a supply chain environment. Most of them focus on the benefits of improving the transparency and visibility of monitoring activities in business operations. Blockchains has been developing in various sectors, such as medical records management, supply chain, banking and financial services, insurance, Internet of things (IoT), sharing economy and distributed access control (Chang, Chen & Lu, 2019). In a global market, customers are often unaware of the sources of the products they buy and consume. To overcome this lack of awareness, blockchain technology can be implemented in supply chains to share information on the origin of products in a more transparent way with customers. (Montecchi, Plangger and Etter, 2019). This level of

transparency and visibility is essential to improve the traceability of the products, guaranteeing their authenticity and legitimacy through real-time monitoring. In addition to the security benefits, blockchain technologies can bring a multitude of management benefits to daily business practices, including:

- Reduction of costs/transaction times deriving from better managed blockchain platforms that do not require the involvement of third parties;
- Improvement of visibility along the entire supply chain, following greater transparency obtained through the open registers that anyone can access;
- Better relationships between business partners through the integration of digital and physical worlds, which includes a sharing of transactions and information flows along the entire supply chain.

Despite these potential benefits, blockchain technology can pose a number of implementation challenges that concern the lack of organizational preparation or expertise on the part of the actors involved, the inadequacy of technical infrastructure, scalability problems and limited financial resources for investments in blockchain. In this regard, it is necessary to develop managerial strategies to help companies overcome these challenges by fully exploiting the advantages of DLT technologies (Min, 2019).

5 Discussion

An growing number of studies are investigating the supply chain not only as a process by which a business obtains goods and services but also as a tool for competitive advantage. The supply chain can indeed be seen as a network of companies that, through cooperation, allow access to a pool of rare and inimitable knowledge. Companies may establish collaborative partnerships with partners in their supply chain to access complementary information sources more easily, at a lower cost and with less risk than would be possible if those expertise were established within the organization (Nagati and Rebolledo, 2013).

In this way, the knowledge base is the only basis for achieving competitive advantage and good management of its sustainability (Azizi, Maleki, Moradi-Moghadam and Cruz-Machado, 2016).

Efficient use of knowledge is critical to companies' survival and success in competitive globalized markets, the knowledge management system (KMS) has become an essential tool for supply chain management (SCM) (Rodríguez-Enríquez, Alor-Hernández, Mejia-Miranda, Rodríguez-Mazahua and Sánchez-Ramírez, 2016).

As global markets grow, supply chain managers face ever-changing markets, new global markets and a competitive environment. Organizations today operate beyond national boundaries so they can not rely solely on their internal quality activities (Azizi, Maleki, Moradi-Moghadam and Cruz-Machado, 2016).

Learning and KM can be seen as drivers for the development of the supply chain and as processes that could introduce innovation in supply chains (Samuel, Goury, Gunasekaran and Spalanzani, 2011).

Knowledge management typically relates to supply chain management by offering the required resources for handling large quantities of data generated by supply chain operators and their customers. Supply chain management requires managers to identify, track and control customer distribution activities across the entire supply chain, from procurement, storage, manufacturing and retail. All of these tasks include managing knowledge not only from the technical side through information systems, but also the consistency of the knowledge given in the supply chain through data processing and analytics, whether tacit or explicit (Schniederjans, Curado and Khalajhedayati, 2020).

The communication amongst partners to accomplish coordination and collaboration can be enhanced by Information and Communication Technology (ICT) (Mariano, Dogan, Mogre, and Perego, 2010). IT refers to the use of any networking, storage, computers and other tools, processes and infrastructures to produce, obtain, process, store, secure and share data or information. IT is certainly an important and productive tool and framework that can be used for information sharing and KM process facilitation. Intelligent hardware computing and software tools can play an important role in KM processes (Jalilvand, Khazaei Pool, Khodadadi and Sharifi, 2019). The technologies consisting of cloud computing and blockchain can be used together on the information systems side to provide the required advantage for KM and CCM. Cloud computing is a massively scalable computing model that provides as a service applications, infrastructure and networks, allowing real-time data sharing across the supply chain (Schniederjans, Curado and Khalajhedayati, 2020). Blockchains permit to store information in a tamper-resistant and irrevocable manner by reverting to distributed computing and cryptographic technologies. The primary purpose is to keep track of the ownership of tangible and intangible assets (Fill, and Harer (2018). Blockchain can function as a distributed, programmable and encrypted ledger to transfer, secure, store and quickly access high-security information. When the information is stored in Blockchain, it can't be rewritten and changed any more. This design makes Blockchain capable of having a permanent historical record. Application of unique features of Blockchain including high reliability, anonymity, transparency and data sharing , information invariance, etc., should respond to conventional knowledge management challenges (Akhavan, Philsoophian, Rajabion and Namvar, 2018).

6 Conclusions

Knowledge management plays a key role in the success of a collaborative network, as information sharing and knowledge assets are vitally important for the network, especially in the context of a supply chain. One of the significant reasons for taking advantage of knowledge management (KM) for each organization deals with using available knowledge in an optimized style, and it has done enough effort to increase

knowledge by its requirements. The use of knowledge management and its instruments assist each organization in learning from its previous mistakes and in using them for future success. The "knowledge governance" is another important aspect in the management of data and information stored in such Information Systems used to manage the knowledge thought the supply chain. The successful adoption of blockchain in the supply chain can be aimed to create a new governance model for creating public value for a specific business process built on a supply chain initiative that put together many stakeholders, both in public and private sector as well as regulators and auditors. This new "Open Government" model will ensure transparency, participation and collaboration (Manuel Pedro Rodríguez Bolívar, 2019). Most of the time the intellectual property of the knowledge produced by the different actors of the supply chain belongs to the customer of the supply chain, who often makes available, or requires the use of their own information system to store knowledge. this article evaluates the use of the blockchain as an information system for knowledge management in the supply chains, where precisely for the mechanisms of trust, interoperability and distribution of ownership of the data stored in the blockchain can be made available to anyone, including the final consumer, which would be given the opportunity to access the original information of the products, inserted in the knowledge base, directly from the source of the information itself, which would ultimately be independent of the will of the client to provide the information. Nowadays, due to the extended amount of knowledge and information, as well as the need for large servers for storing and maintaining the information, the DLT technologies are not yet mature, so the blockchain today can only store a limited amount of data and external systems (E.g. cloud) have to be used to allow the management of the content of the Knowledge base. Several studies and research are underway to allow large amounts of data to be stored in blockchains, such as blockchain databases. Finally, the use of blockchain in the supply chain management can represent a disruptive solution in order to create open market and improve the competitiveness of all markets.

Abstract

Blockchain (BLK) is believed to have the potential to disrupt traditional business models through inherent features such as distributed, decentralized, peer to peer, and security-by-design. However, the academic community mostly dedicated its BLK research to financial and more recent supply chain disciplines, overlooking BLK implications in other domains. This research aims to fill the research gap of BLK implications for knowledge management by investigating the potential effects of BLK use for knowledge sharing. To do so, four state-of-the-art real use cases, namely, Orvium, ARTiFACTS, Everipedia, and Steem, have been reviewed and explored here. We identified the impact of BLK on the antecedents and benefits of knowledge sharing through content analysis of available data on websites and white papers of associated cases. The results were categorized according to benefits (cost reduction, growth, intangible benefits) and individual antecedents of knowledge sharing (intention, motivation, reciprocity, trust). The results of this research paper provide insights into the research community by presenting the current state and future research avenues.

Keywords – Blockchain (BLK), Distributed Ledger Technology (DLT), Knowledge Management, Knowledge sharing

Paper type – Academic Research Paper

1 Introduction

Blockchain (BLK) placed among the top five technology trends in the Gartner Hype Cycle for Emerging Technologies of 2018 (Kietzmann & Archer-Brown, 2019), having the potential to transform businesses, economies, and societies (Kamble et al., 2019). Information System research concerned with BLK sobered from the initial hype to reality by admitting that there exists a lack of technology-driven, systematic approaches to understand the potential of the BLK technology (Ostern, 2019). Thus far, much of the academic attention on BLK has currently focused on its ability to transform the financial services industry. Nevertheless, the implications of BLK are much broader. Organizations across all industries, ranging from finance and healthcare to manufacturing, supply chain, and retail can benefit from BLK (Angelis & da Silva, 2019) because its capabilities and features have the potential to offer opportunities for new ways of value creation (Morkunas et al., 2019).

Although Information Systems (IS) and emerging technologies could be considered as an enhancing contributor to Knowledge Management (KM) processes (Gold et al., 2001), our understanding of the relationships between BLK and KM remains limited. Frozza et al. (2019) reviewed the implications of BLK technology for KM and concluded that the decentralization aspect of BLK had not been explored sufficiently. Moreover, they identified that most studies are applying BLK to meet KM challenges rather than exploring new opportunities or innovative processes. We followed this research gap and described how BLK could facilitate KM. We reviewed four proofs of the concept of innovative BLK-based knowledge sharing platforms (Orvium, ARTiFACTS, Everipedia, and Steem).

The rest of this paper is organized as follows. In section 2, a review of the literature is provided. In section 3, we describe the research method. Section 4 presents the findings.Section 5 is dedicated to discussion. Finally, section 6 concludes the research.

2 Literature review

2.1 BLK

BLK is a decentralized online ledger that facilitates various peer-to-peer value transfers (digital currencies, physical commodities) without the need for having a trusted third party such as banks, accountants, or lawyers (Frizzo-barker et al., 2019). Since BLK is a distributed database comprising of records of transactions that are shared among participating parties, all the transactions must be verified by the consensus of more than half of the participants in the system. Therefore, fraudulent transactions would be unable to pass collective verification (Zhao et al., 2016). This is allowed because BLK works as a sequence of blocks that holds a complete list of transaction records in hash functions with a timestamp and a link to the previous block (Janssen et al., 2020).

As previous research indicated (e.g., A. Hughes et al., 2019), BLK is characterized by essential characteristics such as immutability, transparency, security, speed, and trustworthiness, which will change industry and commerce substantially, and will foster economic change on a global scale. Three main types of BLK platforms can be identified from the literature (Swan, 2015). BLK 1.0 is based on the digital currency and how the deployment of cryptocurrencies in applications relates to cash, such as currency transfer, remittance, and digital payment systems. BLK 2.0 is associated with digital finance and concentrates on applications that are more elaborated than based cash transactions such as stocks, bonds, loans, mortgages, smart properties, and smart contracts. BLK 3.0 focuses on digital society; it is mainly intended to find BLK applications in government, health, science, literacy, culture, and art.

2.2 BLK and knowledge sharing management

Some prior studies focused on BLK implications for KM processes. However, their scope was limited. For instance, BLK could be applied in KM to provide security in knowledge production and transfer, or to use smart contracts as a mechanism to ensure the collaboration of involved parties (Kostin et al., 2017). This is because knowledge and organizational best practices need to be protected from unauthorized copying, as the privacy of data and fairness in knowledge value exchange is increasingly crucial to both customers and organizations

Akhavan et al. (2018), in their study, proposed a Block-chained knowledge management model (BCKMM) through incorporating both KM and BLK concepts. They developed a knowledge services framework for the creation, application, and sharing of knowledge throughout the organization and especially between experts in a company by providing a decentralized framework. This framework exploits BLK concepts to achieve a distributed and flexible network to conquer the problems of traditional centralized KM models through developing the primary process of KM.

Li et al. (2018) developed a platform to make a secure and reliable way for knowledge sharing in untrustworthy environments using two advanced technologies: private cloud and BLK. It is implemented as a distributed network to share knowledge and record transactions, reducing the risk of sharing on the platform. It was primarily designed to minimize the risks of data modification, as it seeks to provide a secure method to ensure data immutability.

Hu et al. (2018) proposed the Reputation Based Knowledge Sharing (RBKS) model intending to explore the copyright protection of the knowledge owner. This system consists of a BLK-based reliable storage server, which is jointly employed to share and store knowledge, the main procedures being implemented through smart contracts to ensure safe execution. BLK is also employed to manage user interaction, ensuring transparent and reliable delivery of messages, while smart contracts are used for knowledge creation and knowledge sharing.

Sychov et al. (2019) view BLK as a way of record-keeping, preserving records, and preventing unwanted changes. They suggest BLK applications for access control and protection. BLK can also be seen as a tool that allows knowledge owners to be held accountable for complying with statements issued in BLK. It is viewed as a means of providing traces of provenance data based on access control, where only authorized users can verify changes made to any data file. Besides, it provides proof of change using digital signatures and timestamps (Mittal et al., 2018; Ramachandran & Kantarcioglu, 2018).

Finally, Frozza et al. (2019), who aimed at investigating the applications and implications of BLK technology in KM, observed that BLK had been mainly applied in knowledge sharing and distribution, retention, and identification domains. They also found that immutability, traceability, and automated decision-making were the main incentives behind BLK applications in KM.

The impact of knowledge sharing on organizational performance manifests in various mechanisms. Knowledge sharing influences organizational collaboration, absorptive capacity, innovative capability, or value co-creation (Cassia et al., 2020). The antecedents of knowledge sharing were identified as organizational culture, organizational structure, reward system, motivation, interpersonal trust, and management support (Farooq, 2018). Another study added individual factors: intention, trust, motivation, and reciprocity (Ali et al., 2019). Because the organizational factors are not relevant for our analysis, we used part of the research model developed by Ali et al. (2019) to link the concepts that can be affected by BLK with the benefits for an organization. The description of the used categories in the model can be found in Table 1.

Table 1. Definitions of antecedents of knowledge sharing based on Ali et al. (2019)

Antecedent	Description
Intention (I)	intention to share knowledge
Trust (T)	Individuals are more interested in sharing knowledge with those that they trust.
Reciprocity (R)	knowledge sharing is expected in return
Motivation (M)	personal benefits, normative consideration and community-related consideration

3 Research method

The empirical research on BLK is scarce, especially in the KM discipline. The novelty and low maturity of a research topic justify exploratory and theoretical research (Saunders et al., 2015, p. 175). Therefore, we conducted an exploratory content analysis of documents associated with the chosen BLK implementations. More specifically, we analyzed a purposive sample (see Saunders et al., 2015, p. 301) of four cases of BLK implementation in the KM field (see Table 2). The main criteria for choosing a case were the availability of the data about each case, the volume of data about the case, and the innovativeness of using BLK in the KM field.

For analysis, we used archival (secondary) data, mainly web presentations, and white papers. We analyzed the content of the data and identified features that can enhance the knowledge sharing process. Each feature is connected either with an antecedent (described in Table 1) or with a benefit that was taken from a research model from Ali et al. (2019). A brief introduction to each case is presented below. Table 2 lists the data sources. The former two cases are platforms focusing on academic publications (a particular case of knowledge sharing). At the same time, the latter two are social media related (for relations of social media and knowledge sharing see Panahi et al. (2016)).

- **Orvium** is a scientific publishing platform that helps researchers and institutions to share their work, create open access journals, and streamline peer review. Orvium aims at connecting researchers and publishers with trusted reviewers to accelerate publishing along with incentivized peer review.
- **ARTiFACTS** provides a platform for academic and scientific research that leverages BLK technology. Researchers can record a permanent, valid, and immutable chain of records in real-time, from the earliest stages of research for all research artifacts, including citing/attribution transactions. ARTiFACTS focuses on capturing and linking knowledge from its initial ideation throughout the research process to informal and formal dissemination.
- **Everipedia**, the world's first encyclopedia based on the BLK, is an open-source wiki network, decentralizing the Wikipedia knowledge base by allowing every editor to become a stakeholder in the network. Everipedia uses the EOS BLK platform to make contributors more accountable. Contributors to the network receive tokens based on their valuable contributions, which will finally represent virtual shares of the platform, meaning that for approved edits, they will get rewards. In contrast, for inaccurate ones, they will lose their credit (coins).
- **Steem** is a cryptocurrency linked to social media and built on content-focused Steem BLK, which was created in 2016. This project aims to provide a platform for decentralized application hosting and data storage. By using delegated proof-of-stake as a consensus protocol, a fast block time of three seconds and zero-fee transactions for users are made possible.

4 Findings

The first focus of our research in this section is on the scholarly research publication and distribution under the BLK platform. The traditional scientific publication industry faces several inefficiencies that negatively affect the research community, such as the high cost of subscription to academic databases, the lengthy and biased peer-review process, copyrights held by publishers instead of authors, lack of rewards and recognition for reviewers, and proliferation of low-quality journals (Martin, 2018; Orvium, 2019). To address these challenges in the field, some startups came with the idea of incorporating a BLK-enabled open source and a decentralized framework for managing scholarly publications. Table 3 summarizes the most significant impacts we identified during an analysis of two BLK cases in the field of scholarly publications. As can be seen from the table, BLK brings potential features such as increased transparency and speed, and at the same time, decreased cost and time, into the scientific community, which will utterly enhance knowledge sharing.

The second area of BLK application for knowledge sharing in this paper is social media. The traditional social media platforms suffer from difficulties, such as the full control of the owners of social media platforms over their user data, earning money from the monetized users' data without sharing any reward with them, and censored or blocked access by some governments (Dhillon, 2018). BLK tackle some of these problems. We chose and analyzed (in Table 4) two examples to link their impact on knowledge sharing.

Table 3. BLK impact on knowledge sharing in academia

Ben	Ant	Feature	Quotations [source id]
CR	M	Streamline processes	[1.1] "*You control when to submit, peer review, and publish your paper in Orvium. We help you to manage all the publishing process.*"
CR	**I**	**Reduce publication time**	[1.1] "*Easy and fast peer-review management to improve the quality and efficiency of your peer review workflow.*" [2.1] "*Provide and receive 'real-time' attribution for novel work so you can rapidly build and demonstrate your body of scholarly contributions.*"
IB	T	Increase transparency	[1.2] "*By keeping track of all the activity that happens in the paper and the publication life-cycle. We use BLK technologies to establish an independent, decentralized, and immutable timestamped proof of what is happening in the publication process.*" [2.1] "*Keep all your research artifacts organized in one place and establish linkages in real-time for discovery and attribution.*"
G	M	Rewards for reviewers	[1.1] "*When you make peer reviews in Orvium you can get economic rewards and recognition badges that increase the impact of your profile.*" [1.2] "*By doing peer reviews and increasing your reputation, you will start gaining more privileges and rewards in the platform. We have several reputation levels to define some unique things that you could do in Orvium.*"
	T	Proof-of-existence	[2.1] "*ARTiFACTS helps to protect your original ideas and share them with other researchers by securely registering a 'digital fingerprint' (proof-of-existence or PoE) of your work to our BLK.*"
G	R	Collaboration	[2.2] "*Researchers will benefit from the ability to easily and securely share in-process work to speed collaboration and build reputation as research is conducted.*"

	M	Rewards for authors	[1.1] "*Orvium is the scientific publishing platform that helps researchers to share their work.*" [1.1] "*Improve your manuscript and increase your publishing opportunities with constructive peer reviews made by experts in your field.*"
CR	M	Free access	[1.1] "*The platform is freely available to all users globally.*"

Table 4. BLK impact on knowledge sharing in social media

Ben	**Ant**	**Feature**	**Quotations [source id]**
G	I	Fast	[4.1] "*Steem has already surpassed Bitcoin in number of transactions and can scale to support 10,000 or more transactions per second.*"
	R	Unrestricted	[3.1] "*Everipedia uses BLK technology to help us fulfill our vision for a world where all knowledge is available to all people - a world in which everyone, everywhere can participate in sharing what they know and providing value to others.*" [4.1] "*Steem offers users the unique ability to publish and store different types of content directly and permanently into the immutable ledger of the BLK as plain text. Once stored in the BLK, data becomes available publicly for developers to build from.*"
	T	Uncensored	[3.2] "*Decentralization makes content immutable, which means censorship is impossible to exist, and knowledge can flow freely without interference*" [4.1] "*There is no single entity in Steem that can censor content that is valued by STEEM holders.*"
G	M	Rewards for participation	[3.1] "*IQ Tokens allow us to keep track and reward people for contributing to Everipedia, and as the value of the platform grows, the people who built it get to share in its success.*" [4.1] "*The users that take time to evaluate and vote on content are playing an important role in distributing the currency to the users who are adding the most value. The BLK rewards both of these activities relative to their value based on the collective wisdom of the crowd collected through the stake-weighted voting system.*"
	M	Democracy	[3.1] "*Anyone with IQ Tokens is a stakeholder in the Everipedia Network. Using IQ tokens to vote, users decide which new articles and edits are added to the knowledge base.*" [3.1] "*Everipedia allows you to create an article about anything as long as you have a citation. This allows for a much broader scope of content in the knowledge base.*"
	T	Ownership	[4.1] "*Steem users become platform stakeholders, maintaining control over their data.*"
CR	I	Free use	[4.1] "*Unlike most BLKs that are too slow and expensive to be used for apps, Steem is fast, free, and scalable.*"

5 Discussion

This section is divided into the interpretation of the findings, limitations of our study, and suggestions for future research.

5.1 Interpretation of findings

The results in Tables 3 and 4 show the main antecedents of knowledge sharing that are affected by BLK and the potential benefits for users that can be achieved by utilizing BLK for knowledge sharing. The technology itself helps mainly through smart contracts and users who get rewards for contribution. Furthermore, the speed at which the content is generated and finally shared is much higher compared to traditional platforms because no central authority needs to approve the content. However, it is done by the network (i.e., users). All of this can reduce costs and motivate the users to share their knowledge, which they would not share.

The first draft of every piece of scholarly research can be early published (before the review) and secured through Proof-of-existence mechanisms. The immutable proof that someone authored the publication brings trust, and the users are willing and able to share their ideas (research) much sooner than it would be possible in the traditional publication process. Due to BLK, knowledge is stored in a safe, secure, and decentralized way with a limited chance to be eroded, manipulated, censored, or blocked either arbitrary or intentionally by any entity. This function of BLK can impact knowledge sharing on a large scale because it increases the trust and reciprocity of the users. The trust of users is enhanced by the ability of users to control the data. Users can choose which information from their profile or even their uploaded content should be available to the public. Besides, BLK knowledge sharing platforms are unrestrictedly and democratically available for all who join the network, without a need to pay for subscription fees.

Motivation is crucial in knowledge sharing, and the possibility of incentivizing users can increase knowledge sharing. Authors, reviewers, or social media contributors get rewarded and recognized for their contribution to the network. It makes data monetization possible for every ordinary user, which was not possible in the past. As users are rewarded for their contribution, based on the peers' assessments, they have no economic reasons to damp the network by fake information or news, because their credit will decrease.

These potential main benefits of BLK application for knowledge sharing go beyond the common understanding of BLK use cases in KM, which are limited merely to curate information gathered in KM processes (Taylor, 2017).

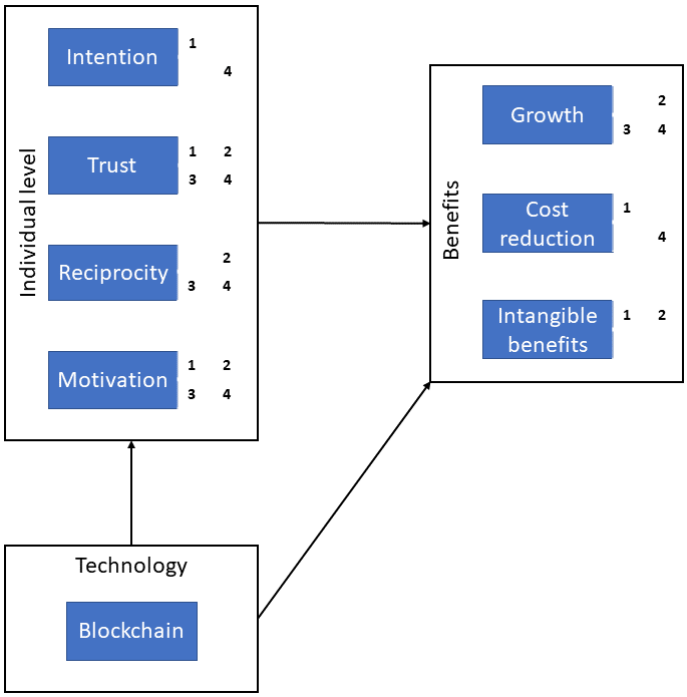

Figure 1. Identified concepts related to cases

5.2 Limitations

This research suffers from three main limitations. First, we used the content analysis of the sources from the white papers and websites of the associated cases. However, some of such texts might be just an articulation of the business owners' ideas and could be far from the empirical situation. At the moment, it is hard to judge the truthfulness of such information due to the lack of empirical data. However, future research is suggested to follow empirical approaches to assess their real impact in practice. Second, we investigated the role of BLK just for knowledge sharing use cases. However, we believe that BLK can also be applied for knowledge discovery purposes. The development of Artificial Intelligence (AI), together with the potentials offered by BLK, creates the perfect combination of KM and BLK. One of the main problems in the current AI market is the availability of accredited data. Decentralized and publicly available databases under BLK platforms have the potential to overcome this challenge. Startups such as Fetch are trying to leverage this opportunity and respond to this market need by processing and analyzing the BLK inherited data, resulting in creating a valuable set of knowledge and monetization of BLK data both for AI developers and organizations. There are lots of potentials to apply such knowledge in practice with the aim of business model innovation/transformation, such as commodity exchange and decentralized finance, smart

cities, smart homes, intelligent autonomous supply chain, and electric vehicle infrastructure. Hence, it could be a useful research agenda for future research. At the time of the current study running period, there is limited information base from such practices that prohibited authors from involving such cases in the research. However, we are aiming at following that research line in the future once the required information gets publicly available. Third, we have not taken the technical architecture of BLK platforms into account. Different DLT platforms (such as Tangle or Blocklattice) and different BLK architectures such as public and private have the potential to impact the realization of the expected benefits. Therefore, future research could investigate how different implementation alternatives of the underlying technologies might impact KM processes.

5.3 Further research

We reviewed four BLK cases intending to discover their role in knowledge sharing through the community. Even though there are other available cases in the field of knowledge-sharing platforms, through initial screening of their websites and whitepapers, we realized that the underlying business models, platforms, and general approaches are somehow similar among all. However, a thorough analysis of other cases, at least those listed in Table 5, would ground our results deeper in the data.

Table 5. Cases for further research

Another way how our research could be extended is to develop and test a similar model (see Ali et al., 2019) that we used for the main categories in our analysis (Benefits and Antecedents). BLK does not have to have a direct impact on the antecedents and benefits of knowledge sharing but could play a mediating role.

6 Conclusions

BLK is believed to have the potential to disrupt traditional business models through the inherent distributed, decentralized peer to peer, and security features. This research

categorized the potential impacts of BLK on the effects and antecedents of knowledge sharing by reviewing four proof of concepts (Orvium, ARTiFACTS, Everipedia, and Steem). We highlighted the potential impact benefits of BLK on antecedents of knowledge sharing, such as trust, reciprocity, motivation, and intention. The role of BLK in knowledge sharing manifests through features such as rewarding and incentivizing, democracy, faster processes, unrestricted and uncensored publishing, and users' control over data.

We believe that this paper will help BLK to penetrate the field of KM research as it is one of the first research attempts (only seven results for "knowledge sharing" AND Blockchain search in WOS) to investigate the usefulness of BLK for knowledge sharing.

Abstract

A narrative is affectively polarized when the distribution of expressed feelings towards such a narrative shows two separated peaks. In this paper, we explore the distributions of feelings expressed by online users on Twitter in March 2020 using a sample of 7.9 million tweets related to the narrative of the COVID-19 pandemic. How people influenced each other affective states? Does affective polarization emerge? To answer these questions, sub-narratives are distilled from Twitter data by thresholding a structural parameter of a graph constructed with hashtags co-occurrence. Here, hashtags are considered as string identifiers of sub-narratives related to COVID-19. For such

sub-narrative, we found a polarized distribution of affective states, in which a radicalization of measured values emerged non-linearly for positive and negative valence of affective states, depending on the hashtag considered. We stress that our findings are not generalizable, but they suggest that such type of polarization was present online during social distancing, and that interactions may have non-linearly impacted the initial affective states of online groups' constituent parts.

Keywords – Polarization, COVID-19, Participatory Sense-Making, Physical Distancing

Paper type – Academic Research Paper

1 Introduction

On 11 March 2020, the World Health Organization (WHO) declared the state of a global pandemic due to the fast spread of the new SARS-CoV-2 virus. The disease caused by the virus, COVID-19, is a severe acute respiratory syndrome that rapidly generated large numbers of deaths worldwide. World countries have quickly implemented countermeasures to reduce the spread of the virus. Among such countermeasures, social distancing aims at minimizing the probability of contagion by forcing citizens to stay at home to reduce face-to-face interactions. This has increased active participation in online social networks, allowing social connections among citizens while still respecting physical distancing. This scenario has enabled the creation, consumption, and diffusion of virus-related content at large-scale using online social networks. Scholars have exploited such large-scale data to propose approaches for surveillance and forecasting of the disease (Dewhurst et al., 2020), to investigate the effect of social media on mental health (Gao et al., 2020), to study the spread of misinformation across different social networks (Cinelli et al., 2020). While on the one hand, people were struggling to distinguish trust-able content from misleading content in such "infodemic" (Cinelli et al., 2020; Ferrara, 2020), on the other hand, activism to fight the outbreak emerged online, thanks to the way narratives are conveyed by users through string identifiers (namely hashtags), e.g. *#stayhomesavelives*. Such sub-narratives related to the main narrative of COVID-19 enabled the active participation of people to "fight against the virus", providing slogans for being supportive and for being not isolated, both socially and emotionally.

While previous studies already found an experimental confirmation of this active participation, less attention has been paid to the distribution of feelings (here named also "affective states") of people participating to such narratives, and to how people influenced each other affective states with online interactions during the outbreak. In this work, addressing such a gap with a sample of Twitter data collected in March 2020, we found an emergent polarization of affective states for a sub-group of hashtags representative of COVID-19 related sub-narratives. The analysis of distributions of affective states containing these hashtags revealed an apparent non-linear relationship between the measured affective states with and without group interactions. This finding suggests that online narratives during a pandemic may have generated a twofold dynamic on affective

states of people: (1) a positive change towards higher positive values of affective valence, and (2) a negative change towards lower negative values, depending on the sub-narrative.

The article begins with a theoretical background section that wants to provide the reader with an excerpt of theories relevant to this work; then, a methodology is presented both as a generalized formulation, and as a particularization to the case study of COVID-19; results and discussion are presented in the subsequent section along with the main findings, while, the conclusion section summarizes the work done and opens reflection for future works.

2 Theoretical background: The networked nature of feelings

Van Kleef (2009) introduced the theory of emotions as social information, according to which the affective states of people should be investigated as a source of social information for the understanding of socio-physical phenomena. The main question that must be asked about the social nature of affective states in this sense is the following: how the emotional expressions of an individual can influence the affective states, opinions, and actions of other individuals? This broad question flows into narrower questions like: when and how do emotional manifestations contribute to the behavior of a group? How do emotional exposures affect conflict resolution or conflict exacerbation? Humans spend a high percentage of their time interacting with each other for a wide range of objectives moved by a diverse range of forces. In recent decades, the advent of social media in people's social lives has favored social-emotional exchanges and increased the speed with which emotions are transmitted (Jalonen, 2014)[1]. Emotions fulfill fundamental social functions, and help society members to face the various problems associated with life (Keltner & Gross, 1999), such as recently, those associated with the COVID-19 pandemic.

In such a problematic situation, the social distancing intervention to prevent the spread of the virus, defined more appropriately as physical distancing (Aminnejad & Alikhani, 2020), has canceled offline interactions and emotional responses transferring them to online social networks, which acted as a back-channel for users' sense-making and participation (De Jaegher & Di Paolo, 2007; Lipizzi, Dessavre, Iandoli, & Marquez, 2016) to the unfolding of events related to the pandemic. Spoor and Kelly (2004) suggested that emotions have a coordinating function in groups; in particular, they hypothesized that such coordination could become evident in two diverse ways: the first way is when perceived affective states are shared with others, which could facilitate coordinated action; the second way is when emotional expressions provide information on the current affective states for the surveillance and forecast, and the subsequent coordination (for example, the surveillance of mental health threats given by the lock-

[1] *It is worth mentioning that this tendency of using emotions to evaluate external stimuli, in particular referring to the consumption of information, it is a matter of debate for the spread of misinformation. The risk behind is that the tendency to react emotionally to information may facilitate the acceptance of information as "trustable" even if it is not.*

down condition during the period of social distancing). With respect to the first form of emotional coordination, Dezecache et al. (2013) support the hypothesis of unconscious tuning of affective states in a group as a form of collaborative behavior for the survival of group members; however, such unintentional emotional tuning combined with emotional vulnerability, typical of a disruptive situation like the recent pandemic, may be also detrimental for a group when the prevalent initial emotional state of group members has already a negative valence (Smith & Mackie, 2008).

It follows that, on the one hand, the social nature of affective states could favor encouragement in dealing with problematic situations that life poses, and in this sense the affective states of a group can converge positively, acting as a catalyst for mutual support; on the other hand, instead, the social nature of affective states could exacerbate an emotional divergence, which may negatively radicalize the affective states towards more extreme values. With such a theoretical background, and in the context of online Twitter discussions around the COVID-19 narrative, we aim at answering the following questions: how do affective states expressed on Twitter varied depending on sub-narratives related to the main narrative of COVID-19? Does a polarization of affective states emerge when comparing first expressed affective states[1] with affective states calculated considering interaction ties with other users contributing to the same sub-narrative? To address such questions, we present a generalized formulation of a methodology that combines subjective computational analysis of text[2] with a graph-based model for the estimation of changes in affective states of individuals contributing to a narrative. Then, we particularized the methods to the case study on COVID-19, and then answer the questions with a sample of 7.9 million tweets posted in March 2020.

3 Methodology

3.1 Generalized formulation: narrative contribution grounding and attributes estimation on a networked medium $\mathcal{M}$

Let N be a set of n string-based messages τ_i, each including a sub-string identifier $\hbar$, published by a set of agents U_N interacting on an online medium $\mathcal{M}$. We define the set N as the narrative shared by the set of agents U_N. Also, let $X_{u_i \in U_N}$ be an attribute (e.g. value of expressed feelings) of an agent u_i evaluated on the following set of string-based messages available:

[1] *Assuming "first expressed" as the first tweet of a user toward a sub-narrative to be available in our data sample.*

[2] *The reader will note that the model described in the methodology section has a generalized formulation, hence, text is generally referred to a string-based message of any kind. However, in the results we present, text is referred to the textual content of tweets, but not referred to the text inside a news hyperlink posted that points outside the social platform for its consumption (the reader may note that such "outside of the medium" text can influence affective states of Twitter users as well as the actual content of tweets. Although the generalized formulation we present can theoretically consider even such texts, the case study does not take them into consideration).*

$$C_{u_i} = \{\tau_i : (u_i \rightsquigarrow \tau_i) \wedge (u_i \in U_{\mathrm{N}})\} \subseteq N \quad (1)$$

Where $u_i \rightsquigarrow \tau_i$ means that the agent u_i published ($\rightsquigarrow$) a string-based message $\tau_i \in N$ on the medium $\mathcal{M}$. Therefore, $\forall\ C_{u_i}$ the attribute $X_{u_i \in U_{\mathrm{N}}}$ is the i^{th} element of the following set of n attributes of $X(U_N)$:

$$X(U_N) = \{X_{u_1}, X_{u_2}, \ldots, X_{u_n}\} \quad (2)$$

Now, let one consider a set of k sub-narratives η of N. Each sub-narrative η_j is a set of n string-based messages τ_i published by a set of agents U_{η_j} that includes in each τ_i the same sub-string identifier $\hbar$ plus also another sub-string identifier h_{η_j}.

Then, let one consider two sub-narratives η_k and η_z and their respective sets of agents U_{η_k} and U_{η_z} that share the two sub-narratives. An intersection $\xi_{U_{\eta_k} U_{\eta_z}}$ of the two sets of agents can be defined as the set of agents that creates a common-ground between η_k and η_z. These agents overlap their respective sub-string identifiers, meaning that their string-based message τ_i includes the sub-string identifier $\hbar$ in each τ_i, and also includes the sub-string identifier h_{η_k}, along with the sub-string identifier h_{η_z}.

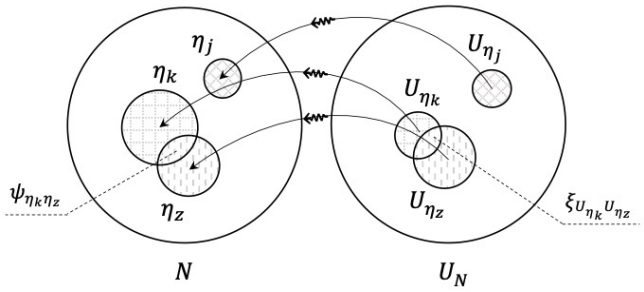

Figure 1 – Intersection of common-grounded sub-narratives of N shared by sub-sets of agents (i.e. users) of U_N.

Thus, the following subset of string-based messages can be formalized:

$$\psi_{\eta_k \eta_z} = \left\{ \tau_i : (u_i \rightsquigarrow \tau_i) \wedge \left(u_i \in \xi_{U_{\eta_k} U_{\eta_z}}\right) \right\} \subseteq N \quad (3)$$

where:

$$\xi_{U_{\eta_k} U_{\eta_z}} = U_{\eta_k} \cap U_{\eta_z} \quad (4)$$

$\psi_{\eta_k \eta_z}$ is what we call common-grounded-narrative since this is an indirect measure of the semantic overlap between the two narratives η_k and η_z shared by the intersection $\xi_{U_{\eta_k} U_{\eta_z}}$ between the sets of agents U_{η_k} and U_{η_z} (see Fig. 1).

Now, let A be an adjacency matrix where the generic element a_{ij} has value equal to 1 if the agents u_i and u_j share a same narrative, otherwise, it has value 0. Given A, the following set of attributes (e.g. expressed feelings) for each node can be defined as:

$$\hat{X}(U_N) = \{\hat{X}_{u_1}, \hat{X}_{u_2}, \dots, \hat{X}_{u_n}\} \tag{5}$$

where the generic $\hat{X}_{u_i}$ respects the following equations:

$$\hat{X}_{u_i} = \hat{X}_{u_i}(\bar{\rho}) \tag{6}$$

$$\lim_{\rho \to \bar{\rho}} \left| \hat{X}_{u_i}(\rho) - \hat{X}_{u_i}(\rho) \right| = 0 \tag{7}$$

$$\hat{X}_{u_i}(\rho) = \frac{\sum_{j=1}^{n} a_{ij} \hat{X}_{u_i}(\rho - 1)}{k_{u_i}} \tag{8}$$

k_{u_i} is the number of shared narratives of the agent u_i with all the other agents; ρ is an iteration parameter that updates the value of the attribute $\hat{X}_{u_i}$ according to the number of shared narratives multiplied by the value of the attribute $\hat{X}_{u_i}$ at the previous iteration. Eq. 8 is an adaption of the opinion estimation model described and used in (Morales, Borondo, Losada, & Benito, 2015; Olivares, Cárdenas, Losada, & Borondo, 2019; Primario, Borrelli, Iandoli, Zollo, & Lipizzi, 2017) with the following two main differences: (1) $\hat{X}$ is an expressed feeling (mood or affective state) rather than a measure of ideological opinion as in the original model; (2) since the present research work focuses on affective states and not ideologies (also called opinions), opinion leaders (elite agents with a fixed ideology over the iterations) are not taken into consideration, thus, we do not maintain fixed any affective state when varying ρ. The initial condition that defines the attribute $\hat{X}_{u_i}$ at iteration $\rho = 0$ is that $\hat{X}_{u_i}(0) = X_{u_i}$.

At this point, two types of attributes of the agents are available: X_{u_i} represents the attribute the agent u_i expressed through the corpus created with the first string τ_i published by u_i on the medium $\mathcal{M}$ contributing to a sub-narrative η_i. $\hat{X}_{u_i}$ represents the attribute of the agent u_i resulting from the interactions with other agents that contribute to the sub-narrative η_i. The initial condition is that $\hat{X}_{u_i} = X_{u_i}$.

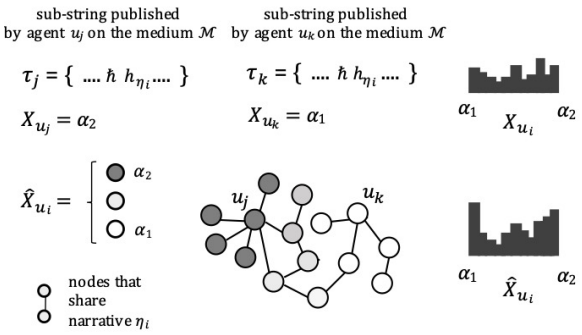

Figure 2 – Construction of frequency distributions of X_{u_i} and $\hat{X}_{\boldsymbol{u}_i}$. The histogram on top-right of the chart shows the distribution of attributes calculated only using string-based messages of agents; while, the histogram on lower-right reports the same attributes altered by graph-based ties with other agents.

It is therefore opportune to point out that this generalized formulation can fall in the context of any online social media ($\mathcal{M}$) with the following particularities: the agents are the users (u_i) of a social media platform, that are accountable for publishing content from which attributes can be extracted (e.g. affective states extraction or any other knowledge extraction). In this work, the published content is intended as textual content that is what we call string-based messages τ_i - e.g. text of tweets when the medium $\mathcal{M}$ is Twitter. The attributes X_{u_i} are values resulting from a measurement of the polarity of affective states extracted from the text posted by online users, a continuous variable defined in $[\alpha_1, \alpha_2] = [-1,1]$,; while, the set of agents' attributes $\hat{X}_{u_i}$ is a set of values resulting from the application of Eq. 8 to the polarity of affective states resulting from networked interaction with content published by other users (see Fig. 2). Given the attributes of individual parts that share a sub-narrative, and given the attributes of the same individuals, after interacting with other users that share the same narrative, we analyze the bi-variate distribution between X_{u_i} and $\hat{X}_{u_i}$ to study the relationship between the two estimations of affective states for the users of $\mathcal{M}$.

3.2 Particularization to the case study of COVID-19 data with Twitter as a medium $\mathcal{M}$

This experimentation presented in this article involves the analysis of 7.9 million of Twitter data to measure the dynamics of changes in affective states expressed in user-generated tweets published in March 2020 during the COVID-19 pandemic. The purpose of the experimentation is to analyze whether and how online users that contribute to a narrative, meaning that they participate to the formation and sense-making of that narrative, will be influenced by each other affective states according to the interaction ties they exhibit. In this sub-section, the generalized formulation of the model presented in the previous sub-section, is detailed for such experimental case study.

The reader can assume the following particularization of the variables presented in the generalized formulation: the medium $\mathcal{M}$ from which data are sampled is Twitter; a generic string-based message τ_i is the text of a tweet; the narrative N is identified by the sub-string identifier $\hbar$ = *#covid19*; the generic sub-narrative η_i is identified by a hashtag (eg. *#pandemic*) that co-occurs with *#covid19*; the agent u_i is a generic Twitter user account; The attribute X_{u_i} of u_i is a measure of polarity of affective states extracted from the text of the first tweet posted by the user u_i in a sub-narrative (identified by a hashtag) co-occurring with the main narrative *#covid19*; $\hat{X}_{u_i}$ is the measure of polarity of affective states calculated considering the influence of users who share the same narrative (Eq. 6-8). The measure of the affective states conveyed in a text is obtained with the approach described in (Lipizzi, Borrelli, & Capela, 2020; Lipizzi et al., 2019) with an unsupervised symbolic pre-processing based on n-grams frequency (Borrelli, Gongora Svartzman, & Lipizzi, 2020; Borrelli et al., 2020). The subjectivity of perception of a text could vary depending on many variables such as: the account considered, the context, the medium itself. The approach described by Lipizzi, Borrelli, & Capela (2020) uses benchmark keywords to be evaluated over a new text from a given point of view. Since the approach does not directly provide a single measure of the polarity defined in $[\alpha_1, \alpha_2] = [-1,1]$, the obtained values for each benchmark keyword had to be compounded in one single value defined in the interval [-1,1] with an appropriate normalization. Since the exposure of a content to a user can generate different affective states depending on who is reading the text, the approach described by Lipizzi et al., (2020) can be used for the calculation of $\hat{X}_{u_i}$ where interactions with content of other accounts are involved.

4 Results and Discussion

4.1 Emergence of common-grounded narratives deduced from $\xi_{U_{\eta_k} U_{\eta_z}}$

Clark and Brennan (1991) define successful grounding in communication when parties that communicate achieve coordination of both the content and the process; with this theoretical definition and inspired by previous works applying it to online social networks (Lipizzi et al., 2016), here, common-ground has been measured with the number of users that share and contribute to the same set of narratives. Here, we consider a high degree of common-ground as proportional to a high number of users contributing to the same set of sub-narratives.

We constructed a network of sub-narratives (identified by hashtags) related to COVID-19 similarly to the approach described in previous works (Bovet, Morone, & Makse, 2018; Etta, Galeazzi, Cinelli, Conti, & Quattrociocchi, 2020). The graph is constructed with hashtags as nodes, connected by an edge when they co-occur within a tweet; differently from previous works, we add a novel attribute to each edge of the graph.

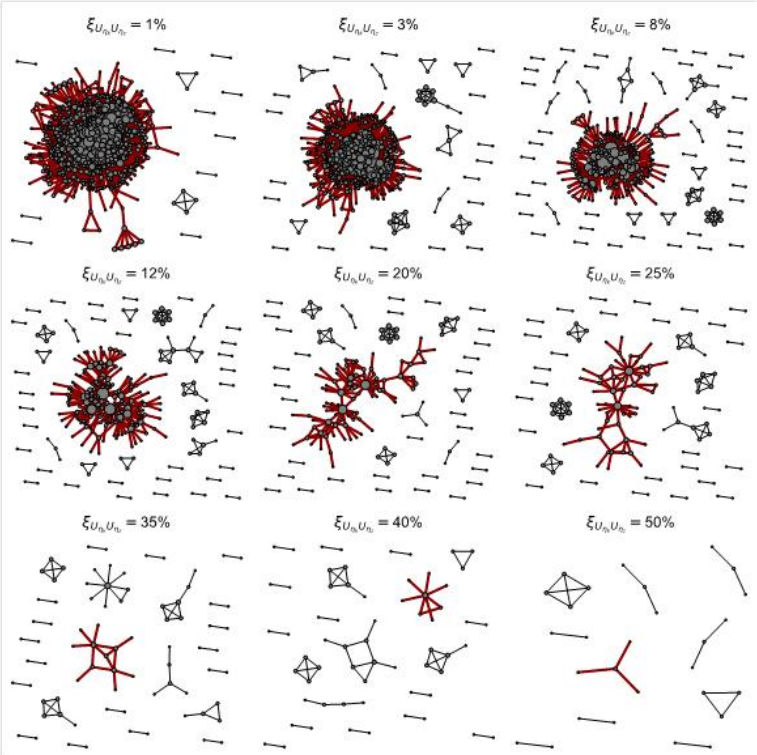

Figure 3 – Graph of sub-narrative (hashtags co-occurrence network), and analysis of common-grounded contribution using a threshold on the fraction of users in common of two generic narratives η_k and η_z. The size of nodes is proportional to the number of users contributing to that sub-narrative/hashtag.

Such attribute is the fraction of users that use the hashtags together, which is deduced from $\xi_{U_{\eta_k}U_{\eta_z}}$ (see Eq. 4). At this point, we are going to filter the graph by gradually increasing the value of $\xi_{U_{\eta_k}U_{\eta_z}}$ as shown in Fig. 3 and Fig. 4. We excluded the main narratives (e.g. *#covid19, #covid-19, #coronavirus,* etc.) leaving only sub-narratives as nodes of the graph; then, we selected ten hashtags that respected the following two conditions: (1) a node that never disappeared from the resulting graph when varying the value of $\%\xi_{U_{\eta_k}U_{\eta_z}}$; (2) a node that was always present in a connected component with the highest number of nodes (In Fig. 3 this components is visualized with thicker red edges). The set of hashtags resulting from the structural filtering is the set $\psi \subseteq N$ listed in Table 1.

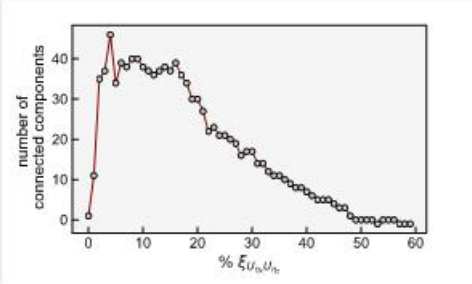

Figure 4 – X-axis represents the threshold that is chosen for the minimum percentage of users who contribute to the creation of a common-ground between different narratives; on the y-axis, the number of connected components that emerge from the hashtags network filtered according to the value of $\% \xi U_{\eta k} U_{\eta z}$

Table 1 – Set ψ of sub-narratives identified via thresholding on %ξ. It is worth noting that hashtags that have been used for running the data collection have been excluded - e.g., #covid19.

Narrative (η)	Narrative Identifier (h)
η_1	#stayhealthy
η_2	#washyourhands
η_3	#quarantine
η_4	#quarantinelife
η_5	#stayhomechallenge
η_6	#isolation
η_7	#highriskcovid19
η_8	#coronaoutbreak
η_9	#pandemic
η_{10}	#lockdown

4.2 Polarized distribution of affective states

For each of the sub-narratives indicated in Table 1, we measured the polarity of the affective states of Twitter accounts that contribute to each sub-narrative. In particular, two distributions of values are obtained: (1) the first distribution Fig. 4A, X_η, includes the polarity of affective states measured using the text of users' first tweet posted that includes the hashtag identifier of the sub-narrative; (2) we applied the model described by Eq. 8 to obtain the distribution $\hat{X}_\eta$ of the values of the polarity of affective states which takes into account the graph created with the group of users who share the same narrative - see Fig. 4B, and Fig. 2.

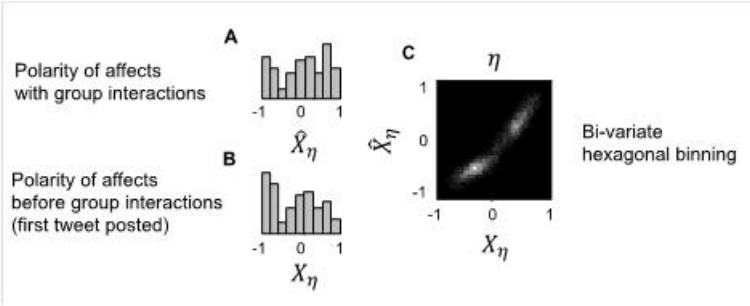

Figure 5 – Visual summary of the analysis carried out on each sub-narrative: (A) shows the distribution of values $\hat{X}_\eta$ obtained by calculating the polarity of affective states considering the influences received by the nodes (users) who contribute to the narrative η; (B) shows values of the affective polarity of the first tweet available of the users who contribute to the narrative η; (C) relationship between $\hat{X}_\eta$ and X_η using a bi-variate hexagonal binning, which is shown in Fig. 6 for each sub-narrative.

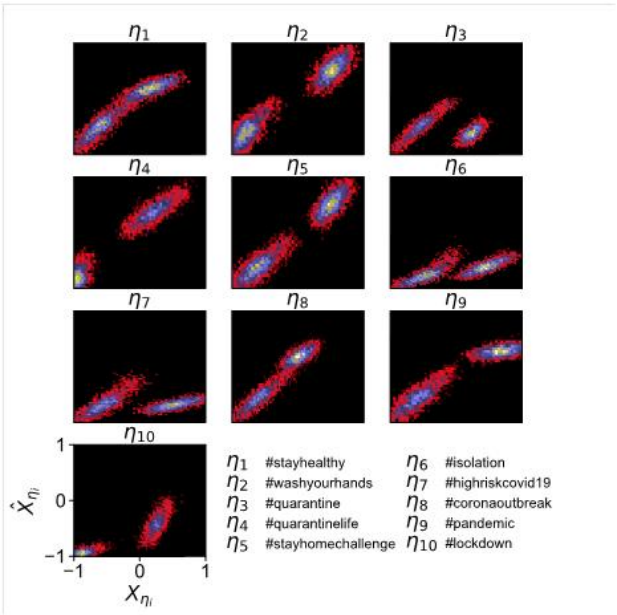

Figure 6 – Hexagonal binning of bi-variate data: X_η on the x-axis represents the polarity of affective states before group interactions (relative to the first available tweet published by users on the narrative η); $\hat{X}_\eta$ on the y-axis represents the values of the polarity of affective states with the influence of interaction ties; for each narrative η_k with $k = 1\ldots10$ the relationship between the two variables is shown. The color of the bin is lighter, where the density of data-points in the bin is higher, while it turns darker when the density is lower.

Fig. 6 shows two poles of affective states, which are distinguishable in each bi-variate distribution. The relationship that exists between the different narratives seems to be non-

linear, thus respecting the group hypothesis according to which the behavior of a group is not a linear combination of the individual parts (Lewin, 1951). The variables that we have analyzed are the affective states measured as a single contribution by a user (the first tweet published with the hashtag identifier of the sub-narrative) and the affective states calculated considering the influence given by the group of users who share the same narrative. It can be observed that the relationship between the two variables in most of cases is non-linear (see Fig. 6). For some narratives - #washyourhands, #stayhomechallenge, #quarantinelife - positive values shifted towards more positive values, while for other narratives - #quarantine, #pandemic, #isolation, #lockdown - negative values shifted towards more negative values. This confirms the twofold effect hypothesis (see Section 2) of social interactions on affective states: 1) a change of positive values of affective states towards more extreme values with the influence of the group, 2) a change towards more negative values of affective states with the influence of the group. In the first case, interactions with users who share the same sub-narrative lead to a positive affective condition (e.g. this could favor optimism, confidence in the fight against the virus – see hashtags: #stayhomechallenge, #washyourhands). In the second case, it may lead to a pessimistic view of the situation (see hashtags: #highriskcovid19, #isolation).

5 Conclusion

The problem of studying changes in affective states due to participation and sense-making in online social networks enabled narratives was studied using the case of the recent COVID-19 pandemic, a worldwide threat to public health. We have presented a generalized mathematical formulation to model the problem on a generic online medium with interacting agents, with a particularization to the Twitter case. In our empirical exploration, we have selected ten narratives (identified by ten hashtags) that emerged via thresholding a graph of hashtag co-occurrence using a parameter representative of the level of co-participation of Twitter users to sub-narratives related to the COVID-19. For such sub-narratives, we found presuppositions for polarization of affective states. This has suggested that interactions with content published by other users could both foster the feeling of mutual support to fight against the virus, but also increase negative affective states that may generate possible exasperation. It is also clear that, although the dynamics seen here are limited to a relatively small sample compared to the entire lock-down period, the reported results on a 7.9 million tweets dataset draw attention to the mechanisms of segregation and how a period of forced closure can potentially produce a non-linear shift of collective conditions of affective states. The non-linear relationship observed may suggest approaches that go deeper into the theory of dynamical systems and chaos. The findings may also have an implication on the design of systems to help reducing dysfunctions in groups and promote collaboration (Iandoli, Klein, & Zollo, 2007; Iandoli, Ponsiglione, & Zollo, 2010; Iandoli, Quinto, Spada, Klein, & Calabretta, 2018), on different contexts where polarization is relevant (Desmarais, Moscardelli,

Schaffner, & Kowal, 2015; Kowal, 2017); moreover, the study may have implications on the understanding of the resilience of crowds after events (Barker et al., 2017; Hosseini, Barker, & Ramirez-Marquez, 2016), and on the diversity and complexity of socio-cognitive mechanisms underlying the subjective perceptions of external stimuli at the scale of individuals and groups.

Abstract

The main purpose of this study is to identify the characteristics of the Intellectual Capital (IC) that can be included in IC studies applied to territorial realities and cities alike. The aim of this study is to analyse the concept of IC and its application to cities, specifically the assessment of IC enabling factors of European capitals of culture (ECoC). Hence, this study explores whether and how IC approach can be applied to study the ECoCs related phenomena from a managerial point of view.
Amongst those which have succeeded throughout the years, there is one, in particular, that is represented by the City of Matera, former ECoC 2019.
Considering the novelty of this topic, neither the approaches nor the impact evaluation related to the appointment as ECoC are known, yet.
The city of Matera was designated in 2014 as ECoC, also because of a gradual process of cultural, economic and tourism development in the decade before. Results show that IC dynamics related to a city with a capital status demonstrate relevant factors and characteristics referring to the traditional dimensions of IC (structural capital, human capital and organisational capital) which are generated before and after the title of ECoC.
There is a common acknowledgement that, so far, theories on IC have primarily concerned companies and firms and have analysed factors enabling visualisation, management, measurement, reporting and disclosure of intangible resources. Some scholars (Dumay 2013; Edvinsson 2013) have called for the need to extend the analysis of the role of IC in different contexts. To this regard, in recent years research work has been much promising on the role of IC for countries (Edvinsson and Stenfelt, 1999), cities (Carrillo, 2004), public sector (Huggins and Weir, 2007; Schiuma et al., 2008; Schneider and Samkin, 2008; Dumay et al., 2015), non-profit (Kong, 2007; Donato, 2008) and for communities (Chatzkel, 2006; Bounfour and Edvinsson, 2005). All that said, in the literature there not much focus on the analysis of implications of being a "Capital City" from an IC perspective. One of the most interesting cases is given by the role played by European Capital of Cultural (ECoC) in contributing to developing the city designed as capital and its surroundings (Burnham, 2009; Campbell, 2011; Garcia et al., 2009; 2010) as well as their reputation at the international level.
As far as this study is concerned, the research methodology is based upon a single case-analysis. This method is particularly well suited to the research in question, as it is very effective for the

analysis of complex phenomena which constitute a new field of research (Eisenhardt, 1989). This study, therefore, aims to show compatibility between ECoCs and IC approach through the presentation of the case of the city of Matera as ECoC 2019. The case-study shows an analysis that focuses on the relevant factors of IC before and after the recognition of the title of capital.
We aim to fill the gap in the existing literature about the IC determining factors of a Capital of Culture. With its results, this study has the ambition to become an effective supporting tool for policy makers, scholars, and practitioners willing to conduct policies of territorial development as connected to a capital. Moreover, this work can contribute to all those who would commit and embark on projects of recognition of their own city as a temporary capital, such as the appointment as ECoC and use IC to development of cultural attractiveness of the city, strategic planning and urban governance, which leads to local and urban.

Keywords – intellectual capital, capital of culture, knowledge management, knowledge city, knowledge-based organisations

Paper Type - Academic Research Paper

1 Introduction

There are arguments in favour of the pivotal role that Intellectual Capital (IC) plays in a knowledge-based society (Bukh et al., 2001; Montequín et al., 2006). As representing the intangible asset of an organisation, IC constitutes a significant portion of its value, which enables to gain advantages over competitors (Andriessen, 2004; Wall, 2005) because it contributes to justify the value difference between market value (Mouritsen et al., 2001; Wall et al., 2004; Beattie & Thomson, 2007; Bozbura et al., 2007; Yang & Lin, 2009). Scientific literature has presented several definitions of IC that are relevantly connected to company organizations and to their intangible asset. By this token, IC has been merely associated with human potential and people's role within organisations, while only a few are suggestions that link IC to cities' dynamics. Cities do also represent organisations and are fuelled by intangible assets hiding human factors and expressing knowledge at all levels. It is important to consider the possibilities of IC models and principles' application at the city level.

As company organisations compete with market competitor, cities also compete on their own platforms to increase competitiveness and welfare standards for its citizens. Hence, it could be argued that city IC is inextricably related to its welfare and competitiveness and its employment for performing the process of urban functions enables the acceleration of knowledge spread within the city itself. As far as cities are concerned, IC can be described by various factors, expressed by quantitative and qualitative indicators.

In the aftermath of the worldwide economic crises during the 2007 – 2010 years, cities all over the world were confronted with serious financial, economic and social challenges that were handled by the employment of IC of the city. IC's involvement into the development processes of the city has enabled to increase cities' business and industry competitiveness as well as spread of specific and high-level community competences as

referred to the spheres of administrative bureaucracy, management and innovation. Cities that have been able to develop knowledge and to build upon it are the same that have employed IC for solving development related problems and for enhancing their competitiveness.

The adoption of IC, related to knowledge and ideas' spread for wealth creation and renewal, in those cities has triggered economic growth and enhanced the establishment of open-to-knowledge sectors and innovation-based enterprises fuelled by creative and learning people.

Cities alike have employed knowledge as well as IC into the city to develop knowledge-based strategies in order to ensure city's successful competitiveness both at the local and international level. This is especially the case of Capital cities, comprising those cities that enjoy the temporary title of Capital. In contexts alike, beside economic functions, the city encompassed organisational, human, collective, social and knowledge functions which require more than the financial capacities of the city. As argued, IC has been conferred so much importance (Lu et al, 2010) in successfully ensuring competitive advantage, organizational success and performance that cities acting as Capital cities cannot do anything without IC to improve their new development and organisational performance and enhance community value.

In recent times, academics and researchers have opened the challenging avenues of IC research, labelled as the fourth stage. By this perspective, Dumay (2013), for instance, has suggested to investigate on how to leverage knowledge resources at the city level to be able to construct sustainably strong social eco-systems enabling organizations t flourish in a healthy way. Advocates of the fourth stage of IC research (Gray, 2006; Yeh-Yun Lin and Edvinsson, 2008) suggest to extend the fields of interest and connect IC role and value to the building of tightened economic, environmental and social eco-systems that are no longer viewed as single organizations but as a multiple actor-network acting at different levels (cities and communities, regions, countries). According to these views, knowledge is not only a crucial resource driving firms towards success, but it ensures that social, economic and environmental issues are addressed and managed in such a way to contribute to create sustainable and liveable social eco-systems.

This study has the ambition to contribute to the emerging fourth stage of the IC research and to do so it explores how ideas behind ECoC are highly compatible with the IC tradition. However, it is important to argue that a gap between IC and research on Capital of Culture has not been filled, yet due to the different disciplinary backgrounds between the two communities of research. If IC community is traditionally based on accounting and management disciplines, ECoC practitioners lay their basis on a multi-disciplinary root that goes from social and political sciences, development studies to culture and heritage management. Although such a high complementarity between the two realms, cross-fertilization between them has a great potential. From one hand, capital of culture approach overcomes the narrow correlation between IC and competitiveness as well as financial performance (Dumay and Garanina, 2013). ECoC's view, based on

public value's literature (Fontana, 2014) as well as on quality of life e resilience can be useful to extend IC outcomes. From the other hand, research outcomes of IC have not enjoyed consideration in innovations conducted in the realm of public management and administration (Dias et al., 2014). However, ECoC initiatives need to be governed, managed, and evaluated and there is a lack of research relating to the management, assessment and monitoring of ECoCs being poorly rooted in management studies. In other words, there is a compelling demand for tools enabling to manage and monitor ECoC initiatives from a managerial point of view.

Therefore, this study suggests a specific version of IC approach adapted to ECoC contexts to fill the gap in the literature. To do so, Matera 2019 is analysed through the IC perspective, with the purpose to extend the traditional IC framework and propose a new one that could be called the Capital of Culture IC framework that takes into account existing characteristics and factors of IC proper of ECoCs. Consequently, this study is guided by the following research question: *What are the IC enabling factors at the basis of ECoCs?*

The reminder of this article is organised as follows: Section 2 presents the literature review; Section 3 introduces the methodology. Section 4 shows the results of the study while Section 5 deals with the discussion. The last section draws the conclusions.

2 Literature review

2.1. IC of the city

Descriptions of IC refer to three main sets of a company's resources: human capital, organizational capital (or structural capital), and relational capital (or social capital or customer capital) (Stewart, 1997; Bontis, 1998). Intangible assets in the knowledge economy are considered important economic factors that generate wealth (Haskel and Westlake 2017). Considering this premise, over the last two decades IC has represented the lens through which researchers have conducted analysis on the value creation at all levels: at a micro-level, hence organisations and institutions (Fletcher et al., 2003; Kong 2010; Edvinsson, 2013; Guthrie and Dumay, 2015), at a meso-level, regarding local communities and eco-systems (Schiuma et al. 2008; Bounfour and Edvinsson, 2012; Guthrie et al. 2017) and at a national level (Lin and Edvinsson 2010).

Only recently, the concept of IC has been extended to analyse territory's entities as nations and regions (Dunleavy and Hood, 1994; Bounfour and Edvinsson, 2012). City level of analysis has been rarely studied since investigations have been conducted, mainly, at the national level after that some distinguished authors declared that IC is a strategic factor of economic development (Choo, Bontis 2002; Bontis 2002, 2004; Ginevičius, Korsakiene 2005; Cabrita, Vaz 2006; Alexander 2006; Lerro and Schiuma, 2008). Nevertheless, being in the process of its formation, IC is today anchored to

concepts related to economic and management perspectives that do not sufficiently analyse IC-related issues.

Emphasis on the study over IC at the territorial level has renovated the discussion on IC tout court by offering new frameworks to evaluate nations beyond the traditional financial indicators, hence, beyond their GDP. Krusinskas and Bruneckiene (2011) have contributed to the definition of IC of the city as its overall set of intangible assets that allow citizens, communities, institutional and economic actors to build and implement ideas, products and processes which are transferred into outcomes of city's economic, social and sustainable development. These authors suggested that because IC is a form of capital used for value creation processes aimed at generating welfare for the city, it follows that if not used yet, it can be treated as a set of intellectual resources available inside the city.

In the scientific literature there is discussion on the type of components of intangible assets that are comprised into IC, therefore, several definitions are put forward. If at one side, some authors take into account all components that compound IC, at the other side, some authors emphasise on large-scale sets of components. For instance, Edvinsson (2002) introduced the Skandia Navigator model that makes a clear distinction of the basic IC's components: human, process and customer capital. Other authors, instead, in assessing IC at the European level, have divided IC into human, structural and relational capital (Andriessen and Stam, 2005). Important contributions that initiated the analysis of IC, at the conceptual level, including nations argued that leaders of nations started to be aware of the importance in measuring knowledge assets whereas these determine the success of their economies (Malhotra, 2001). Moreover, as Choo and Bontis (2002) declared that it is important to understand the relationships that can increase the value of each sub-component of IC in order to approach success factors for each nation's economic development. Along these lines, another important contribution to discussion on IC of the city comes from Bontis (2004) who, while assessing the IC of Arab regions, revised the IC framework of organisations (Edvinsson and Malone, 1997) into the IC framework of nations. Such framework that moved to a national level perspective from a company level consists of five value-creating fields: national wealth (which replaces market value), financial wealth (instead of financial capital), market capital (rather than customer capital), renewal capital (it was innovation capital before). The same labels remained for the remaining constructs (see Figure 1). According to this view, IC of a nation comprises all those values of individuals, companies, institutions, communities which are hidden but that represent existing or potential sources for the creation of wealth. In other words, such hidden values stand as the roots for cultivating future prosperous wellbeing for the city as a whole and its communities.

Nevertheless, the dimensions of national IC that is found in the extant literature can be seen as similar to those developed for city's IC models whose approaches are similar to each other (Viedma, 2003; Carrillo, 2004; Schiuma and Lerro, 2008; Cabrita and Cabrita, 2010; Uziene, 2013). If is important to point out that IC contents, even though labels that

are given to each of them are different, converge towards the traditional IC elements: human capital, organizational/structural capital and relational/customer capital. Ricciardi and Dameri (2015), along Bontis' categorisation of the national IC components into subcategories, suggested the following main indicators of IC of the city:

1. Human capital indicates the key knowledge resource in the city. Amongst its indicators there are: numbers of graduated citizens, number of schools per capita, all elements that are useful to measure the capacity to transfer knowledge and education to citizens.
2. Knowledge and learning potential comprised into inter and intra-territorial relations established between citizens, companies and other territorial actors is labelled in different ways and its indicators include foreign trade in terms of export, tourism from abroad, incoming students and workers.
3. Potential learning and knowledge expressed by cultures, entities and institutions as well as rules is labelled in different ways and its indicators include measures of trust, respect, and confidence towards the rule of law as well as measures regarding observation and compliance to norms as proxy of positive social relationships.
4. Innovative products and organisations are labelled as renewal capital and their meaning goes beyond the mere intellectual property rights. Referring to the territory's capability to express innovation, indicators include the number of patents, scientific publications in highly ranked journals, innovative start-ups.
5. Processes, practices and procedures are labelled into process capital. Indicators include the number of software usage and availability, volumes of databases, archives, repositories, digital store per capita.

These models of IC at the national and city level stand as conceptual grounds enabling cities to contemplate effective strategies that may generate public value for the communities by leveraging on the endogenous IC (Benington and Moore, 2010).

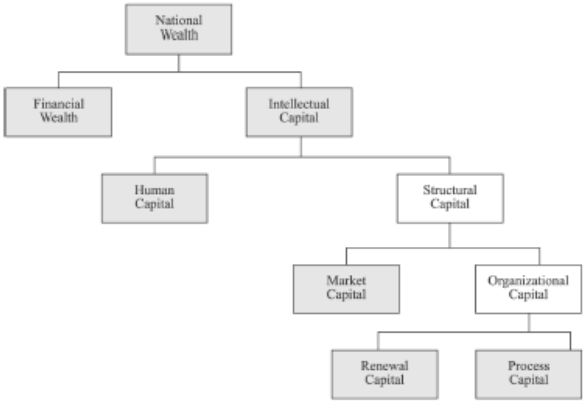

Figure 1 – Intellectual capital of nations (Bontis, 2004) – modifications of Edvinsson and Malone (1997)

2.2 An IC perspective for Capitals of culture

Little attention has been given to the realm of culture within the discourse of IC although it expresses itself in an intellectual and intangible resources based environment in terms of production and outcomes (Chong 2009). Culture is profoundly connected to knowledge that lies at the core of cultural cities that derive from the ideas of learning cities, information city, knowledge city (Donato, 2008; Sundström, 2011; Dumay, 2014).

On these premises, the character of cultural cities is shaped by the capacity of the city itself in building and consolidating knowledge as well as innovation that are functional in activating innovative processes, with a domino effect, inside the city and in compliance with the so-called fourth stage of IC as Dumay suggested (2016). According to the IC fourth stage authors' assumptions (Bounfour and Edvinsson 2005; Dumay and Garanina 2013), knowledge does not merely develop within organisations but flows out from dialogue and exchanges occurring between organisations and their networks, hence, between ecosystems with which businesses interact.

With reference to IC developed in cultural cities, Capital of Culture is the flagship cultural initiative of the European Union (ECoC) that moves into the field of the cultural strategies of the city aimed at improving its image and raise its visibility and profile, at the international scale, while exploiting local opportunities to generate considerable cultural, social and economic benefits that can help foster urban regeneration (European Commission, 1985). Launched by the European Union in 1985, ECoC was initially called the European City of Culture and was conceived in 1983 by the Greek Minister urging the need to give culture the same attention as politics and economics and to establish a project for promoting European cultures within the member states. Originating from a political awareness, the tile of ECoC has been given, since 1985, to cities designated by the European Union for one calendar year during which series of cultural events are organised within the designated city with a strong pan-European dimension. ECOc stems from the idea of enhancing richness and diversity of European cultures in order to maximise the social and economic advantages related to the long–term culture-based development strategy of the city and its surrounding region.

However, the ECoC idea is also grounded in the pivotal role that cities play in creating knowledge, culture, innovation and economic development. Hence, for these reasons, ECoCs are gaining an ever central role in territorial government and development which enable the conceptualisation of ECoC as related to the knowledge city. Or, as Ergazakis et al. (2004) have suggested, a knowledge city is a city that aims at a knowledge-based development resulting from knowledge creation and sharing at both the individual and institutional level (Edvinsson, 2006; Yigitcanlar et al., 2008).

In order to be selected, the cities are encouraged to apply by presenting a plan that shows resources, activities and expected impacts. As far as the candidature in 2019 of the City of Matera is concerned, its payoff phrase was "Together" that was also used for the first Dossier submitted for the application in 2013. After the designation of Matera as ECoC 2019, the city initiated a medium-long term cultural program aimed at sustaining

the urban renewal processes and new model of development for the newly designated Capital. To do that, the city leveraged on knowledge, research, new technology and innovation aimed at generating a sustainable participatory context through inclusion and social cohesion.

To be able to conceptualise and understand the multidimensional impacts of cultural initiatives through the IC lens it is important to cross-fertilise the IC discourse with the challenges posed by the cultural sector and vice versa in the context of cities of culture, more specifically, temporary Capitals of Culture.

3 Methodology

3.1 Research method

As far as this study is concerned, the research methodology is based upon an exploratory case study (Stebbins 2001; Yin, 2008). This method is particularly well suited to the research in question, as it is very effective for the analysis of complex phenomena which constitute a new field of research (Eisenhardt, 1989). This research method enables the authors to carry out an empirical investigation that analyses *"a contemporary phenomenon inside its real-life context (*Yin 1984, p. 23). Moreover, this method is consistent with that analysis to the extent that: (i) it focuses on a current situation; (ii), it involves collection of information to provide the neatest picture of the phenomenon; (iii) the research question refers to "how" or "why" events happen (McCutcheon and Meredith 1993: 240).

The exploration focuses on the City of Matera as ECoC 2019. The analysis is mainly developed at a micro (single organisations) and meso (community/neighbourhood/city) level. Empirical information has been collected through different sources of evidence in order to improve the validity and reliability of the findings (Dul and Hak 2008).

3.1 Selecting case-study

This study requires an in depth analysis of the case on Matera 2019. For this reason, it focuses on the City of Matera which stands as a unique phenomenon in the Southern Italian context as far as the European Capital of Culture realm is concerned. Although the unfolding of similar examples in Europe, it is a unique case because it shows structural and context characteristics which are completely different to former European capitals of Culture.

Other European experiences of ECoC all represent cross-scalar and cross-sectoral initiatives combining cultural and urban innovation with community's capacity building. All former ECoCs experiences, in fact, have leveraged on strong and rooted civic activism resulting from people's capacity of producing cultural innovation. Contrariwise,

the lack a model of assessment of IC of ECoCs in Europe, hence, in the city of Matera, represents a specific element of the analysed case.

3.2 Profile of Matera as ECoC2019

Matera 2019 has involved more than twenty thousand people and citizens, 350 cultural and social entities (amongst those companies, universities and research institutions, citizens and customers) and has developed across the city of Matera, its Province and Region (Basilicata). The Municipality of Matera, for this purpose, has been allocated financial resources by the EU Programme on Capitals of Culture.

Matera 2019 is the result of thousands of events, workshops, walking tours, conferences and concerts running over 48 weeks after four years of programming and planning (2015 – 2019), of co-creation activities spread across the city and the Region and in different places (associations, impact hubs, parishes, cooperatives, etc).

3.3 Procedures of Data collection

This study uses a mixed methodological approach following Yin (2003, 2006, 2008), and McLeod (2008). Data has been collected through secondary data, such as documents and reports, and primary data (interviews and direct observation by the researchers).

Primary data (interviews) refer to interviews addressed to different categories of stakeholders (representatives of institutions, NGOs, non-profit and for-profit associations, companies, schools, universities, healthcare, churches and citizens). Questions were of an open-ended nature to elicit the most thorough answers from the respondents (Rubin and Rubin 2005).

Amongst the key actors interviewed there are: the Mayor of the City of Matera, the director and the president of Matera 2019 Foundation, the President of the Region Basilicata, the President of the Province of Matera, 5 representatives of the most active cultural organisations, three professors of the University of Basilicata and 5 citizens living in the city of Matera.

The choice of organising interviews for a multitude of stakeholders has two reasons: the first one has a technical nature and is connected to triangulation of data; the second one, with a substantial nature, refers to the analysis of different perspectives derived from the different nature of the stakeholders been interviewed. In the first phase, interviews were not structured and were aimed at providing interviewees with a first approach to the subject under investigation and helped a better understanding of the real-life context and the contingent complexity of the phenomena (Qu and Dumay 2011). The first round of face-to-face conversations lasted about two hours, were recorded, and notes were taken. Then, a follow-up meeting for each interviewee took place later to validate the answers and gain more profound insights into some topics. In the second phase, interviews have

been semi-structured and aimed at enhancing the phenomenon compared to this study's research goals.

Secondary data (documents) – with reference to analysed documents, this study has investigated the following documents: official documents, social media (i.e. Facebook), websites and press releases. Documentary analysis concerned, inter alia, official documents: the first and the second bid books, reports of the formal monitor meetings by the Selection Panel and the Monitoring and Advisory Panel.

3.4 Data validity and reliability

The nature of data collected, for the purpose of this study, is qualitative. To the aim of guaranteeing data validity and reliability we have proceeded with aggregation of data, at first, and later, with their triangulation. Such technique has been considered by Creswell (2007), to be equivalent to quantitative studies' reliability testing and it also guarantees that results deriving from quantitative research are credible, valid and accurate (Denzin, 1984; Stake, 2000). Authors have used four types of triangulation.

The first type is represented by data triangulation on the basis of research conducted by Katamba et al. (2016). Authors have analysed the data collected from different sources (interviews and direct observations, documents) which have been, later, compared to each other. The reason why triangulation of sources is important is twofold; first of all, it contributes to give a total and more complete vision of the analysed phenomenon. Secondly, it enables comparison of gathered data while allowing their reliability.

The second type of triangulation has a methodological nature and utilises different methods of gathering data from several sources in order to ensure that collected data is cleansed from those eventual weaknesses that each methods used could bring in.

The third type is called investigator triangulation. In this context, researchers have conducted autonomously, hence individually, the analysis of the phenomenon as far as documents are concerned. With regards to interviews, one of the researchers has personally conducted them and their contents have been analysed by each single researcher at a later stage. Considering direct observation, instead, researchers have investigated social networks of Matera2019 channels in an autonomous manner and at the individual level. Such technique has been functional to cleanse collected data from bias (personal opinion, ideas, perceptions, feelings) brought by each single researcher.

The last but not the least is the theoretical triangulation. According to this technique examination and implementation of data analysis have been conducted by each researcher who owns and carries theoretical background. In particular, one researcher has a background in organisational theories; the other one owns a management and accounting background. The positive implication of this technique is that it has emphasised on the common elements brought by each single researchers so that results appear cleansed by each researcher's theoretical background.

The overall benefit of using all types of triangulations is related to the fact that they have favoured validity and reliability of data and enhanced awareness and acknowledgement of the phenomenon that is subject of this research. Using all triangulations has led to understand better and gain an overall knowledge of the context where Matera2019 has taken place and has enabled the implementation of positive outcomes or, eventually, negative ones.

3.5 Data analysis

The stage of analysis represents the interaction between researchers and data aimed at identifying its real meaning (Strauss & Corbin, 1998). Considering the qualitative nature of used data, the approach that authors have used makes reference to Charmaz (1983) "Grounded Theory". He suggested a methodology that is based, in the first stage, on identifying "key points" that are later transformed in "codes" (Katamba et al., 2016). In the second stage, methodology advances that the "codes" selected are gathered to be able to recognise "concepts" that allow to use data.

Thirdly, there is recommendation to start from concepts to later form "categories" standing as the basis upon which discussion of hypotheses are formulated.

As far as the research question at the basis of this study is concerned, it refers, in the first place, to the understating what are the IC factors that enable European Capital of Cultures, and, in the second place, to the role of the local government to support ECoCs.

However, to optimise the level of analysis with methodological debates and ideas, authors have widened Charmaz's theory (1983) in accordance to other researchers' speculations (Strauss & Corbin, 1990; Miles & Huberman, 1994; Creswell, 2007; Katamba et al., 2016).

4 Results

4.1 Description of the case-study Matera 2019

Matera 2019 is a longitudinal process initiated in 2008 and that culminated in 2019 with the exploit of projects and events, worth the nomination of the City as ECoC. Originated from the European Commission's initiative on culture, Matera 2019 stood as a cultural but also social experiment that has challenged the current way of planning activities within the city. What has been produced in terms of contents and impacts was made in the perspective of collaborative-based governance to the extent that innovation in terms of creativity, collaborative networks and organisation was brought in.

Different actors have been engaged at multiple levels and at different stages. Three are the phases that have led to Matera to leverage on the IC of the city and to bring the city itself to ECoC 2019:

1) The first one refers to the role played by a local cultural Association named Matera2019 that started a process of community engagement (citizens, local firms, other associations, professionals, institutions and NGOs) to collect the human capital available in the city. The objective of this phase was to obtain the designation of Matera as ECoC2019 which was, hence, fulfilled. This phase also showed a massive participatory and inclusive approach whereas many young, small businesses and various cultural and social associations of Matera were engaged;

2) The second phase refers to candidacy that is, when an institutional committee was established to steer the decision-making process at a more institutional level and to organise knowledge and learning potential in inter and intra-territorial relations. In this phase fall the two dossiers that defined define the principles, the structure of the program, the organization as well as financial resources. Also in this phase, participation of multiple subjects has represented a landmark: a consistent group of "digital" volunteers had been involved in the dossier drafting to narrate the experiences and the history of Matera on the websites.

3) The third phase refers to implementation after designation that leveraged on knowledge and potential learning expressed by cultures, entities and institutions as well as rules implying a high level of trust, respect, and compliance to EU clauses and parameters. The main goal of this phase related to the definition of an effective governance and a corpus of binding regulations for all actors and partners involved whereas, as an European award, ECoC means to comply with standard criteria and objectives defined at EU level.

Matera 2019 is the result of a long and enduring process devoted to promoting the development of a culturally and socially engaged community oriented towards the exploitation of intangible assets and resources to support future urban strategies policies. Matera 2019 was expected to deliver three different but interweaved impacts: social, cultural and economic. Indeed, results have been represented by a novel tourism for visitors, a renewed model of local development, a potential creative industrial workplace for European youth, a new lifestyle model for EU citizens.

4.2 IC enabling factors

The adoption of IC perspective to cities temporary named as capitals of cultures has allowed considering several enabling factors for Matera 2019. The presence of these factors enabled the city of Matera to imagine processes of development and innovation that with the appointment as ECoC2019 resulted in the built up of a reputation, hence, a strong brand, able to attract people and investments. More specifically, it is possible to identify three enabling factors that, together, enable a city to develop IC and lead to define the atmosphere of a Capital of Culture: creativity of the city, critical mass, and governance organisation structural capacity.

Amongst creativity related factors, it is important to make reference to the huge city's creativity potential that stimulates production of creative content or work in a creatively manner. Following Florida and Tinagli (2004) assumptions, creativity encompasses the creative class of scientists, engineers, university professors, poets, novelists, entertainers, artists, actors, designers, architects, nonfiction writers, editors, cultural figures, think-tank researchers, analysts and other opinion-makers. Besides, such creative class include young, highly educated and talented people.

The former President of the EU Commission, Manuel Barroso, mentioned creativity in the document (European Capitals of Culture: the road to success. From 1985 to 2010) and defined it as a source of stimulus for the EU policies of sustainable development in the EU. Hence, creativity is seen at the basis of ECoC's success, which leverages on the capacity to aggregate the highest number of creative actors.

With this regards, during an interview, a professor of the University of Basilicata claims:

> *"disposing of creative people has brought fresh life to our community and the city as a whole, boosting the local cultural, social and economic development".*

Continuing along these lines, another actor the cultural sector, during the research interview, declares:

> *"being rich of creativity for us has been functional to give a fresh look at the history and heritage of the city itself".*

In another interview, a cultural operator affirms:

> *"Commitment by each single actor to the vision of Matera 2021 has been shared from the very beginning to fight against the label given to this city as the Italian shame. Sharing the same desire and enthusiasm has been pivotal to maximise efforts toward a unique goal: making Matera the Capital of Culture"*

To demonstrate what has been declared during the interviews, there are document data that portray in a clear way the importance of creativity as a factor that enables the development of IC in ECoC.

The value of critical mass, as an existing factor in the city, is not only one of the main prerequisite to develop IC in a city, but it is also the result of a significant eradication by the engaged actors in the social fabric of the community of the city. As argued, it induces widespread collective action (Oliver and Maxwell, 1985) which is, otherwise, difficult to mobilise.

The Mayor of the City of Matera, after the nomination of Matera as ECoC, declared:

> *"Matera2019 is a social and cultural revolution that has been possible to carry on thanks to a significant people's support, in other words, people's critical mass. To be clear, critical mass has been so relevantly high that the old way of thinking in this city has been subverted".*

Critical mass, as a factor enabling IC in a city, is also found in the words of one of the headmaster of one of the most prestigious high school in Matera:

"pure communality and collaboration on Matera2019 project has is the result of each citizen's enjoyment in thinking critically of the future of this city. Critical mass has given the community the potential to magnify the capacities of single members far beyond what they could accomplish acting alone".

Another interviewee from the cultural sector, during the interview, affirms that:

"this is the project of a city that wants to take decisions. It is a city filled with critical mass and shared willingness to work collectively to connect people and its territory to enhance its heritage of all forms".

Demonstration of critical mass as a factor enabling IC is given in terms of people collaborative actions and communalities. In terms of collaborative action, critical mass is demonstrated by the fact that all actors participating to candidacy of Matera2019 have a strong spirit to share a common vision for the territory where they are eradicated. In terms of communality, critical mass is demonstrated by the high percentage of participation of actors during meetings and plenary assemblies. Belonging to a common place and history is at the basis of joint actions conducted by actors holding different skills and background.

As far as governance and organisation structure capacity is concerned experience has shown that the governance structure is a crucial factor in an ECOC's success (EU Commission, *European Capitals of Culture 2020 to 2033. A guide for cities preparing to bid*). Structure and governance refer to a system of institutional rules, policies and processes at the basis of management and coordination of roles and responsibilities. The organisational structure, therefore, has an impact on the development of an environment which stimulates creativity and innovation in a territory of reference. However, to be successful, a structure needs to have a supportive organisational culture meaning that culture has be attuned to the aims and functions of an organisation. When our interviewees were questioned on the role of culture in organisational capacity, there was consensus among all interviewees that a crucial relationship exists between culture and structure capacity. One of the interviewees affirmed:

"without the right values, cultural beliefs, behaviours, attitudes and norms organisation structure is less likely to be successful in supporting the management of events as ECoC".

During a public assembly, the representative of Matera Foundation 2019 publicly affirmed:

"context is critical in developing performing governance and organisation structure. An organisation may be responding to accountability and political pressures while attempting to support a reform or modernisation process".

Or, a less enthusiastic statement by one member of the cultural sector who states:

"the organisational structure and governance do not often create further value due to difficulty in ensuring a fair balance between decision-making and collaboration with other actors concurring in the realisation of ECoC as a big event. The risk is that part of the knowledge generated by putting people, attitudes, skills and capacities of all go to waste due to the fact that they are hard to manage".

Demonstration of the value of governance and structure capacity is given in terms of the capacity of an organisation to promote an environment that favours innovation within the territory where it operates in order to stimulate learning, create new knowledge, allow knowledge sharing and facilitate problem-solving.

5 Discussion

Since their conception, ECoC's projects have significantly put development and regeneration at the heart of cities to strengthen their sense of community. Former ECoCs have delivered positive outputs that are visible across their cities and give proof of an improved image of the city. Starting from a strong awareness about the city's identity, ECoCs have demonstrated a solid background in terms of stakeholder's participation and engagement. In fact, such EU appointment has been a great opportunity for all to take part in the year-long activities who have played a bigger role in their city's development bringing creativity, developing community's skills, both expressed and tacit knowledge, know-how, tangible and intangible resources. ECoC, as a project, represents a tool to develop the exiting IC of a city starting from factors that are already there and which may stimulate further development. These factors provide a practical advice to leverage on the concepts of creativity of a city and critical mass, and governance and organisation structural capacity.

These latter concepts belong, in this case, to the intangible assets that stand as enabling factors of IC of a city. It is possible to assume that these factors are very much connected to one another: creativity, emerging from creative connections of people operating in a context so as to stand as a constructive process out of social practices is critical to aggregate that critical mass that is treasured within a community. ECoC as an experience shows that existing critical mass can be strengthened, or even multiply, knowledge of a city for its development. Matera2019 demonstrates a significant increase of the city's existing IC which is originally enabled by endogenous factors at the city level, to ensure the success of ECoC performance.

Matera2019 leverages on the presence of specific enabling factors showing that structured creativity (meaning that it encompasses different actors at all levels: cultural, economic, social, etc.) and structured pre-exiting critical mass (meaning that it critical mass is reached by transferring individuals' thinking into an engaged constructive reaction leading to co-creation activities) do fit with the existence of a solid structure organisational capacity in the strategic management of the initiative and strategic thematic guidance on actions. Nevertheless, if the presence of co-governance giving the overall direction of the strategy should, in principle, catalyse the creation of further value related to knowledge generated by cultural events and programmes, in practice, it creates a knowledge management implication. The qualitative investigation has led the authors to converge on such critical concern connected to the managerial challenges implied in the practice of ECoC as mentioned in one of the interviews.

The sources of information convey the fact that Matera2019 Foundation, the organisational entity that has governed ECoC projects, showed a complex network including people from different institutions, such as public administration bodies, universities, business actors and other foundations. The implementation of ECoC programmes has implied intense interactions within and across emergent actors going beyond any organization's boundaries and traditional managerial control.

Matera2019, as a phenomenon, has implied the emergence of novel types of networks, shaped forms of organization where organizational boundaries became blurred and where the needs of the new governance and its related coordination and management issues have emerged. According to Borgatti and Foster (2003), the latter are the typical challenges of emerging network forms of organizations at the core of a possible research stream. Such a management challenge above leads to develop new and specific organizational solutions in order to effectively implement ECoC as a whole.

6 Conclusions

This article can be considered as a contribution of the so called fourth stage of IC research (Dumay, 2013) because it develops the IC perspective into a wider and different context than the company one. The application of the IC perspective to the ecosystems where business finds its space in a large standpoint has been present in the literature for some years, being applied in the context of countries (Edvinsson and Stenfelt, 1999), cities (Carrillo, 2004) and communities (Bounfour and Edvinsson, 2005). In the literature review we showed the specificities of these different studies and their characteristics in reference to the role of IC, its components and dimensions, and some possible ways of representation.

Despite the presence of these studies in the literature, our research has shown that a topic of increasing interest such as the role of the recognition of the title of capital has not had specific insights, under a IC perspective.

In particular, the meaning of the ECoC title from an IC perspective has not yet been the subject of specific studies, prior to this work. A fundamental premise of this work is therefore the recognition of the importance of the ECoC title, in light of its potential linked to the economic growth of the territories and the activation of sustainable development paths, based on culture and tourism, as well as that of enhancement of cultural identity in a perspective not only national, but also supranational (such as the European one).

In light of these considerations, the work went specifically to investigate, by means of a specific research question, what the IC enabling factors at the basis of ECoCs are. The answer was provided in this research through the use of a single case study, identified in Matera2019 European capital of culture. The analysis of the case, conducted through a deep relationship with the stakeholders directly involved in the pre-recognition application process and subsequent management of the qualification, led to the observation that three enabling factors appear to be the most relevant.

These enabling factors have been recognized in creativity, critical mass, and effectiveness of governance and organisational structure. These factors therefore do not represent the specific characteristics or attributes of the IC of a capital of culture, but are those that allow it to emerge and favour the development of the IC potential included in the city that has obtained (or wants to obtain) this recognition.

The development of IC for the city that competes for the appointment (or is nominated) to ECoC is therefore based primarily on the presence of a basis of creativity that can act as a driving force behind this process. Such creativity must have a sufficient critical mass in order to emerge, but must be managed in the correct way at the same time and for this a governance and organizational system is needed that is able to fully exploit these resources. The path of ECoC in a certain sense favours this activation in itself, because the process on which both the candidacy and the appointment is based, seems to be a natural driving force of these factors.

The considerations here developed can have interesting implications for all those who intend to propose for their city the path of candidacy for capital of culture (a process that takes place not only on a European scale, but in some countries also on a national scale). The observations presented are therefore potentially useful both for policy makers, but also for communities organized in associations, who want to promote the cultural identity of their territory, in a perspective of openness and comparison with the outside.

However, this study has an important limitation: being referred to a single case study, the concepts presented here cannot be considered generalizable, but can only constitute a first basis of analysis and debate on the enabling factors of IC in the context of cities, in particular of the ECoCs. This article claims potential future research concerning the study of new ECoC cases in order to confirm, expand, or even refute the perspective offered here. Potential future research developments also concern an expansion not only to the ECoCs, but to all those contexts in which the city obtains a title or recognition, for a limited or lasting period of time.

Rethinking Sustainable Change within Public Organisations by Information Technology

Mauro Romanelli

Department of Business and Economics
University of Naples Parthenope
Via G. Parisi, 13 Napoli 80132, Italy

Abstract

Public organisations are changing by using the potential offered by information technology in order to better contribute to value creation moving towards sustainability as a vision for change and action. As organisations seeking sustainability by strengthening sources offered by use of information technology, public organisations select a community-driven approach and adopt a logic service view as strategic choice to enable and facilitate public value creation within society. Information technology is leading public organisations to identifying a pathway towards sustainability for driving change moving from providing information to managing and using knowledge, enhancing openness between transparency and accountability by developing smart and digital platforms as a mean that enables both knowledge and openness views. Public organisations contribute to value creation, innovation and sustainability within communities improving technological advances in government in order to develop digital, smart, lean and open platforms for social and knowledge exchanges that open up to promoting public value creation processes.

Keywords – public organisations, change, value creation, information technology.

Paper type – Academic Research Paper

1 Introduction

Today, public organisations have to deal with change by embracing information technology as a source to drive better functioning of organisation, services and communication with citizens. Public organisations serve the public interest as the result of dialogue with citizens (Denhardt and Denhardt, 2000) following a sustainability-oriented view as a vision for change to drive public decision-making, management and governance (Goodsell, 2006; Fiorino, 2010). Public organisations contribute to facilitating value creation-oriented processes by using the potential offered by the advent of information technology. The advent of information and communication technologies (ICTs) helps public organisations to communicate with citizens and various stakeholders as active co-producers of social, democratic and public value (Moore, 1995). Technology helps public organisations to drive change by involving civil society within a networked governance and developing open innovation by including external knowledge in decision-making processes (Hartley, 2005; Mergel, 2018).

ICTs help drive organisational change enabling technological, human, social and managerial sources (Orlikowski and Yates, 2006). In particular, ICTs help both to support institutional change within public administration (Gascó, 2003) and to focus on the interface between citizens and government, and facilitate the flows of information within government and for citizen right and access to information (Mayer-Schönberger and Lazer, 2008).

Technologies open up to digital and smart ecosystems where public organisations act as enablers of social and public value creation by involving civil society and following a service logic view and promoting shared community values in order to support dialogue, knowledge and information sharing, social exchanges, interaction and citizen-centred services effectiveness (Osborne, 2018; Dumay, Guthrie and Farneti, 2010; Stoker, 2006; O'Flynn, 2007; Moore, 1995). ICTs help public organisations drive networks that involve private and public actors, developing knowledge and capabilities in the pursuit of public goals (Janowski, Pardo and Davies, 2012). ICTs help strengthen collaboration and support the exchange between governments and civil society for service innovation, governance, administration effectiveness and support to institutional reform (Lips, 2012). ICTs are driving public organisations as digital and smart communities to support public value creation within open ecosystems (Larrson and Grönlund, 2014; Granier and Kudo, 2016).

Even if some studies elucidate the importance of information technology as a source to enable innovation and transformation of public organisations, there are few studies that investigate how public organisations adopt a change view by using the potential of information technology, Thereby, technology can work as an enabler of forces that drive public organisations into change. The study aims to elucidate how changing public organisations use technology as a means to develop digital and smart institutions that enable knowledge management approach and openness view as values and drivers of change within sustainability-oriented public organisations.

The use of information technology drives public administration to follow a sustainability-oriented view for change within public organisations that rediscover the importance of developing an orientation towards a knowledge management approach, enhancing openness as public value between transparency and accountability, developing the potential offered by information technology in order to build a community vision by encouraging the participation of citizens in public policy and services design.

The contribution of this study is to propose a framework of analysis to identify how public organisations are changing by embracing ICTs to develop as knowledge, open and community oriented institutions. This study relies on the analysis of literature that refers to the relationship between ICTs and knowledge management, openness and smart and digital advancements in designing and promoting the relationships between public organisations and citizens. Technology contributes to influencing the extension of change and exerting influence on three areas of managerial capabilities and development: implementing a knowledge management approach; promoting openness between

transparency and accountability; strengthening a community vision by smart and digital platforms opening up to a new season of the relationship of confidence between the citizen and the government.

The paper is structured in six sections. Following the introduction and methodological section, the third paragraph elucidates the role of information technology within public organisation seeking a sustainable change. In the second section, the fourth paragraph identifies the areas for driving change as enabled by the advent of information technology: developing a knowledge management approach to processes; promoting openness between transparency and accountability for revitalising democracy and participation; promoting a community vision by strengthening digital and smart platforms for value creation. In the fifth paragraph a framework of analysis is elucidated and the discussion follows. Finally, conclusions are outlined.

2 Methodological section

The study is theoretical and relies on a literature review relating to public organisations that aim to change by embracing information technology in order to develop knowledge management processes and enhance openness and promote a community-oriented vision by strengthening digital and smart platforms to contribute to value creation for public wealth. The selected contributions refer to the relationship between ICTs and knowledge management, openness, digital and smart platforms as evolution of advanced information technology in government. The selected contributions are interpreted in a narrative synthesis in order to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods, Agarwall, Young, Jones and Sutton, 2004).

3 Public organisations changing as technology-enabled and logic service-driven institutions

After the promises emerging by the wave of New public management doctrines and practice about efficiency and effectiveness, public organisations adopt a public value management view as a vision for change and value creation (Stoker, 2006; O'Flynn, 2007), moving towards an ecosystem and community view to sustaining knowledge and public value creation within society (Osborne, 2010).

According to Osborne and Brown (2005) while innovation as the introduction of new elements into a public service is considered to be as discontinuity with the past, change represents continuity with the past refers to the gradual improvement and development of the existing services provided by a public sector organization. Electronic government is emerging as a catalyst for driving strategic and organisational change within public organisations (Yeo, 2009). Technology provides resources that open up to successful change within public organisations promoting value creation processes, involving civil society and promoting collaborative processes (Fernandez and Rainey, 2006). Thereby, it

is necessary to pay attention to the risks of bureaucratization in terms of supporting bureaucracy than minimizing by using and developing information technology (Cordella and Tempini, 2015).

Public organisations adopt a sustainability-oriented approach as a vision for managing *res publica* within communities and creating value within ecosystems (Fiorino, 2010; Goodsell, 2006; Dumay, Guthrie and Farneti, 2010) by engaging stakeholders and involving civil society in constructing governance networks and shared partnerships (Hartley, 2005). So, public organisations have to adopt a logic service and new public service to drive policies and practices in delivering public services and interacting with citizens (Denhardt and Denhardt, 2000; Osborne, 2018). Following a logic service, public organisations drive change enabling the users to create value because «it is the citizen and/or service user who creates the performance and value of a public service, with the PSO acting as a facilitator of this process» (Osborne, 2018, p. 229). Public organisations adopt a service logic view (Osborne, 2018), promoting collaborative processes in order to achieve policy objectives within a community (Bourgon, 2007).

ICTs help both open up to and drive organisational and institutional change within public administration (Gascó, 2003; Orlikowski and Yates, 2006) for public value creation (Moore, 2003), and improving the administrative action and enabling government to better connect with citizens (Meijer, Bannister and Thaens, 2012). Information technology helps cultural and operational change within public administration by enabling a knowledge management approach in process management, promoting openness and revitalising democratic values and mechanisms for citizen participation, leading to digital and smart platforms for value creation. Information technology helps change within public organisations that benefit citizens by improving the efficiency of services (e-government) (West, 2004) and enhance democratic processes by involving citizens in policy-making and fostering public values as transparency, participation and accountability (e-governance) (Dawes, 2008; Bannister and Connolly, 2012). ICTs are driving digital and smart public organisations that contribute to supporting public value creation (Larrson and Grönlund, 2014; Granier and Kudo, 2016). As using information technology, public organisations have to become smart institutions engaging citizens (Mellouli, Luna-Reyes and Zhang, 2014).

4 How technology helps public organisations to change

Information technology can emerge as a source to drive innovation and change within public administration with regards to strategic, organisational and managerial issues. Changing public organisations follow a community-oriented vision driving digital and smart platforms as spaces for dialogue, move from an information provision approach embracing information technology to develop knowledge management in processes and to promote an openness-oriented view in transitioning from transparency to accountability.

4.1 Rediscovering knowledge capabilities: from information to knowledge management

Investigating the aspects related to knowledge management in the public sector is becoming a relevant research theme. Knowledge management refers to what an organisation knows and implies to transform data in information to use and value it as a strategic source (Bellamy, 2003). Managing knowledge as a fundamental resource in public policy formulation helps responsive governments meeting the needs of citizens to design and implement information systems by using technology in order to improve the organisational (Gates, 1975; Henry, 1974). Developing knowledge management within public administration helps improve quality of life for citizens within society (Wiig, 2002). As following a knowledge-driven and sustainable-oriented view, public sector organisations learn how to create, use, manage and share knowledge to contribute to value creation processes achieving social and environmental issues (Massaro, Dumay and Garlatti, 2015; Bratianu and Bolisani, 2015; Leon, 2013). Moreover, public organisations should move from an information management approach to knowledge management vision to driving and restructuring systems, processes and operations. Technology is a key driver for leading to enhancing and implementing knowledge management processes to sustaining organisational culture within public organisations (Girard and McIntyre, 2010). People, processes and technology enable knowledge management processes within public organisations. Developing technological and organisational sources and infrastructures opens up to knowledge management vision and culture within public administration processes (Cong and Pandya, 2003). ICTs help to transform public organisations by driving innovation and developing a knowledge management approach to problem solving in defining public policies (Edge, 2005) strengthening knowledge management-oriented processes and fostering citizen participation and governance (Al-Sudairy and Vasista, 2012). As knowledge-driven and technology-enabled responsive institutions engaging citizens, public organisations develop effective two-way transfers of knowledge between public organisations and stakeholders to better develop sustainable policy solutions (Riege and Lindsay, 2006). ICTs help support knowledge management development and implementation within public sector organisations (Suurla, Mustajarvi and Markkula, 2002). Thereby, while information management systems are well developed, technology tools for governing knowledge management sources are still in infancy. Public organisations have to invest in information technology systems and sources in order to drive knowledge management systems in transitioning from infancy to maturity in order to enhance knowledge as a source for value creation (Cong and Pandya, 2003; Wiig, 2002). Technology helps public organisations to develop knowledge management systems and enhance knowledge sharing culture using knowledge as a source to improve public services quality, accessibility, productivity and innovation (Fang, 2002).

4.2 Rediscovering the importance of openness: from transparency to accountability for citizen participation

Information technology makes public organisations as open, responsive institutions willing to serve the interest of citizens (La Porte, Demchak and Jong, 2002). Enabling openness, transparency and accountability by using information technology helps drive, support and facilitate cultural and technological change within public organisations. According to Grimmelikhuijsen, Porumbescu, Hong and Im (2013) transparency means «the availability of information about an organization or actor that allows external actors to monitor the internal working or performance of the organization» (p. 576). Transparency is seen by policy makers as a panacea for enabling good governance by driving democratic institutions as transparent organisations that restore public trust by empowering citizens in order to monitor government performance using ICTs and the Internet as enablers of transparency (Curtin and Meijer, 2006; Grimmelikhuijsen, 2009). Informing citizens helps to improve policies and enhance governmental legitimacy (Meijer and Thaens, 2003). Digital government relies on creating a digital ecosystem for public value creation by strengthening cooperation and opening to a data-driven culture and strategy ensuring openness, inclusiveness, engagement and participation in policy-making and service design to better serve citizens and business that access to social and informative exchange (Oecd, 2014). Governments use ICTs to promote information access and transparency of government organisations making public organisations directly accountable to citizens (Meijer, 2003). Public organisations should develop a citizen-centred view proceeding along a *continuum* between transparency and accountability (Fox, 2007). According to Bertot, Jaeger and Grimes (2012) using information technology helps change by sustaining a culture of transparency that is citizen-centred. Promoting transparency enables participatory, collaborative and open government that drives cultural change, supports citizen engagement and interaction with the public (Mergel, 2012; Jaeger and Bertot, 2010). Technology helps promoting a flow of information citizenry-government and effective citizen participation in the political process (Watson and Bundy, 2001) by enhancing the quality of democratic governance by providing better information to citizens enabling them to exert influence on policy making (Kakabadse, Kakabadse and Kouzmin, 2003).

4.3 Rediscovering a community-oriented view

The advent of ICTs and the Internet in government processes open up to a new digital governance era in terms of citizen-centred processes that facilitate the interaction government-citizen, drive the transition to client-based re-organisation and services digitalization (Dunleavy, Margetts, Bastow and Tinkler, 2006). In particular, Web 2.0 is driving e-government towards an integration and participation in terms of knowledge and services for an active citizen engagement (Dixon, 2010). Promoting change relies on developing a community/citizen centred approach (Meijer, 2011) and sustaining public

innovation by involving public and private actors to cooperate for value creation (Ansell and Törfing, 2014). The role of digitization is to help to facilitate and accelerate change within public organisations. E-government maturity models relate to technology as a source for human-centred change to benefit customers and citizens too (Andersen and Henriksen, 2006).

Technology helps empower the citizen as responsible partner in delivering public services (Linders, 2012). Technology enables smartness in government by enabling openness and knowledge (Gil-Garcia, Zhang and Puron-Cid, 2016). The advent of interactive and digital technology helps public organisations to adopt and strengthen a community/citizen and smart approach in order to sustain public values, equity and development (Larsson and Grönlund, 2014; Dunleavy, Margetts, Bastow and Tinkler, 2005). Technology facilitates networked co-production of public services strengthening a community vision (Meijer, 2011; Bovaird, 2007). Successful digital policies imply to build collaborative digital systems that involve public, private and no profit organisations working to achieve shared objectives (Dawes and Pardo, 2002). Building digital platforms and spaces contributes to developing services co-production and value co-creation (Fishenden and Thompson, 2013) in order to promote innovation and transparency, support citizen engagement, knowledge and information sharing (Harrison, Pardo and Cook, 2012). Digital technologies are leading public organisations to promote policy driven e-governance platforms (Janowski, 2015), evolving as smart communities that rely on proactive citizen participation, and help drive smart culture in government, empowering citizens as co-designers and co-producers of public services and leading to innovation and knowledge development (Larsson and Grönlund, 2014; Gil-Garcia, Zhang and Puron-Cid, 2016).

5 Discussion

As sustainable change-oriented institutions, public organisations tend to develop both knowledge approach to processes and openness view to communication as values that orient administrative action leading public organisations to embracing digital and interactive technology to build a community approach to value creation processes. As knowledge-driven and open institutions, public organisations aim to promote collaboration encouraging inter-organisational and long-terms relationships, and interacting with civil society. Public organisations develop the potential of technology to advance digital, smart and open communities as spaces and platforms that help encourage partnerships and collaboration among private and public actors within ecosystems.

As shown in figure 1, the main contribution of this study is to identify some pathways that enable public sector and services organisations as public value-oriented and sustainable-driven organisations that contribute to wealth of communities within social and economic ecosystems.

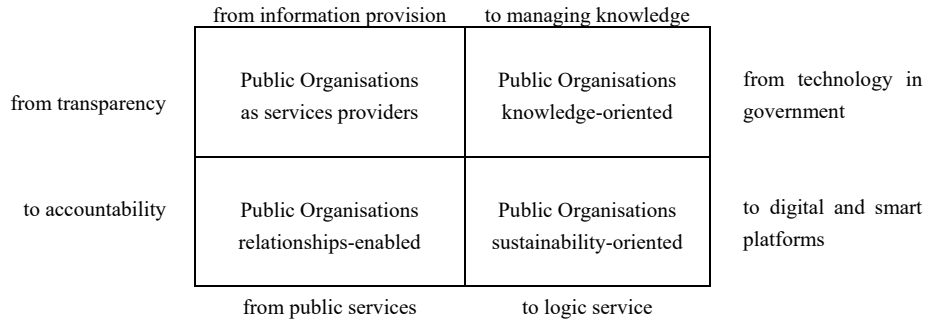

Figure 1 – Towards public organisations as sustainable communities

Public organisations consider the sustainability as a source for change that helps value creation processes and enables the wealth of people and business ensuring social, financial, economic and democratic performances. Developing digital and smart platforms offers a means for public organisations that change by following a knowledge management approach by ensuring openness, transparency and accountability as values that drive public organizations, companies, groups and people to interact for value creation processes.

6 Conclusions

Innovation and change always concern the life and development of public organisations over time. The advent of information and digital technology offers public sector organisations to take opportunities and face challenges to solve problems and questions related to efficiency, effectiveness, equity and democracy in redesigning and driving the relationships with citizens and/within communities. In particular, the themes of sustainability and change tend to strictly converge as drivers for identifying a value-oriented pathway that concerns the improvement of the relationships between public administration and communities. As developing the potential offered by information technology, service logic driven public organisations as select a community-oriented view to drive change and value creation processes adopting a knowledge management perspective to process, work and system innovation (proposition 1), strengthening openness from transparency to accountability (proposition 2) and developing digital and smart institutions (proposition 3).

In this study, there are some limitations. This study identifies some theoretical propositions and provides a framework of analysis in order to drive change within public organisations that follow a sustainable view to public value creation within communities. Thereby, empirical research and case studies are absent in the analysis because public organisations are still in infancy in dealing with technology and change for sustainability

as a source that enables innovation in governance and services design within ecosystems that helps change processes.

In this study, there are theoretical, managerial and organisational key implications. Developing the potential of information technology in government helps public organisations to bring together knowledge management approach and openness building collaborative spaces for social and information exchanges, and shared value, promoting a public value view to driving change and innovation within social and economic ecosystems. The advent of digital, smart and interactive technologies helps social and cultural change in the minds of employees, providers, people and groups enabling policies that foster continuous search of exchanges and interaction between public sphere and community sphere following an evolutionary approach to living the change. Technology-oriented changes contribute to reshaping and redesigning the structure of public organisations leading to a more flexible and *ad-hoc* organisation learning to understand how to contribute to value creation processes.

Further research perspectives imply to investigate how local autonomies and governments design and implement managerial, organisational and technological policies and practices that involve human resources and capital. Technological advancements and digital platforms contribute to enhancing the community development within public organisations that interact with civil society to develop knowledge sources and capabilities, value-oriented processes, and shared culture within public sector ecosystems.

Abstract

The effect of digital transition on today's knowledge creation processes is becoming relevant for companies operating in different industries, and the body of literature examining this impact is fastly growing. Nevertheless, systematizing existing studies on digital technologies supporting the firm's knowledge creation processes to reconceptualise existing knowledge management models and paradigms is still a challenge. In this scenario, the SECI model can provide theoretical guidance to achieve this research objective. Indeed, through the implementation of digital technologies, firms are redesigning the way they access and manage knowledge. Therefore, this paper aims to critically analyse the literature on the impact of digital transition on knowledge creation by providing a novel structuring model. This model seeks to analyse the role of digital transition along the innovative digital knowledge creation processes identified (Webinarisation, Informalisation, Systematisation, Explication, Digitalisation), according to the traditional epistemological and ontological dimensions. Integrating these perspectives, the authors design the WISED model to evaluate the impact of digital transition on the knowledge-creating companies.

Keywords – knowledge management, industry 4.0, bibliometric analysis, literature review.

Paper type – Academic Research Paper

1. Introduction

Nowadays, knowledge is considered to be one of the most important and delicate resources to manage. In recent years, there has been a growing spread of industry 4.0 technologies at everyday life level, as well as the intensive use of social media for communication between people. Even knowledge had to confront and conform to these new realities. Industry 4.0 is characterised by a mass creation of smart objects for everyday life (e.g., smart mobility, home applications) and technologies for working life (e.g., Artificial Intelligence, Internet of Things, Big Data, Blockchain). Industry 4.0 technologies have great versatility, so they have penetrated every working sector (e.g., food, medical, luxury, services) and at every "value" stage (e.g., procurement, production, logistics, distribution) (Kumari et al., 2018; Majeed & Rupasinghe, 2017; Mattei, 2019; Miranda et al., 2019; Pace et al., 2019; Yin & Qin, 2019). Through sensors and man-machine interfaces, in each of these phases, information relating to the processed product and the provided service is generated; instead, the various applications to live the city and own home smartly generate information on the habits of the people. It follows that the technologies of industry 4.0 have both a technical and a social aspect as regards the people who interact with them (Oks et al., 2017). Industry 4.0 marks a shift in the production of goods and service provision towards a dimension that is no longer only real, but also digital (Kagermann et al., 2011; Lee et al., 2016; Leitao et al., 2016). Parallel to the development of a digital reality in which products, services and people have their virtual twins, the spread of Internet-based software tools, namely social media, has developed in recent decades with the main purpose of improving virtual users communications, interactions and communications (Thomas & Thomas, 2012). These social media have radically changed the way people interact with each other and search for information of interest (Macnamara & Zerfass, 2012). These tools have removed the spatial and temporal barriers that existed between people, by radically changing the way social relationships occur; in fact, people from different places and cultures can communicate easily and instantly (Galli et al., 2019). Then, people become part of a social network where information and communications take place intensely and immediately. Precisely, this high amount of information, together with the possibility of breaking down the space-time barriers of communication, has made these tools attractive also for companies and public administrations (Valkanas et al., 2017). Researchers have shown how social media, implemented adequately in companies, manage to have a positive impact on factors such as innovation, efficiency, productivity and decision making (Murphy, 2010).

From the synergy of industry 4.0 and social media tools, it has been possible for organisations to get, store and process an ample amount of data both from within and from externally a firm (Escribano et al., 2009; Laursen & Salter, 2006; Mazzola et al., 2016). For example, manufacturing firms can now obtain individualised customer data to personalise the sales process, product design and service. One application of this is through smart devices which record and shared data in order to identify opportunities

using learning algorithms (Feng & Shanthikumar, 2018). Digitalisation also allows for demand information to be shared directly both to actuators in plants and to the supplier in the supply network, leading to shorter changeover time and enhanced supply service level. The amount of data stored and disseminated has also enhanced both predictive accuracy and facilitation of prescriptive solutions (Schniederjans et al., 2020).

In today's highly competitive and knowledge-based economy, digital knowledge has become a fundamental resource for the development of any organisation (Acerbi et al., 2020; Eaton & Pasquini, 2020; Facer, 2011; Laudien & Pesch, 2019; Li et al., 2018; Rajabion et al., 2019). Digitalised knowledge management results in one of the most critical resources to achieve the level of successful organisation (Li et al., 2018). The digital revolution of industry 4.0 has questioned extant innovation and organisational learning theories (Natalicchio et al., 2017). For instance, Nambisan et al. (2017) analyse how organisational axioms has changed by the rise of digitalisation, such as the role of knowledge management (KM) processes to renew knowledge base and improve innovation performance (Nambisan et al., 2017). This evolving technological and organisational environment has required organisations to improve their KM processes (e.g., acquisition, storage, transfer) since a focus on internal knowledge or exposure to external knowledge is not sufficient to increase innovativeness (P. Centobelli et al., 2019; Ekbia, 2009; Lyytinen et al., 2016; Passaro et al., 2018; Trantopoulos, von Krogh, & Wallin, 2017).

Planned organisational processes affecting KM strategies are likely changing together with the direction identified by the adoption of advanced digital solutions (e.g., advanced business analytics, digital platforms, machine learning) for product and process innovation. For instance, the processes of knowledge acquisition, storage and transfer are changing not only in terms of data amount but also depending on the emergence of specific digital infrastructures (Li et al., 2018). Similarly, in adopting digital solutions, organisations have to acquire and transform different types of external knowledge compared to non-digital realities, so requiring the opportunity to use new knowledge management systems (KMSs) (P. Centobelli et al., 2019). It means that digital innovation has revolutionised the innovation processes flow, however asking organisations to think again the ways they can explore and use knowledge flows, and the way they can leverage on the adoption of digital platforms, infrastructures and artefacts (Ekbia, 2009; Lyytinen et al., 2016; Saini et al., 2010; Tiwana et al., 2010).

In this context, the main aim of this paper is to conduct a bibliometric review of knowledge management circulation literature in the era of industry 4.0 and social media. These types of literature analysis are very worthwhile in any research field because they provide the state of the art of a research field in terms of countries, topics and areas of research (Mishra et al., 2018). Scholars widely acknowledged the imperative role of classifying the research published on an exponentially growing research field to facilitate researchers and practitioners in attaining a deeper understanding of the field (Merigó et al., 2016; Blanco-Mesa et al., 2017; Nunen et al., 2018). The application of the

bibliometric approach based on performance analysis and network analysis techniques may enable to achieve this objective.

To provide a structured and encompassing overview of the knowledge management research field, this paper proposes: (1) a review of the knowledge management literature during this period of digital transformation; (2) an insight into the research field by using performance analysis and network analysis applied to a total of 5,416 publications, to identify key contributing countries in the field; (3) the identification of research clusters based on co-occurrence analysis within the string research domain; (4) therefore, this paper tends to formalize the actual knowledge creation model bridging a research gap concerning the lack of a comprehensive overview of the knowledge creation. The outcomes of this analysis offer deep insights into contemporary discussions, advancing the research field related to the contextual and multi-level phenomenon of knowledge management, and pointing out directions for future research.

This review is expected to make considerable contributions to the extant literature for the following reasons: 1) it offers an overview of the recent knowledge management researches that are facing with the digital transformation 2) it provides important information for future researchers summarizing the most significant field of interest and the most prolific countries; and 3) it identifies research scopes and empirical issues adopted by this stream of research. Besides, this study identifies new research streams and perspectives for further investigation that warrant special attention and offers valuable insights for future research.

The remainder of the paper is structured as follows. After the introduction, section 2 analyses the theoretical background and conceptual framework existing. Section 3 presents the methodology and data collection. Section 4 presents the results of performance analysis, whereas section 4 deals with the network analysis. Future trajectories for research on the topic are discussed in section 5. Finally, section 6 reports the conclusions and implications of this research.

2. Theoretical background and conceptual framework

2.1 Knowledge management and digital transformation

In recent decades, the knowledge management topic has become increasingly relevant within the debates on the management of an organisation. Starting from the first studies carried out by Nonaka, there have been many theoretical elaborations and practical applications related to this topic. However, during the fourth industrial revolution, a fundamental step forward on the subject took place since industry 4.0 technologies completely revolutionised the industrial landscape. If during previous revolutions the technology always changed, keeping the human at the decision-making process centre, in this case, the technology joins the man also in the decision-making phase. That happens

because the machine is no longer just a simple data collector, but is able to contextualize this data and make decisions by imitating human cognitive processes.

Furthermore, it should be emphasized that all people are always connected via mobile devices and social media platforms (Colbert et al., 2016; Haas et al., 2015; Schwarzmüller et al., 2018). This changed not only the way of communicating in the workplace and private life but also the social and communicative skills that people develop (Schwarzmüller et al., 2018; van Knippenberg et al., 2015). Therefore, it is inevitable that the model proposed by Nonaka for the creation and circulation of knowledge will also become involved in the change process brought about by the fourth industrial revolution since human is no more the only actor in the process and the human mind and human behaviour the only background for the knowledge spiral circulation.

The knowledge creation model proposed by Nonaka is based on two types of knowledge, namely, explicit knowledge and tacit knowledge (Nonaka et al., 2000; Nonaka & Konno, 1998). Explicit knowledge is a type of knowledge expressed formally through documents or formulas and usable quickly by everyone as it is structured formally and systematically to be acquired. Tacit knowledge, on the other hand, is not easily transferable as it is highly personal, intrinsic in behaviour and therefore challenging to encode in a unique language easy spreading. In order to transmit this type of knowledge, it is necessary to observe and try to reproduce this knowledge since it is achieved the right empathic process to be able to internalise this knowledge. So, it is possible to affirm that tacit knowledge is representative of the fluid state of knowledge, free to move where there are space and conditions to hold it. When this fluid knowledge is crystallised through formalisation, it turns into explicit knowledge that can be quickly passed on to other people and remains so until it comes into contact with another knowledge.

Knowledge then transits between these two forms, transforming itself and, therefore, generating new knowledge (Figure 1); this process is called by Nonaka the knowledge spiral evolution (Nonaka et al., 2000; Nonaka & Konno, 1998). The first step of knowledge transfer occurs when two people socialise and interacting with each other; they unconsciously assimilate ways of doing and thinking. From tacit, knowledge can be transformed into explicit through its translation into a form that is understandable by other people. On an excellent externalisation of knowledge, it is necessary both that tacit knowledge is well articulated through clarity of thought, use of metaphors or anecdotes, and that the way it is translated is understandable. Once formalised, this type of knowledge has much more simplicity not only to be transmitted to others but also to be combined with other explicit knowledge types and transcend own level. When explicit knowledge can be put into practice and internalised, it becomes not only an integral part of the person who has learned it but also a broader knowledge since personal knowledge has also been added to what has been learned. These four phases, namely, socialisation, externalisation, combination and internalisation, give life to the model known as the SECI model (Figure 1).

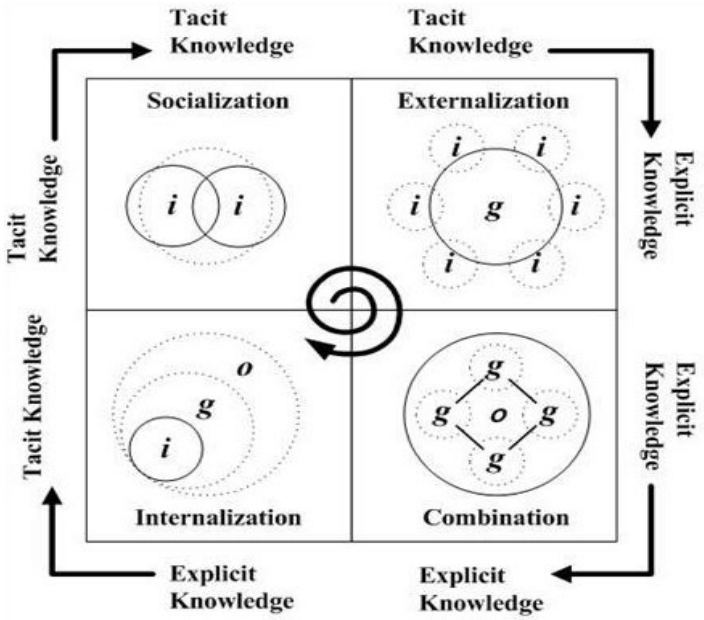

Figure 1: SECI model (Nonaka et al., 2000)

With the advent of industry 4.0 and the enabling technologies, new channels of knowledge creation have opened in which behind human interaction, there are also the human-machine and machine-machine interactions. People communicate with each other using social platforms, in the company, cyber-physical systems are used for production management. At the same time, private citizens increasingly integrate their home with sensors to be able to manage it remotely in a smart way; online data libraries are loaded daily by users so that other users from all over the world can consult them. Finally, there is to consider that artificial intelligence systems can process all the data uploaded to the network to support human decisions or even artificial ones. From a knowledge point of view, therefore, alongside the human one, which can be both tacit and explicit, there is a digital knowledge space that represents a node that is no longer inalienable in the model of knowledge management. In figure 2, there is a formalization of this new knowledge flow.

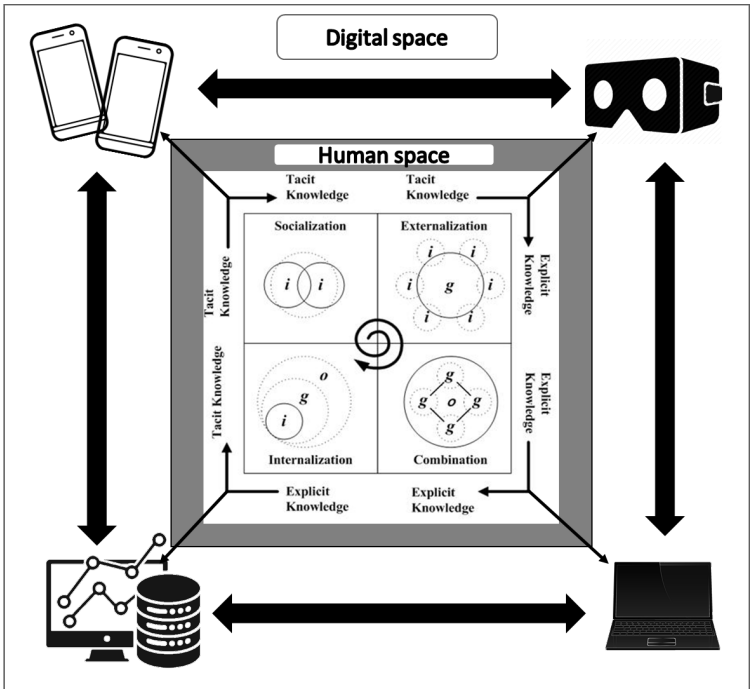

Figure 2: Digital - SECI model

This new dimension not only changes the spatial but also temporal dimension of knowledge sharing, having as a medium the digital structure, this can take place without people being physically close and deferred over time, thus also having significant time gaps between when a person passes on their knowledge when it reaches another person.

2.2 Explicit – Digital knowledge

The innovations in the digital field have made possible to bring many of the activities previously carried out into presence on social platforms; such as training courses, meetings, presentations and all those other educational or information activities that take place with the remote participation of the participants through the use of the web. Bringing explicit knowledge to the digital dimension is a catalyst for innovative processes; in fact, many companies take advantage of this opportunity offered by social platforms for crowdsourcing of information both within their organisations and with their customers. Social platforms have managed to leverage one of the fundamental points of the dissemination of knowledge, namely that of networking (Maravilhas & Martins, 2019). More extensive is the network of people who can learn, higher is the chances of combining this knowledge, and therefore higher the chances that new knowledge is created. The digitalisation of knowledge, therefore, has both the potential to create a culture of open innovation through collaboration within the entire network and to make

the network competitive with others (Almeida et al., 2011; Neto, 2005; Rodriguez & Martius, 2013). Considering also that enlarging the network, digitalisation allows having information exchanges in an almost immediate manner comparable to the timing of exchanges of information in presence; digitalisation can be defined as an expansive catalyst of explicit knowledge.

2.3 Tacit – Digital knowledge

Although there are schools of thought that support the non-digitisation of tacit knowledge, there have been various demonstrations of how web tools, albeit alternatively, manage to support the assimilation of tacit knowledge.

The question on the transformation of tacit knowledge into digital, as well as the passage through the digital channel of tacit knowledge itself is a slightly more delicate topic than the previous one and on which there is no unanimity of thought (Hislop, 2001; Jasimuddin et al., 2005; Maravilhas & Martins, 2019). There are two schools of thought, one, affirms that knowledge as tacit is hidden in a thought, actions and decisions taken by the human mind and as such not accessible to an artificial intelligence devoid of adequate cognitive and adequate dimensions (Johannessen et al., 2001; Mohamed et al., 2006). The second school of thought instead states that knowledge has different shades of tacitness and explicitness degree so that it is possible to pass from a purely explicit knowledge that can be easily converted and transferred digitally, up to a purely tacit knowledge that also could be assimilated and transmitted digitally provided that the digital system is capable of imitating human cognitive and emotional processes (Ambrosini & Bowman, 2001; Chennamaneni & Teng, 2011; Jasimuddin et al., 2005). As the degree of tacitness increases, the effectiveness of digitalisation decreases and therefore, the amount of tacit knowledge that can be transferred (Khan & Jones, 2011; Mayfield, 2010) However, different empirical studies have shown that the technologies of artificial intelligence, neural networks, IoT and virtual reality have reached such levels of efficiency that they are able to simulate human cognitive and emotional states (Brandon et al., 2020; Brown & Sandholm, 2019; Seo & Huh, 2019).

The leading IT tools useful in the transmission of tacit knowledge, range from communication tools (e.g., instant messaging, forums) to collaborative systems, multimedia sharing tools, video conferences, online communities and Web 2.0 tools (e.g., blogs, wikis and social media) (Davidaviciene & Raudeliuniene, 2010; Khan & Jones, 2011; Mayfield, 2010; Murphy & Salomone, 2013; Panahi et al., 2016). It is possible to transform digital knowledge into tacit knowledge through the demonstration or imitation of activities or processes that are reproduced through video, audio or text in order to unconsciously activate skills that are necessary for the performance of that given process or activity (Hildrum, 2009; Panahi et al., 2016).

2.4 Digital – Digital knowledge

The hypothesis that there could also be a digital dimension of knowledge was already proposed by Nonaka (Nonaka & Toyama, 2015; Nonaka et al., 2000), but it had never been possible to consider it a separate dimension until the era of Industry 4.0. The enabling technologies of this new industrial revolution have a power that has allowed the digital world to establish itself as an autonomous space for the creation and sharing of knowledge. The data collected by the sensors are transferred to the cloud, which increases the size of the web, creating an increasingly large Internet of things. The information accumulated here in a simple way or as big data, without a contextualisation, would remain a pure cluster of information (Dragicevic et al., 2019), but the different artificial intelligence technologies now have ample ability to reason, contextualise information possessed, represent knowledge, plan and learn (Kurzweil, 2005; Luger & Stubblefield, 2004; Parisi et al., 2019; Russell & Norvig, 2003). Both explicit and tacit knowledge can pass through the digital dimension. That allowed the creation of ontologies and rules to deconstruct/structure the natural language providing a digital ontological system which can be used for digital communication with other devices but also allows them to deconstruct it in a language that can be understood by human intelligence at all times, both to process decisions that are equivalent to those made by a man (Sikos, 2017).

2.5 Towards a digital knowledge-creating company framework

All in all, we contend that digital transformation, based on the use of fundamental digital technologies, is linked to knowledge management. This is enabled by the possibility to create knowledge along with traditional and digital processes. More in detail, there exist many digital technologies, each of which may serve one or more knowledge creation processes. In line with this reasoning, we seek to understand from extant literature on the digital transformation of business, on one side, which technologies contributes to the knowledge creation process, how, and related performance implications. Consequently, we propose a two-dimensional framework (Figure 2) to understand the digital transformation of the business that concurrently considers knowledge creation processes.

For instance, the Internet of Things represents a twin of the real world where data and information flow from a device to one other where these devices represent the interface between the real world and the digital one (Xue et al., 2013). These significant amounts of data are often structured as big data, and artificial intelligence techniques are able to analyse them and give back more and more straightforward data and information useful for the decision making (Grover et al., 2018; Delen et al., 2013; Lu et al., 2015; Metaxiotis et al., 2002; Wilson, 2007). By combining the types mentioned above of knowledge, it is possible to have nine different knowledge circulating ways. The first four ways involve human cognition only and have been already identified by Nonaka within the SECI model, that is, tacit-tacit, tacit-explicit, explicit-explicit and explicit-tacit. The

other five, instead, involve the digital dimension that knowledge can have, that is, explicit-digital, digital-tacit, tacit-digital, digital-explicit and digital-digital.

3 Methodology

Performance analysis and science mapping are bibliometric techniques that can help researchers to outline intricate knowledge patterns of the research field, investigate their properties employing statistical and mathematical methods, and monitor the field evolution in order to identify how authors, themes and researches are related (Morris and Van Der Veer Martens, 2008; Cobo et al., 2014; Mora et al., 2019).

In this paper, a bibliometric analysis based on performance analysis is adopted because the bibliometric analysis can deeply analyse, with mathematical and statistical methods, relationships among different bibliometric objects (e.g., authors, country, keywords) (De Bellis, 2009; Aria and Cuccurullo, 2017; Mora et al., 2019).

Citation analysis is one of the most common techniques used in the bibliometric analysis. Higher is the number of citations received by a paper, and higher is the relevance of that paper in the body of literature (Aria and Cuccurullo, 2017). Citation analysis is based on the assumption that authors cite papers they consider essential for the topic under investigation. In this sense, citations can be considered as a reliable parameter that measures how researchers or institutions interact with each other (Garfield, 1970; van Raan, 1996; Aria and Cuccurullo, 2017).

Citation analysis can be divided into two main techniques: bibliographic coupling and co-citation analysis (Small and Koenig, 1977; White and Griffith, 1981; McCain, 1991; White and McCain, 1998; Zhao and Strotmann, 2008; Gao and Guan, 2009; Yan and Ding, 2012).

A bibliographic coupling connection is established when two documents cite the same third document, whereas a co-citation connection is established when the same third document cites two documents. Bibliographic coupling analyses the citing documents (Kessler, 1963), whereas co-citation analysis, studies the cited documents (Small, 1973). Bibliographic coupling helps detect the actual connections into research groups (Yang et al., 2016), co-citation analysis helps see through a shift in theories and paradigms when examined over time (Aria and Cuccurullo, 2017). Usually, co-citation analysis is performed for mapping older papers, and it is a dynamic analysis which performs better within different time slices, whereas bibliographic coupling is used to map a current research front in a retrospective analysis (Aria and Cuccurullo, 2017). Therefore, in this paper, co-citation analysis has been performed to analyse the knowledge management body of the literature.

Figure 3 reports a conceptual scheme of the methodology adopted in this paper, which consists of three main steps:

1. **Material collection phase:** a detailed discussion about the academic database and keywords used to collect papers.

2. **Material pre-processing:** all the pre-processing operations to clean data and remove spelling mistakes from the database.
3. **Results analysis**:

   Performance analysis. This phase classifies papers from different perspectives:

   i. *Papers by time.* Chronological distribution of publications*;*
   ii. *Papers by country.* Papers distribution per country;
   iii. *Most relevant keywords.* Analysis of most used keywords.

Network analysis. In this phase, statistical and mathematical methods are used to examine the research field from an objective and quantitative perspective and identify different maps based on the research field structure (Mora et al., 2019; De Bellis, 2009; Ding et al., 2001; Godin, 2006). These maps are complex networks in which two or more units can be interconnected each other (Mora et al., 2019; Hashem et al., 2016; Ding et al., 2001) and they make it possible to understand "how specific research fields are conceptually, intellectually and socially structured" (Cobo et al., 2011, p. 1382). Once defined the aspect of the paper to analyse (e.g., authors, journals, documents, cited references, institutions, and countries), it is possible to build a graph where the nodes are the bibliographical elements considered, and the edges are the link between them (e.g. co-occurrence). The similarity degree between each node affects the network connection degree (Mora et al., 2019) and according to the similarity criteria, connections in the network can be different. The most common criteria used to measure similarity are co-citation analysis, coupling analysis, and co-occurrence analysis (He, 1999; Glanzel and Thijs, 2011). In this work, only a co-occurrence analysis has been used in order to underline the research field conceptual structure. Co-occurrence analysis is a content analysis technique that provides information about the similarity between two data by considering the references that they cite (Callon et al., 1991; He, 1999).

The details of each step will be discussed in the following sections.

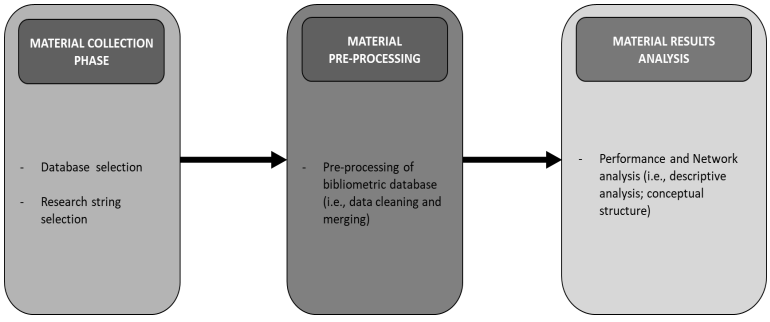

Figure 3. Methodology proposed

3.1 Material collection phase

In this paper, data was collected from Scopus database. This database represents a reliable and high-quality data source for literature analysis (Johnsen et al., 2017; Rebs et al., 2019). The search string used is:

> *TITLE-ABS-KEY ((("blockchain*" OR "block chain*") OR ("iot*" OR "internet of thing*") OR ("ai" OR "artificial intelligence" OR "machine learning" OR "deep learning") OR ("social media" OR "social network*" OR "social platform*" OR "social technolog*")) AND "knowledge" AND ("tacit" OR "explicit" OR "digital" OR "socialization" OR "externalization" OR "combination" OR "internalization"))*

In this way, it is possible to get all the documents dealing explicitly with the topic investigated. The asterisk was used to include a wide range of results (Chen and Jung, 2019). Data collection phase was conducted in March 2020, Papers since 1974 until nowadays are in the results list, but only papers in the English language published between 1985 and 2019 have been considered in the final sample; the papers before 1985 do not match with the research topic, and papers related to 2020 do not characterise the researchers' interest of the year entirely. Finally, to ensure the quality of review analysis, conference proceedings and book chapters were excluded, and only articles and reviews published in peer-reviewed journals were included in the final sample (David and Han, 2004; Newbert, 2007). At the end of this phase, the total number of papers considered for the following steps is 5,416 (5,069 articles and 307 reviews).

3.2 Material pre-processing

During this phase, the file including the database of papers was submitted to a pre-processing process to avoid duplications for spelling mistakes or contractions (e.g., *network* and *networks*, *IoT* and *Internet of Things* or *Internet-of-Things; knowledge-based system* and *knowledge-based systems*).

4 Findings

This section reports the descriptive and content analysis results, which will be discussed in detail in the following subsections.

The papers included in the research list are 5006, and they cover the period between 1985 until nowadays. Papers related to 2020 have not been considered because they will not represent the reference year, so in figure 4, it has been shown how these papers are distributed from 1985 to 2019. The first works concern the possibility for the Artificial Intelligence (AI) to support the knowledge engineering, maybe with the scope for the AI researchers to open new research direction due to get again found from the American

government (Russell & Norvig, 2003). In the ’90s, new technological development in the integrated circuit field relaunches the study in the AI field. Meanwhile, the Internet of Things (IoTs), formalised at the beginning of ’80s, starts to be studied as a technology able to return essential pieces of information, becoming a precious resource in the field of knowledge management. Whit the beginning of 21st century, the trend of papers published has grown exponentially. The IoTs has enlarged its data volume exceeding the ratio of 1 device connected for people between 2003 and 2010. The IoTs has become the most prominent knowledge network where information can be stored and transferred; it has made the internet sensories (e.g., temperature, pressure, vibration, light, moisture, stress), allowing us to become more proactive and less reactive. On the wake of a world overconnected, the artificial intelligence, with the help of machine learning and deep learning techniques, becomes the first technology of Industry 4.0 involved in the knowledge management field because able to acquire, process and information useful for the managing of organisations or own house. However, in 2008 also the blockchain technology faces up in the technological background and in the last few years becomes strong support in the storage and transfer of knowledge guaranteeing the possibility to verify the trust of information.

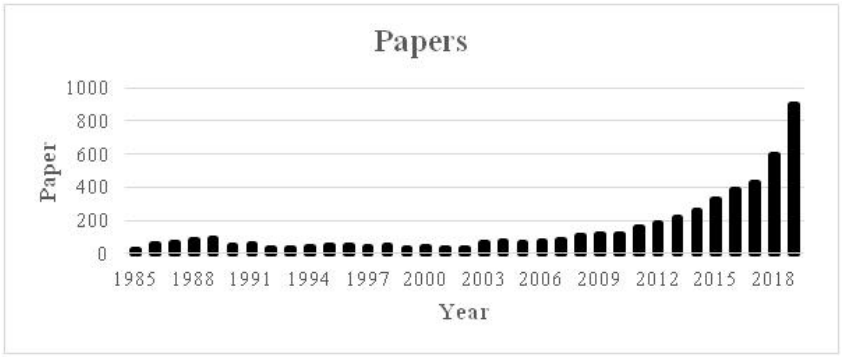

Figure 4. Chronological distribution of publications

From all the 92 countries involved in this field, only the first seven of them have a production higher than the 5% of the whole published; the rank is headed by the USA (1362 papers - 27%) followed by China (553 papers – 11%) and United Kingdom (527 papers – 10%). Also considering only the single country production (SCP), the podium stays the same, this phenomenon can suggest that the technological innovation in the field of knowledge management is a core business for the most productive countries. The only nations with a considerable multi-country production (MCP) index are Vietnam (1.00), Russian Federation, Bosnia and Bahrain (0.50) and Jordan (0.17). Figure 5 can better explain the geographic distribution and the differences in the top10 of country publications.

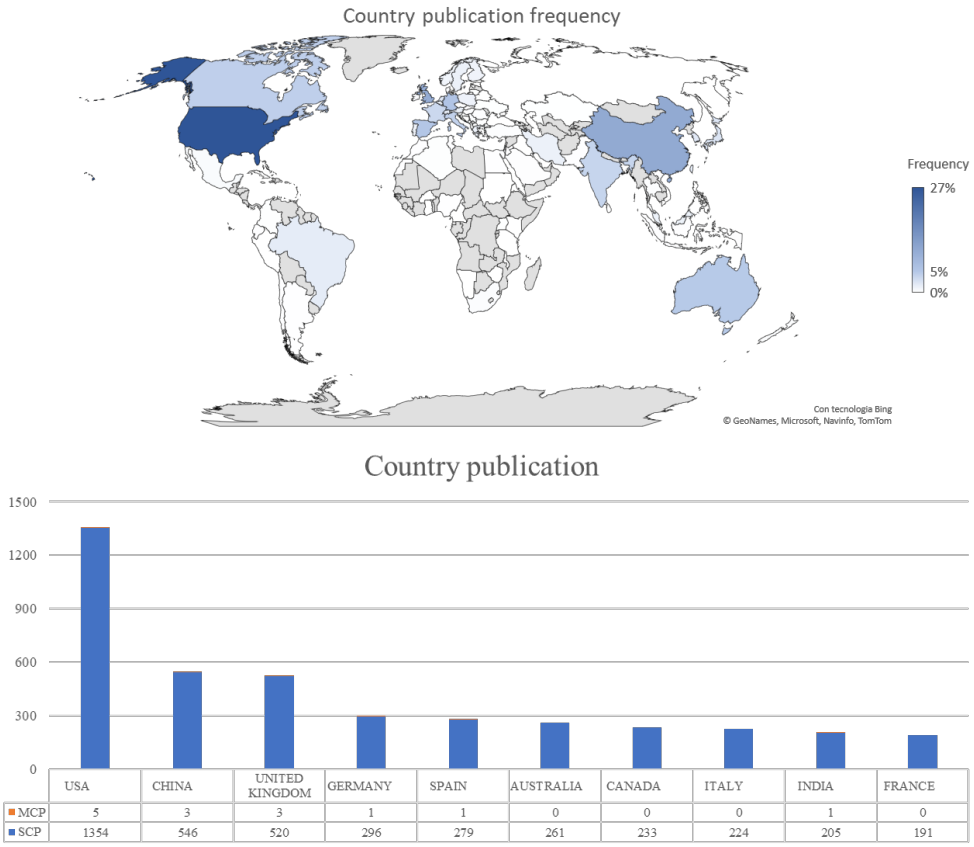

Figure 5. Papers distribution per country (grey countries do not belong to the list) and top10 of country publication

Figure 6 depicts a word cloud of the most used words included in the dataset. The dimension of each word in the word-cloud depends on its frequency in the dataset (consisting title, abstract and keywords). As expected, basic terms like knowledge, data, network, system, are the most common. On the contrary, there is a low frequency of the other concepts like creation, transfer and sharing or blockchain, Internet of Things and artificial intelligence; only machine learning looks to be underlined in the number of words.

Figure 6. Word cloud.

Focusing only on the author's keyword used, the research topic structure looks a little bit clearer. In table 1, it is possible to note that the leading technologies used in the field of knowledge management are the AI family (Artificial intelligence, Pattern Recognition, Machine Learning, Artificial Neural Network and Deep Learning) with a presence in the 10.73% of papers. This predominance over other technologies seems justified by the fact that AI technologies have entered the world of knowledge management much earlier than the other two IoT (3.18% of papers) entered during the last year of the '90s while blockchain (0.32% of papers) only since 2017.

The central aspect in knowledge management investigated is the generation phase, knowledge discovery, knowledge acquisition and knowledge extraction are present in the 1.50% of papers.

Tabella 1: Most used author's keywords

	Author Keywords (DE)	Articles	Frequency
1	Artificial Intelligence+Pattern Recognition+Machine Learning+Artificial Neural Network+Deep Learning	537	10,73%
2	SOCIAL MEDIA	371	7,41%
3	IoT+Internet	159	3,18%
4	KNOWLEDGE MANAGEMENT/ENGINEERING	96	1,92%
5	KNOWLEDGE Discovery + Acquisition + Extraction	75	1,50%

6	EXPERT SYSTEM	69	1,38%
7	DATA MINING	57	1,14%
8	DECISION SUPPORT SYSTEM	48	0,96%
9	KNOWLEDGE REPRESENTATION	47	0,94%
10	LEARNING	47	0,94%
11	EXTREME LEARNING MACHINE	43	0,86%
12	KNOWLEDGE SHARING	40	0,80%
13	ONTOLOGY	38	0,76%
14	KNOWLEDGE	37	0,74%
15	KNOWLEDGE BASED SYSTEM	33	0,66%
16	SOCIAL CAPITAL	26	0,52%
17	FUZZY LOGIC	25	0,50%
18	NETWORK	25	0,50%
19	BIG DATA	24	0,48%
20	INNOVATION	23	0,46%

In this section, the co-occurrence analysis with author's keywords is performed (Figure 7). Ignoring isolated nodes, author's keywords plotted are 720.

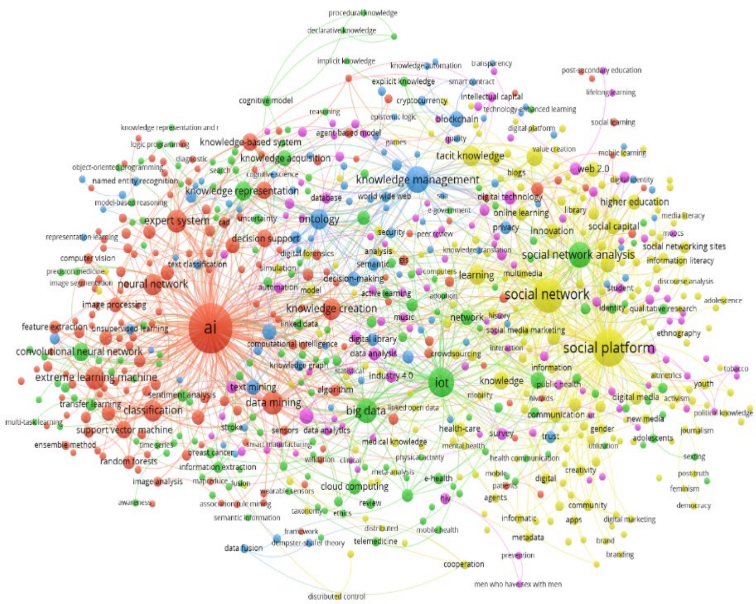

Figure 7. Keyword Co-occurrences

Four different macro clusters emerge in Figure 10:

- *Cluster 1: Webinarisation* (yellow cluster with 208 keywords)
- *Cluster 2: Informalisation (*pink cluster with 107 keywords)
- *Cluster 3: Systematisation* (dark blue cluster with 85 keywords)
- *Cluster 4: Explicitation* (red cluster with 160 keywords)
- *Cluster 5: Digitalisation* (green cluster with 160 keywords)

Herein, we try to understand how extant literature on the digital transformation of business investigated the relationship between digital technologies and knowledge creation processes.

4.1 Cluster 1 - Webinarisation

Webinarisation involves all those activities of sharing explicit knowledge through social platforms or other web tools that transform this knowledge in digital knowledge.

Cluster keywords concern with two fairly specific terms: *social network* and *social platform*. For all the papers in this cluster the knowledge is submitted at the social media world, and this has been possible thanks to the mass diffusion of IT services and facilities (Fakhar Manesh et al., 2020).

In the digital era, each one around the world can access to the internet, and each person or company can be own media brand; in a particular way, social media platforms (e.g., Facebook, Twitter, Instagram, LinkedIn, Pinterest) can give, for able people, the opportunity to have high visibility all around the world (Mary Jeyanthi & Mansurali, 2020).

Kroenke defined social media, "the use of information technology to support the sharing of content among networks of users" (Kroenke, 2018). It is out of doubt how the internet has shifted communications over the last 25 years, transforming interactions to enabling communication between dispersed and decentralised individuals and entities (Cripps et al., 2020; Y. Wang et al., 2017)

Furthermore, it is precisely this excellent dissemination power possessed by social media that makes them a relevant field for knowledge management and knowledge engineering, especially in the phase of sharing and dissemination. The high volume of knowledge that flows across the different network platforms, has made that attractive for companies, they can learn from users, competitors and industry as a whole, thereby try to support innovation in both social and commercial contexts (Perez-Gonzalez et al., 2017). Crowdfund knowledge is more comfortable for the company than before, and that let them have both a higher control and a high degree of openness in their crowdsourcing activities, enabling the opportunity to create products and services with current or potential customers, particularly in the B2C context; in this way, organisations are able to increase their degree of innovation and competitive sustainability (D'Andrea et al., 2019).

Cripps et al. (2020), with the help of a structural topic modelling, elaborated how the use of the social platform, like Twitter, represents a source of valuable information

regarding innovation in business markets and for the exchange of both high quality and relevant information (Cripps et al., 2020; D'Andrea et al., 2019). Similarly, Quinton and Wilson's (2016) highlight how the use of platform Linkedin could enhance business relationship development and business performance (Quinton & Wilson, 2016). The learning sector represents a critical sector where knowledge sharing and diffusion are fundamental. Many schools, universities and organisations have approached a method of teaching and collaborations creation that is no longer face-to-face limited classroom, but online courses open to everyone, namely, *MOOCs* (Massive Open Online Courses) (Brahimi & Sarirete, 2015). This method indeed allows extending the possibility of learning to a larger pool of people, different in gender, age and origin, thus widening the network in which knowledge can flow and therefore be renewed. Many platforms were born in the last years; the most known are Coursera and Audacity in the USA while FutureLearn, Iversity and FUN in Europe (Brahimi & Sarirete, 2015). However, if explicit knowledge of these methods finds great benefits, unfortunately, the tacit component is penalised. Physical contact and interpersonal interactions are lacking, so there are the main ways to transfer tacit knowledge (Voss, 2013).

4.2 Cluster 2 - Informalisation

Informalisation involves all those activities of sharing digital knowledge through social platforms or other web tools that transform this knowledge into tacit knowledge.

Within this cluster, the issue of the transfer of digital knowledge to tacit knowledge is addressed through collaborative systems and digital communication. Generally, how knowledge is transformed into tacit has always been few explored then all the other ways in which knowledge is transformed. As a consequence, the weight of this cluster in terms of keywords or occurrences is lower than the others (Haldin-Herrgard, 2000; Metaxiotis et al., 2002). When social media are used, hidden tacit knowledge is always present alongside explicit knowledge. Browsing, organising and playing with the sources of knowledge allows to unconsciously come into contact with mental patterns and ideas that start to cultivate tacit knowledge (Panahi et al., 2016). Various studies have shown how the use of social media enables to transfer not only the explicit component but also the tacit one. Indeed, the social dimension manages both to have a facilitating role in the knowledge sharing since it allows the comfortable meeting of people and professionals, and as an amplifier, because it allows widening the knowledge that is made available to a broader audience (Buunk et al., 2019)

Grum and Gronau (2017) modelled a linguistic system based on augmented reality and cyber-physical systems (Grum & Gronau, 2017). Through the suggestions given by the augmented reality device, the digital system manages to transfer what are aspects of tacit knowledge assimilated previously into given ontologies.

4.3 Cluster 3 - Systematisation

Systematisation involves all those activities of sharing tacit knowledge through social platforms or other web tools that transform this knowledge in digital knowledge.

This cluster addresses the challenging problem of how tacit knowledge passes into the digital space; the main keywords used are text mining, Natural Language Processing (NLP), knowledge-base, digital library and ontology. Text mining is about a human-machine operation in which, starting from human speeches or text, the machine extracts data that can be relevant even though the text in which they are present is very elaborate and inaccurate. Text mining has three different perspectives, namely, information extraction, data mining and knowledge discovery in database (Hotho et al., 2005). Through the use of Natural Language Processing (NLP) and machine learning algorithms, text mining is able to access hidden information in the text and build mind semantic patterns for the human behavioural prediction. In this way, it is possible to enter the field of ontology which, by combining data and rules extracted, tries to create a digital encyclopaedia that AI programs can consult when it is necessary to elaborate or predict human behaviour.

There are sectors (such as education, research, health care, security) where tacit knowledge plays an essential role; this is the reason why it is necessary to keep up with the times to find the way to bring tacit knowledge to the digital level. As already said, the researchers prefer to deal with the issue of explicit knowledge, leaving aside the tacit one. However, in the literature there are various attempts to digitalise tacit knowledge in order to be able to keep it available within the company in the time; through the use of text mining and NLP, it is possible to build computer ontologies systems, able in generating human behaviour (Atrash et al., 2015; El-Diraby & Zhang, 2006). In this way, it is possible to predict illegal or terroristic web activities, or predict costumers churn in order to reduce their attrition or to extract physician-asserted drug side effects from electronic medical record clinical narratives (Coussement & van den Poel, 2008; Sohn et al., 2011; Zanasi, 2009)

However, the acquisition of knowledge does not necessarily come from one's own company within, but it is also possible to exchange it with other sector organisation creating a knowledge network (Li et al., 2018). When it opens up to knowledge synthesised by other entities, arises the problem on the knowledge quality; in particular on its trust and traceability. Li et al. (2018) proposed a knowledge exchange model between the various companies in the supply chain based on blockchain technology (Li et al., 2018). Each company contributes limited to its core business to increase the decentralised database. So, blockchain technology thus allows all companies to have this accumulated knowledge available, where the trust of each contribution is certified by blockchain protocols that also provide traceability information. In the context of the ontological construction of the tacit knowledge, this system is particularly useful since it allows companies to reduce the time spent in the process having a more extensive knowledge contribution (Atrash et al., 2015; Li et al., 2018). Furthermore, it is possible to

have the certainty of having data so much more secure as the knowledge chain grows, which is created as the ontology grows.

4.4 Cluster 4 - Explication

Explication involves all those activities of sharing digital knowledge through social platforms or other web tools that transform this knowledge into explicit knowledge.

Inspecting the nodes of this cluster, it has been observed how the main knowledge activities are the knowledge creation and the decision support through the use of any Artificial Intelligence technologies family (e.g., Artificial Intelligence (AI), Pattern Recognition (PR), Artificial Neural Network (ANN) and Deep Learning (DL)). All these are techniques capable of predicting the behaviour of a system by a data set or previous behaviours. That is the reason why it is possible to assume this cluster analyses the knowledge passage from the digital world (e.g. data present in a cloud) to an explicit knowledge formalised in a text, in an image or even in the behaviour of a robot.

There are many techniques for data analysis, but all data are processed, and the numerical result is converted in an explicit form standing by the available human behaviour database for the conversion algorithms (Delen et al., 2013). One of the most used techniques is the ANN. This technique, simulating the human behaviour mind, manages to acquire different cognitive patterns and to rework them. These non-linear algorithms are very flexible since they allow to work and predict even starting from incomplete, noisy and fuzzy information (Delen et al., 2013). The Bayesian network is another widely used method, mainly when the data is structured in groups. The algorithm is particularly useful when faced with multi-level learning problems: in fact, it manages to return a framework able to explain how to use the knowledge analysed inductively and how to acquire further abstract knowledge from the path (Lu et al., 2015; Wilson, 2007). No matter the data origin, AI technologies will always return to a new cognitive level in a systemic and clear form; for this reason, it is possible to assume that these technologies have a high learning power, both in knowledge creation and in knowledge representation (Delen et al., 2013; Lu et al., 2015; Metaxiotis et al., 2002).

One of the most widely used applications of knowledge passage from explicit to digital is in the field of marketing. Companies have information from external sources in the form of big data that, after right processing, can return information on customer behaviour when they buy online and what service characteristics they prefer based on the basket of preferred products during the purchase (Grover et al., 2018). In the same way, it is possible to characterize the sales and production strategies of its competitors (He et al., 2017). Artificial intelligence technologies not only carry out data mining processing but also make predictions starting by ontologies built over time. The information that can be reported to decision-makers is not only related to the current market situation but can also present any future scenarios based on past behaviour. Just think about the use of these technologies in the agricultural field to predict which fertilizer it is preferable to stock due

to support the next soil cultivation rightly, or in the tourist, field to predict which destinations will be more interesting in the coming seasons and what services offered are going to make them more desirable (Cattaneo et al., 2016; Piera Centobelli & Ndou, 2019; Garg et al., 2019; J. N. He et al., 2016).

4.5 Cluster 5 - Digitalisation

Digitalisation involves all those activities of sharing digital knowledge between machine entities; in this way, knowledge remains digital in the different steps of sharing.

The Internet of Things has a central role in the growth of this way to share knowledge.

The Internet of Things is one of the 4.0 industry technologies that are most deeply rooted in everyday life; people work, interact with other people and manage their private life moments through devices that IoT connects (Vanitha et al., 2020). At the same time, cloud computing was born, new services offered remotely to the various users of the network; these services can then be customised to improve their experience (Minh Dang et al., 2019). However, by personalising the requested service, users grant personal information about their lifestyle and their needs. That has led to the rapid development of virtual storage of such information which, having a large volume and a large variety of information within them, require structured techniques of big data analytics for their management and coding (Bibri, 2018; Gil et al., 2016). This cluster concerns the theme of knowledge that flows between different digital devices, and that is always stored and reworked within a digital dimension.

Social Network Analysis (SNA) can be the first useful method to investigate this field, considering that the first massive flow of information comes from social media network and social media platform.

Through SNA techniques, it is possible to understand what are the needs and slopes of a group of people and how they change over time. Being able to generate a historical data of this type, is very important both because it is possible to get information on current trends in a particular geographical region, and because it is also possible to summarise information on future trends thanks to machine learning algorithms (de Laat et al., 2007; Xu et al., 2014). For instance, it has been possible to make prevision about the preferred politic candidate during the 2007 democratic campaign for the Presidential election basing on American twits, or prevision about the most required professions in America during 2014 considering Linkedin database and the users' interaction on this platform (de Laat et al., 2007; Xu et al., 2014). However, SNA has not only a social aspect (e.g., polling, marketing) in fact, implementing the SNA jointly with cloud computing systems allows companies to improve the process of acquiring information with significant implications in every business area (e.g., operations, sales, purchasing function) and on operational and financial indicators (Castagna et al., 2020; Cegielski et al., 2012). Environmental, tasks and inter-organisational uncertainties are reduced since information flows are both better managed and well-integrated with previous classic knowledge

management systems; but this improvement has a minor impact on SMEs because they are not able to respond rapidly to technological changes that are affecting knowledge management (Castagna et al., 2020; Cegielski et al., 2012). If the IoTs cloud computing technologies are combined with the AI technologies analysis capabilities and the blockchain capability to certify the information that passes between the various devices, it is possible to create an open and decentralized manufacturing ecosystem (Li et al., 2018). In the framework proposed by Li et al. (2018), knowledge circulates through the phases of the SECI model, but in a wholly digital way. This knowledge of digital production would allow the achievement of high levels of efficiency and flexibility of the entire supply chain trying to optimize corporate objectives with lean manufacturing and green practices ones.

5 WISED framework

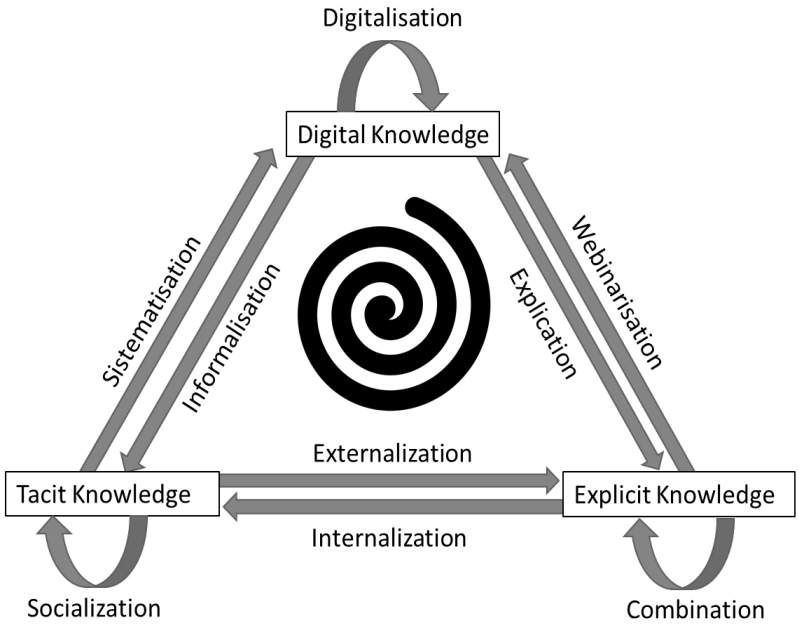

Figure 8 WISED framework

In this section, we develop a conceptual model to summarize the findings of bibliometric analysis.

The idea of such a model could be interesting from several viewpoints. In fact, despite the processes of knowledge management in this new era of the social media generation and fourth industrial revolution has been analysed in different areas of management literature, they have been generally analysed separately.

Bibliometric analysis can link together the various research conducted on a specific topic or more and to create a network in which the main clusters and the topics covered within them are highlighted. In this way, it was possible to highlight three fundamental aspects. The first is that the information technologies available are now at a high potential: they are capable of managing vast amounts of data and processing them to transform them into useful resources for decision making. The second is that these technologies did not remain within the company domains, but entered into the everyday life of all people; the cities are converting themselves into smart cities, automation is conquering the house management while online purchases have become real private advisory buying counters where every consumer is already projected towards the products that could better satisfy him. Finally, the third aspect, but certainly not less imperative there is the spread of social media and related social platforms that have allowed anyone with a web connection to communicate in real-time with any person on the globe. A large amount of data circulating through the web generated by a large number of people and with the possibility of being stored, processed and used has therefore allowed knowledge to find this new living space. That radically changes the possibilities of knowledge creation which is not limited to the single spiral of knowledge that takes place between two human minds, but there is a whole other combination of passages that also involve artificial intelligence. With these empirical pieces of evidence, this work aims to provide a conceptual model of knowledge creation that takes into consideration this new space of knowledge creation and the new methods by which knowledge can flow from one intelligence to another.

Webinarisation

Webinarisation is the process of embodying explicit knowledge into digital knowledge. Through the Webinarisation, the explicit knowledge created is shared via the web platform and converted into digital knowledge by the system (Cripps et al., 2020; Kroenke, 2018; Y. Wang et al., 2017). At this step, the text and multimedia acquisition systems are mainly active, and crowdfunding information is done in order to be redirected to the platforms that request it in a second step (D'Andrea et al., 2019). Once knowledge is registered on the network, it is difficult for it to be deleted from the digital space.

Informalisation

Informalisation is the process of embodying digital knowledge into digital knowledge. Through Informalisation, the digital knowledge that has been accumulated or generated is shared via the web platform and converted into tacit knowledge by the person who receives it (Panahi et al., 2016; Buunk et al., 2019). Neural network systems, pattern recognition, augmented reality, and cyber-physical systems are mainly active in this phase (Grum & Gronau, 2017). By simulating certain situations, the system induces the person to synthesize behaviours and ways of doing related to that situation.

Systematisation

Systematisation is the process of embodying tacit knowledge into digital knowledge. Through Systematisation, the tacit knowledge that impregnates actions on the web of the various users can be summarized and digitized (Atrash et al., 2015; El-Diraby & Zhang, 2006; Li et al., 2018). In this phase, the data mining, deep learning and NLP systems are mainly active, in this way artificial intelligence is able to synthesize behavioural and cognitive ontologies that can then be used in other cognitive processes by other artificial or human entities (Atrash et al., 2015; Li et al., 2018).

Explicitation

Explicitation is the process of embodying digital knowledge into explicit knowledge. Through Explicitation, digital knowledge stored on the web is reworked in the form of texts or multimedia files and proposed to users who are consulting it. Artificial intelligence systems are mainly active in this phase, and they are capable of synthesizing data and multimedia files capable of transferring the required concepts to human intelligence (Delen et al., 2013; Lu et al., 2015; Metaxiotis et al., 2002; Wilson, 2007).

Digitalisation

Digitalisation is the process of converting digital knowledge into a new and higher-level digital knowledge set. Through Digitalisation, digital knowledge stored on the web is analyzed, deconstructed and reworked by extracting information that previously had not been provided or was not accessible; this information is then redirected to other artificial intelligence if it is requested (Vanitha et al., 2020; Minh Dang et al., 2019; Li et al., 2018; Bibri, 2018; Gil et al., 2016; Xu et al., 2014; de Laat et al., 2007). In this phase, the IoTs systems are active, big data analytics, artificial intelligence that is able to manage the data flowing through the web independently.

6 Conclusions, implications and future research directions

This paper conducts a bibliometric review of knowledge management circulation literature in the era of industry 4.0 and social media. The application of the bibliometric approach based on performance analysis and network analysis techniques may enable to achieve this objective. The paper also visualizes the bibliometric networks for citations, keywords, and co-authorship patterns. There have been a good number of papers published in the KM domain over the years, many of them in the last decade. However, despite the fact that few good studies on KM have been reported in the last few years, a detailed bibliometric and network analysis to systematically and objectively recognize principal contributions, authors and growing research clusters have not been performed yet. This paper contributes to the body of knowledge by providing a comprehensive overview of KM literature in this way.

This study gives a noteworthy contribution to the body-of-knowledge on KM while broadening prior reviews (Kuah and Wong, 2011; Durst and Edvardsson, 2012; Ragab

and Arisha, 2013; Asrar and Anwar, 2016; Cerchione et al., 2016; Massaro et al., 2016; Centobelli et al., 2017) in seven ways. First, the present study applies bibliometric and network approaches to uncover the most influential articles, scholars, institutions, and countries as per the number of articles published and citations. Thus, this study goes beyond the systematic review of the domain. Second, scholars working on the logical intersection between digitalisation and KM domains may easily recognize the countries paying to continue research attentions in the KM areas; thus, interested scholars can perform joint research projects, share their ideas and results as well as can accept academic positions to research the mentioned field further. Third, it proposes five clusters based on keyword co-occurrences, namely webinarisation, informalisation, systematisation, explication, and digitalisation. Fourth, it proposed a conceptual model, i.e. WISED framework, to analyse the digital knowledge-creating processes. Fifth, the study supports researchers to underline the most influential articles. Sixth, the findings can assist the industries and governments to identify the leading research and development centres working in the field of KM for research projects. Seventh, editors organizing special and regular issues on the topic can invite leading authors and institutions.

As the managerial contribution is concerned, the present study offers opportunities to the practitioners and organizations engaged in KM in the era of the digital transition. The study further provides managers with diverse outlooks that enable them to enjoy the benefits of KM in their work. The bibliometric information about the KM literature has immense value for managers as it enables them to spot the KM expertise globally. Accordingly, the research projects on digital knowledge management can be developed considering this information.

Although this article significantly contributes to state of the art in the field of KM, nevertheless this study has selected only research articles and review articles; therefore, the inclusion of other types of documents (e.g., conference proceedings, book chapters, and editorial material) may lead toward different conclusions. Thirdly, we performed the co-citation analysis using network analysis with R and VOSviewer software. However, other methods and software may be used, such as Gephi. Lastly, the bibliometric analysis in the present study focuses on the general themes of digital knowledge creation processes, and not restricted to KM up to a particular topic.

Some gaps in the literature have emerged from the study of the five new areas of knowledge creation. The first is the lack of theoretical and practical studies on how tacit knowledge interfaces with the digital sphere. Although tacit knowledge is difficult to manage, research efforts are required to be able to have solid theoretical bases and application cases to be able to debate on the topic (Brown & Sandholm, 2019; Johannessen et al., 2001; Maravilhas & Martins, 2019; Mohamed et al., 2006; Seo & Huh, 2019). Another gap is the lack of empirical studies on corporate performance of the impacts of digital knowledge on business models (Torres et al., 2018; Trantopoulos, von Krogh, Wallin, et al., 2017).

Abstract

The paper aims to discuss the role of Innovation Labs as innovation management model fostering continuous innovation practices within organizations operating in the digital ecosystem. An Innovation Labs management framework is proposed, through the analysis of a case study, with the main purpose to collect further insights on the field and to catalyse research interests in a field on which the attention of the academic and practitioners' world is growing even more.

Innovation Labs are Innovation management models based on the construction of an innovative space with physical, virtual, hybrid and relational features. They are based on the development of a platform that contemplates tangible and intangible infrastructure dimensions aimed at fostering creative and critical thinking, promoting and supporting user-driven, open, and continuous innovation approaches; to facilitate stakeholders' engagement in innovations processes; to better understand users' needs; to drive digital transformation; to imagine and defining innovation opportunities; and to continuously develop new solutions capturing and delivering value to society in order to drive the organization in finding the best ways to generate knowledge and digital culture, introduce technology, digitize operations, and implement digital strategies for continuous and digital innovation. The research of new solutions, practices, and management models enabling continuous innovation dynamics and digital exploitation is a current hot topic both for scholars and practitioners (Fecher et al., 2018). Among emergent practices, Innovation Labs have appeared as a valuable answer to organizations' needs to develop digital culture and continuous innovation

attitudes (Osorio et al., 2019). Although the practice of Innovation Lab is raising interests among scholars and practitioners, the literature in this field still reveals a lack of management models based on innovative approaches and methodologies and addressing current competitive challenges (Osorio et al., 2018). To address this gap and catalyse research interest, the paper is based on the analysis of a single case study. It has been conducted in an Innovation Lab to understand its functioning, and its management logic, as well as proposing a framework for its organizational management that could increase knowledge and suggest guidelines on the field, both for academic and practitioners.
The paper combines the insights from theory with the empirical evidence gathered by adopting a case study approach. Therefore, the proposed framework springs from a case study, i.e., an Innovation Lab designed to develop and foster innovation capacity and digital continuous innovation among organisations and stakeholders of a tourism regional ecosystem.
The originality and the value of the paper stand in the contribution aimed to enrich theoretical and practical knowledge on management issues of Innovation Labs and proposing a cycle-based framework for their successful management. The study puts particular attention to management issues of Innovation Lab as a "guide" of the digital innovation journey of an organization.
The study advances theoretical and practical knowledge about how effectively manage Innovation Labs and provides scholars and practitioners with useful insights and managerial implications for the development and management of these initiatives.

Keywords – Innovation Lab; Continuous Innovation; Management Framework; Digital Innovation

Paper type – Academic research paper

1 Introduction

The paper discusses the role of Innovation Labs as innovation management models fostering digital innovation practices within organizations operating in the digital ecosystem. An Innovation Labs management framework is proposed, through the analysis of a case study, with the main purpose to collect further insights on the field and to catalyse research interests in a field on which the attention of the academic and practitioners' world is growing even more.

Innovation Labs are Innovation management models aimed at fostering creative and critical thinking, to drive the organization in finding the best ways to generate knowledge and digital culture, introduce technology, digitize operations, and implement digital strategies for continuous and digital innovation.

The relevance of innovation to guarantee companies' competitiveness is acknowledged among scholars and practitioners (Schiuma, 2012). It is also true that innovation is a high-risk process that requires resources, competence, culture, and attitudes not even easy to raise and manage (D'este et al., 2012). In this regard, often, organizations rely on external entities for the exploitation of innovation processes, namely innovation intermediaries, R&D labs or innovation centers (Corre et al., 2005).

Nowadays, however, in the Digital Era innovation dynamics are changing. The digital ecosystem is even more dynamic and unpredictable, even more after the Covid-19. The global and virtual competition, as well as the fast development of digital technologies and solutions, raise the efficiency standards, increase the speed of market dynamics, and

decrease the product lifecycle (Schiuma, 2012). Moreover, consumers are evolving in prosumers aiming at getting engaged in co-creation processes of products, services, and experiences. Their needs and habits are changing, as well as the ways and speed of exploiting goods. Therefore, innovation rapidly and easily becomes common and replaced by new emergent innovative solutions. It follows that organizations operating in the digital ecosystem have to become resilient, proactive and able to evolve in the same way the competitive landscape does. Innovation, then, must be recurrent, cyclical. Continuous innovation is required and has to be pursued through a holistic engagement of the whole organization, stakeholders, and customers, rather than just of top management and dedicated facilities. Each actor engaged in innovation must be aware of the organization's vision, goals, and strategies in order to be able to effectively contribute and generate value (Lianto et al., 2018; Nonaka and Takeuchi, 2019).

Moreover, innovation is increasingly digital and data-driven and frequently organizations have to embark on a digital innovation journey and not without problems.

The fast development of digital technologies contributes to the generation of a high amount of data, information, and knowledge that increase even more the innovation barriers and accelerate the pace of change. To effectively understand and manage technology, codify and exploit generated knowledge, specialized skills and new governance models are required (Joshi et al., 2010). But, even if equipped with high tech infrastructure, and skilled staff, current innovation actors, like R&D labs, or innovation centers, are not able anymore to sustain and enhance the innovation capacity of companies (Capgemini, 2017). These environments are still conceived as separate entities and are not able to guarantee a stakeholders' commitment and a prolific dialogue with the entire organization. Employees, due to a mismatch in terms of digital skills and awareness, are not able to understand the reasons and potential of new technology implementation and shift.

Digital innovation, indeed, is not only about technology innovation. It is more about the innovation of knowledge and cultural attitudes. Therefore, a further challenge in the digital ecosystem is the promotion and definition of conditions, roadmaps and management models for the implementation of digital innovation strategies, to manage digital knowledge and foster continuous innovation (Bharadwaj et al., 2013; Nonaka and Takeuchi, 2019).

The research of new solutions, practices, and management models enabling continuous innovation dynamics and digital exploitation is a current hot topic both for scholars and practitioners (Fecher et al., 2018). Among emergent practices, Innovation Labs have appeared as a valuable answer to organizations' needs to develop digital culture and continuous innovation attitudes (Osorio et al., 2019).

Although the practice of Innovation Lab is raising interests among scholars and practitioners, the literature in this field still reveals a lack of management models based on innovative approaches and methodologies and addressing current competitive challenges (Osorio et al., 2018). To address this gap and catalyse research interest, the

paper is based on the analysis of a single case study. It has been conducted in an Innovation Lab to understand its functioning, and its management logic, as well as proposing a framework for its organizational management that could increase knowledge and suggest guidelines on the field, both for academic and practitioners.

2 Theoretical background

The notion of Innovation Lab has been introduced in the management literature to distinguish the creation of organisations' spaces dedicated to supporting, in different ways, the enhancement of innovation capabilities, and for developing and testing innovative ideas and solutions. Lewis and Moultrie (2005) define an Innovation Lab as a dedicated facility that encourages creative behaviours and promoting innovative projects by providing appropriate resources. Similarly, Magadley and Birdy (2009) point out the role of creative spaces to enhance innovation and describe an Innovation Lab as a physical environment in which employees can engage with each other to explore and extend their creative thinking beyond and above usual boundaries. So, the identification of the physical space dedicated to the development of creative and innovative skills is generally defined as the main feature of Innovations Labs (Bloom and Faulkner, 2016; D'Auria et al., 2017; Schmidt and Brinks, 2017). Magadley and Birdi (2009) state that there is a direct relationship between creative spaces, innovation and performance. Accordingly, an Innovation Lab is considered as a collaborative ideation space that helps organisations to break down the walls of the traditional laboratories and enable different people to get involved in creative and innovative activities. Not only employees but also the users and other potential stakeholders get involved in the activities of an Innovation Lab. A first fundamental distinguishing feature of Innovation Labs is that they are innovative spaces enabling organisations to embrace the paradigm of open innovation, user-driven innovation, and collaborative innovation by overcoming hierarchy and by promoting stakeholders participation into the co-creation of potentially successful innovations (Lewis and Moultrie, 2005, Memon et al., 2018; Osorio et al., 2019; Schmidt et al., 2015).

However, as pointed out by some authors, when just focusing on the creation of innovative spaces, Innovation Labs may become a kind of "*innovation theatre"* rather than an "*engine*" to successfully spur and support the development of the organisation's innovative behaviour. The idea of innovation theatre denotes that a significant pitfall of Innovation Labs is that they can be implemented mainly as promotional actions to demonstrate innovation. Instead, to be designed and implemented as management initiatives focusing on developing the capacity for innovation of an organisation (Blank, 2013). An Innovation Labs should foremost a management initiative to affect organisational behaviour in terms of propensity to innovation (Lewis and Moultrie, 2005; Magadley and Birdi 2009; Memon et al., 2018; Zurbriggen and Lago, 2019). For this reason, Innovation Labs' activities must be aligned with the organisation' vision and strategic goals and should be inspired by innovative methodologies and approaches

fostering stakeholders' engagement and satisfaction (Fecher et al., 2018; Osorio et al., 2019; Bogers, 2018; De Silva et al., 2019; Whicher and Crick, 2019).

Based on that, this paper proposes the following innovation lab's working definition.

Innovation Labs are Innovation management models based on the construction of an innovative space - physical, virtual, hybrid, relational -; on the definition of dedicated time for innovation; and on the development of a platform that contemplates tangible and intangible infrastructure dimensions.

Innovation Labs are aimed at fostering creative and critical thinking, promoting and supporting user-driven, open, and continuous innovation approaches, to facilitate stakeholders' engagement in innovations processes, to better understand users' needs, to drive digital transformation, to imagine and defining innovation opportunities, and to continuously develop new solutions capturing and delivering value to society.

Innovation Labs can drive the organization in finding the best ways to generate knowledge and digital culture, introduce technology, digitize operations, and implement digital strategies for continuous and digital innovation.

Considering this definition and that the academic literature, as well as common practices, reveal the lack of management models that improve the efficiency of an Innovation Lab and decrease the high rate of failure in this field, in the following, a real Innovation Lab has been analysed to gather insights to propose a management framework.

3 Research design

As previously highlighted Innovation Labs are emerging as management initiatives to address organizations' needs of developing digital culture and strategies and flourish continuous digital innovation attitudes.

Recently, several researches have addressed the phenomenon of Innovation Labs, but they have mostly analysed the structure and functions of these Labs. To date, there is still a lack of studies regarding the management models of these initiatives. (Osorio et al., 2018).

In such a prospect, the research aims to enrich theoretical and practical knowledge on management issues of Innovation Labs and proposes a cycle framework for their successful management. The study puts particular attention to management issues of Innovation Lab as a "guide" of the digital innovation journey of an organization.

The management framework has been developed by drawing from the literature on Innovation Labs and the analysis of activities carried out by a real Innovaiton Lab.

The paper combines the insights from theory with the empirical evidence gathered by adopting a case study approach. Therefore, the proposed framework springs from a case study, i.e., an Innovation Lab designed to develop and foster innovation capacity and digital continuous innovation among organisations and stakeholders of a tourism regional ecosystem. The research focused on the specific ways – the 'how' – in which Innovation Lab should be managed to: focus on the scenario to identify challenges and market needs;

transform challenges into opportunities; propose, design, experiment and validate possible innovative solutions; refine and reflect on solutions and lesson learned to enable continuous innovation. Data was collected through a variety of methods, including participant observations, semi-structured conversations with organizations' managers and project stakeholders, and active listening and understanding of online webinars carried out with actors involved. Data emerging from this fieldwork was integrated examining methodologies and paradigms on the basis of innovation lab theory.

This, to triangulate data gathered with various methods (Eisenhardt, 2002) to control and reduce the bias of single observation (Tarrow, 1995).

4 Research methods

The paper builds on an analysis of a single case study, i.e. the Transformalab, an Innovation Lab supporting companies wishing to undertake innovation paths, to be able to seize opportunities and generate innovative solutions for the relaunch of their business; as well as developing an entrepreneurial mindset and a culture for continuous innovation.

This research adopts the method of the case study (Yin, 2009) to test and validate the proposed framework through a contextualized analysis. The case study method is particularly recommended for the identification of relevant insights and the elaboration of theory starting from the analysis of examples and real situations (Eisenhardt and Graebner, 2007).

4. 1 Background – research context

The Lucanian tourism sector is strongly affected by the ongoing crisis.

It is estimated that Lucanian tourism in 2020 could register a drop of 47.75% (Statesman, 2020). The recovery of the Basilicata tourism sector will depend on the response and ability of adaptation of the tourist destination "Basilicata" to new challenges imposed by COVID-19.

The future of tourism industry should be rethought and designed based on tourists' new habits, needs, and expectations; active engagement of local communities; operators and organisations needs. Their creativity and innovative thinking should be stimulated and encouraged to find and adopt new approaches, mindset, processes, and to innovate tourism offer. New form of communication should be explored, as well as new relational dynamics able to guarantee the promotion of the territory and the development of a tourism ecosystem that should become authentic, welcoming, safe and that instills well-being and trust in tourists who will come back to visit the territory.

The Transformalab for tourism is an Innovation Lab promoted by the University of Basilicata which aims to support the development of digital innovations and business models of Lucanian tourism organisations by leading them in this period of crisis to become even more competitive and to be able to design and implement development

strategies. The activities combine the richness of the real experiential process with digital products and services so as to increase the value created and transferred to customers.

The Transforma Lab is a management model, based on 5 phases management framework, aimed at increasing the entrepreneurial and innovative capacity of organizations to create excellent value. It is configured as an innovation program that accompanies companies in the process of transformation and development of product, process and business model innovations, starting from a market need, or organizational challenge.

It follows the "Innovative Thinking" method by combining models and tools based on the principles of Open Innovation, Design Thinking, User-driven Innovation, Lean and Agile Methods. The aim is to lead organizations in the digital transformation process, in the development of innovative capacity, in change management, so as to better react to crisis, adapt to market changes, and improve the operational efficiency and profitability of the company.

The Transforma Lab for Lucan Tourism started with a phase of diagnosis of the challenges of Lucanian tourism companies. The auditing of involved companies has been accompanied by a series of thematic webinars broadcasted live on the social media. These webinars involved the actors of the regional tourist panorama.

The goal was that of defining, through the creation and proactive involvement of a community of experts, entrepreneurs, tour operators, DMOs, citizens, tourists and institutions, the main business challenges in the sector due to the covid-19.

The identification of these challenges should be considered as as the starting point at the basis of the constitution of innovation teams to set up with the ambitious goal of transforming challenges into opportunities, and then to generate innovative solutions during a final hackathon. Then, innovative digital responses and proposals has been appropriately tested and evaluated. Therefore, it results that validated outputs solving identified challenges in an innovative, efficient and remunerative manner have been generated. These have been then proposed to companies and stakeholders involved. Finally, Innovation Labs managers and operators made reflections on carried-out activities collecting feedbacks from participants and involved actors. This to verify the effectiveness of the program, if proposed objectives have been pursued, and to improve the method in order to propose even more effective innovation to customers and to generate valuable offer for companies and the ecosystem.

4.2 Data collection and analysis

One of the authors as part of the Transformalab had the chance to gather data during the exploitation of the project and beyond. His role was to lead the exploitation activities of the project and, as such, he was particularly interested in examining and documenting knowledge flow, objectives and key results occurring across the carried-out activities. Data was collected through a variety of methods, including participant observations

(Czarniawska, 2012) and semi-structured conversations with key project stakeholders. Data emerging from this fieldwork was integrated by further research carried out together with the other authors of this paper, particularly examining methodologies and paradigms on the basis of innovation labs theory. The idea here was to triangulate data emerging from various gathering methods (Eisenhardt, 2002) as to reduce the bias of a single observation (Tarrow, 1995).

The research was enriched by semi-structured conversations with key informants (Kumar et al., 1993), including internal and external stakeholders, and by active listening and understanding of online webinars carried out with actors involved. These webinars were based on semi-structured schemas using a flexible approach that allowed gathering the informants' perspectives on specific issues and checking whether informants could confirm insights and information the researchers already held (Myers, 2013).

Processes of data reduction, data display, inductive and iterative data analysis and conclusion drawing and verification were carried out (Corbin and Strauss, 2008; Miles et al., 2014).

The backbone of these processes was the creation and continuous editing of reports, in which keywords for the future of tourism experience, key challenges, main opportunities, and possible innovative solutions for Lucanian tourism ecosystem were identified and discussed. Moreover, a final hackathon with the participation of 36 team and more than 20 experts contributed to the realization of 23 possible innovative solutions in the form of digital prototypes delivered to the local tourism stakeholders and operators.

5 Findings: The Innovation Labs' management framework

Innovation Labs can represent an effective and efficient way to answer to the organisations' challenges of continuous improvement fostering digital innovations development. In this regard, a framework that supports academics and practitioners in the management of an Innovation Lab is required. The above described case study has been conducted to gather insights and understand the functioning, and common management practices of an Innovation Lab. The main emerged outputs have been compared and integrated with a previously conducted review on Innovation Labs.

As a result, five key subsequent phases distinguishing an Innovation Lab emerged: *focusing, engagement and enabling, developing innovative solutions, delivering and application support and reviewing and consolidating.*

The '*focusing'* phase is aimed at defining strategic intentions, developing a shared vision, and identifying necessary resources in order to develop a project plan. The second phase, namely '*Engagement and Enabling',* is devoted to the activation of facilitation mechanisms to engage users and encourage a working atmosphere that reduces hierarchy, provides stimuli to empathize with given challenges, and stimulates creativity and innovation (Lewis and Moultrie, 2005; Schmidt et al., 2015). Moreover, according to users' needs and pursued innovation goals, the Innovation Lab may act as an innovation intermediary in order to provide opportunities to build communities and partnerships with

various stakeholders (Memon et al, 2018; Meyer et al., 2019). The phase of '*Developing innovative solutions'* starts once the challenges and objectives have been addressed. Here, traditional innovation management stages follow each other in order to exploit innovative projects transforming ideas into solutions or to develop innovative skills and mindset in users (Morel et al., 2016; Thorpe and Rhodes, 2018). During this phase, Innovation Labs should provide services like mentoring, coaching, or facilitating sessions with final users in order to gain feedback and control the risk of failure. Moreover, tools, equipment, and technologies for testing and prototyping should be made available under assistance. After the innovation development, the *'Delivering and application support'* phase is aimed at delivering and/or applying the generated value. In this phase, Innovation Labs provide consulting or mentoring services, assisting users in activities like developing time-to-market, go-to-market or growth hacking strategies; codifying learned knowledge; or improving routines. Moreover, Innovation Lab may play a strategic role in building bridges between companies and markets (Fecher et al., 2018). The last phase is about *'Reviewing and consolidating'* where activities carried out are reviewed and reflections come out. Final results from activities are compared with initial objectives to detect insights from which to learn and design new innovation activities and strategies.

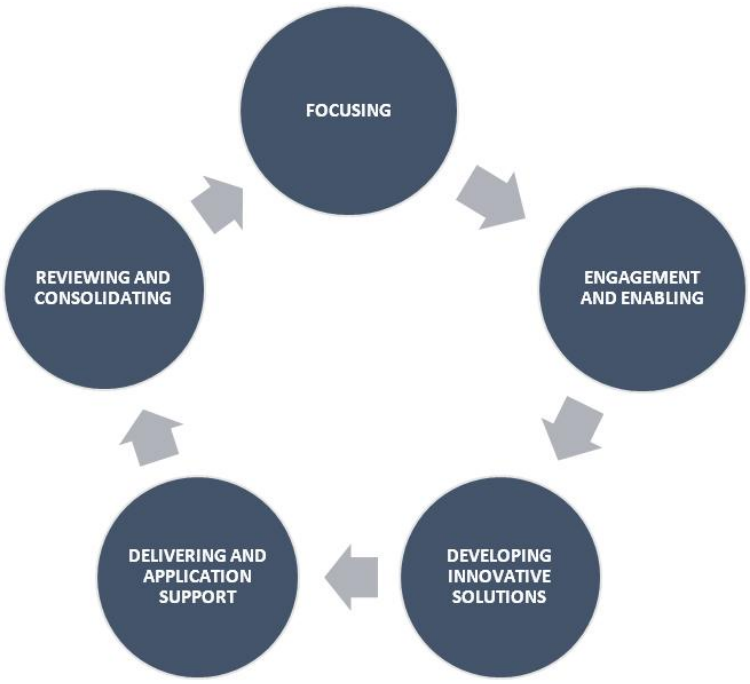

Fig. 1. "The Innovation Lab's management framework

6 Final discussions

In the digital ecosystem, competitive organizations are asked to introduce and accept technology, as well as evolves their business models and operations simultaneously with the scenario's evolution. Equipping traditional R&D labs or innovation centers with the latest technology and highly specialized team didn't turn out with expected results. The need for new practices to address current competitive challenges has emerged.

The paper proposes Innovation Labs as an answer to the organisations' needs to develop digital culture and continuous innovation attitudes. This study, analysing a case study, proposes a management framework built on the Innovation Lab perspective to explore some of the important issues that could contribute to an effective management of Innovation Labs.

The study advances knowledge about how effectively manage these Labs and provides scholars and practitioners with useful insights and managerial implications for the development and management of these initiatives. Although the framework requires more investigation to be validated, and the implications need further examination, this paper aims to catalyse research interest and calls for further research in this field.

Abstract

Nowadays, Living Labs have become a very popular research topic in Innovation Management literature. The existing literature suggests that the Living Lab is a multidisciplinary phenomenon that can be seen simultaneously as an environment and methodology rooted in open and user innovation paradigms. These Labs are conceived as physical or virtual space in which to solve social challenges, especially for urban areas, by bringing together various stakeholders for collaboration and collective ideation. In a broader perspective Living Labs are user-driven open innovation ecosystem where business, citizens, government, institutions take an active part in innovation processes.

This paper analyses Living Lab as a catalyst of entrepreneurship development and innovation in a peculiar context such as a European Capital of Culture (ECOC). ECOC represents a yet under-utilised opportunity for cities and regions to develop existing and prospective local businesses, firstly via their engagement in the event. ECOC programme, indeed, has great potentials to trigger, strengthen and diversify local entrepreneurship by encouraging innovation, cross-sectoral cooperation, networking as well as internationalisation.

The study provides an analysis of the Open Design School, i.e. a Living Lab designed to invent, prototype and build creative and technological solutions to have been made available to the events planners of Matera European Capital of Culture 2019.

The Open Design School (ODS) has engaged in its activities many actors, such as businesses, entrepreneurs, citizens, an international team of professionals with the most diverse stories behind them. In doing this, the ODS has given to these actors the opportunity to approach interdisciplinary

experimentation and innovation, learn new skills and build new relational networks, in a process that has put the community at the centre of the mega cultural event.
Among the different actors involved in the ODS' activities, the study - Upon the Matera Basilicata 2019 Foundation's request who financed the research – looked at the Living Lab's suppliers and has investigated the following issues: what impact has the collaboration with the ODS generated on innovation capacity of its suppliers? What are the effects that cooperating with the ODS has generated on business model of its suppliers? More generally, has the ODS helped create a fertile milieu for developing innovative and entrepreneurial skills, new medium-long term opportunities for local community?
The study adopts an exploratory approach based on case study methodology.

Keywords: Living Lab, Entrepreneurship, Innovation attitude, ECOC, case study, Matera 2019.

1 Introduction

In an increasingly unpredictable and complex market, characterized by the rapid emergence of new technologies and growing globalization, organizations are discovering the advantage of creating innovation spaces, i.e. spaces dedicated to stimulating and cultivating creative and innovative thinking that can guide the dynamics of creating value (Wagner et al. 2017). Innovation spaces provide opportunities to engage with people, ideas, and technologies, experience participatory culture, and acquire the literacies and skills needed to prosper in the 21st century (Prefontaine, 2013).

Among the different forms of innovation spaces there are Living Labs. These Labs are conceived as physical or virtual space in which to solve social challenges by bringing together various stakeholders for collaboration and collective ideation. In a broader perspective Living Labs are user-driven open innovation ecosystem where business, citizens, government, institutions take an active part in innovation processes.

Living Labs can stimulate knowledge co - creation and co-design by exploiting the newest opportunities offered by ICT. They represent a novel system where increasing its own skills and improving competitive advantage. Regarding businesses, for example, Living Labs can give them the opportunity to develop and validate new ideas and have innovation process more effective thanks to the greater openness to collaboration with other companies and with end-users. About citizens or community, these Labs can offer them the chance of orienteering the production and delivery of services and products that serve real needs (Uzunidis, 2018, Leminem, Westerlund and A-G. Nystrom 2012, European Commission 2009).

Made-up by different stakeholders, resources and activities that enable and support innovation, Living Labs act as intermediaries between users and developers for the creation, the prototipation, the validation and the testing of new solutions and necessary lab infrastructure to do so, making organizations and all the local network more competitive (Bernhard R. 2012, Leminem, S., M. Westerlund and A-G. Nystrom (2012).

This study explores the role of Living Lab as a catalyst for innovation and entrepreneurship in the peculiar context of a European Capital of Culture (ECOC). The

context of investigation is one of two cities designed ECOC in 2019, i.e. Matera. In particular, the research analyses a Living Lab, that has been built to support the development of skills and infrastructures needed for the mega event of the European Capital of Culture Matera 2019, namely the Open Design School (ODS).

Specifically, the study explores the role of the ODS as a facilitator of innovation and entrepreneurial development in local community, and reports the results of a case study which has involved some ODS' suppliers and professionals who closely worked with the Lab to implement Matera 2019 program. In particular, the research investigates the following questions: what impact has the collaboration with the ODS generated on innovation capacity of its suppliers? What are the effects that cooperating with the ODS has generated on business model of its suppliers? More generally, has the ODS helped create a fertile milieu for developing innovative and entrepreneurial skills, new medium-long term opportunities for local community?

The remainder of this paper is organized as follows. Section 2 provides a general overview of the ODS project. Section 3 describes the methodological approach. Section 4 presents the findings of the case study analysis. Finally, in Section 5, concluding remarks and directions for future research work are presented.

2 The ODS project

The ambitious project of the Open Design School (ODS) was conceived as a "Living Lab", an innovation space to produce infrastructures and skills necessary for implementing the mega event Matera 2019, and to provide long-term benefits to ECOC citizens.

More specifically, the ODS project was inspired by "Open Culture" principles and designed to create and prototype creative and technological solutions in order to solve real-world problems and challenges, emphasizing the role of design as a form of collaborative cultural practice in a community development process, eliminating mistrust in creative skills and avoiding the loss of an important artistic and creative heritage for the production sector and community (Open Design School User Manual, 2019).

Open Design School was born from an idea by Joseph Grima. It was conceived as a fucina of ideas where teachers and students of the world can meet and design the essential concepts for the Matera 2019 preparations.

School because it is an opportunity to learn points of view, trades and cultures. Learning takes place between peers. A committee comprising, from time to time, a team of professionals with the most diverse stories behind them: the important thing is that each work group is one third foreign nationals, one third Italians and one third Matera citizens (source: https://www.matera-basilicata2019.it/it/programma-2019/progetti-pilastro.html).

In addition to the 13 staff members and the 64 external experts involved, the ODS hosted 39 highly qualified professionals and experts in different sectors, who have formed the pool of skills to approach complex research projects, that require rapid immersion and

a broad vision, and a dialogue between the creative scene of Basilicata and European partners.

Design because is the workshop watchword. The ODS teams have invented, prototyped and built creative and technological solutions to be made available to the event planners who will take charge of the exhibitions for Matera: European Capital of Culture.

Open because every project in the ODS actively involved residents and encouraged them to participate.

As an open innovation ecosystem based on knowledge sharing and continuous learning, the ODS has involved heterogeneous users, including ordinary people who have attended Lab workshops, designers or groups of students from several European countries interested in studying the ODS model and even local creatives who wanted to put some ideas into practice with the ODS team.

The ODS was also conceived to develop new networks and new economies and regenerate abandoned public spaces through the engagement of professionals and citizens in planning and implementing regeneration projects.

The variety of solutions produced by the ODS in response to its stakeholders' needs has been impressive. The Living Lab has developed 122 projects, including 76 installations and 38 research projects. Wider citizens' involvement was guaranteed through open events which included 37 talks involving 2020 people, and 28 workshops, involving 600 participants.

3 Methodological notes

To explore the role of the ODS as a facilitator of innovation and entrepreneurial development in Matera community, a case study was developed. In particular, at the Matera Basilicata 2019 Foundation's request who financed the research, the study looked at the ODS' suppliers and professionals who closely worked with the Lab to implement Matera 2019 program and has attempted to understand what effects the collaboration with the ODS generated on their innovation capacity and business model. Moreover, the study has sought to analyse if the ODS helped create a fertile milieu for developing innovative and entrepreneurial skills and new medium-long term opportunities for local community.

The case study method is applied since this is the most appropriate one for achieving a deep understanding of the investigated phenomenon. Over the past decades, numerous studies have demonstrated that the case study method can be successfully to probe beneath the surface of a situation and to produce a rich context for understanding.

For the purpose of this study, a "case" was defined as an in-depth interview with three suppliers and two professionals who closely collaborated with the ODS for Matera ECOC event.

The interviewees for the study enjoyed describing their own views on the collaboration with the ODS and Matera 2019 experiences. Therefore, participants' bias presented a very small problem in the study.

During the course of the first interview, several slight revisions were made to the interview protocol to adjust or rearrange questions that seemed unproductive. Notes from each interview were reviewed and highlights were identified. The transcript from each interview was reviewed and coded. The main approach to data analysis involved a detailed analysis of the interview transcripts. In addition to the interviews a documentary research has been carried out.

The interview was structured considering two main dimensions of analysis:

- the impact on the respondents' business model, generated by the collaboration with the ODS. The impact was analyzed referring to the Canvas model showed in Figure. 1;

- the improvement of entrepreneurial attitudes and propensity to innovate, as result of the collaboration;

<table>
<tr><td>KEY PARTNERS</td><td>KEY ACTIVITIES</td><td>VALUE PROPOSITION</td><td>CUSTOMER RELATIONSHIP</td><td>CUSTOMER SEGMENTS</td></tr>

Figure 1. Canvas model and investigation areas

4 Findings

In the following the main results of the case study analysis are reported.

4.1 Impact on business model

Value proposition

From the interviews different effects on value proposition were highlighted. One supplier revealed that, inspired from some creations made during the collaboration, enlarged the range of products offered to its customers. Another interviewee noted an improvement in its design skills of wooden products and structure, and in turn, the possibility to add further value to its products.

Market Segments

Most of the interviewees have pointed out that collaborating with the ODS has allowed them to acquire new customers and expand the number of potential new customers as well as to improve knowledge about their customers 'requests and needs.

"Through the ODS I have expanded my contacts and networks "-

from the interview with a professional.

Customer Relationship

The analysis of the interviews revealed that thr ODS has meaningfully contributed to improve how most of the interviewees establish and manage relationships with their users/customers. Particularly working with the ODS has helped both suppliers and professionals to better involve their customers in co-creation of products and services.

Channels

Four respondents stated that the collaboration with the ODS has enabled the development of policies and strategies to reinforce their presence in market different from the local one.

Revenues Stream

According to the interviewees, working with the ODS has resulted in new business opportunities in the local context.

Costs & Financial Resources

The relationship with the ODS, did not produce worthy impact on cost structure and financial resources of interviewees.

A couple of them stated that the experience with the ODS has improved, even to a limited extent, their ability and propensity of searching for new funding.

Moreover, one supplier declared that collaborating with the ODS helped to better manage costs of its company.

Key Partners

The respondents highlighted the contribution of the ODS in establishing new relationships and greater dialogue with own stakeholders. Indeed, the collaboration with the Lab was an opportunity to broaden their relationship network and to get in touch with other actors involved in the planning and implementation of Matera 2019.

For four interviewees, working with the ODS has helped the search for and the creation of new partnerships.

Key Activities

The analysis of the data shows that the collaboration with the ODS has improved the ability to program and manage processes and activities for the majority of respondents.

> *"In addition to working in a team, I saw their design approach, their planning, and also how they manage the budget and apply their design system. It was an interesting lesson."*
>
> from the interview with a professional.

Furthermore, an interviewee declared that acquired more propensity to experiment new technology and channels and to adopt different work practices. In three cases, the collaboration allowed to try new work tools and equipment. One supplier had opportunity to try new technology to produce his handcrafts.

Key Resources

Physical resources

One professional declared that thanks to the experience gained by collaborating with the ODS, he has learnt the use of modular systems for different arrangement of spaces. Four interviewees stated that would invest to create innovation space in their own organisations.

Intangible resources

Among the most important knowledge resources acquired thanks to the relationship with the ODS, interviews analysis has highlighted knowledge regarding the application of new technologies in daily respondents' job, small woodworking techniques and design methods.

Collaboration with the ODS was also an opportunity to improve, even if to different extent for all the respondents, the ability of acquiring, transferring and sharing knowledge (Singh, 2008, Stockes, 2004; Werner et al., 2015).

Even if to different extent, all the interviewees declared they perceived some improvement in their ability to: managing complex projects; monitoring and evaluating projects, managing communication, building partnerships at national and international level, adapting to market needs, solving challenges and achieving goals in short time.

The collaboration with the ODS also helped four interviewees to enhance their speed of decision-making processes.

Finally, an improvement of reputation and recognisability at local level was an impact revealed by all the interviews.

4.2 The impacts on entrepreneurial attitudes and propensity to innovate

In order to evaluate the effects ***on entrepreneurial attitudes***, each interviewee was asked to indicate how much he/she had acquired or improved the following entrepreneurial attitudes, thanks to the collaboration with the ODS:

- communicate own ideas effectively to third parties and negotiate with them, understanding their viewpoints;
- solve challenges, take risks and face situations of uncertainty;
- gain confidence in own skills and decisions;
- solve problems in a creative way, following new and unusual paths;
- wait patiently for the results of own efforts;

All the interviewees declared that they have acquired / improved the ability to solve problems in a creative way, following new and unusual paths; four of them have acquired / improved greater confidence in their abilities and decisions; three subjects noted an improvement in the propensity to take risks, to face situations of uncertainty and accept the possibility of making mistakes; have acquired a better ability to effectively communicate their ideas to third parties and to negotiate with them, understanding third parties' viewpoint and have acquired / improved the ability to wait patiently the results of their efforts.

To investigate changes occurred in the propensity to innovate, "Innovation Questionnaire" proposed by APQI and Confindustria (2018) was used. From the interviews it arisen that working with the ODS has improved ability to explore, identify and select new ideas and opportunities; propensity to acquire innovative suggestions and proposals from employees, for the majority of the interviewees.

5 Final remarks

This paper has attempted to provide some first insights about how Living Lab can be catalyst of entrepreneurship development and innovation in a peculiar context such as a European Capital of Culture (ECOC). ECOC represents a yet under-utilised opportunity for cities and regions to develop existing and prospective local businesses, firstly via their engagement in the event. ECOC programme, indeed, has great potentials to trigger, strengthen and diversify local entrepreneurship by encouraging innovation, cross-sectoral cooperation, networking as well as internationalisation.

Referring to Matera 2019 setting, the study has focused on the Open Design School, i.e. a Living Lab designed to invent, prototype and build creative and technological solutions to have been made available to the events planners of Matera ECOC 2019.

The Open Design School (ODS) has engaged in its activities many actors, such as businesses, entrepreneurs, citizens, an international team of professionals with the most diverse stories behind them. In doing this, the ODS has given to these actors the opportunity to approach interdisciplinary experimentation and innovation, learn new skills and build new relational networks, in a process that has put the community at the centre of the mega cultural event.

Upon the Matera Basilicata 2019 Foundation's request who financed the research, the study looked at the Living Lab's

suppliers and professionals who closely worked with the Lab to implement Matera 2019 program and has tried to understand what effects the collaboration with the ODS generated on their innovation capacity and business model.

For the purpose of this study, a set of in-depth interview with three suppliers and two professionals who closely collaborated with the ODS for Matera ECOC event was carried out.

The interviews' analysis gives back a positive image of the impacts on innovation capacity and business model both of suppliers and professionals. Certainly the intensity of the impacts varied for each interviewee.

The ODS has activated a creative exchange between art, science and technology giving the opportunity to its users to learn new skills and build new relational networks, in a process that has put the community at the center.

After Matera 2019, the Living Lab with its know-how, talents and technologies, is still considered as an opportunity to give impetus to the future of local businesses. It can help local businesses to acquire new attitudes, to share ideas, to embark innovative scenarios, to prototype concrete applications and to boost research and training.

The ODS represents a strategic legacy of Matera 2019, to capitalize in order to continue to stimulate interest in the search for new ideas and opportunities, in the exploitation of new technological solutions and adoption of new approaches to products and services innovation. Investing in the ODS means to fuel local economy and boost the future of local community.

This study focused on a few number of suppliers and professional who collaborated with the ODS. Therefore, the research results cannot be generalized. Future developments of the study regard the implementation of further interviews as well as a longitudinal evaluation of the project impacts.

Abstract

There is an interesting debate around the role played by a European Capital of Culture in the development and growth of creative and cultural organisations working in the city designed as cultural capital, in the sub-region and. Whilst it is understandable that the designation of European Capital of Culture of a city has an impact on the broader profile of the city and can give an improved credibility of the city's creative offer, there is a variety of experiences about direct impact on cultural organisations engaged with the development of the mega event European Capital of Culture. Leaving out the broader understanding of the changes occurring in cultural and creative industry in a European Capital of Culture, this study focuses on an analysis of the impacts of big cultural projects co-created with citizens on cultural organisations that have developed these projects. The impacts mainly concern changes occurred in organisation's business model, capabilities, growth and position in creative and cultural sector. The study adopts an exploratory approach based on multiple case studies. The cases regard five cultural organisations that have lead as many big projects within the Matera ECOC 2019 programme.
The cases provide a consistent scenario for deepening understanding of changes experienced by cultural organisations engaged in the development of big projects involving citizens in ECOC context.

Keywords: ECOC, cultural project co-created with citizens, evaluation, case studies.

1 Introduction

According to the EU commission report, the scope of a European Capital of Culture (ECOC) is to bring fresh life to the chosen cities, boosting their cultural, social and economic development. The involvement of citizens in the creation and implementation of cultural events is an essential trait of ECOC. In fact, the success of an ECOC and its legacy, closely depends on the broad and active participation of its citizens to cultural events and the creation of opportunities for a wide range of people to attend or participate in cultural activities.

Creative and cultural organisations play a key role in engaging citizens and favourite their large participation to ECOC program. Through their activities and projects, these organisations enable and widen the access to the culture and act as a powerful engine of ECOC.

On the other hand, for their part, creative and cultural organisations involved in the implementation of an ECOC program, experience the wave of this great event and its impact.

In the last years there was an interesting debate around the role played by ECOC in the development and growth of creative and cultural organisations working in the city designed as cultural capital, in the sub-region and beyond (see, e.g. Campbell, 2011; Garcia et al., 2010; Langen and Garcia, 2009).

Whilst it is understandable that the designation of ECOC of a city has an impact on the broader profile of the city and can give an improved credibility of the city's creative offer (Garcia et al., 2009), there is a variety of experiences about direct impact on cultural organisations engaged with the development of the mega event ECOC (Garcia et al., 2009). These experiences tend to remain under investigated. Over time most attention has been paid to macro effects generated by this peculiar mega event.

However, analysing the experiences and reflections of arts and cultural organisations of different sizes, working in different art form, based within an ECOC, is essential to understand more in depth how an ECOC can affect cultural organisations' capacity to sustain themselves and develop. This analysis can offer an accurate picture of the effects generated by an ECOC on micro scale, that can deeply affect also the legacy of the event.

Therefore, leaving out the broader understanding of the changes occurring in cultural and creative industry in a ECOC, this study focuses on an analysis of the impacts of big cultural projects co-created with citizens on cultural organisations that have developed these projects.

In particular, the study seeks to answer the following research question: does co – creating big cultural projects with citizens produce some impacts on capacities building, business model, growth and position in creative and cultural sector of cultural organisations leading the projects? To what extent? Does experiencing an ECOC produce changes in how cultural organisations connect with the external social landscape and catalyse social innovation dynamics (e.g. to boost citizen's cultural participation and civic engagement)?

The study adopts an exploratory approach based on multiple case studies. The cases regard five cultural organisations that have lead as many big projects within the Matera ECOC 2019 programme. The projects were designed to increase the interest of citizens in attending cultural events by experimenting in new ways of listening, of sharing experiences and of producing. They were carried out with the cooperation of a number of citizens, to infuse them with a sense of ownership and responsibility for the care, protection and regeneration of community culture.

The research sought the views of the cultural organisations on their experiences of active actors of Matera's year as European Capital of Culture (ECOC) in 2019 and explored impacts on their business development and growth.

The remainder of this paper is organized as follows. Section 2 provides the research background and introduces the conceptual model. Section 3 briefly describes the research method. Section 4 presents the case studies analysis and findings. Finally, in Section 5, concluding remarks and directions for future research work are presented.

2 Research background and conceptual model

Evaluating the impact generated by a cultural project / initiative is still a challenge. Recently, several scholars have produced some conceptual frames and notions to describe the value and impacts generated by arts and cultural initiatives (see e.g. Bunting, 2008; Coles, 2008; Holden, 2006; Knell & Taylor, 2011; McCarthy et al., 2004).

An analysis of the differences and interrelations of the notions and conceptual frames, as well as of the perspectives of analysis around the impacts of arts and cultural events, suggests an alignment around different kind of value and impacts generated by a cultural program / activity, which ranges from a micro to a macro perspective, according to a frame that considers the following dimensions strongly interrelated:

1. The generated value / impact for individuals experiencing the arts/cultural event/project;
2. The value generated / impact for cultural organization, that produces the arts/cultural event/project;
3. The value generated for the community / society.

These dimensions suggest that the value and impacts generated by an arts/cultural event or project can be examined according to a multilevel conceptual model which includes several level of analysis (see Figure 1).

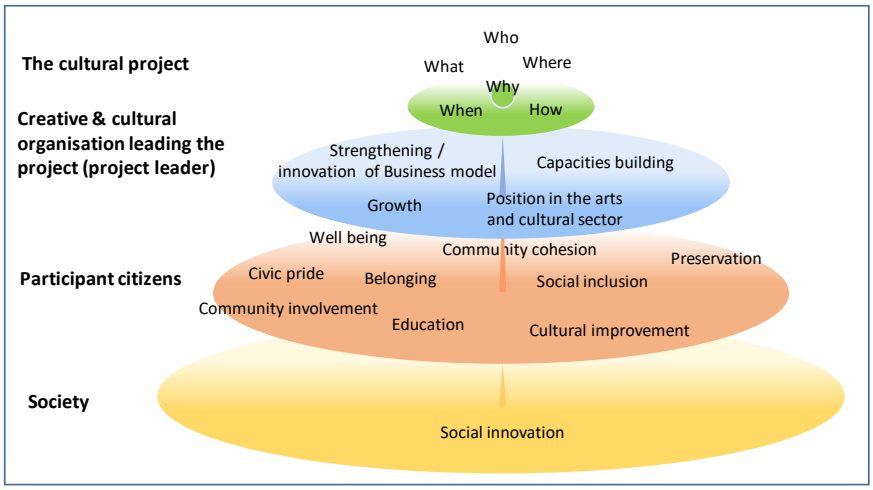

Figure 1. The multilevel conceptual model

The first level of analysis concerns a deep understanding of the event/project through a questioning method including six Ws which embrace as many questions, as follows:

- Why (the scope): what is the scope, the reason for implementing the cultural event/project?
- What (the focus): what is the key focus of the cultural event/project?
- How/Which (the process and the resources) what is the process, the set of activities and the resources to be deployed for the cultural event/project?
- When (the schedule): what is the schedule and pace of activities related to the cultural event/project?
- Where (the place and the context): in which context and place the cultural event/project will take place?
- Who (the stakeholders): what are the stakeholders involved in the cultural event/project?

The second level concerns the impacts of the event/project on cultural organization leading the project.

The impacts embrace capacities building, business model innovation and strengthening, growth and position in creative and cultural sector. The evaluation of the impacts can be carried out through several approaches and tools such as interview, questionnaire, observation, etc.

The Business Model Prism (Schiuma e Lerro, 2017) represents a useful tool to use in order to analyse the impacts regarding business model innovation and strengthening. It is a multidimensional framework derived from a wide review of the literature which can support the identification and the mapping of the peculiarities of the business models of the arts and cultural organisations. It takes into account the specific features of the value creation focus and the operation mechanisms of such organisations. It allows to analyse

the "as is" structure and logic of an arts and cultural organisation business model as well as to drive the design of innovation initiatives, i.e. the "as should be" business model.

The Business Model Prism is a three-dimensional prism that includes seven facets. The upper and lower facets indicate respectively: *the value and the social and cultural impact and the financing and the financial resilience*. The other five facets describe the remaining key dimensions of a business model of an arts and cultural organization, i.e.: *stakeholder, strategies, processes, organizational resources and partnerships* (see Figure 2).

The seven distinct but inter-linked facets, indeed, provide an ideal lens to understand the business model of an arts and cultural organization starting from addressing the following key questions:

- Social and Cultural Value & Impact – Why do we exist? What impact do we want to have? Which values do we want to propose and offer? What are our mission and vision?
- Stakeholders – Who are our key-stakeholders? What are their wants, needs, expectations and dreams?
- Strategies – What are we doing to satisfy our stakeholders and deliver value for them? What are the main products and services we are doing? What is our legal structure? How is currently our organizational structure?
- Processes – What are our existing processes? How do we manage our projects and programs? What are the characteristics of our productions? How do we generate and sustain demand? How do we do Research & Development (R&D)?
- Organizational Resources – What resources do we need to put in place, exploit and enhance to operate our processes?
- Partnerships – What partnerships do we need to build and enhance to implement our strategy and guarantee social and cultural values and impact?
- Funding and Financial Resilience – What are our current costs and incomes? What is our financial status?

The seven facets of the Business Model Prism provide as many lenses through which to analyse changes occurred in business model of the cultural organization that has lead the project.

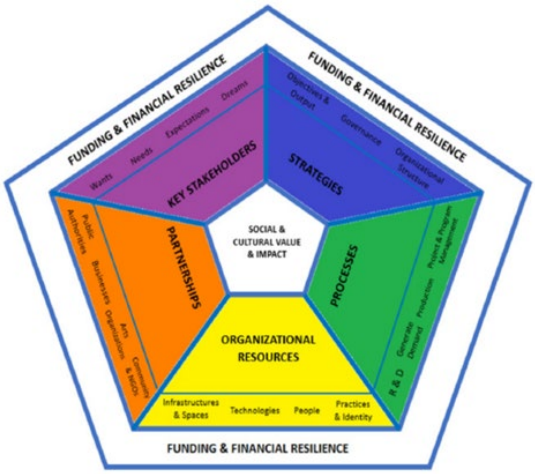

Figure 2. The Business Model Prism

The third level of analysis considers the effects of cultural event/project on citizens involved in the project development. The range of these effects is wide and covers four main individual's spheres: cognitive, ability, health and well-being, motivation (Matarasso, 1997, Michalos, 2005). The effects concern education, social inclusion, preservation cultural improvement, community cohesion, well being, civic pride, belonging, civic pride, community involvement. They can be evaluated through several tools such as interview, questionnaire, focus group (see e.g. Jackson, 2004; Matarasso, 1997, Michalos, 2005).

Finally, the fourth level of the model, concerns the impacts of the event/project on social innovation. It is well acknowledged that arts and culture represent fruitful field for the development of social innovation and civic engagement, as—by their own nature—they establish meaningful forms of dialogue among different societal actors (Cancellieri et al., 2018). Cultural events/projects can generate positive waves and activate processes that see citizens as active actors of social and cultural changes, but these "positive waves" occur in medium-long time and can be evaluated only over the years. Longitudinal studies referring to medium – long terms are required to evaluate these impacts.

3 Methodology

The study is developed as an exploratory research and uses a qualitative approach. The exploratory nature is justified by the fact that there is scarce research on the investigated questions. While, the adoption of the qualitative approach, it is explained by the fact that the investigated issues i) are focused on “specific meanings, emotions, and practices that emerge through the interactions and interdependencies between people” (Hogan et al., 2009, p.4); ii) are “pragmatic, interpretive, and grounded in the lived experiences of

people" (Marshall and Rossman, 2006, p.2); iii) regard somewhat "discerning humans' participation in what happens to them" (Fischer, 2005, p.411).

In particular, a multiple case study method is applied since this is the most appropriate one for achieving a deep understanding of the investigated phenomenon. Over the past decades, numerous studies have demonstrated that the case study method can be successfully to probe beneath the surface of a situation and to produce a rich context for understanding.

The study analyses five case studies regarding as many cultural organisations who had received funding from the Matera Basilicata 2019 Foundation to create and produce cultural events calling for citizens 'involvement and collaboration, under the ECOC 2019 programme. These organisations were labelled "project leaders".

The focus is on the effects that experiencing Matera 2019 and leading big cultural project in cooperation with citizens, have generated on the examined cultural organisations. In particular, the study seeks to analyse the changes occurred in their capacities building, business model, growth and position in creative and cultural sector. Moreover, the research enquiries if Matera 2019 experience has made cultural organisations more active in boosting citizens cultural participation and civic engagement.

The analysis of the impacts of cultural project on participant citizens and community (see third and fourth level of the proposed conceptual model) goes behind the scope of this research, therefore it is not treated.

For the purpose of this study, a "case" was defined as an in-depth interview with the project and arts manager of each cultural organisation. Data were collected from the managers over a four-month period using a pre-tested interview protocol that included questions designed to address one or more of the issues encompassed in the first and second level of the proposed conceptual model.

In general, the project and arts managers interviewed for the study enjoyed describing their own views and Matera 2019 experiences. Therefore, participants' bias presented a very small problem in the study.

During the course of the first interview, several slight revisions were made to the interview protocol to adjust or rearrange questions that seemed unproductive. Notes from each interview were reviewed and highlights were identified. The transcript from each interview was reviewed and coded. The main approach to data analysis involved a detailed analysis of the interview transcripts. In addition to the interviews a documentary research has been carried out. Data triangulation was obtained by the fact that the informants came from different types of organizations.

4 Cases analysis and findings

As previously mentioned, the study involved five cultural organisations, i.e. project leaders, that designed and developed as many big cultural projects under Matera 2019 programme. They are *Tx*, *Sx*, *Ax*, *Lx* and *Gx*. Organisations' names have been changed for confidentiality reasons.

The projects were original production in which temporary and permanent citizens became actors and co-authors themselves. Moreover, the projects proposed to break the barriers between the creators of culture and those who enjoy it, by giving to citizens an opportunity of playing an active part in the creative process and choose their level of engagement. This was with the aim of stimulate social innovation in the community.

As previously mentioned, in the light of the research focus, in the following the main results of the case studies analysis are reported for the first and second level of examination of the proposed model.

Understanding the event/project

An analysis of the big cultural projects was carried out through the questioning method including six Ws, i.e. Why (the scope); What (the focus); How/Which (the process and the resources); When (the schedule); Where (the place and the context); Who (the stakeholders), in order to gain a deep knowledge of the projects. For this purpose, primary and secondary data were collected and analyzed respectively through interviews and collection and analysis of reports, data from websites, magazine and newspaper articles.

Even though the focus of each project was different (see Table 1), the analysis highlighted some features concerning scope, stakeholders, process, resources, schedule and place, common to many projects.

Table 1. What – The focus of the projects

Organisation	The focus (What)
Gx	The project leader built a traveling theatre, similar to an abandoned ship in their town, that travelled through 5 peripheral communities by narrating stories extrapolated from the experiences of people living the peripheral areas. The aim of the project was to communicate the identity of peripheral areas of Basilicata all over Europe.
Tx	The project leader wanted to promote a totally different way to live the city. 300 Matera citizens co - created an emotional map with the project leader. This map was an exhibit that illustrates the important *places of memories* of Matera inhabitants.
Sx	The project leader's intent was to stimulate inclusion and social integration through work and art. The project leader shared and gave voice to the immigrants' talent, through a widespread academy, organizing workshops and events.
Lx	The project was a sort of itinerant Museum. The project leader revised some stories narrated by local communities concerning some objects recovered in the Mediterranean areas. Through the project, the organization wanted to create a bridge in the Mediterranean area and spread the real essence of the place identity.
Ax	The project leader produced a film to highlight some big issues of the peripheral European areas and involved the community in the production Literacy and in the cinematographic work. The objective was to promote a cinematographic language, stimulate the audience development and education and give voice to the territories of Basilicata.

About the scope (why), all the project leaders worked to stimulate social innovation as a source of growth and wellbeing and to translate the value dimensions proposed in the bid book of Matera 2019 into concrete purposes and activities by means of their projects.

The focus of each project, indeed, was the active participation of permanent and temporary citizens and the development of co-creation activities.

The analysis of the in depth interviews with the project leaders has highlighted some keywords characterizing the scope of all the projects, i.e. comparison, dialogue, encounter, memory, awareness, identity, integration, change and construction. These "key words" were the leitmotif of each project.

The interviews have also confirmed that in each project citizens were considered key resources to build and communicate the real identity of Matera 2019. Through their deep engagement in cultural activities, citizens experienced European social values, opened their minds, approached new ways of thinking, etc. In the same time, they had the opportunity to share with the rest of the world the ancient history of the city, its uniqueness, its renovation and its values.

The process and the resources (how) used by project leaders were quite heterogeneous. They employed different amounts of human, financial and material resources to accomplish their projects and chosen different methods to involve citizens. Moreover, some projects had international breath, while other ones were developed basically at local and national level.

About projects' stakeholders (who), the citizens were the main stakeholder. Thy were actively involved as volunteers and co-creators by each project leader in various phases of project, from the design phase to its implementation. Further stakeholders, involved, albeit to varying degrees in the various projects, were public bodies, associations, institutions and companies.

Finally, about the schedule (when) and the place (where), all the projects, after a crash test in 2018, were implemented during the 2019 and followed different calendar. Most of the evaluated projects were developed in Basilicata. In few cases, the project leaders decided to perform in national and international contexts.

The impacts of big cultural project on cultural organizations

The evaluation of the project impacts on the cultural organization leading it, interested three different areas: business model innovation and strengthening, capacities building, and growth and position in creative and cultural sector.

Business model innovation and strengthening

The analysis of changes occurred in business model innovation and strengthening as result of Matera 2109 experience was conducted referring to the seven components of Business Model Prism (2017).

From the interviews' analysis it arose that the participation to the ECOC program reinforced the value propositions of all the examined organizations. It is about value propositions mainly focused on promotion of cultural regeneration, enhancement and strengthening of awareness and identity of communities, regeneration of peripheral areas, by means of arts and cultural activities.

All the project leaders stated that Matera 2019 corroborated their purpose of using arts as a social enabler, a tool to connect people and a powerful channel to communicate with citizens and communities.

As a consequence of Matera 2019, the examined organizations have defined new strategic objectives or merely revised the old ones, in order to capitalize as much as possible their projects and the overall ECOC experience.

Even if each organization defined its peculiar objectives, there are some macro objectives that all the organizations mentioned in the interviews, such as:

- Reinforcement of cooperation at national and international level;
- Participation to international/ European calls;
- Scalability and capitalization of methodologies founding the implemented projects;
- Continuation of the project activities at regional, national and international level;
- Enlarging and improvement of the executed projects, by involving also public bodies;
- Achievement of financial sustainability in medium/ long term (without public funding).

All the examined project leaders faced the challenge to carry out a complex project with a medium budget.

This pushed them to modify and reorganize their internal processes. In particular, they learnt how to improve:

- Complex processes management - in particular cost and time management;
- Objectives' achievement by focusing on efficiency and time management;
- Projects' selection;
- Simultaneous management of parallel processes and activities;
- Programming and management of advertising, promotion and marketing;
- Communication activities, especially communication through social media.

The participation to the ECOC program, allowed the analyzed organizations to enhance their organizational, relational and human capital.

First, in the designing and planning of such huge cultural projects, organisations have developed innovative methodologies that now represent strategic assets that can be used to design future projects and activities.

The participation to the program encouraged also a wider use and adoption of technological solutions. Every project leader has improved its website and communication channels and has started to use social channels, (combined with traditional ones), innovative apps and technologies (e.g. AR, VR), in a more systematic way.

The participation to the ECOC program, allowed to the project leaders to acquire new competences and technical knowledge as well as an increased level of recognition and reputation at local and national level.

Unfortunately, the positive wave of impacts did not result in an increase of stable partnerships. The development of the projects allowed the project leaders to widen the networking with other actors in the creative and cultural sector and with public and private bodies, at a local, national and international level. However, these networks, turned into stable partnerships just in few cases.

Referring to stakeholders' network, the situation was different. In general, all the project leaders widened their networks, as a consequence of their project activities and their increased reputation.

They reinforced their relationships mostly at a local level. Most of the new or improved relationships involve:

- Local communities;
- Public administrations (even if in some cases public administrations slowed down the regular project development);
- Public bodies (e.g. schools, universities);
- Associations and organizations that operate in the creative and cultural sector;
- International artists and artistic organizations.

None of the mentioned changes that occurred in the business model can be properly exploited in the future without a stable financial situation and economic resilience.

The impact of ECOC participation on the financial dimension of business model was the most debated one. The project leaders payed in advance their project suppliers (with temporary debts). Unfortunately, the rules for expenses reporting were not clearly defined and were corrected many times during the projects development. This has generated frustrations and financial worries among the project leaders. From the interviews it arises that the major organisations 'concerns for the future are:

- The recovering of financial resources needed to capitalize the outputs of their projects. In this regard, the project leaders claimed their willingness to rely more on private funds (e.g. sponsor) and on their own profits rather than on public funds. They aim to obtain new funds thanks to the participation at public/European calls and to find new ways to exploit the value of the project outputs.
- The absence of policy directions and programs for capitalizing as much as possible the projects.

Capacities building

Human resources play a key role in the management of complex events such as the ECOC. For this reason, Matera Basilicata 2019 Foundation designed a capacity-building program (i.e. Build Up) for local cultural organizations involved in Matera 2019 activities. The characterizing topics of the program were: guidance to collaboration, overcoming state assistance dependency, setting up international networking, researching new models of sustainability and entrepreneurship, sensitiveness to social issues.

The Build-up process allowed to the project leaders to acquire a common language linked to the philosophy of Matera 2019 and to the development and implementation of the projects.

Overall, the Build-up phase was appreciated by the project leaders as an innovative training practice and a legacy for future ECOCs. However, the interviews analysis revealed non-homogeneous opinions regarding the Build Up effectiveness for the improvement and development of participants' competences. Most of the interviewees stated that attending the Build Up allowed them to improve their competencies merely in the following areas: communication, event organization and digital content management. In fact, according to the project leaders' opinions most of their knowledge and competencies enhanced mainly by implementing project activities, learning by doing and maintaining great perseverance. The project leaders improved their ability of how managing time, costs and teams effectively in complex settings, as well as they increased their willingness to set up international networking especially by planning and implementing their project.

Growth and position in creative and cultural sector

Most of the interviewed project leaders stated that their participation to the ECOC program did not result in more stable, improved and durable relationships with other cultural organizations operating at local and regional level.

Additionally, all the interviewees affirmed that despite the undeniable growth of organization's reputation and image, their position in creative and cultural sector is not changed. Undeniably being key actors of a mega event such as Matera 2019, has given them the opportunity to be associated to a strong brand. However, this has not changed meaningfully their position in the creative and cultural setting.

According to the project leaders this was motivated by several issues. Among these, the absence of a common vision and mission for all the actors operating in creative and cultural sector at local level, the reluctance to exchange and share information among the same actors, the lack of a stable and durable financial resilience.

About growth, all the interviewees stated that participating to a big and complex program such as Matera 2019 was a unique opportunity. Unfortunately, according to the respondents, the ECOC legacy is still undefined and there are not clear programs for the future. In this regard this study detected a high level of disenchantment and frustration among the respondents.

Even though there is not a common vision and clear plan of growth for cultural organizations that contributed to build and implement ECOC program, every project leader is formulating new solutions to capitalize and enhance its project.

However, this is not enough to guarantee a successful ECOC legacy. The positive waves generated by Matera 2019 will disappear quickly if all the different private and public actors involved in the mega event will fail to identify policies and concrete growth perspectives for local communities and production systems.

5 Conclusions

This research has focused on an analysis of the impacts of big cultural projects on business model, capabilities, growth and position in creative and cultural sector cultural of organizations leading the projects, in a European Capital of Culture.

The study has adopted an exploratory approach based on multiple case studies. The cases regarded five cultural organisations, namely project leaders, that have lead as many big projects within the Matera ECOC 2019 programme.

The analysed cases have provided a consistent scenario for deepening understanding of changes experienced by cultural organisations engaged in the development of big projects in ECOC context.

In particular, the on-field analysis showed that Matera 2019 has represented a fundamental opportunity of development and growth for the examined organisations. After the ECOC experience, they can leverage their strengths and reinvent their future in an Open future perspective – as the Matera 2019 slogan says.

However, the research has also revealed several problems faced by the investigated project leaders during and after the mega event.

The following table summarizes the main impacts on business model innovation and strengthening, capabilities, growth and position in creative and cultural sector, arose from the interviews. The impacts are reported according to the SWOT analysis template.

Table 2. SWOT analysis of the program

Strength	Weakness

- Improved knowledge and competences for:
  ▪ Management of complex projects;
  ▪ Management of simultaneous projects and activities;
  ▪ Communication;
- Higher reputation at local and national level (in a limited way at international level);
- New artistic and cultural outputs to capitalize;
- Improved planning ability;
- Research of new sustainable models that, over time, allow to reach a stable financial sustainability;
- Improved marketing/ promotion and advertisement capabilities;
- Scalability of the methodologies founding the projects;
- Reinforced relationships with the local communities (with some PA, citizens, associations and schools)
- New relationships with artists, organizations of creative and cultural sector and public organizations.
	- Lack of adequate financial and tangible resources to capitalize the projects;
	- Limited relationships with:
	  ▪ The other project leaders;
	  ▪ PA;
	  ▪ National and international institutions;
	- Uncertainties concerning the project accounting (timing and rules changed many times during the development of the projects);
	- No availability of suitable spaces for further development of the projects.

Opportunity	Threat
- Strength and awareness – at national and international level; - Attractiveness of Matera for new private investments; - Acknowledgment of Matera as a place where to live and create culture, innovation, good practices and economic growth; - Matera as a central point in the regional and extra regional tourist dynamics.	- Lack of cooperation between the project leaders – they are still not an influential group; - Lack of public program and policies, aimed at gaining a common vision and mission for all the project leaders; - Lack of common policies and programs formulated with the project leaders –regarding post Matera 2019; - Uncertainties about the availability of public funds to capitalize the outputs of the implemented big cultural projects, i.e. artistic and cultural, tangible, intangible and organizational heritages.

The results of the study are essential to understand more in depth how Matera 2019 has affected capacity of cultural organisations engaged in the ECOC program, to sustain themselves and develop. They offer an accurate picture of the effects generated on microscale and provide useful insights about the perceived legacy.

This study focused on a few number of project leaders involved in Matera 2019 program. Therefore, the research results cannot be generalized. Future developments of the study regard the implementation of further case studies as well as a longitudinal evaluation of the projects impacts.

Abstract

Over the past few decades, the attributive point of view on “information” entered the discussion as something constituting or directly characterizing the physical world. Thus, some scientists, like L.Floridi, began developing the "philosophy of information." In the 80s, a four-level representation of "knowledge" spread (DIKW-structure), preceded by two-level representation. The basis is “data (concepts)” – individual facts characterizing objects, processes, and phenomena of the subject area. The DIKW-structure includes "data (concepts)", "information", “knowledge” itself and “wisdom”. For the two-level structure of “knowledge” graph and other mathematical methods of representation and processing have long been used, but not for DIKW. In 2012, a version of the graph and mathematical representation of the DIKW-structure was published in Russia. This shows that the four-level representation is most constructive for working with knowledge and information, and also provides the opportunity to objectively understand different approaches to information, their rationale formerly built on a verbal basis. We go from 500 different definitions to 6 small groups. A powerful group of attributive point-of-view remains as “information1”. “Information2” is the result of actions/communications of highly-organized living or technical entities. The Shannon approach based on statistical estimation is called "information3". Information derived from a data-links is “information4”, corresponding to “information” (in narrow sense) used in DIKW-structure of knowledge. The sentence plays an important part, acting as “information4”. From the linguistic point-of-view, it carries a semantic content, from the semiotic - a set of signs. The legal definition of information is called “information5”, defined as “the total amount of knowledge accumulated by mankind”, the “information in a broad sense”. Such an interpretation is the result of combining all types of knowledge components from the DIKW structure in a graph representation based on the

rules of discrete mathematics. This graph G is very complex, can also be obtained practically, in a special form based on the technology of direct imposition of knowledge via methods of AI and computer linguistics. The philosophical point-of-view we'll call "information6". An ontological comparative analysis of the four-level structure of knowledge with some interpretations of information and knowledge was carried out.

Keywords – data, information, knowledge, knowledge structure, wisdom.

Paper type – Academic Research Paper

1 Introduction

Scientists have been studying the problems of "*knowledge*" for thousands of years and began to pay attention to the problems of "*information*" only from the beginning of the twentieth century. A few decent interpretations of information existed already, based on semiotics (Eco, 2016), emerging from linguistics, but they gradually grew irrelevant. So, while some scientists worked only with "knowledge" (Alexeyeva, 1993), others - only with "information" (Floridi, 2011; Chernavskiy, 2009; Kolin, 2010). Few understood their tight interconnection (Cleveland, 1982; Ackoff, 1989; Zeleny, 2000; Kamp and Stokhof, 2008). Many definitions of "information" and "knowledge" appeared, in particular, the definitions of "information" numbered more then 500 (Beckman, 2009).

For a long time philosophers were engaged in the problems of knowledge (Alexeyeva, 1993). In the second half of the twentieth century, IT specialists actively joined in this, in particular, the area of "artificial intelligence" (AI) (Newell, 1982; Pospelov, 1990). To actively work with "information" and "knowledge", they applied various mathematical models, and began to move further away from the ideas of philosophers. Part of the clash took place about implicit knowledge (Polanyi, 1974).

Statistical theory of information (STI) of C.Shannon was a great success (Shannon, 1948). Some scientists decided to develop this success based on the *Theory of Semantic Information* (TSI) (Bar-Hillel and Carnap, 1953). However, they simplified the presentation of the semantics of the transmitted information, and information contained in texts, in comparison with the achievements of linguistics/semiotics. Constructive results were limited, as indicated by L.Floridi (Floridi, 2011).

Over the past few decades, the *attributive point-of-view* on "information" has begun to be discussed as constituting or directly characterizing the physical world (Burgin, 2016). At the same time, some scientists, in particular, L.Floridi, began to develop the "*philosophy of information*" (PI) (Floridi, 2011).

In the 80s, a *four-level representation* of "knowledge" spread (DIKW-structure) (Cleveland, 1982; Zeleny, 2000). Before that, a *two-level representation* was used in AI research (Newell, 1982). The DIKW-structure includes "*data* (*concepts*)", "*information*", "*knowledge*" itself and "*wisdom*". For a two-level structure of "knowledge", graph and other mathematical methods of representation and processing have been successfully used

for a while. But for DIKW-structure this was not done. In 2012 and subsequent years an approach to the graph and mathematical representation of DIKW-structure got published (Bronfeld, 2012b; 2016a; 2016b) and validated. This shows us that the four-level representation that is the most constructive for working with knowledge and information, and, on the other hand, provides an opportunity to objectively understand the different approaches to information, the rationales of which were built on a verbal basis. Then the number of definitions of "information" begins to fall, some turn out to be wrong, some duplicate the semantic meaning and you can go from 500 definitions to 6 small groups of definitions.

It should be noted that PI was actively developed and supported (Grnkovic and Hofkirchner, 2011; Burgin, 2016). Unexpectedly, the situation has escalated, the question arose about the existence of philosophy in a form that has been formed over thousands of years. Even L.Floridi himself claims "PI risks becoming synonymous with the philosophy" (Floridi, 2011). Some other scientific and technical areas also came under attack and peculiar interpretations. We act as representatives of the direction of AI, and we hope that our ideas will protect several scientific and technical areas, while the fate of the philosophy is for philosophers to decide.

2 Approach to the classification of points-of-view on information

There's a powerful group with an attribute point-of-view on information, as a component or directly characterizing the physical world. It's supported by some philosophers, physicists, and other scientists (Kadomtsev, 1999; Kolin, 2010; Burgin, 2016). Included are adherents to the theory of dynamic information (TDI) (Chernavskiy, 2009). We call this group of definitions "*information*1".

"*Information*2" is the result of actions/communications of highly-organized living or technical entities. (Wiener, 1948). STI of Shannon (Shannon, 1948) based on a statistical estimate of the amount of information, we'll call "*information*3".

Information derived from a data-links is "*information*4", corresponding to "information" (in narrow sense) used in the four-level structure of knowledge (Zeleny, 2000). It has many supporters from seemingly different backgrounds. Similar formulations appear among various respected specialists, for example, J.Martin (Martin, 1977), L.Floridi (Floridi, 2011), Russel S. and Norvig P. (Russel and Norvig, 2002).

The "*sentence*" plays an important part, acting as "information4". For linguistics, it carries a certain *semantic content* - propositionallity, for *semiotics* - a set of symbols. V.Tsvetkov (Tsvetkov, 2012) suggested calling it a *semantic information unit* (SIU), professor MacKay (MacKay, 1969) suggested calling it *logon* to calculate the amount of information.

The legal definition of the term "information" occupies a special place (RF FL, 2006) as "*information*5", "...information is: information (messages, data) regardless of the form of their presentation...". In (Verevchenko et al., 2002) it's noted that this interpretation is more important than just the legal "concept of "information" can be defined as the total

amount of knowledge accumulated by mankind." Let's call "information5" – "information in a broad sense." Such an interpretation is obtained via superimposing all knowledge components from DIKW-structure on each other in a graph representation based on the rules of discrete mathematics. This graph G ("information5") is very complex. It can also be obtained practically, in a special form based on *the technology of direct imposition of knowledge* via methods of AI and computer linguistics as described in (Bronfeld, 2012a; 2014a; 2014b).

The philosophical point-of-view on information, which includes PI, we'll call "*information6*" (Floridi, 2011; Grnkovic and Hofkirchner, 2011; Burgin, 2016).

3 Analysis of knowledge representation structures and ties to information

Now let's pay more attention to knowledge. Firstly, we'll look into scientific knowledge, personal knowledge, and the surrounding nature.

"Scientific knowledge claims to adequately reflect reality and speaks in the name of truth" (Kokhanovsky et al, 2004).

Personal knowledge is knowledge of a particular person, reflecting their experience and ideas about reality, usually not theoretical and systematic in form, and which helps them to navigate the world (Kokhanovsky et al, 2004).

Reality is the world around us with the totality of all existing objects, their interconnections, and natural phenomena (Kokhanovsky et al, 2004). Reality is objective and exists independently of a person, although there're other points of view. Let's, for now, consider the basic concept for many scientific and technical areas, which is also the basis of epistemology.

In any case, a person can describe the world only with the help of linguistic means, recorded as texts (Solomonik, 2016).

A text is a sequence of symbolic units united by a semantic connection, the main properties of which are connectivity, integrity, completeness, etc. Typical representatives of the structural-semantic units are words that serve as certain concepts, reflecting phenomena of reality.

Personal knowledge a person can express either with linguistic units or actions (Polanyi, 1974), which are also described using texts.

It turned out that we have concepts or data that reflect the level of certain parameters of reality (known or unknown to us) and expressed in the textual form (Kamp and Stokhof, 2008).

Let's take into account that knowledge is divided into explicit and implicit (Polanyi, 1974; Russel and Norvig, 2002), focusing on scientific knowledge, personal knowledge, and the surrounding nature.

To describe knowledge in AI, an idea of a two-level structure of knowledge, most widespread, has long since been formed (Newell, 1982; Russel and Norvig, 2002). The basis is data (concepts) - individual facts characterizing objects, processes, and

phenomena of the subject area with their properties. Then knowledge is well-structured data or data about data - metadata.

3.1 Four-level knowledge representation

Let's consider in more detail the four-level representation of knowledge, which we think is a more interesting concept of the systematology of knowledge in relation to information, and is acceptable for describing scientific knowledge, personal knowledge, and reality. Then, from the perspective of new results, we'll analyze the mentioned structures again.

Per DIKW-structure (authors M.Zeleny (Zeleny, 2000), H.Cleveland (Cleveland, 1982) and close to them in essence, R.Ackoff (Ackoff, 1989)) knowledge consists of:

- data (concepts);
- information;
- knowledge (in a narrow sense);
- wisdom.

Data is "...simplest element of knowledge, its purpose is unclear and ambiguous, it has a large degree of freedom..." (Zeleny, 2000).

"Information is characterized by higher concreteness of the goal, with combining of concepts or data ... Once the data is converted into information, it's difficult to return it to its original state (just as it's impossible to reconstruct individual observations from their average value) ..." (Zeleny, 2000).

"Knowledge covers the real process of processing input data ... including coordination of actions to achieve results, goals, or obtain products" (Zeleny, 2000).

"...wisdom is related to explainability: if a person knows why - not just what and how - then he's not only well-informed or well-grounded but possesses knowledge and competence..." (Zeleny, 2000).

This approach accurately describes the view of M.Zeleny (Zeleny, 2000) on knowledge - "...knowledge is a purposeful coordinated action...". Its only evidence or method of demonstration is to achieve the goal. Its quality can be evaluated by the quality of achievement (its product) or coordination (its process), especially if uncontrolled factors interfere.

Let's clarify some concepts, firstly, data (concepts), though this proves to be very difficult.

What can act as basic data elements? It's (Martin, 1977; Floridi, 2011) a number, aggregate of numbers, word (concept), phrase, individual letters and sounds, elements of graphics, images, audio and video recordings. Moreover, from any kind of media, both printed, handwritten, and machine sources, as recordings of individual signals from any kind of sensors.

What's important, the data can appear as a result of any type of processing, manual or machine-based, and take the form of tasks (orders) from a person. For systemics, what we consider "data" at the moment, will be considered as such in a specific system.

The basic data elements (X) will be represented as a set of unconnected vertices $v_1, v_2, \dots, v_i, \dots, v_k \in V$ (fig.1).

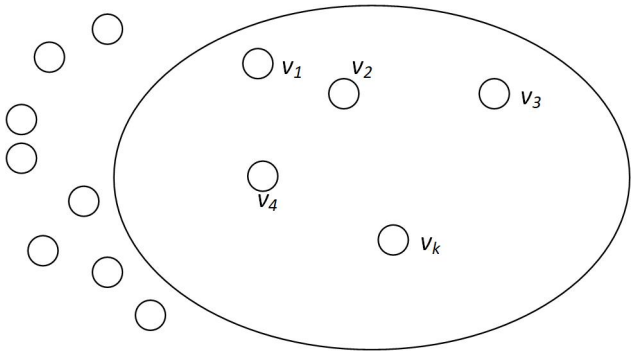

Fig.1 Data

On other components of the DIKW-hierarchy more below.

The well-known abovementioned representation of knowledge models as a two-level structure using semantic networks, which can be described as an undirected graph $G(V, E)$, where V – vertices, E – edges (relations) between them. Vertices correspond to definitions of data (concepts) in the form of a set X. Definitions of types of relations (connections) are defined as the set T connected by mappings $D: X \to V$ and F: $T \to E$.

3.2 Formal representation of the four-level structure of knowledge

Let's extend a formal representation of a two-level structure of knowledge to four-levels:

- data (concepts) – vertices V' of the graph $G_D(V', \emptyset)$ correspond to them, where $E = \emptyset$ - fig.1 (V' and E' to be defined later);
- information – graph $G_I(V', E')$, has at least one edge – fig.2;
- knowledge – path in the graph leading to a certain result (vertex) – fig.3;
- wisdom – explanation why this particular path is chosen from an infinite set – fig.4.

Data (concepts), in particular, include vertices $v_1, v_2, \dots, v_i, \dots, v_k \in V$ (fig.1), which are set directly. However, when solving a specific problem, an unlimited additional set of data may be required V_g, moreover $V \cup V_g = V'$ - the original fixed set X and additional X_d, analogously connections are fixed T and additional T_g, and $D_g: X_g \to V_g$. Therefore $D \cup D_g = D'$.

Both scientific knowledge and personal knowledge are full of additional data and concepts X_g (with connections T_g), relevant to reality, and necessary to solve emerging problems.

Information (fig.2) includes edges $v_1v_4, v_2v_4, \dots, v_3v_k \in E$.

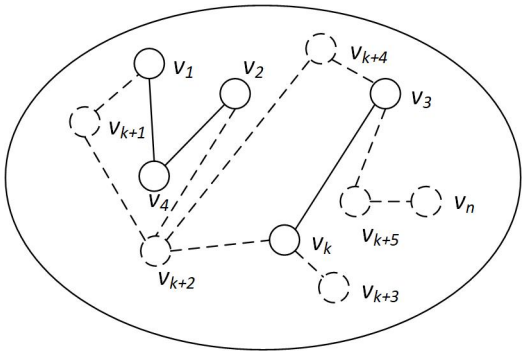

Fig.2 Information

I.e. hidden next to the basic data set V, an additional data set (concepts) V_g implicitly appears, connected with the initial data (concepts) in some way.

$v_1v_{k+1}, v_{k+1}v_{k+2}, v_2v_{k+2}, v_{k+2}v_{k+4}, v_{k+2}v_k, v_{k+4}v_3, v_kv_3, v_kv_{k+3}, v_3v_{k+5}, v_{k+5}v_n \in E_g$

These connections can apply to both *explicit* and *implicit* (personal) knowledge.

Then $E \cup E_g = E'$, which corresponds to $F_g: T_g \to E_g$ and $T \cup T_g = T'$.

The knowledge (fig.3) is known here, correspondingly, the solutions are known. But if the solution is unknown? This is what a new technology for IS-development based on TDIK is aimed at. Bear in mind that for many specific tasks (problems) it's initially known that there's a solution, just need to determine which one, specific parameters and clarify the implementation process

.

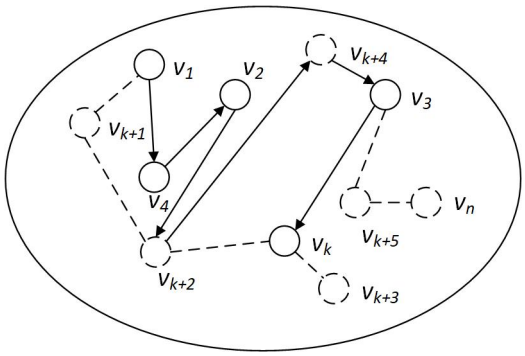

Fig.3 Knowledge

In fig.3 it's a set of specific routes from a group of starting vertices $V^0 \subset V'$ to a group of ending vertices $V^R \subset V'$:

$s_i = v_1 v_4 v_2 v_{k+2} v_{k+4} v_3 v_k \in S$,

where $v_1 \in V'$, and $v_k \in V^R$, $v_1, v_4, v_2, v_{k+2}, v_{k+4}, v_3, v_k \in V_S$,

$v_1 v_4, v_4 v_2, v_2 v_{k+2}, v_{k+2} v_{k+4}, v_{k+4} v_3, v_3 v_k \in E_S$,

and knowledge is a graph $G_K(V_S, E_S)$.

Wisdom (fig.4) is in explaining why a specific solution is needed compared to others, in a multitude of interpretations M_{si}, the usefulness of the i-th path s_i:

$m_{si} = v_{k+1} v_{k+2} v_k v_3 v_{k+5} \in M_{si}$.

And wisdom itself can also be represented as a graph $G_W(V_{M_{si}}, E_{M_{si}})$,

where $v_{k+1} v_{k+2} v_k v_3 v_{k+5} \in V_{M_{si}}$, $(v_{k+1} v_{k+2}), (v_{k+2} v_k), (v_k v_3), (v_3 v_{k+5}) \in E_{M_{si}}$.

In the explanation m_{si}, data can be used that's not involved in the original description V, but which is included in V_g.

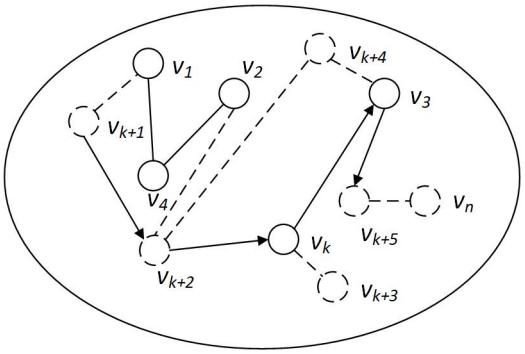

Fig.4 Wisdom

Let's note, graph $G_I(V', E')$ can generally have the form of a hypergraph with increasingly complex types of connections, and the paths s_i and m_{si} can have closed loops with the repetition of vertices and edges. A simpler example is considered here, more complex representation in any nonlinear variant won't change the essence of the issue.

It should be noted that graphs $G_D(V', \emptyset)$, $G_I(V', E')$, $G_K(V_S, E_S)$, $G_W(V_{M_{si}}, E_{M_{si}})$ can be combined the join operation of discrete mathematics, since $V_S \subset V'$, $V_{M_{si}} \subset V'$:

$$G_U = G_U(V', E') = G_D(V', \emptyset) \cup G_I(V', E') \cup G_K(V_S, E_S) \cup G_W(V_{M_{si}}, E_{M_{si}}) \quad (1)$$

The graph G_U is shown in fig.5, where it's shown that all vertices V' can be directly or potentially connected. The graph G_U is the "information5" - information (in the broad sense) that we've already talked about. The V' contains all information (concepts) available to a person, both specifically for the task being solved, and in any possible variant of its expansion. Within G_U are not only all possible kinds of information $G_I(V', E')$, but all possible kinds of graphs containing knowledge $G_K(V_S, E_S)$ and wisdom

$G_W(V_{M_{si}}, E_{M_{si}})$. Currently, there's no constructive option to pull some new, meaningful knowledge (a new path s_i') or explanation (wisdom) m_i' out of the chaos of the graph's connections, other than the approach worked out by millennia of consistently developing worlds science.

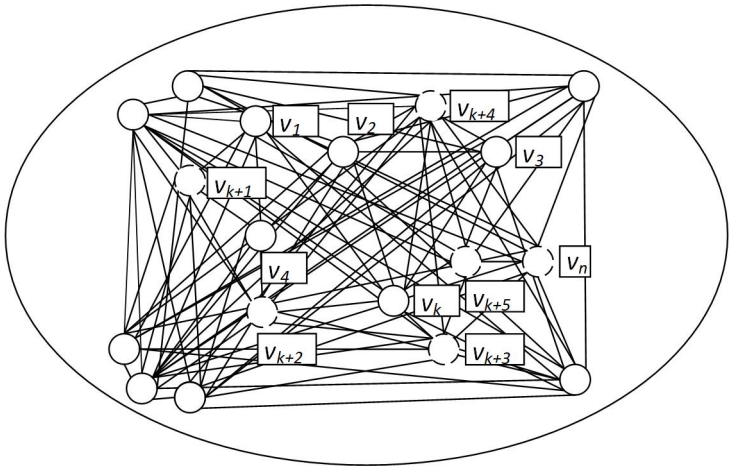

Fig.5 "Information5" – information in broad sense

The full formal description of the DIKW-structure (Bronfeld,2012b;2014b):

$$ZN = < X'^0, X'^R, D', F', G_I(V', E'), S, M_{sk} > \quad (2)$$

where X'^0 – subset of initial datapoints (concepts), $X'^0 \supseteq X^0 \subset X \subseteq X'$,

and X'^R – subset of final datapoints (concepts), $X'^R \supseteq X^R \subset X \subseteq X'$, relatively to which knowledge exists;

D' – definition of source data (concepts);

F' – definition of connections;

$G_I(V', E')$ – information;

S – paths on the graph that provide a useful transition from the initial subset X'^0 to final subset X'^R;

M_{sk} – interpretations explaining the utility of the k-th path s_k.

4 Ontological comparative analysis of the four-level knowledge structure with some of information and knowledge definitions

Let's carry out an ontological analysis of existing theories using a wider range of concepts, including meaning. We won't proclaim our creative impotence in the face of diverse nature, as a considerable number of authors do (Fridland, 2008; Grnkovic and Hofkirchner, 2011; Burgin, 2016),

We'll analyze the situation with the key definitions "information2", "information3", "information4", "information5" and identify some of their ontological connections between them and the DIKW-structure of knowledge.

We'll start with the data, having already examined its conceptual interpretation in section 1. It can include individual numbers, signals, and words – concepts (Martin, 1977; Verevchenko et al., 2002; Floridi, 2011; Solomonik, 2016). On one hand, it's known that the parameters are measured with certain accuracy and subjected to specific processing, often strictly standardized (ISO/IEC, 2009), on other hand, the verbal concepts are vague (Zadeh, 1973; Solomonik, 2016). L.Floridi (Floridi, 2011) also speaks about this and puts forward special, not easy to satisfy, requirements for the veracity of data.

The sharp contradiction between the real problems of practice (Zadeh, 1973; Dibrova et al,2008) and some theoretical constructions is important, for example, D.Chernavsky (Chernavskiy, 2009) - "…Information is the remembered choice of one option from several possible and equal…". This definition applies to data. What's different and equal about options in "the apple is on the table"? If the apple is a lemon, then information is completely different. Each concept may be inaccurate, but not so much as to be considered equal, although exceptions do occur. We must recall the point-of-view on the meaning of the speaker and the perceiver - "the speaker ... in the ability to express the same thought in different ways, and the listener in the understanding of semantic identity or the similarity of outwardly different statements" (Zholkovsky and Melchuk, 1967). The same contradiction is in (Brillouin, 1964).

Some have already sunk to levels of - "Information exists... It doesn't require mental efforts for interpretation. To exist, it doesn't need to make sense." (Stonier, 1990). But for the widest areas of scientific and technical fields, data/information without meaning is useless.

Moving on to "information2". The main interpretation here is the many definitions related to versions of the *theory of reflection*, both by man and sophisticated technical means (Wiener, 1948; Ursul, 1973; Fridland,2008), which may also be associated with information transfer processes. The peculiarity of such definitions is in only tracing how "something" is perceived by a person or complex technical means, without saying anything about what this "something" is. But since this process of "reflection" is taking place, it cannot be ignored, especially when transmitting information. Therefore, we'll use definitions of the "information2" as auxiliary ones.

This group also includes the "*semiotic theory of information*" (SemTI) (Eco, 2016) and TSI (Bar-Hillel and Carnap, 1953; Floridi, 2011; Zercal, 2014a). We'll note that SemTI is

a serious theory and science of semiotics, tried and tested for more than 100 years, and has serious practical applications. It would have had a lot in explaining problems with the information, if not for relative lack of knowledge of mathematical methods among its supporters, which had pushed semiotics aside when discussing problems with information.

Then TSI came to the fore as a reaction to the great and resounding success of C.Shannon with his STI. However, it always considered very simple structures in the context of information, which was quickly noticed by professionals. I.I.Grishkin has a good critical analysis (Grishkin, 1973). Still, real information, its semantic content, which has long been studied by linguists and specialists close to them (Eco, 2016; Solomonik, 2016; Russel and Norvig, 2002), in particular, semiotics and AI experts, were more complicated than those models used in the TSI. It now looks like a “child assembling a lego-car" instead of examining a real car. But we must admit that between back then and actual application of AI methods with knowledge models and a real study of the complexity of texts and working with them was at least a quarter-century. Now even synergetics is seeing use to study the depths of textual content (Belousov,2016). The criticism of TSI by L.Floridi, who called one of its key contradictions "the Bar-Hillel–Carnap paradox" (Floridi, 2011), was already a "belated shot" at something that hadn't yielded any new theoretical and practical results except more and more new publications.

Regarding the Shannon approach in the framework of STI (“information3”) and the approach related to G – it’s suitable for obtaining vertices, and for the analysis of edges and routes in the graph of both the graph G_I and the graph G_U. Consider fig.6.

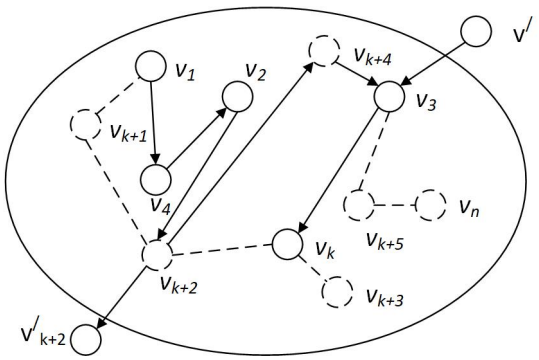

Fig.6 Interaction of the system within with the environment

It presents a system of interaction of certain data/information flows (in a narrow and wide sense) inside the system and with the environment. All real systems of this kind are open systems (Uemov, 1978), except in rare special cases when they're considered as closed. In fig.6, it's not just a transition from one vertex to another according to a formal representation, there can also be some data/information flows, for example, from v_1 to v_4

or from v_3 to v_k, when interacting with the external environment from v_{k+2} to v'_{k+2} or from v'_3 to v_3. Here you can apply the Shannon STI to evaluate the transfer of data/information, calculate the bandwidth, provide noise immunity, etc..

The STI fits perfectly with the four-level approach to the structure of knowledge (Cleveland, 1982; Ackoff, 1989; Zeleny, 2000) and people supporting this approach (Russel and Norvig, 2002; Tsvetkov, 2012; Zercal, 2014b), even more so in the advanced version (Bronfeld, 2012b; 2014b; 2016a; 2016b; 2017). There's no conflict here, and the semantics associated with connections and structures at the level of knowledge and wisdom have nothing to do with Shannon's approach.

Definitions of "information4" are among the main ones in our consideration. Firstly, the definition of information as a "data structure" which is the basis of the DIKW-structure of knowledge, discussed in section 3. The same view corresponds to a structural approach to information, supported explicitly or implicitly by very prominent specialists and scholars – J.Martin (Martin, 1977), S.Russel and P.Norvig (Russel and Norvig, 2002), academician A.Ershov (Ershov, 1988). The key point of the approach to the GDI information structure from L.Floridi fully consistent with the definition of information in paragraph 3.1 and graph G_I.

Here goes an idea of D.M.MacKay (from the 1950s) on the structural representation of units of information as a whole - sentences, and calling it logon (MacKay, 1969), and counting the amount of information in logons, each of which can carry its semantic content. Sadly, people didn't listen to him and almost forgot, while this proposal was perfectly aligned with the approach of linguists and semiotics, and later wouldn't contradict the direction of AI.

V.Ya.Tsvetkov's modern point of view considering "…the sentence of the text as a semantic information unit (SIU), which has indivisibility in the semantic union of related words and expresses a complete thought…" is also aligned with this view (Tsvetkov, 2012).

Already noted, data - corresponds to the vertices of a certain graph *G*. Information (in the narrow sense) is a graph G_I, with at least one edge (set of different graphs) with vertices from $G(G_I \subset G)$. Then knowledge (in the narrow sense) is a path/s in the graph $G(G_K \subset G)$, leading to some result. Wisdom – the clarification of why this particular route was chosen for specific knowledge – representing paths, differing than for knowledge. "Information4" is a set of subgraphs G_I in graph $G(G_I \subset G)$.

The legal definition of the "information" is very important (RF FL, 2006,Verevchenko et al., 2002), named by us "information5" (Bronfeld, 2012b; 2014b; 2016a; 2016b) - "Information (in the broad sense)". Per it - "...information is "data (messages, signals) regardless of the form of its presentation..." (RF FL, 2006). It's also obtained via the mathematical operation of combining the graphs of "data", "information (in the narrow sense)", "knowledge", "wisdom" in the form (1). As a result of (1), we obtain a very complex graph G_U – the graphical representation of "information5".

A way to do this not only mathematically, but practically, via the TDIK in the framework of AI and linguistics methods, is described in (Bronfeld, 2012a; 2014a; 2014b; 2017).

It's necessary to clarify that since in the general case the components of "information5" may initially not be interconnected, be very heterogeneous, and when superimposed, new relationships arise that completely distort the original ones (even for just two components), then collectively, this new entity hardly deserves a name other than "garbage" (fig.6). There's a gigantic difference between the original "information4", which may carry some kind of small semantic content and "information5". For STI this doesn't matter as anything can be sent via the transmission channel in any form, incl. encrypted.

But many don't share these concepts/states of the term "information", building it up, almost as "…foundation of the world…", for example, as I.Yuzvishin (Yuzvishin, 2000), T.Stonier (Stonier, 1990), M.Burgin (Burgin, 2011). Certainly, some subject areas can use their private terms for their purposes, which is connected with the well-known problem of the fuzziness of natural language, but in our opinion, it's not serious to substantiate and solve certain general scientific problems on this basis.

On this point, I.Kant wrote his famous work "Critique of Pure Reason" (1781), expressing the point-of-view that all our ideas are subjective, we can go far in our minds, but we need to verify this with theory and practice and gradually reveal the "thing-in-itself".

Now, about the what we called "information6" (Bronfeld, 2012b; 2016a; 2016b). It includes the most popular "philosophy of information" (Floridi, 2011; Burgin, 2016), as well as several others. One of its main promoters in the world is L.Floridi (Floridi, 2011; Grnkovic and Hofkirchner, 2011). It's interesting that he actively applies fairly complex mathematical methods. Among the minuses of his views from the point-of-view of philosophy is that he's trying to draw into the sphere "philosophy of information" (Kamp and Stokhof, 2008; Floridi, 2011; Grnkovic and Hofkirchner, 2011) epistemology (which philosophers have been doing successfully for more than 2000 years) and even the problems of the modern AI development. Other highly controversial philosophical concepts related to information are also known (Stonier, 1990; Yuzvishin, 2000; Burgin, 2011; Grnkovic and Hofkirchner, 2011). As already noted, these latter concepts can be considered the development of (relation of) some attributive approaches to information, wherein fantasy begins to overflow and the scientific approach along with the Occam's razor get completely forgotten.

In our opinion, people with these refinements and studies in physics and philosophy, and with disputes among themselves in the areas of "information1" and "information6" will probably spend millions of years, perhaps even with variable conclusions.

Now let's consider the ontological connections of the concepts of knowledge. As a rule, there're fewer discrepancies, firstly because philosophers have already slaved away discussing them for more than 2000 years. However, the 20th century brought new ideas.

The first of them, and one of the most discussed, is a four-level structure of knowledge (Cleveland, 1982; Ackoff, 1989; Zeleny, 2000), proposed by H.Cleveland, management specialist in 1982. Supplemented by us (Bronfeld, 2012b; 2016a; 2016b) and with mathematical justification, it turns out to be quite competitive with other concepts for mass practical use, fitting perfectly with some seemingly opposing (Kamp and Stokhof, 2008; Floridi, 2011).

From the very beginning, 2000 years ago, knowledge was considered on an *active basis* (Johannessen, 1988; Alexeyeva, 1993), which doesn't contradict the modern DIKW-structure of knowledge (Zeleny, 2000).

Even easier with unformalized knowledge (tacit knowledge) that's contained in a person's head, as M.Polani considered (Polanyi, 1974). It exists and many IT, in particular, of AI-development, are aimed at integrating it into useful activities.

In theory and practice, the concept of meaning is actively used (Averyanov, 1993; Kamp and Stokhof, 2008; Lukin, 2009). Since it's related to user perception (Lukin, 2009; Belousov, 2016), it can be ambiguous when read from texts, starting with individual sentences and individual words. This is even more emphasized in semiotics, where the important role of symbols is noted (Eco, 2016). In general (in our opinion) the concept of *meaning* contains both knowledge and wisdom, which differ in a four-level structure of knowledge (Zeleny, 2000). And the meaning is naturally contained in the texts, but linguistics, as a rule, doesn't distinguish them (knowledge and wisdom) (Lukin, 2009; Belousov, 2016), rarely even recalls information.

At last, *texts* (Kamp and Stokhof, 2008; Lukin, 2009; Belousov, 2016). It's precisely because of them about 70 years of heated discussion of the problems of "information" have unfolded. Indeed, it's their different content from individual characters to gigantic volumes, especially in an encrypted form, that will look to the outside observer like "garbage", for example, in case of a malfunction in the information transfer channel or very strong interference. It's the content of texts carried by the structures of "information" that can affect people, technologies, technical, natural objects, and phenomena. Why such confusion has arisen and has been maintained for 70 years and the severity of problems and fantasies centred on "information", is a different complicated question to answer.

5 Conclusion

As a result, the 70-year period of chaos in the problems of "information" and "knowledge" can end for practical application in many areas of science and human activity, and get a mathematically constructive basis via a four-level structure of knowledge for research in this area. This approach allows you to go from 500 different definitions to 6 small groups of definitions.

Abstract

Responsible Research and Innovation (RRI) is characterized by a different attitude towards scientific research and development processes taking in account potential impacts on the society and ecosystem previously to the actual implementation. RRI has spread as a new approach towards the design of policies, services and products including the various actors not only in the final solution but also throughout the entire development. Even this perspective has been widely discussed in theory, it is facing issues in being transformed into practice.
This article discusses design thinking in RRI as an approach to stakeholder engagement aiming at operationalizing RRI while exploring its impacts.
This is done by means of ten real-life experimentations within the project SISCODE funded under the Horizon 2020 programme.
The experiments are conducted by 10 different innovation labs across Europe launching bottom-up initiatives to work on context-based challenges producing new forms of evidence for policy makers about the effectiveness of co-design in RRI and how co-design can contribute to shorten the distance between STI policy making and society.
This potential is explored concretely to feed theoretical studies on putting RRI into practice. At the same time, it is aimed to open the practices of policy making to evidence coming from real co-design: context-based initiatives shall trigger and reinforce the learning process of policy makers to become more open to experiment with policies.
This paper describes the design research for SISCODE that is mainly based on the notion of codesign experiment in real contexts as a playground for policy makers and its following

application to verify the assumption that: local design projects developed in response to specific societal challenges could work as living prototypes for the policy makers to observe directly how codesign work and to take advantage from the evidence produced during these experiments to develop and better define policies.
The paper reports the main results obtained during 1 (January 2019-January 2020) year of experimentation in the 10 labs with respect to the engagement of policy makers and the effectiveness of design thinking as an approach to make RRI into practice. Results discussed in the following are based on the triangulation of the data coming from a self assessment exercise conducted by the labs at the beginning of the project (co-creation knowledge baseline) and after 1 year of development, and the data from the labs case studies as developed by project researchers.

Keywords – Co-design, knowledge exchange, Responsible Research and Innovation (RRI), policy making, bottom-up initiatives

Paper type – Academic Research Paper

1 Introduction

Responsible Research and Innovation (RRI) has been upcoming and spreading as a new approach towards public engagement in STI (Science, Technology and Innovation) initiatives proposing a new attitude of anticipating and evaluating potential impact of initiatives including societal actors in the field of research and innovation rather than making effort to create accurate representations of former initiatives (Wouters, 2017).

Those initiatives can be traced back to a detected lack of consciousness regarding the needs and roles of actors in the development of STI initiatives (Rask et al, 2018). Therefore, new approaches are necessary to explore those needs and include those societal actors from the beginning into the process (Jacobsen et al, 2019).

The emergence of RRI practices therefore does not only determine project results, but mainly the way in which participants relate to each other and collaborate as well as the manners and methodologies of work. Including actors into the development to obtain a more holistic view and better predict impacts makes it a promising approach towards the development of STI initiatives raising the interest of both researchers and practitioners.

Despite the amount of attention RRI has received in the field of research and theory, it has been struggling to prove its potential in practice and its capacities to make an impact (Rowe and Frewer, 2005; Emery et al 2014).

This can be traced back on the lack of evidence of impact on policy, and lessons of what worked are still very limited (Deserti, Rizzo & Smallman, 2020). This appears to be because there has been little research into policy impact (Rowe and Frewer, 2005; Emery et al 2014) and because research has found little evidence of impact (Hansen & Allansdottir, 2011; Kurath & Gisler, 2009; Loeber et al., 2011). The reasons for the lack of impact focus on the reflexivity of the policymaking institutions – that the problems policy sets out to solve and the role of STI in that solution is pre-determined and not open for discussion. This leads to potential misunderstandings and frustrations as public

participants feel simply being asked to market-test the acceptability of technologies while institutions appear to see public participation as a way to gain trust for a predetermined approach, rather than to rethink policies and practices (Chilvers, 2012; Macnaghten & Chilvers, 2014; Stirling, 2007; Thorpe & Gregory, 2010; Wynne, 2006). Instead, scholars argue that it is vital that the problems to be solved and the kind of solutions sought are framed by public participants from the identification of the problem to then co-create solutions. The 'ScienceWise guiding principles for participation in science and technology policy' (Sciencewise, 2018) echo this, recommending that participation commences as early as possible in the policy/decision process. They also suggest that "where appropriate, we will work with participants to agree framings that focus on broad questions and a range of alternatives to encourage more in-depth discussion. For example, we might start by asking, "How do we provide for our energy needs in the future?" rather than by asking "should we build new nuclear power stations?" (Sciencewise, 2018).

The motivation to explore the potential that co-design may hold to operationalise RRI roots in the lack of investigation in practice and evidence of impact (Rowe and Frewer, 2005; Emery et al 2014).

2 Co-design as an opportunity to operationalise Responsible Research and Innovation (RRI)

The issues stated above demand a new and different approach to overcome the existing barriers in operationalizing RRI. While the theoretical concept reached wide interest and is in line with recent trends of tackling big societal challenges (Von Schomberg, 2013) there is still a lack of definition and methodology on how RRI could be turned from a theoretical concept into practice (Von Schomberg, 2013).

Co-design and design thinking have been identified as an approach that may hold the potential to overcome those barriers (Blomkamp, 2018) since it withholds promising aspects to tackle issues identified in the operationalization of RRI. On one hand, co-design is an approach to practice that, rooted in participatory processes, allows a wide range of actors to contribute to a solution starting from the analysis of the problem until the implementation of a solution (Brown, 2009).

The variety of actors involved with diverse concerns require mutual comprehension and collaboration to align the different interests. On the other hand the particularly practice-based approach of co-design could contribute to the definition of the role and impact of citizen engagement in research and innovation development and the formulation of STI policies.

Very few contributions in RRI literature have introduced the perspective of co-design and co-creation, borrowed from the literature previously mentioned, with the aim to evolve the concept of RRI from a model of two-way communication towards a process of research and innovation development. These contributions have introduced co-creation to overcome some of the current limits and weakness in RRI aiming to:

- fill the gap on how to introduce RRI into real solutions/implementations; deal with wicked problems often identifying societal challenges and that require a non-linear model of innovation (iterative design);
- introduce a mechanism for getting equal partnership between diverse stakeholders (including citizens).

Nathan (2018) discusses the shortcomings of linear innovation process models, especially technological innovation, and introduces design thinking (and co-design) as an improved, circular responsible innovation process model, especially for wicked problems, in order to embed ethical decision-making at the organizational level by taking into consideration both internal and external stakeholders and networks. Gudowsky and Peissl (2016) report the experience conducted within CIMULACT with co-design workshops led by expert designers who involved citizens in the prototyping of different research agendas to support the idea selection process and include citizen knowledge in a European research programme. The authors underline the role of co-design tools as fundamental and a common language among the participants that were co-designing prototypes of agendas to be further discussed and re-designed.

Within the frame of the FoTRRIS H2020 project, the partners carried out a "co-created RRI experiment". Bajmócy and Pataki (2018), synthesizing the results of one of these experiments, underlined the role of co-creation as a trans-disciplinary knowledge creation mechanism for getting equal partnership of diverse stakeholders (including citizens) in concretely addressing societal challenges. Co-creation also brought a different distribution of power into the process that resulted in changes regarding the aims, the process, the timetable and the success indicators.

However, until now co-creation and RRI have developed as two separated areas of knowledge with rare intersections and cross fertilisation among each other. Even if the EU research policy has conceived co-creation as a new and promising paradigm of innovation to be funded, it has been separated from RRI as an ethical perspective from which to face science and innovation development.

In principle, upstream citizen participation in science and technology implies mechanisms to enable two-way exchanges between different publics and powerholders about technology governance with its development still in an early stage aspiring to align the goals of the techno-scientific enterprise with societal values.

However, in practice many engagement processes still "fall short in terms of true citizen participation, as an evaluation of 70 international engagement initiatives on nanotechnology found. When evaluated against the 'Ladder of Citizen Participation' most fell in the lower categories of manipulation or tokenism" (Sutcliffe, 2011).

With respect to its practical viability, RRI has massively recurred to the use of tools to support user and stakeholder engagement producing toolboxes collecting tools and instructions for future uses. RRI has primarily focused on media, political and social sciences (Burns, O'Connor, and Stocklmayer 2003; Durant 1999; Schuurbiers and Fisher 2009) where there is a long tradition of research on two- and multiple-way

communication models and tools to support the democratisation of policy making processes political decision making.

However, the tools and toolkits developed in RRI present limits and controversies that seem to be in line with findings from literature:

- tools and toolkits in RRI are developed to support the integration of stakeholder knowledge, requests and needs in policy development. These are mainly linear upstream processes rarely including long-term experimentations or a trial-and-error approach
- tools in RRI are mainly used and manipulated by researchers;

RRI practice does not include prototypes, representing a specific category of tools in design thinking culture to co-design and test solutions

On the contrary, tools and toolkits for design thinking are developed for a process of innovation from ideation to prototyping and the delivery of a solution based on an iterative process (through experimentation) to reach a solution aligned with all needs and interests identified (Sanders and Stappers, 2014). Design Thinking tools are visual-based, meant to be directly manipulated by the stakeholders allowing discussions among participants until reaching a common representation (iteration). Finally, Design Thinking is based on massive use of prototypes as particular tools to represent a possible solution and support the phase of experimentation in the process of innovation.

Therefore, the aspect of actor involvement in Design Thinking and RRI is somewhat similar and the methodologies and techniques used in Design Thinking eventually hold the potential to be applied in RRI landscapes to overcome some of the limitations mentioned above. In particular, the practice-based approach of co-design could feed this lacking aspect in RRI initiatives translating tools, practical methodologies and suggested activities from the field of design thinking into a new context of application.

The creation of this interconnection to operationalize RRI is the core objective of the SISCODE project described in the following.

3 The SISCODE project, its methodology and model of knowledge exchange

SISCODE[1] (Society for Innovation and Science through CO-DEsign, n°788217) is a project funded within the European Union's Horizon2020 programme aiming to explore the use of co-creation in STI policies making to understand its potential and build up an evidence-based learning framework.

SISCODE's research develops around a reflective framework and knowledge repository and consists of extensive desk research including case studies, a co-creation experimentations conducted as pilot projects and a series of workshops with policy makers to emphasize the specific aspect of co-design in policy making (Figure 1).

[1] *https://siscodeproject.eu/*

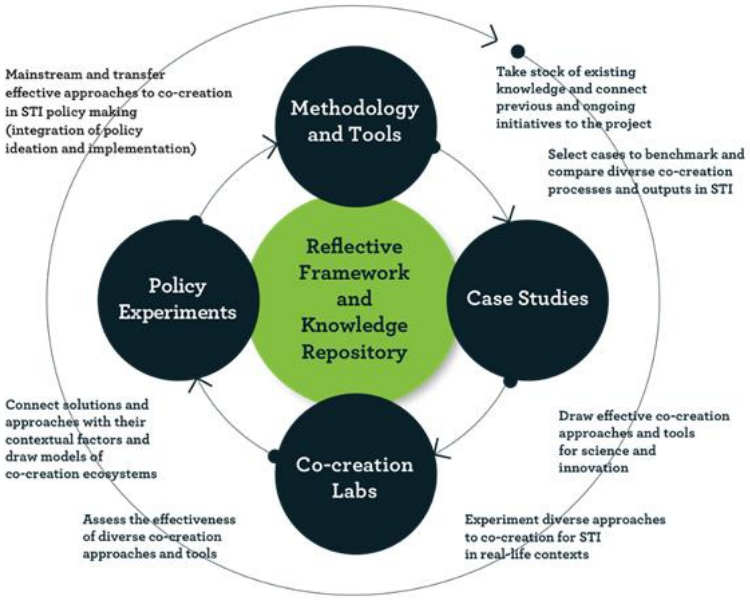

Figure 1 - SISCODE's learning model

The objectives of the SISCODE framework are on one hand to trigger reflection on a more practical and context-sensitive perspective in the actual application of RRI. On the other hand, the application of co-design could open new ways for participative and experimental policy making (Deserti & Rizzo, 2015; Brown, 2009).

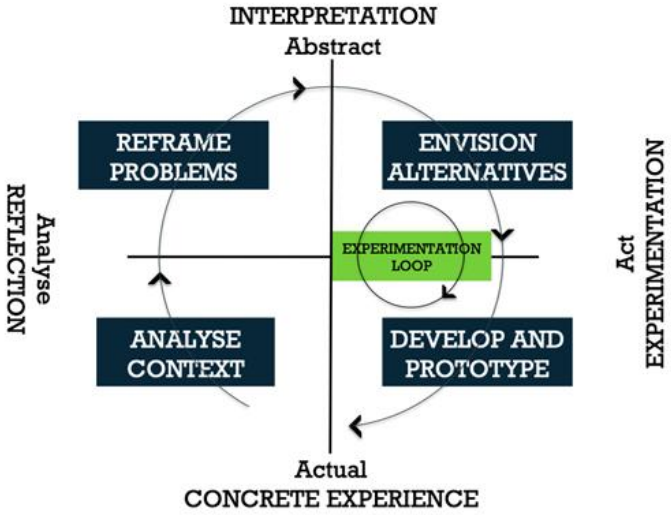

Figure 2 - SISCODE's experimentation model

The pilots' model is based on the adoption of co-design methodology for the conduction of real-life experimentations that have been carried out with local actors of each lab's ecosystem in a process of action research (Figure 2). The pilots' role in the overall project is to improve knowledge on design thinking in a learning-by-doing process that may fit to operationalise RRI as a long-term co-creation process in real contexts.

10 pilot projects set up in 10 European countries operating in various fields like healthcare, education or environment are creating solutions and influencing policies to actively involve society in innovation and science.

The pilots were developed bottom-up analyzing the context in terms of local challenges and policies, reframing the identified problem and envisioning alternatives. The idea has then been co-produced and prototyped to be evaluated leading to a new loop of co-design and prototyping in an iterative process (Figure 2).

Each lab identified a challenge particularly relevant in their specific context (Table 1) to consider its potential of being scaled up and transferred also to different contexts later on.

Table 1 table of all labs, their challenges and solutions developed

Lab	Location	Challenge	Solution
ThessAHALL	Thessaloniki (Greece)	Preventing **social exclusion** through life-long learning	**Partners of Experience,** a participatory research programme for older adults and chronic patients
Traces	Paris (France)	Raise awareness on **algorithmic decision making** in cultural activities	**Co-construction and culture for and by AI,** an informal learning show with artificial intelligences as the audience
KTP	Krakow (Poland)	Improve the **air quality in Krakow**	Preparation of the new **Air Protection Programme** for Malopolska
Underbroen	Copenhagen (Denmark)	Create a **circular plastic recycling system**	**PIPO,** a circular system for local sourcing, recycling and production of plastic
Polifactory	Milan (Italy)	Improve **movement** of children affected by **cerebral palsy**	**BODYSOUND**, a system of motor stimulation based on the transformation of movement into sound
Fab Lab BCN	Barcelona (Spain)	Synergise for **redistributing, upcycling and composting food waste**	**El Barri Circular**: a Symbiotic System for food surplus and bio waste valorisation
Ciencia Viva	Lisbon (Portugal)	**Rise interest in & improve accessibility** to the Lisbon **river**	**Build your own boat:** A yearlong workshop for the construction of usable watercrafts

PA4ALL	Novi Sad (Serbia)	Introduce **ICT in high-schools specialized in agriculture**	**ICT based education programme** in high-schools specialized in agriculture
Science Gallery Dublin	Dublin (Ireland)	Improve **mental health and well-being** management with young people	**Open Mind:** Empowering young people to understand the importance of mental health and creating clubs for them to support each other
Cube	Kerkrade (Netherlands)	**Improvement of life quality** for people of **all ages**	**Citizens Lab X Ransdaal:** Supporting bottom up social innovation

The pilots designed their project plan together with citizens, users, stakeholders and policy makers to provide an extensive overview of possible pathways taking all actors in consideration and therefore set up a more realistic and holistic journey.

The projects all applied the cyclical process of co-design (Fig 2), and using different co-design tools and methodologies.

The variety of parameters and kinds of data to be collected throughout the development of the 10 pilots journeys required the development of a framework going beyond one single tool for monitoring and assessing:

- the knowledge exchange and uptake in the pilot's organisations and ecosystems was to be assessed as a crucial point to be able to draw conclusions on the learning model and its functionality. Therefore, the diffusion of co-creation as a methodology and the identification of problems related to its application together with potential ways to overcome those issues has been investigated.
- the interactions with policy makers and activities related specifically to policy making needed to be monitored to produce insights on the effectiveness of tools and techniques and best practices to be further disseminated.

4 Monitoring and assessing (in) the SISCODE project

As stated previously, one of the difficulties in operationalizing RRI and spreading it in practice is its difficulty to be measured and assessed and the resulting issue in proving impact and success.

In order to cope with this issue the SISCODE project defined an assessment framework to keep together the general success of the pilots (including single methodologies and tools applied to validate their effectiveness and appropriateness in the different contexts) and the overall project capacity to cope with short and long terms expected impacts.

The framework has been created defining a set of indicators both taking the specific objectives of the project and the relevant factors of RRI in consideration.

The indicators on RRI initiatives have been extracted and adapted from the MoRRI project, a 4-year project with the aim to monitor and assess ongoing RRI initiatives and

their benefits. The project has produced a total of 36 indicators on 6 different dimensions to be measured in RRI initiatives (Meijer et al., 2016) SISCODE applied to develop its own indicators.

The elaboration of the SISCODE assessment framework led to the division in three different areas to be specifically explored during the assessment:

- **Stakeholder engagement**, as one of the core aspects of the project, explores how and which actors labs involve in their activities and their general strategies for actor identification and engagement.
- **Co-creation**, as the overall practice to be investigated in SISCODE draws a focus on the kind of activities related to co-creation that are carried out, the tools used and the ways and methods to reflect on these activities to evaluate their effectiveness and effects on the participants
- **Dissemination**, as the capacity to practice dissemination and contribute to knowledge exchange

Three different tools have been developed to assess the key themes on various levels (Figure 3):

- **An excel spreadsheet** as a continuously edited file with fixed parameters concentrated on objective observations and numbers;
- **A self-assessment questionnaire** periodically filled by the labs requesting a broader and more qualitative reflection on practices and methodologies rooted in the entire organization;
- **Scenarios** to illustrate potential situations for the near future, having an outlook on how the organization and the entire ecosystem could evolve and how they are influencing each other. The ongoing reflection and discussion on possible futures of the ecosystems, especially in the light of the current Covid-19 crisis, is to be concretely formulated and visualized for each pilot after the conclusion of the experimentation.

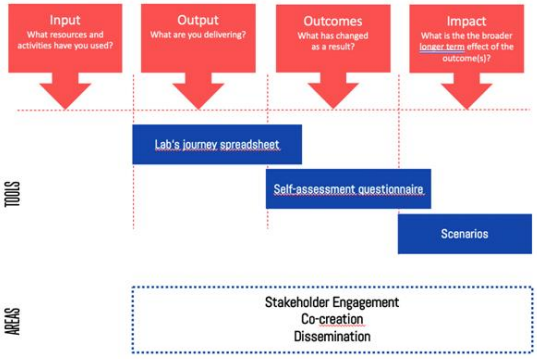

Figure 3 - SISCODE's kinds of results and the corresponding assessment tools and themes developed

The monitoring and assessing activity is being conducted in parallel to experimentation to then continue beyond with its results feeding a broader reflection on the effects of applying co-creation in RRI initiatives.

Concretely, the three tools described above are being applied throughout the experimentation by the members of the labs themselves either in a continuous way as for the spreadsheet or punctually at specific points in their journey as for the self-assessment questionnaire (Figure 4).

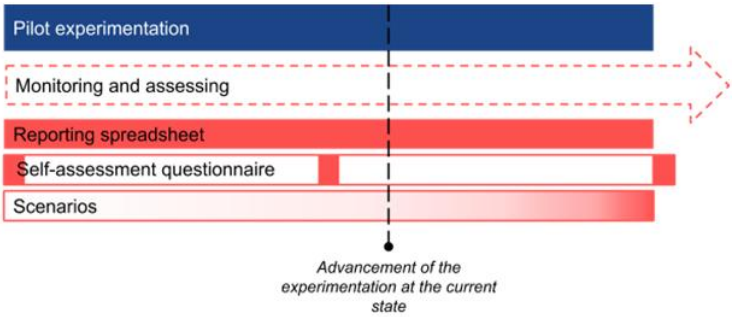

Figure 4 - Scheme of the monitoring and assessment activity throughout SISCODE

5 Evidences from the first cycle of assessment

In this section, the main insights gained from the assessment are reported, with a focus on the self-assessment providing insights and broader reflections on organizational change, capacity building and the implementation of co-creation. The activities conducted until May 2020 are taken into account with the experimentation ongoing until September 2020. Nevertheless, the collected data has been continuously evaluated and reflected on and already provides meaningful insights at present.

These have been organised under the three macro dimensions of the SISCODE assessment framework: stakeholder engagement, co-creation and dissemination.

In general, what emerges from the comparison of the baseline assessment with the one after the first year is the initial overestimation of the labs regarding their level of competences in all three areas.

The authors tend to interpret this as an effect tied to the notion of innovation journeys as a long term process based on four main phases: context analysis, ideation, prototyping and implementation. When co-creation moves from the stage of ideation to prototyping, testing and implementation it requires more complex capacities in respect to all three areas. The authors hypothesize that the labs initially estimated their competences as robust enough to govern co-creation with stakeholders to then realise the full extent (and therefore their lack) of capacities needed to adopt co-creation entirely.

This shows that knowledge about co-creation does not necessarily imply the capacity of an organisation to implement concrete co-design activities particularly relevant to go beyond sheer ideation.

On the basis of this assumption, in the following we discuss specific evidence found.

The direct results are mostly concentrated on smaller scales regarding the project-, organizational- or ecosystem level to then provide more extensive reflections on the application of co-creation in the final chapter.

5.1 Stakeholder Engagement

Generally speaking, the complexity of the process itself, scepticism towards co-creation and the need for constant engagement of stakeholders have been reported by the pilots as main reasons for difficulties.

One of the main barriers identified by the labs is related to the complexity in keeping the engagement constant throughout the process. While typically in co-design workshops the engagement is limited to single activities, the innovation journeys of the labs in SISCODE contemplated a constant network of interested stakeholders throughout the process until the real implementation of the solution. To reach this goal, specific knowledge was to be acquired and applied inside the labs' organisations (also testified by the request to use part of their budget to hire external competences to deal with this phase of their journeys). While this steadiness required effort it also functioned as an opportunity to motivate stakeholders fully including them into the process representing their interests and acquiring new capacities themselves.

The diverse stakeholder groups have been initially involved through co-design workshops where insights and ideas regarding the specific challenge have been generated to then lead to the acquisition of other engagement activities specific to the phases of prototyping and testing. As mentioned, here the support of the consortium was needed to learn about the notion of prototypes and their role in the process of engagement together with external support recruited at a local level.

In particular, the involvement of citizens in the process of co-design benefitted from the support of some level of tangibility and materialisation of the solutions/policies themselves resulting in a shortening of distance between policies and citizens with a prototype as a tangible object.

At a local scale, the importance of local characteristics and culture emerged with respect to the process of engagement requiring an adaptation of the methodology according to the local culture both related to the organization itself and the greater ecosystem.

Concerning the involvement of policy makers, both for single activities and constant engagement, the overarching difficulties met are rooted in their scepticism towards the new approach, the different mindset in terms of processes and implementation and their complex profiles and schedules.

The experiments show the difficulties in involving policy makers in the entire process and their preference to take part only in the light of concrete results or evidence fitting to their agenda. Also the need to convince policy makers of the value of co-creation

activities that involve lay people is confirmed by our experimentation. Different labs are facing the issue of how to improve the credibility of co-creation among policy makers, dealing with the problem of how to keep them involved in the process and how to produce concrete results for them to be used to inform policy.

At the same time, the challenge to convince citizens that participatory processes are not instrumental to predefined political goals and gaining consensus has emerged. This last observation is coherent with other results of our experimentation. IThe labs reported positive interactions with policy makers at a local level showing interest in the challenges being linked to their local context and concrete issues.

5.2 Co-creation

Co-designing and -producing all materials in the labs' processes, especially the introduction of prototyping as a principle to move from ideation to iterative testing revealed itself to be demanding on several levels.

A fear due to the uncertain nature of the prototyping process withholding the possibility to result in a failure and request a redefinition of the entire solution emerged from the side of the labs themselves while policy makers tended to be doubtful about the long process not providing immediate results or a clear evidence of impact.

This interference with traditional methods where the final solution is often immediately implemented has been detected as a point of insecurity and concern for organizations starting to be familiar with the practice. With an emphasis on long-term impacts rather than short-term outcomes this meets the general idea and goals of RRI to achieve stable and long-term solutions, but makes it often difficult in earlier stages.

The actor involvement in the prototype production strongly depended on the various cases, but all have been then involved in its testing and subsequent iterative phases. These iterated interactions are essential to the co-design process, ensuring user insight to influence the process not just in the early development phases, but also towards implementation, where ideas turn into solutions with concrete implementation plans.

The iterative involvement of users through feedback loops of insight, input and testing can help bridging the gap between ideation and implementation achieving higher levels of citizen & policy maker engagement, but requesting a certain amount of time.

The results from the labs show the importance of an overall vision of the co-creation process sharing it with actors and stakeholders involved. The engagement of citizens and 'non experts' appears easier in ideation, while implementation tends to remain in the hands of experts possibly leading to a feeling of losing ownership or mismatches between intentions and results requiring specific co-production strategies. In this, the role of prototyping is crucial, engaging all actors and stakeholders in different ways either in prototyping or experimenting the solutions. As a result, taking part in co-production helps all the involved stakeholders, including policy makers, to improve their understanding of

both opportunities for implementation and scaling up of the solution and constraints that may hamper its implementation, reflecting on those to produce implementable outcomes.

5.3 Dissemination

The findings and results, especially of the activities related to stakeholder engagement and co-creation shed light on the necessity of dissemination and exchange of practices beyond the project.

Sharing past experience has been found as an opportunity not only to motivate stakeholders to join similar activities and to stay informed about ongoing initiatives, but also potentially trigger new ones in similar ecosystems.

Furthermore, the dissemination of their experiences forced the labs to draw conclusions and functioned as a way of self-reflection, the results of these are outlined in the previous points due to the strong interconnection of the three themes.

6 Conclusion

The gap between ideation and implementation is a long-standing question in policy making. It is intrinsically bound to the complexity of problems, means that it is difficult to find causal links or to help multiple actors (possibly with diverging goals and mindsets) interact across different levels of governance (Matland, 1995; Hill & Hupe, 2002). In exploring ways to deal with this gap in the intermediate 'playground', SISCODE's experimentation identified a number of challenges establishing connections between bottom-up initiatives and top down policies.

Experiments show that sharing the challenge with policy makers and engaging them in co-creation activities from the beginning is important to obtain legitimation. Nevertheless, experiments also demonstrate that policy makers are difficult to be involved in the process from co-design to co-production and that they usually prefer to take part in the process when concrete results are already there and can be used if they fit with their agenda.

Also from the labs' journeys emerges that knowledge about co-creation does not necessarily imply the capacity of an organisation to conduct co-design activities. Co-design processes and competencies are particularly relevant to go beyond sheer ideation. To support capacity building in the labs, training before starting the co-creation journeys and learning-by-doing/learning-by-reflecting during the experimentation have been put in place. Experiments show that the engagement of citizens and 'non experts' is easier in ideation, while implementation tends to remain in the hands of experts. As this may lead to a feeling of losing ownership and to mismatches between intentions and results, it is important to put in place co-production strategies. In this, the role of prototyping is crucial.

Finally, all the 10 experiments show that taking part in co-production helps all the involved stakeholders, including policy makers, to better understand both opportunities

for the uptake or scaling up of the solution and constraints that may hamper its implementation, and reflect on enablers and obstacles to come out with implementable outcomes.

More in general, there is evidence from SISCODE that the outputs of participatory exercises still have little credibility within policymaking (compared to more traditional forms of expert advice) and when taken seriously, they struggle to be accommodated within the existing systems. A paradox emerges here to be addresses in future works and experimentations: on one hand, for co-creation to offer policy making a valid alternative to top down or expert based policy advice modes it needs to find legitimation by producing radically different and useful perspectives; on the other hand, if co-creation is too "alternative" the risk is being ignored or not fully adopted by policy makers that are eventually relegating it to peripheral applications that do not impact the core process and issues in policy formation.

Open innovation Capability Maturity Model and Inside - In Innovation

Abstract

Open Innovation (OI) is still a young phenomenon and its adoption by industry subject to a number of still poorly understood context factors and drivers. The development and implementation of the OI paradigm in business poses specific challenges not only to the management of the external environment but also to the development of organizational skills that would specifically prepare the organization to operate in OI networks and successfully integrate external knowledge flows into the innovation process and products. Each organization is at some level of maturity, but imperfect signalling and deliberate withholding of firm-internal information prevent the necessary alignment both among units of the same firm and between corporate entities as a whole necessary for external and innovative collaboration. This study applies the concept of the Capability Maturity Model (CMM)—which focuses on the quality of organizational processes—to the domain of intra- and interorganizational collaboration for innovation (open innovation). We propose the organizational-internal concept of inside-in innovation to complement boundary-spanning innovation flows such as inside-out and outside-in innovation. Based on research of three case companies, we outline an OI-CMM, identifying some of the key capabilities needed, and suggesting further avenues of research.

Keywords – open innovation, Capability Maturity Model, organizational collaboration

Paper type – Academic Research Paper

1 Introduction

„The smartest people in every field are never in your own company".
Bill Joy

Interest in Open Innovation (OI) has grown fast within the management field. For instance, since its first introduction by Chesbrough in 2003 more than 3,600 articles were published on this topic as per a review on Scopus. But Open Innovation is important both for academia and for practice. From a practice point of view, the importance of OI in today's business is growing for several reasons: broadening and deepening of technical

knowledge makes technology ownership impossible for individual companies, competition in the global marketplace forces collaborative behavior, product development cycles are shortening, and markets are becoming more complex. For instance, a comparison of Procter and Gamble's innovation projects showed that their OI projects outperformed closed innovation projects by achieving a 70 percent higher net present value (Enkel et al., 2011; Hosseini et al., 2017). According the Corporate Innovation Center and the Fraunhofer Society that examines OI activities in large organizations, most organizations fail in the change process from closed to open innovation, and more knowledge is needed about capabilities such as managing and organizing OI (Hosseini et al., 2017). Small and medium sized enterprises (SMEs) in particular face managerial, organizational and cultural challenges (van de Vrande et al., 2009; Enkel et al., 2009). Another challenge for organizations is how much they are able to maintain identity, adapt to a changing economy and adjust business models accordingly. These challenges can undermine the survival prospects of even successful firms. For instance, Fiskars Group, which was founded in 1649, continues to produce the best plastic handles scissors in the world, only in a different environment than when they were first developed in 1977. On the other hand, Xerox PARC, which was a very innovative company having developed important technologies such laser printing, the PDF file format, and the GUI, never managed to appropriate these inventions for its own innovation leadership. Kodak is another example of a company that was unable to recognise new opportunities in the photography market and lost to new and unexpected competitors (Tripas and Gavetti, 2000). It can be argued that organisations must transform in one way or another in order to achieve long-term competition (Schmitt et al., 2018; Enkel et al., 2020).

The original idea of the OI model was somewhat underestimated due to its rapid development and its diverse manifestations in different contexts (Teplov et al., 2018), resulting in a different understanding of what OI is in the scientific literature and how its definition has evolved. The flexibility and applicability of the concept of OI have been a source of its strength and success, but it has also prevented the adoption of a uniform, standardized theoretical framework for its management. Our paper aims at closing this gap by proposing such a framework, building on the established Capability Maturity Model (CMM) on the one hand, and empirical insights on both intra- and interorganizational practices of open innovation in industry.

The structure of the paper is the following: in the next sections we will review the OI and CMM literature. Then, we introduce the research methodology used in our survey and results of analyses. Finally, we will discuss future research opportunities.

2 Reviewing the Literature on Open Innovation and Organizational Maturity

2.1 Open Innovation

Open innovation is a multi-faceted complex phenomenon (Ahn, Lee, & Mortara, 2020; Bogers et al., 2017) that refers to unlimited access to inbound and outbound knowledge (Ahn et al., 2020; Enkel et al., 2020; Bacon et al., 2019; Roszkowska, 2017), addressing, but not limited to, the organisational level (Bogers et al., 2017; Enkel et al., 2020; Hilbolling et al., 2020). OI is focused on cost reduction for technology development, reducing risk for market entry, achievement economies of scale for production, reducing lead times for product or service development, and promotion to share learning. The fundamental principle of OI is to be ahead of the trend (Franke et al., 2006). Hence, organizations acting in OI are not limited to internal ideas, but also use those that rise outside the boundaries of the organization for product, service and technological development. OI has been likened to a combination of internal and external ideas system that enables the organization to enter new internal technologies into the market through external channels. Auch a system helps organizations open their boundaries for cooperation with external partners (e.g. universities, research institutes or competitors) and contribute to the internal technologies development and open new possibilities of profitable business (West & Bogers, 2014).

Chesbrough and Bogers (2014) defined OI as "a distributed innovation process based on purposively managed knowledge flows across organizational boundaries." Thus, knowledge inflow and outflow can be used for innovation development (Enkel et al., 2009). Gassmann and Enkel (2004) identified three processes of OI: *outside-in* or inbound OI when integrating external knowledge for innovation development for the organization; *inside-out* or outbound OI when ideas or new technologies of organization are taken to the market through the sale of intellectual property (IP) and *coupled* when is a combination of *outside-in* and *inside-out* (Chesbrough et al., 2006). For instance, Philips is engaged in two kinds of OI: through *inside-out* innovation (skills and are made recourses available to the outside world, e.g. contract research for external parties, providing technical facilities and support and assist with IP licensing) and through *outside-in* innovation (drawing on the capacities of individuals, organizations, and even small start-ups from around the globe, e.g. by providing a broader window on the world of health and wellbeing, strategic partners help us gain new insights and access to new technologies) (Philips, 2020).

Thus, the excess to external knowledge sources is very important for new insights and new technologies development. The Bogers & West (2012) model (Figure 1) shows that innovation does not take place in a single organization but is distributed around multiple stakeholders.

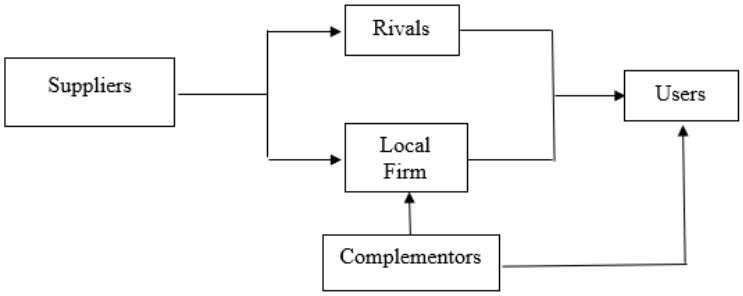

Figure 1. External Sources of innovation (Bogers & West, 2012)

Hence, even though OI concept is described as knowledge inflows and outflows (Chesbrough, 2003; Chesbrough et al., 2014; Dahlander and Gann, 2010), the understanding of OI concept remains underdeveloped (Bogers et al., 2017; West and Bogers, 2014, 2017). During the past three years trend in OI importance for organizations show that intellectual property protection, in-house R&D and open innovation should succeed only together (Bogers et al., 2019) and digital age for open innovation provides many opportunities for knowledge flows across organizational boundaries to support innovation process (Bogers et al., 2018; Enkel et al., 2020). While there is ample literature on cross-functional collaboration, the not-invented-here syndrome, and other conventional aspects of interdepartmental management, the intra-organizational dimension of collaborative innovation seems to be under researched in the context of open innovation. Internal open innovation, or *inside-in* innovation, in analogy to the Gassmann and Enkel (2004) terminology, should be prevalent in large multi-unit firms that often operate more like a collective of independent organizations than an integrated whole. But large SMEs may equally benefit from inward-oriented openness of innovation processes. In fact, technology exchange platforms (such as Yet2.com, and others) have noticed that much of the trade—anonymized initially to protect the integrity of the transaction—has been between different business units of the same firm (explained as a natural interest in technology of business units operating within the same general market). We conclude that Open Innovation is therefore important not only to coordinate innovation processes with external partners—inside-out and outside-in—but also among business units of the same firm, especially if the are managed at arm's length by the firm's headquarters, i.e. without an orchestrating decision center on innovation. Any reference model for Open Innovation must therefore also incorporate an inside-in perspective of Open Innovation.

2.2 Organizational Maturity

The Capability Maturity Model (CMM) was developed as a framework that reflected areas for improvement recommended for software organizations looking to increase the capabilities of their software processes (Humphrey, 1988). Although these definitions provide a basic understanding of this concept and the logic of how maturity models work, they do not explain either the meaning of maturity or the elements or content of such a model. In addition, they differ in terms of application and purpose, making it necessary to review one of the most important models of maturity in history.

Many scholars highlighted that organizations with high innovation capability are an important source of company performance (Aziz & Omar, 2013), innovation performance (Mir et al. 2016) and the opportunity to achieve a competitive advantage to pursue value creation (Battista et al. 2020). According Wendler (2012) innovation maturity models derived from dynamic capability maturity models can be used to measure the level of innovation maturity. The use of innovation maturity models allows assessing the level of innovation maturity of an organization and mapping areas that the organization can achieve a higher level of innovation maturity and competitive advantage.

The Capability Maturity Model (CMM) is the most well-known maturity framework for evaluating and improving the software development process within organizations. The model describes five levels of maturity (Humphrey, 1988):

1. The *Initial* level. Processes are chaotic, not documented with low communication. Success is based on individual skills
2. The *Repeatable* level. Basic project management established. The cost, schedules, and functionality are tracked.
3. The *Defined* level. Processes are standardised and documented.
4. The *Managed* level. Processes control through data collection and analysis.
5. The *Optimizing* level. Processes continue improved in order to innovate according the organization's particular needs

CMM has been applied to post-project management (von Zedtwitz, 2002), business process management (Röglinger et al., 2012), innovation (Essmann et al., 2009; Carnes et al., 2017; Arends, 2018), team collaboration (Boughzala et al., 2015), HR management (Curtis et al. 2009; Funchall et al. 2011) and other domains, but not yet to open innovation.

CMM are not the only capability frameworks possible: capability-based frameworks for OI have been proposed by Lichtenthaler and Lichtenthaler (2009) and Hosseini et al. (2017), and maturity-based models for OI by Habicht et al. (2012). Enkel et al. (2011) presented a CMM-inspired application to OI where organizational maturity was assessed in terms of partnership capability, innovation climate, and internal processes. However, their study had some limits, as only fifteen organizations were studied and were not included in the OI aspect, which has become quite important in recent management practices.

According to Chesbrough & Brunswicker (2013), organizations face challenges in adopting OI processes as they require changes in organizational structures, mechanisms, and practices at strategic and organizational levels, as well as the adjustment of the organizational learning for development, maturing and further improvement of OI. These organizational changes are related to capabilities for internal innovation with external ones (West & Bogers, 2014) and capabilities for collaboration with external partners (Niemelä, 2004). However, research on OI organizational capabilities is still limited (Enkel et al. 2011). Aiming at managing internal and external OI process in the firm, one of the first theoretical OI capability-based framework substituted the absorptive capacity concept with six "knowledge capacities" (inventive, absorptive, transformative, connective, innovative, and desorptive capacity) (Lichtenthaler and Lichtenthaler, 2009; Podmetina et al. 2019). Hosseini et al. (2017) presented and OI capabilities framework called OICF that describes 23 capability areas grouped in larger domains of "strategic alignment, governance, methods, information technology, people, and culture". Combining the three key elements of OI (ability to collaborate, innovation environment, and internal processes) with five levels of maturity (initial, repeatable, defined, managed and optimizing) provides a preliminary basis for OI maturity (Enkel et al., 2011).

One of the latest OI maturity framework was introduced by Enkel et al. (2020), delineating traditionalist, modernist, and visionary aspects of OI. Their model emphasized that these stages of transition do not have to be continuous. A company's culture may delay or prevent further development, or a company's strategic position may enhance OI performance. Thus, each organization needs to find a balance in its innovation management. At all stages, the traditionalist, the modernist, and the visionary need different options that must respond to external change. In slow industries, the transition from traditionalism to modernism may take time, and in fast-growing industries, these stages may be necessary to survive (Enkel et al., 2020).

We conclude that CMM is a well-established framework for organizational process maturity in at least several domains closely relevant to open innovation. However, no attempt has been made thus far to apply CMM to mapping and describing open innovation processes such that both intra- and interorganizational innovation process maturity is reflected.

3 Research methodology

We chose a qualitative research approach to examine OI capability in industrial multinational organizations. The data collection is performed through individual interviews to gain a deeper understanding of OI maturity in firms (Enkel et al., 2011). Between December 2019 and March 2020, we conducted 6 interviews with selected vice presidents of business management & innovations and director of new product development. Participants were from four different multinational organizations based in Europe and the USA. (This number is too low to warrant in-depth statistical evaluation, but it does allow some interesting observations about OI maturity in multinational

organizations. As this is research in progress, we are planning to continue with the empirical part and conduct at least 25-30 expert interviews in this phase.) The interviews lasted between 30 and 45 min and were transcribed verbatim and maintained anonymously. Our focus areas were climate for innovations, innovation processes, internal processes, collaboration, and partnership capacity.

The data was then interpreted, categorized and ranked according perceived levels of process maturity. We used the five generic CMM levels as a starting-point for classification and reference, populating the emerging OI-CMM from the bottom up and complementing generic definitions and properties from the OI literature. Two independent coders were used in this step, and any coding mismatch was addressed and either resolved or put into a backlog for eventual clarification and confirmation once more data is available. We are aware that this model has that status of a proposition until it has been fully verified and validated with additional companies not included in the research sample.

4 A Capability Maturity Model for Open Innovation

4.1 A High-Level Summary of the Results

All respondents agreed that organizations are applying external knowledge into a new product, service, and process development. But there are some limits with accepting and disseminating new external ideas as no formal guidelines on how to be done. Climate for innovation is on a quite good level, but there is a need for closer collaboration between employees and communication improvement. Some of the respondents indicated that there are no incentive systems for innovations. One of the most important aspects that defined OI is collaboration both inside the organization and outside. Respondents were divided into camps: two of them stated that the borders of the organization are not open for knowledge flow from outside-in and from inside-out and the other two answered the opposite: the borders of the organization are open for knowledge flow from outside-in and from inside-out. However, we also heard that "it might be that our organization doesn't have knowledge for such collaboration or there is a lack of trust."

4.2 A CMM Framework for Open Innovation OI-CMM

Based on the original CMM as presented by the Software Engineering Institute we defined a five-level capability maturity model for open innovation (Figure 2). The maturity model is organized into five levels: Initial; Repeatable; Defined; Managed; Optimizing.

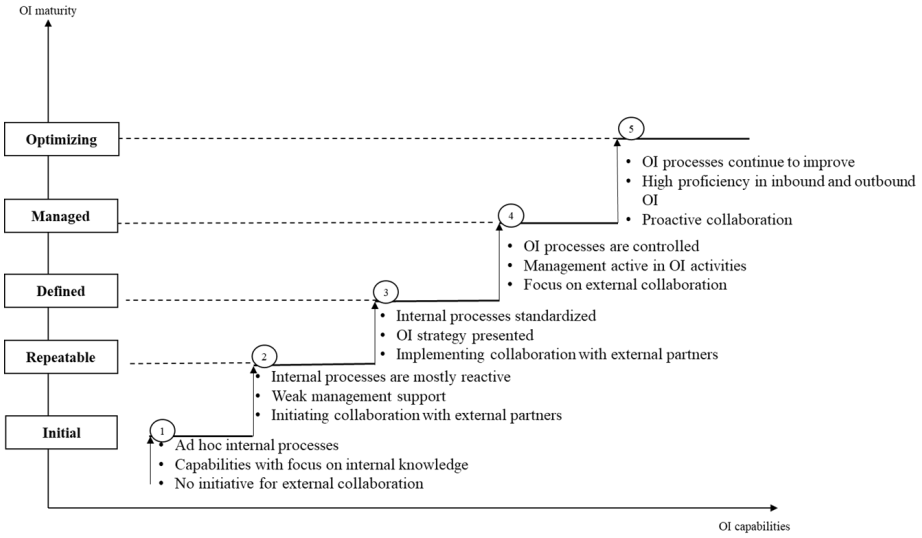

Figure 2. OI-CMM: A capability maturity model for Open Innovation (OI) maturity

Level 1: Initial. At this level of maturity organization's internal open innovation processes are unstructured or even chaotic. Internal knowledge sharing is weak und uncontrolled. Exertnal innovation collaborations occur ad hoc, but no guidelines as to how important aspects (e.g., IP ownership) are managed exist. Management in general does not support OI activities. Success of any collaborative innovation projects depend on the skills and performance of individual managers.

Level 2: Repeatable. At this maturity level organizations demonstrate some achievements in willingness to collaborate with external partners and to share knowledge. Still low level of internal information sharing and management support, although general appreciation for any benefits of OI is present. According to our survey results, OI projects are held by special teams. Basic templates for managing OI with external collaborators exist and are generally followed.

Level 3: Defined. Internal open innovation processes are documented and standardized. Definition and adherence to OI processes are owned by a dedicated unit (perhaps even just a single OI manager), which also follows up with implementation advice. Top management is committed to open innovation, presenting a clear strategy for OI, encouraging OI in core domains.

Level 4: Managed. Organizations at this maturity level have not only defined key open innovation processes at all levels—inside-out, outside-in, coupled, and inside-in—but also have developed metrics that permit them to motivate and support employees in OI activities. OI is a company-wide shared practice, with most processes, whether in R&D, product development or elsewhere, are by default considered for open, collaborative

execution. The OI unit provides relevant training for employees and increases skills for OI activities.

Level 5: Optimizing. In this final maturity level, the organization is proficient and proactive in proposing, designing, and executing collaborative inbound and outbound OI practices. OI supporting activities are integrated into corporate life and supported by a dedicated budget. Internal borders are open for knowledge sharing, and clear rules exist for interorganizational sharing. New ideas are welcome and tend to be easily accepted by management. Employees are rewarded for OI activities, and encouraged to improve existing OI practices and OI metrics.

5 Discussion and Conclusion

Given the limited empirical (but on-going) data collection, we are aware that the OI-CMM framework still has mostly propositional value. However, the application of CMM to a number of similar and related domains—we mentioned product development, post-project reviews, software development, team collaboration in the literature review—instils us with confidence that completing this template with solid data from multiple industries and sectors is just a matter of time.

Considering OI process maturity at the firm level, our interview respondents highlighted the fact that the culture of the organization and its employees are one of the keystones for successful open innovation. Interfaces with outside organizations are usually conservatively managed and dominated by legal, strategic and tactical considerations. Historically, the emergence of organization as a system of hierarchies and functional specialization has been driven by the need to limit information flow and focus on improving the quality of unit-internal work rather than cross-functional collaboration (Jensen & Meckling, 1976). Driving the development of an OI-CMM past the cultural acceptance levels of the host firm is likely leading to adoption failure, and we tentatively propose that OI-CMM success depends more heavily on overall corporate culture than more functionally limited or technical CMM implementations in e.g., software development or post-project reviews.

Our data has so far been too limited to support empirical extension of OI theory towards inside-in innovation. However, conceptually the view of a large organization to consist of multiple subunits with individual micro-cultures for openness for innovation and change permits to formulate inside-in innovation as an intra-organizational equivalent of coupled inside-out and outside-in innovation flows. Aggregated at the firm-level, these microcosms of innovation behaviors of individual units constitute not only a firm's inside-in open innovation but also its capability maturity to engage in open innovation with firm-external innovation partners. Inside-in innovation therefore plays a mediating role in firm-level OI-CMM and deserves more attention in future research (and, of course, by innovation management practitioners).

The preceding literature review in innovation management and OI revealed that there is no quantitative validation of CMM. Our future research focus is thus on solidifying our

qualitative model development before validating the OI-CMM framework in quantitative empirical studies. We also will develop an integrated perspective on outside-in, inside-out and inside-in processes of OI, including capabilities that relate to collaboration, strategic alignment, governance and culture conducive to collaborative innovation success.

However, we are aware of the limitations of our investigations due to restricted scope and scale of the survey and interviews, which need to extend both internal to our case firms as well as include other firms. As this study is part of a PhD project of one of the authors, we are lucky to have the time and resources to engage in this process.

Abstract

Due to the important role of knowledge in the sustainable development of organizations, this topic still attracts several practitioners and researches. Therefore, knowledge management research area is considered as a young discipline that needs further exploration. The purpose of this study is to map the challenges in knowledge management by investigating the key themes and their relationship for the period 2009-2019. The study updates the previous study of Gaviria-Marin et al. et al. (2019) by specifically investigating the challenges in knowledge management to identify current research gaps and future research directions. This study utilizes the bibliometric analysis technique to identify the challenges in knowledge management. The dataset for this study was retrieved from the Scopus database. In total, 915 articles published between 2009 and 2019 were retrieved. These articles cover 2215 authors, 277 journals and 5400 keywords. The bibliometric analysis was conducted through the VOSviewer software. The study included activities like co-author and co-word analysis by mapping it to the theoretical foundations. The co-word analysis identified three broad themes of challenges in knowledge management: *Organizational learning, knowledge development and sharing; optimization through knowledge management; knowledge sourcing and planning.* This study helps researchers to understand the challenges in knowledge management studies in last decade and the direction that challenges research is taking in order to identify available avenues for future research.

Keywords – Knowledge management, challenges, bibliometric, Scopus, Co-occurrence analysis

Paper Type - Academic Research Paper

1 Introduction

The continuously challenging business environment is pushing companies to strive for forward-thinking solutions to remain competitive and grow sustainably. According to Lee et al. (2013), knowledge is an organizational resource that provides a competitive edge to companies if exploited effectively. Knowledge management (KM) is defined as a process/practice of creating, acquiring, capturing, sharing and using knowledge by firms to enhance their learning and performance (Gaviria-Marin et al., 2019). It is vital for firms to improve the efficiency of project delivery and gaining competitive advantage. According to Tzortzaki and Mihiotis (2014), the body of research on KM is classified into three generations (i.e. knowledge as tool (1960's); knowledge as process (1990's) and the role of knowledge to the success of organizations (2000's decade). Serenko (2013) further argued that the fourth generation of KM leads to new KM tools and paradigms and remains to be developed. Although, the fourth-generation approaches have predicted as offering a promising future for KM, unfortunately, organizations are having challenges in implementing fourth generation KM (Gaviria-Marin et al., 2019). Both the technological (i.e. hard) and human and organizational (soft) aspects are crucial for KM (Yap and Lock, 2017). Hard issues that generally arise from hardware problems like the breakdown of information technology tools can be solved straightforwardly. Soft issues underpin the capability of companies to successfully implement KM practices.

A firm relies on its employees to acquire experience, create knowledge from different learning situations and reuse the developed knowledge for continuous improvement. According to Tan et al. (2010), sharing of knowledge within or across firms is generally inhibited by management issues like organizational policies, confidentiality & security of knowledge, lack of rewards and incentives to encourage a knowledge sharing culture. Sharing of knowledge is also inhibited by cultural issues that are affected by the practices, values and norms within a company. In addition, the soft dimensions of KM facilitate a better understanding of organizational knowledge transfer and help in formulating guidelines for managerial actions.

Given the changes in the KM paradigms that have emerged in the last decade (i.e. fourth generation of KM) and have affected research, it is important for the KM field to trace the challenges scholars have discussed in literature. To address this research gap, and in continuity with the previous evaluation of KM (Gaviria-Marin et al., 2019), the objective of this systematic review is to understand the evolution direction of fourth generation KM challenges research in the period between 2009-2019 and to identify future avenues for research.

Bibliometric analysis offers a thorough evaluation of publications trends and patterns and helps in identifying established and emerging themes in the literature (van Eck and Waltman, 2017). Therefore, this study is designed to map the scientific literature of fourth generation KM challenges using the bibliometric analysis approach. The above-mentioned research objective is achieved by reviewing 915 articles published in the last decade in the area of fourth generation KM challenges literature (2009 – 2019). This study applied bibliometric techniques like co-citation and co-occurrence analysis to recognize challenges in the fourth generation KM and provide future research avenues. The next sections describe the research methodology and analysis, briefly followed by findings and discussion.

2 Methodology

A bibliometric study provides a broad analysis of a research field or the intersection of two or more fields through a combination of classification and visualization techniques (Verma, 2018). More specifically, a bibliometric study helps in understanding connections that exist in the corpus of a research field. It provides a macro picture of an area and its evolution to guide further meso and micro level investigations of the literature. The main bibliometric techniques are related to co-citation and co-word analysis. Co-citation analysis is used to measure similarity between documents, journals or authors through the frequency with which two units (i.e. documents, journals and authors) are cited together (also known as co-citation counts). Bibliometric methods to analyze citations have some limitations and, therefore, have been subject to criticism (Verma, 2018). Co-occurrence analysis is a bibliometric analysis technique that complements citation analysis. In co-occurrence analysis when keywords frequently co-occur in the document, the concepts related to those keywords are closely related (Bhattacharyya and Verma, 2019).

Bibliometric analysis helps in finding connections among the corpus of analyzed studies (van Eck and Waltman, 2017). Co-citation analysis was used to measure similarity between articles by using the frequency in which two articles are cited together content (van Eck and Waltman, 2017). This study also used co-occurrence analysis to investigate a semantic map to understand the conceptual structure of challenges in KM. Data for this study was extracted from Scopus database. Instead of other databases like Web of Science, Scopus was used because of its wide coverage of scholarly journals. The bibliographic records in the Scopus is searched using the following keywords as proposed by Gaviria-Marin et al. (2019): (‘‘knowledge management’’ or ‘‘organizational knowledge’’ or ‘‘knowledge acquisition’’ or ‘‘knowledge creation’’ or ‘‘knowledge integration’’ or ‘‘knowledge transfer’’ or ‘‘knowledge sharing or ‘‘knowledge diffusion’’ or ‘‘knowledge spillover’’ or ‘‘knowledge use’’ or ‘‘knowledge application’’) AND (‘‘challenge’’ or ‘‘risk’’ or ‘‘barrier’’). Only peer reviewed articles were retained and a total of 915 papers resulted in the final data set. This study analyzed the obtained datasets using the bibliometric tool VOSviewer 1.6.8, with co-citation analysis as the ratio to

aggregate the data. VOSviewer offers a different analysis of a large set of information through a single graphical map. The graphical map is a network of items built through text mining. The distance between items in a network is interpreted as an indication of the relatedness of the items. More specifically, the smaller the distance between the items (e.g. keywords), the stronger the items are related to each other. Further, the co-citation analysis highlights diversity in the knowledge base in an aggregate manner.

3. Results

3.1. Distribution of articles and most cited journals in challenges in KM (2009 – 2019)

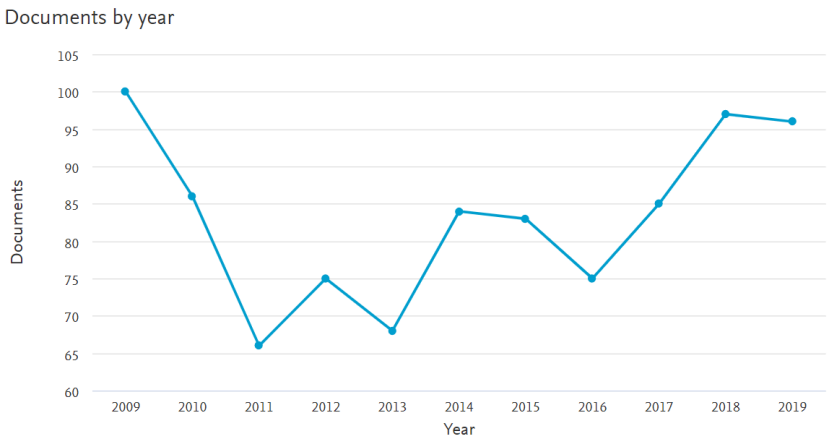

Figure 1: Distribution of challenges in KM (2009 – 2019) articles.

Figure 1 shows how the publication of challenges in KM studies has grown consistently in the investigated timeframe (2009-2019), with 2018 being the most prolific year. In total, the field produced more than 915 articles, published by 277 journals, confirming the growing trend in the field. Co-citation analysis was used to map and aggregate journals. Figure 2 shows that Cluster 1 (red) is more about general management journals, Cluster 2 (green) is KM and information systems journals and Cluster 3 (blue) is technology and innovation management journals.

The co-citation analysis of authors for the years 2009-2019 shows that authors in the field of challenges in KM tend to aggregate on three clusters (Figure 3). Figure 3 demonstrates that authors interested in challenges in KM in the last decade focus more on a managerial perspective of KM (red cluster).

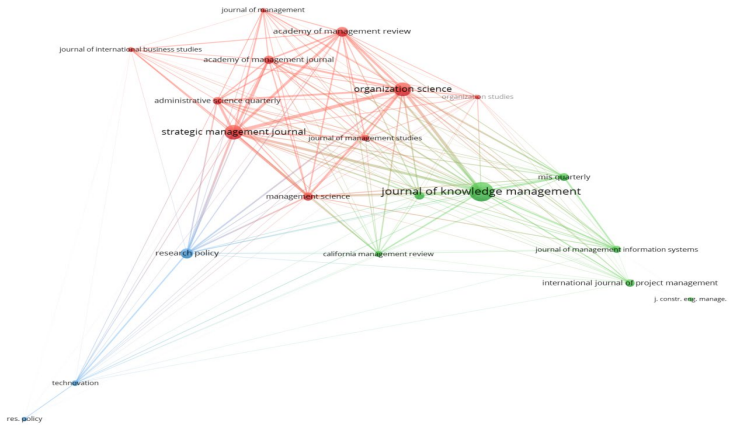

Figure 2: Visualisation of the social network of journals in challenges in KM literature (2009-2019)

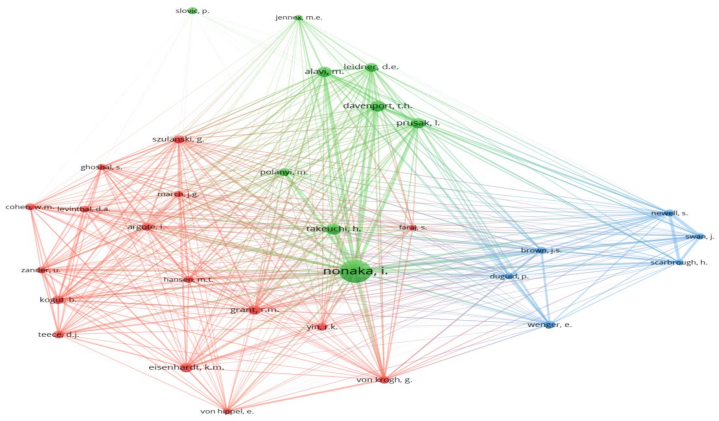

Figure 3: Visualization of the social network of scholars in challenges in KM literature (2009-2019)

3.2. Co-occurrence analysis

Figure 4 demonstrates that the co-occurrence analysis aggregated keywords in three cluster including: Organizational learning, knowledge development and sharing (red), optimization through KM (green) and Knowledge sourcing and planning (blue).

Cluster 1- Organizational learning, knowledge development and sharing:

Knowledge is a strategic resource and organizations should leverage their existing knowledge as well as create new knowledge for sustainable competitive advantage. Therefore, several researchers have tried to understand the challenges in knowledge

management processes and systems. According to Yap and Lock (2017), knowledge management is related to managing the created knowledge, while organizational learning (OL) manages the creation of a firm's knowledge. Between 2009 and 2019 researchers tried to investigate challenges of knowledge management by studying variables like organizational learning capability, organizational learning, effectiveness etc. Organization's learning culture is a continuous effort of an organization towards creating learning opportunities for its employees. The last decade articles in knowledge management literature mostly focused on understanding the challenges in organizational learning processes. An organization learns when the learning process is embedded among individuals. The knowledge sharing among individual is core of knowledge management (Feng and Shanthikumar, 2018).

Knowledge sharing (KS) is the process of getting the right knowledge to the right person at the right time to gain competitive advantage. Knowledge is developed and shared at the individual, group or the organizational level. KS describes how to share work related knowledge with other individuals in an organization. The main inhibitors of knowledge sharing behaviour include information acquisition and distribution, knowledge flow, knowledge claim formulation and evaluation. Finally, several researchers recommended that challenges related to OL should be reduced first in order to facilitate KS.

Cluster 2- Optimization through KM:

Several researchers have in last decade studied challenges related to knowledge development and sharing that inhibits optimization and reform of knowledge management. Organizational structure and management of firms in the modern world highly depend upon information system and innovation. The improvement in information acquisition, sharing, integration can therefore be promoted through process optimization and reforming knowledge management. Different researchers have developed their own unique perspective towards optimization through knowledge management. For example, according to Feng and Shanthikumar (2018), coordination and balancing of limited resources requires optimization of resource allocation as well as human resource capability in knowledge sharing. In addition, optimization through knowledge management leads to perfection of the quality of knowledge management circuits of the process, organizational structure and management methods. A platform for knowledge exchange and sharing helps optimization by building a flat organization of knowledge management processes that further facilitates joint efforts to innovate and enhance efficiency.

Cluster 3- Knowledge sourcing and planning:

According to Anderson et al. (2014), innovation is the combination of idea generation and implementation. New idea generation requires domain expertise and knowledge and it is nearly impossible for individuals to generate all the knowledge required for each task

(Huggins et al., 2010). Therefore, sourcing others' knowledge plays an important role in innovative performance and new ideas can be generated through knowledge sharing (Amayah, 2013). Knowledge sharing can maximise the use of existing knowledge and generate new knowledge. Knowledge exist either in tacit (implicit) or explicit forms in organization (Amayah, 2013). Knowledge sourcing includes both tacit and explicit knowledge. Individuals could source for tacit knowledge for domain knowledge, ideas and selection. Explicit knowledge sourcing includes the individual search for organization's knowledge management systems. Both tacit and explicit knowledge sourcing help individuals in companies to generate new ideas and induce innovation behaviour (ibid.).

3.3. Overlay Analysis

It is evident from Figure 5 that keywords like tacit and explicit knowledge, product development and culture appeared near 2012 and 2013. Most research in this timeframe focuses on using knowledge in projects in an effective and efficient manner. The keywords that were used towards 2014 and 2015 included knowledge sharing, knowledge transfer, innovation ecosystem, competition etc. Most research in this period focuses on organizational knowledge creation. Around/after 2015 challenges in KM literature focuses on knowledge and capacity development using technology.

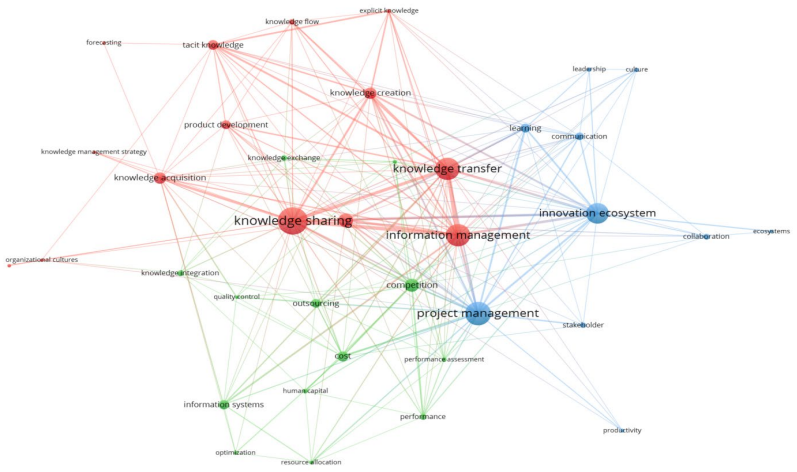

Figure 4: Visualization of the co-occurrence analysis in challenges in KM literature (2009-2019)

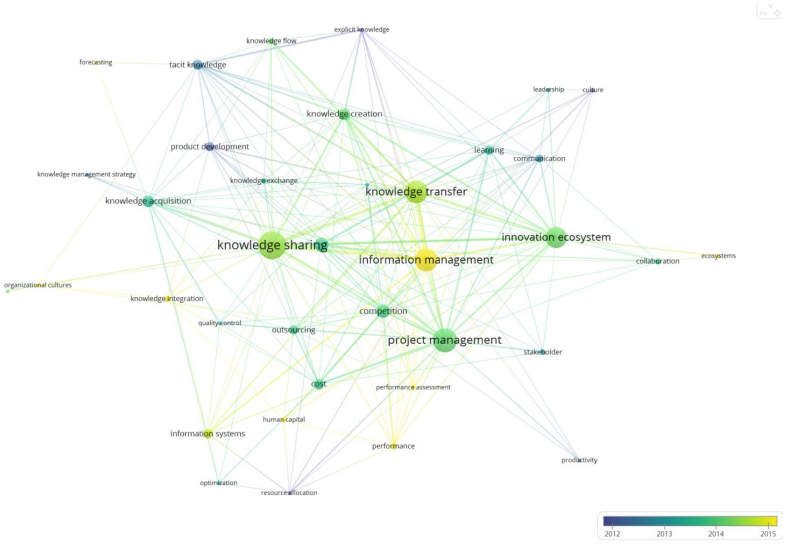

Figure 5: Overlay of keywords in challenges in KM literature (2009-2019) with timeframe

4 Limitations

The limitations of this study are related to the article inclusion and exclusion criteria based on the time period (i.e. 10 years), database selection and disciple (i.e. business, management and accounting). The results presented in this study are based on network analysis - in the future, in-depth content analysis of articles is required. This study has analysed academic publications obtained from the Scopus database. In the future, it is important to consider other databases along with the Scopus as they may contain excellent and relevant articles that are not indexed in Scopus. Future study should also consider relevant books e.g. Nonaka and Takeuchi (1995) or Polanyi (??add year) in the analysis to include perspectives from founders of knowledge management.

5 Conclusion

This study contributes to the area of KM research in multiple ways: First, the results present a viewpoint different from conventional literature reviews by visualizing the fourth generation KM challenges by using the bibliometric analysis. Second, the networks and clusters identified through co-citation and co-occurrence reveal interesting patterns and insights in the fourth generation KM challenges research. These insights can further lead to theoretical and empirical development and possibilities of relating different challenges of KM including the distribution of articles and most-cited journals and authors and finally keyword analysis. Third, this study provides an understanding of the influential forces that direct literature by identifying three main research streams in the challenges in fourth generation KM.

Based on these findings, this study proposes areas for future research that will advance the understanding of the challenges in the fourth generation KM. Also, future research can include articles from other databases like Web of Science, Google scholar etc. as this study only included scholarly articles from Scopus.

Abstract

Based on panel dataset of 33100 Italian firms collected by the MET company, this paper compares the differences in the innovation value chain of Knowledge-Intensive Business Services (KIBS), manufacturing and other services. The study demonstrates the relative importance attributed to different internal and external sources of information on innovation outcomes of KIBS in terms of product, process and organization, compared to manufacturing industries and to other services. Significant similarities exist between some aspects of firms' innovation behavior in these sectors: strong complementarities emerge between firms' internal and external knowledge. However, the outsourcing to Italian firms, to foreign partners or to other institutions and the local, domestic and international networking are valued differently across the three sectors. The findings shed new light on the innovation process of Italian firms and can be used in innovation management decisions.

Keywords – Knowledge-intensive business services; innovation; manufacturing; services.

Paper type – Academic Research Paper

1 Introduction

While analysis on innovation activities was mostly concerning the manufacturing sector, over the last 20 years the attention has raised for the service sector, and for KIBs, which after the revolution of Information and Communication Technologies have grown

in size and weight in the economic systems. While the less recent literature found that R&D activities are a much weaker competitive factor in services in general with respect to manufacturing (Hollenstein, 2003; Cainelli, Evangelista and Savona, 2006), and are an important innovation source only for a small number of science and technology-based service industries (Evangelista, 2000), more recently many studies on innovation in services, alone or in comparison with other sectors of activity, have reached different conclusions. Coombs and Miles (2000) propose that differences between the manufacturing and services have been blurred in recent years, a statement confirmed by a large ensuing evidence. In some studies the manufacturing industry has been compared to services in general (Álvarez at al., 2013; Sirilli and Evangelista, 1998), in other to KIBS (Cainelli, Marchi and Grandinetti, 2019; Teixeira and Santos, 2016; Asikainen 2015; Carlborg et al., 2014, Freel, 2006; Wong and He, 2005). From these recent studies, mostly on developed countries, the conclusion is that services firms and KIBS above all, are as innovative as firms in the manufacturing industry and appear no longer as "laggards" in terms of technology or dependent from the manufacturing industry, being the engine of the new knowledge-based economy. The role of KIBs emerges as crucial in the current global economy innovation process, where these firms act as fundamental providers, users, and intermediaries (Lafuente et al., 2018; Gallego et al., 2013; Cáceres and Guzmán, 2014; Gallouj and Savona, 2009; Czarnitzski & Spielkamp, 2003).

Despite the increased attention received by innovation in KIBS over recent years we argue that further research is still needed to gain a comparative view of manufacturing, other services and KIBs innovation patterns. The study of the determinants of the innovative performance of Knowledge Intensive Business Services (KIBS), as compared to manufacturing companies and to the sub-set of services companies, demand further exploration particularly in what concerns the relation between different sources of internal and external R&D.

We address these gaps of knowledge by considering firm's internal sources of information for innovation, taking into account many external sources (the impact on innovation of companies' outsourcing of R&D activities, the development of networking activities at domestic and international level) as innovation determinants.

Our empirical comparison proposes a comparative panel-data analysis developed in two steps.

Our aim is first to look at the complementarity between sources of knowledges that we detect by adopting a Multivariate probit analysis (Cappellari and Jenkins, 2003), and presenting the error correlations.

In the second step we try to answer a set of questions related to the innovation production function in which the effectiveness of firms' knowledge transformation activities is influenced by firms' internal and external knowledge resources in addition to other control variables. Firms' knowledge sourcing activities are used in the innovation value chain to study the transformation of knowledge into new products or processes or new organization of production.

There are several novelties of the analysis that are worth highlighting.

Firstly, we consider firm level data on a large sample of firms located in Italy (33100) including 4822 KIBS companies and 10153 other service companies drawn from the MET database, a wide firm level survey administrated in Italy. Secondly, a unique advantage of our analysis is the opportunity of using different types of innovation (product process, organizational) and many different proxies for knowledge activities. We have several determinant of innovation: 1) R&D dummy; and of external sources measured by 2) R&D outsourcing to Italian firms; 3) R&D outsourcing to other Italian organizations; 4) R&D outsourcing to foreign; 5) R&D networking local, domestic and international.

2 Data

We consider firm level data on Italian firms drawn from the MET database; this is the widest survey administrated in a single European country. We will use the dataset drawn from merging six waves of the Survey (2008, 2009, 2011, 2013, 2015, 2017) to which information from CRIBIS and ASIA ISTAT database had been added. Differently from other Italian and European datasets, the sample contains information on firms of all size classes, including firms with less than ten employees.

Each wave of the surveys contains about 25,000 observations belonging to the manufacturing (about 55%), KIBS (about 15%) and other (about 30%) services. The sampling design aims at having representativeness at the size, region, and industry levels.

For our analysis we have used a selected sample of 33.100 observations that includes only firms appearing at least in two consecutive waves from MET survey 2008, 2009, 2011, 2013, 2015, 2017. From the dataset we have extracted the following firms: 4822 KIBS firms, 18125 manufacturing firms and 10153 other services firms.

Table 1 contains the definition of the variables used for the analysis, and Table 2 their descriptive statistics for KIBS, manufacturing and other services.

Table 1. Variables definitions

Variables		Variables
Production innovation	Prod_inn	dummy = 1 if the firm has either introduced a new product on the market, radically changed an old one or a significantly improved product
Process innovation	Proc_inn	dummy=1 if the firm has changed its production process or introduce a significantly improved production process
Organizational innovation	Org_inn	dummy=1 if the firm has changed the organisation of its activity
R&D activity (dummy)	R&D	dummy=1 if the firm carries out R&D activity
R&D outsourcing with Italian firms	R&D_out_it_firms	dummy=1 if the firm have relations for Research and Development activities with Italian firms

R&D outsourcing with other Italian institutions	R&D_out_it_other	dummy=1 if the firm have relations for Research and Development activities with other Italian organizations
R&D outsourcing with foreign institutions	R&D_out_foreign	dummy=1 if the firm have relations for Research and Development activities with foreign organizations
Network local	Net_local	dummy if the firms have significant and ongoing relationships with other companies, organizations or institutions at local, international and domestic level
Network international	Net_internation	
Network domestic	Net_domestic	
Group (dummy)	Group	dummy=1 if the firm belongs to a group of enterprises at time t
Size	Size	ln(1 + number of employees)
Age	Age	natural logarithm of the age of the firm computed as the difference between time t and the date of its establishment
International (dummy)	International	dummy=1 if the firm participate in any international activities
Region (dummy)	Region	20 Regions of Italy
Investments (dummy)	Investments	dummy = 1 if the firm has made any type of investments
