enterprises that innovate is always greater than the percentage of firms that are involved in R&D. This is true in all the cases examined. At the same time, we observe in all the graphs the break around in 2013, in the sense that the percentage of firms that innovate and invest in R&D increases.

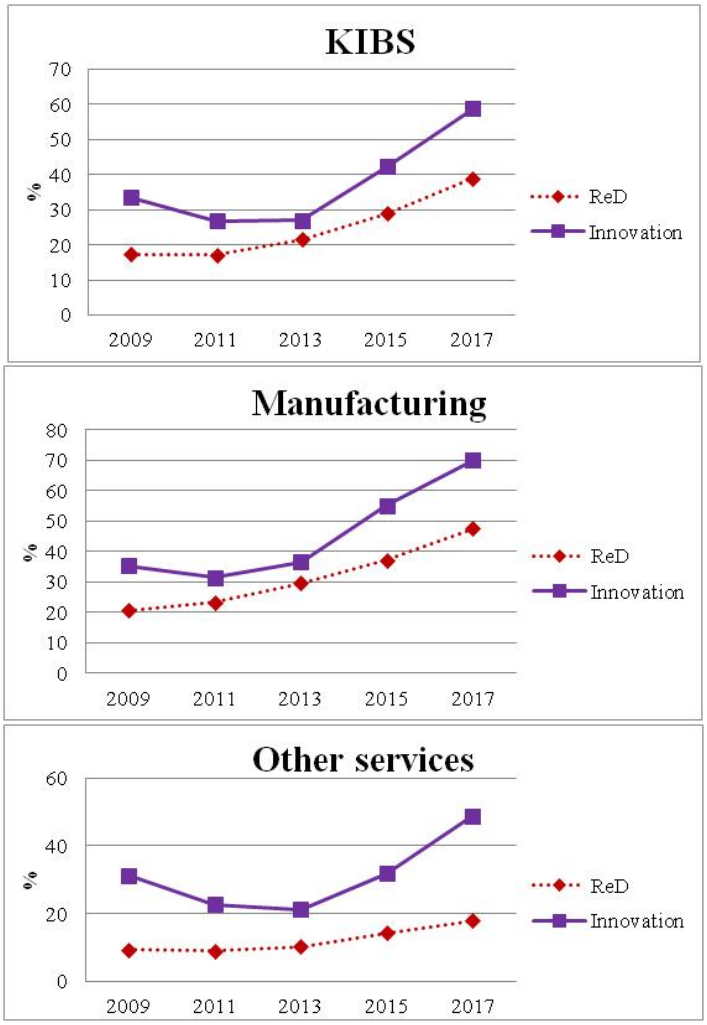

Figure. 1. Time series for innovation and R&D indicators

3 Methodology

We consider the knowledge inputs for innovation, that are the key variables. We identify seven alternative routes through which firms may source the knowledge inputs for innovation reflecting both internal knowledge creation and external sources of knowledge acquisition. We have in-house R&D measured by R&D and six external sources measured by R&D outsourcing to Italian firms; R&D outsourcing to other Italian organizations; R&D outsourcing to foreign; Networking activities to domestic firms; Networking activities to domestic firms; Networking activities at international level.(see Table 1 for additional details).

We summaries the probability that firm *i* will engage in each of the seven knowledge sourcing activities as follows:

$$RDN_{ijt} = \beta_0 + \beta_1 \mathcal{X}_{it} + + \varepsilon_{it} \qquad (1)$$

Where RDN_{it} represents the vector of Research and Development and Network variables i.e. its firm's knowledge sourcing activity j (j = 1, . . .7); $\mathcal{X}_{it}$ is the vector of explanatory variables, a set of indicators of the firms' resources such as size, age, international activities, shortage of finance; ε_{it} is an error term assumed to be independently and identically distributed with a mean of zero and a variance of σ^2.

We adopt an approach explored in Cassiman and Veugelers (2006) and also followed by Roper and Arvanitis (2012) estimating a Multivariate Probit model for firms' participation in the seven knowledge sourcing activities to catch the potential correlation. Positive error correlations then provide an indication of complementarities.

To keep building the innovation value chain, in the second step, we consider the process of knowledge transformation, in which knowledge sourced by the enterprise is translated into innovation outputs.

We check how key innovation determinants influence innovation outcomes in service (and, within it, in KIBS) and in manufacturing industries at three main levels: first, investigating the role of R&D; secondly, looking at companies' openness and at the relative importance attributed to distinct external sources of information for innovation via outsourcing (firm, market and other), and thirdly, considering the external local, domestic and foreign entities, with whom companies cooperate for innovation.

We first estimate a probit model for the innovation output, because the dependent variables are binary indicators. The baseline equation tests the effect of different drivers of innovation according to the following equation[1].

$$Y_{it} = \beta_0 + \beta_{1a} R\&D_{it-1} + \beta_{2a} R\&DOUTfirms_{it-1} + \beta_{2b} R\&DOUTother_{it-1} + \beta_{2c} OUTforeign_{it-1} + \beta_{3a} Networkdomestic_{it-1} + \beta_{3b} Networklocal_{it-1} + \beta_{3c} NetworkForeign_{it-1} + \beta_4 \mathcal{X}_{it-1} + \mu_i + \delta_t + \varepsilon_{it} \qquad (2)$$

[1] *The IV probit is estimated on the basis of equation 2 but considering the lagged (at time t-2) variables as instruments.*

Where:

Y_{it} is the dependent variable above described (product, process, organizational innovation), for firm i at time t ; All the $R\&D_{I,t-1}$ variables represents the vector of Research and Development variables for the alternative knowledge sources identified earlier; $\mathcal{X}_{it-1}$ is the vector of other explanatory variables: Region, Investment, Group, Size, International and Age; μ_i and δ_t denotes firm and time fixed effects; finally ε_{it} is an error term assumed to be independently and identically distributed with a mean of zero and a variance of σ^2 .

At this stage a potential issue is the endogeneity of the knowledge sourcing and network variables. Hence, we also estimate a model instrumenting the knowledge sourcing and network variables. More in detail, the IV strategy that we perform is related to the GMM in the sense that we consider the lagged values of the knowledge sourcing variables as instruments.

Basically with respect to the innovation production function we will test the following hypotheses:

H1: *R&D is positively and significantly associated with innovation.*

H2: *The power of the impact of R&D differs across KIBS, manufacturing and other service sector.*

H3: *Outsourcing relationship with different organizations are positively and significantly associated with innovation .*

H4: *The power of the impact of R&D outsourcing relationship with different organizations differs across KIBS, manufacturing and other service sector.*

H5: *The degree of openness to cooperation for innovation with different types of networking (local, domestic and international) is positively associated with innovation.*

H6: *The power of the impact of the degree of openness to cooperation for innovation with the entities differs across KIBS, manufacturing and other service sector.*

4 Empirical results

The initial link to innovation activity is firms' knowledge sourcing. Multivariate Probit models, employed for the reason above clarified, for firms' knowledge sourcing is shown in Table 3 with error correlation matrix in Table 4. The remarkable role of size, investment and credit access emerges as robust evidence across the different sources of knowledge. International activities are also a positive determinant of knowledge with the exception of the channel from local networking and from foreign R&D.

Complementarities between knowledge sourcing activities are numerically and statistically strong for all sectors of research interest with positive and statistically significant error correlations in all combinations (Table 4).

Note: Derived from Multivariate Probit models in Table 3.

The key econometric results for the innovation production function are reported in Tables 5 and 6. Tables 5 shows the main results of the RE probit for KIBS, manufacturing and other services in three different types of innovation: product, process and organizational. Table 6 shows the results of the IV strategy.

Regarding the RE probit (H1) the result for the R&D activity is positively and significantly associated with all types of innovation in manufacturing, other and all firms, while in KIBS, R&D activity is positively significant only for product innovation. In summary, H1 is only partially approved. Moreover, we can also emphasize that there is a sort of complementarity with the accumulation of physical capital given that also the probability to innovate increases with the firm size in all the estimations made (see Accetturo et al 2013 for a discussion). Besides, R&D activities have greater positive effects in the manufacturing sector on all types of innovation, therefore H2 is approved (Table 5).

As to the R&D outsourcing with Italian firms, the effect is positive on product and process innovation when the whole sample is taken into account, and on product innovation in manufacturing, but the estimation doesn't present remarkable results for the KIBs and for other services.

We underline similar effects when the R&D outsourcing with other Italian organization is consideredbut. in addition we also note that the impact on process and organizational innovation is also positive for the KIBS.

As to the Research and Development activities with foreign organizations, this does not exhibit interesting value. So the H3 and H4 are not confirmed (Table 5).

As to the H5, it is approved at margins as the networking activities are more important for some sectors in particular innovation types. The local networking is significant for organizational innovation in Other sectors, while international networking is positively significant for organizational innovation in Manufacturing, but negative for process innovation in other and for product innovation in KIBS. The domestic networking is important for process innovation in KIBS and in other services.

The robustness check carried out in Table 6 conducts to very similar results to those obtained with the probit regressions, but some novel results can be pointed out. Looking at R&D as to KIBS sector the effect is positive also on process innovation. Moreover as to the R&D outsourcing with Italian firms the effect in IV probit is stronger and this is verified especially in all the sample and in manufacturing sector and for process innovation in KIBS and product and organizational ones in other services. Moreover, differently from before when the R&D outsourcing with other Italian organization is considered, we observe only the organizational innovation in KIBS improves with that.

In addition, it seems that the importance of network is increasing more than before, especially if we measure the relevance of network domestic; this drives the innovation in

all the forms, and this is true in the total sample and in the other sectors. But the process and organizational innovation in the KIBS sector also exhibits a significant value, even if at low level such as the product innovation in manufacturing.

Abstract

The use of Enterprise Social Media (ESM) platforms is rapidly diffusing in the business context, as they are increasingly considered crucial for the future competition. In particular, as commonly underlined by scholars, ESM can bring substantial benefits to companies and especially to their knowledge management (KM) processes. However, such benefits can materialize only if the active use and contribution by individual employees to ESM are ensured. Therefore, it is crucial to better understand how and how much an ESM platform is used by a company's employees. This explains why the literature is devoting particular attention to the analysis of the level of participation and the type of activity performed by the users of such platforms. While "frequency of use" is the most considered dimension to classify different users' groups, scholars also resort to other dimensions, as the distinction between passive and active users, sometimes called as "posters" and "lurkers". The paper proposes a new typology of ESM users based on the results of a survey, which involved 262 employees of an international engineering project-based service company that has adopted an ESM platform. What emerged from the analysis of the survey data confirmed the existence of different types of ESM users and provided the empirical basis to develop a users' typology based on two dimensions: frequency (high vs. low) of use and kind (active vs. passive) of use. This allowed identifying four different users' groups (of different size but all populated), that were denoted as: "frequent contributors", "sporadic contributors", "frequent lurkers" and "sporadic lurkers".

Furthermore, applying descriptive statistics and variance analysis on the survey data allowed to verify the reasonableness of the proposed new typology and identify the main aspects that characterise the different users' groups such as: position in the company, role inside the community, specific types of relevant knowledge sources, perceived usefulness, information novelty and satisfaction with the platform and the Community of Practice. The findings of the study have both academic and managerial implications. As regards the latter, managers should consider that different employees might behave differently with respect to new media, so that an undifferentiated approach to different behaviours may be ineffective. The main limitation of the study is that only one company was analysed belonging to a particular sector with specific knowledge needs and capabilities.

Keywords – Knowledge Management, Enterprise Social Media, Users' behaviour, Survey

Paper type – Academic Research Paper

1 Introduction

Enterprise Social Media (ESM) are social media platforms arranged for being used by company's employees (Leonardi et al., 2013; Hacker, 2017). Their application is rapidly becoming common in the business context, as this technology is increasingly considered important for the future competition. Many scholars underline that ESM can bring substantial benefits to companies and especially to their knowledge management (KM) processes (Nisar et al., 2019). However, such benefits can materialize only if the active use and contribution by individual employees to ESM are ensured (Guinan et al., 2014; Mäntymäki and Riemer, 2016). Hence, it is crucial to understand how companies adopt an ESM platform and how employees get support regarding their knowledge-related activities. This explains why the literature is devoting particular attention to the analysis of the level of participation and the type of activity performed by the users of such platforms (Schwade and Schubert, 2019). While "frequency of use" is the most considered dimension to classify different users' groups, scholars also take into account other dimensions, as the distinction between passive and active users, sometimes called as "posters" and "lurkers" (Engler and Alpar, 2018; Chin et al., 2020). Even if it is plausible that active users are also frequent users (or vice versa passive users are sporadic users), the relationship between the two dimensions deserves to be further investigated, not only to find confirmations, but also to understand if a new typology can be constructed based on these two dimensions.

This is what the present paper aims to do, by illustrating the findings of a study concerning the use of an ESM platform as a tool to support the knowledge management activities of the employees of an international project-based service company. Specifically, based on the results of a survey, which involved 262 company's employees, a new ESM users typology was first proposed, and then by means of a statistical analysis the main aspects that distinguishes the different kinds of user were identified and examined.

The paper is organised as follows. Section 2 illustrates the conceptual background of the study, while section 3 presents the research goals and method. Section 4 is devoted to the findings of the study that are discussed in the next section 5. The last section contains some conclusions, together with academic and managerial implications and the limitations of the study.

2 Background: ESM users typology

There is wide consensus in the literature on the fact the failure of many ESM platforms is due to (as well as testified by) they are underused by the workforce (Guinan et al., 2014; Alarifi et al., 2015; Giermindl et al., 2018). Hence, there is the need to understand how companies can act in order to motivate and induce employees to use ESM platforms more intensively. This can be effectively done only by taking into account that there exist different forms of usage. Indeed, empirical evidence shows that ESM participants perform various activities (from simple consumption to content production and contribution) and with different frequency. This is why scholars have devoted specific attention to analyse and classify the different behaviours adopted by ESM users.

It is worth noting that the spreading of online communities, spurred by the availability of the new social media applications, has brought about the introduction of new terms to indicate possible user behaviours, as, e.g., posters and lurkers. The former term is used to indicate users who assume an active behaviour by posting new contents, replying or commenting content posted by others, etc. On the contrary, the term lurker denotes users who observe the community activity but do not actively participate.

The research about Enterprise Collaboration Systems (as ESM are) users typology is very fragmented and offers a lot of classifications that are based on different aspects and dimensions, as e.g. type of use, frequency of use, variety of use. This is confirmed by the findings of a recent literature review made by Schwade and Schubert (2019) that identified 102 definitions of user types, that they summarised in 6 typologies, as follows: creators, contributors, lurkers, inactives, non-users, users without an account. The review also revealed that scholars deserved particular attention to the role and characteristics of lurkers, while the discussion about other user types results to be comparably limited. Furthermore, scholars do not even agree on the definition of the single types, so that e.g., they found 22 different definition for lurkers, as well as the distinction between contributors and creators is all but clear.

The strong interest of scholars about lurkers is probably due to the fact that in most online communities the 90-9-1 rule applies (Nielsen, 2006): 90% of users are lurkers who read or observe, but do not contribute; 9% of users contribute from time to time, but they have other priorities. Only 1% of users are very active and account for most contributions. Such rule, originally defined for Internet users, seems to be applicable also in the business context, even if with different percentages, as revealed by empirical evidence (Oettl et al., 2018; Schwade and Schubert, 2019).

In general, typologies employed by ESM scholars to differentiate and analyse users' behaviours focus on a single dimension. In particular, ESM scholars tend to distinguish between content contributors (posters) and content consumers (lurkers) and investigate the factors that drive the behaviours of the two groups (Alarafi et al., 2015; Engel and Alpar, 2018; Chin et al., 2020). However, two interesting exceptions deserve to be mentioned here.

The first one is the study by Oettl et al. (2018) that, on the basis of the findings of 28 interviews with experts of a company that introduced an ESM platform, distinguishes the different user types resorting two dimensions: individual openness to ESM and perceived task-fit, where the latter is derived from the technology acceptance theories (Ngai et al., 2015). Accordingly, the authors identify four user archetypes, i.e. power users (denoted by high openness and high task fit), limited users (denoted by high openness and low task fit), reluctant users (denoted by low openness and high task fit) and repudiators (denoted by low openness and low task fit). They also identify two mixed user types, i.e. hidden champions (placed halfway between limited and power users) and question marks (placed halfway between repudiators and limited user. The results of the study suggest that the different groups have different perceptions about the value added by the platform as well as the obstacles to its use, which has relevant implications for managers who want to promote the use of the platform.

The second one is the work of Giermindl et al. (2018) that proposes a classification than can be regarded as bi-dimensional. The authors examine why posters and lurkers differ in their motivations for participating in ESM by referring to the social exchange theory. This theoretical approach considers that in ESM, individuals exchange socioemotional resources, and hence their participation is affected by the motivational factors that are central to the characteristics of a social exchange, such as: reputation, common identity, common bond, social interaction and community commitment. The authors further split the two groups based on the frequency of their activity as follows: super frequent posters, frequent posters, infrequent posters, frequent lurkers, infrequent lurkers. The general findings of their study indicate that posters show significant higher mean values for all the five motivational aspects when compared to lurkers.

To sum up, studies that analyse the factors that distinguishes the different kinds of ESM users are still scarce and offer fragmented results. Furthermore, since most of the proposed typologies are unidimensional, it would be appropriate to try to use a bi-dimensional classification.

At this point, an aspect deserves to be recalled that concerns the role played by lurkers for the success of an ESM platform. While initially lurkers were negatively connoted, recently they role was revaluated since they provide the audience for posters (Cranefield et al., 2015; Ridings et al., 2006). Furthermore, even consumption alone helps the whole users' community to increase its knowledge, transfer it and apply where it is need (Engler and Alpar, 2018; Pohjola and Puusa, 2016). In this regard, Havakhor et al. (2018) suggest

naming the individuals who only consume content as “seekers”, term that has not a negative connotation.

3 Research goals and method

3.1 Research questions

What emerged from the previous discussion suggested us formulating the following two research questions:

RQ1. Can a bi-dimensional classification based on kind of activity and frequency of use allow to better identify different types of ESM users?

RQ2. Which factors characterize the different user types?

3.2 Research method

In order to answer the above-formulated research questions, we investigated how the members of internal communities of practice in a global engineering company are using an ESM platform to access and interact inside their communities. At this aim, we developed a questionnaire with 22 questions. In addition to demographic questions, we asked which knowledge sources and need for information the employees have, what the activities they perform by means of the platform are, the difficulties they perceived in using the platform to interact with the other members, and their satisfaction with their communities. In particular, we asked them to indicate how frequently they access their communities by means of the platform and which kind of use they make. Questions either used a 5-point-Likert scale or were multiple-choice questions. Additionally, we used open-answer questions to collect more opinions about their community. The survey was administered online between September and October 2018.

In order to analyse the data, we used descriptive statistics, content analysis to analyse open answers and one-factorial ANOVA and Tukey-B tests to detect differences between the identified user groups.

4 Findings

4.1 Case company

The investigated enterprise is a global engineering company specialized in the pharmaceutical industry, with around 2,000 employees in 15 offices dispersed in Europe, China, India, and USA. Communities of practices, that they call Communities of Interest (CoI), as a central part of the strategy to become a world leading pharma engineering company, that has a local presence and use the knowledge of experts around the world.

Since 2008, the company has organized 20 global CoIs, whose size ranges from 67 to 373 members and approximately 1,400 project execution employees are members of at least one CoI. Participation is voluntary continuously, and the CoIs define their own task, are responsible for stewarding knowledge within the enterprise, and have a long-term focus. CoIs are responsible for writing the global engineering standards and implementing best engineering practice derived from projects throughout the world. CoIs are supported by several ICT tools including the ESM platform Connect. Each CoI has a Chairman who is overall responsible for the community and key members' engagement. He/she is also responsible for the mainly administrative tasks of inviting to meetings, reporting on CoI performance, maintaining the dialogue with the CoI board, and following up on budget. A CoI has several Key members that are voluntarily appointed to the position because they are recognized experts within their field, and these are central to developing knowledge, sharing knowledge and answering questions. Usual members have no responsibility but contribute to the knowledge sharing and development.

4.2 Deriving User Groups

We received 262 valid answers from the employees of the case company. We defined a frequent user as a person that uses Connect for accessing his/her CoI at least on a weekly basis, while a sporadic user is only active on a monthly basis or even more seldom. Furthermore, we asked employees whether they are rather passive users, or actively involved, e.g., by answering questions or motivate colleagues to contribute. Based on the two dimensions, users' frequency and kind of activity, we have derived four user groups, as indicate in table 1, that are named according to the definition typically employed in the literature (see section 2), i.e. frequent contributors, sporadic contributors, frequent lurkers and sporadic lurkers.

Table 1**:** User groups according to frequency and activity of users

	Active user	**Passive user**
Frequent user	46.9% frequent contributors	9.2% frequent lurkers
Sporadic user	21.4% sporadic contributors	22.5% sporadic lurkers

The group of frequent users is with 56.1% slightly bigger than the group of sporadic users, which can be mainly explained by the fact that the survey was administered online by means of Connect. Furthermore, 68.3% of respondents are active users. The high share of active contributors, much higher than that usually characterises a social media platform, may be linked to the fact that the platform is used inside a favourable organisational context as that of communities of practices. The biggest group, according to table 1, is the group of frequent contributors. However, as previously underlined, "lurkers" are important for the CoI functioning (they could be people who find within the

CoI the knowledge they need for their job). In the following, we analyse these user groups if they show some specific characteristics.

4.3 Characterizing user groups

Table 2 provides an overview of the demographic information. Half of the engineers and more than half of the managers consider themselves as frequent contributors. For project and engineering managers, we do not have a clear picture between frequent contributors and sporadic lurkers. The different behaviour of project and engineering managers can be ascribed to the fact that they may also use other tools to coordinate their teams. Chairmen and key members are fulfilling their role well, because their majority considers themselves as frequent contributors. It is worth noting that all the Chairmen declare to be contributors, even if with different frequency. Regarding the duration of being a member of a CoI or the length of working in the company, no patterns could be found.

Table 2: Demography of user groups

	Frequent contributor (N=123)	**Frequent lurker (N=24)**	**Sporadic contributor (N=56)**	**Sporadic lurker (N=59)**
Position in the company	**50% engineer/ specialist** 31.4% project/ engineering manager **55.6% manager**	10.9% engineer/ specialist 5.9% project/ engineering manager 0% manager	20.8% engineer/ specialist 23.5% project/ engineering manager 22.2% manager	18.2% engineer/ specialist **39.2% project/ engineering manager** 22.2% manager
User role in primary CoI	**89.5% Chairman** **77.4% Key Member** 34.4% Member	0% Chairman 1.9% Key Member 12.2% Member	10.5% Chairman 17% Key Member 23.3% Member	0% Chairman 3.8% Key Member 30.2% Member

We used an ANOVA analysis in order to identify differences between the four different groups. Table 3 lists the mean values of Likert-scaled variables that showed a significant F-Test (p=0.05). The first four variables concern the management of knowledge needed for the own daily job, the second five how much CoIs help in satisfying such needs.

Table 3: Mean values of significant dependent variables in ANOVA analysis

Variable	**F-value (sig.)**	**Frequent contributor**	**Frequent lurker**	**Sporadic contributor**	**Sporadic lurker**
Relevance of external knowledge sources for own job (magazines, conferences)	F=6.047 Sig .001	3.37	2.83	2.96	2.64
Relevance of Connect as knowledge source for own job	F=8.818 Sig .000	3.58	3.09	3.05	2.84
Relevance of formal meetings for own job	F=2.698 Sig .046	3.88	3.92	3.61	3.53
Importance of information	F=7.304	4.07	3.50	3.51	3.51

about new tech solutions for job	Sig .000				
CoI fulfils own needs	F=15.99 Sig .000	3.55	3.17	3.11	2.71
Satisfied with level of collaboration in CoI	F=6.629 Sig .000	3.40	3.21	3.02	2.79
Find often answers to questions in CoI	F=15.514 Sig .000	3.44	3.04	2.89	2.49
Satisfied with CoIs ability to receive own ideas	F=8.019 Sig .000	3.63	3.33	3.20	2.95
CoI keeping up with industry	F=5.968 Sig .001	3.58	3.58	3.14	3.09

Looking at data in table 3, sporadic lurkers have indicated the lowest values while frequent contributors have higher values (apart from the relevance of formal meeting whose value, however, is very close to the higher one): hence it seems reasonable to presume that these two groups are very different. Furthermore, the level of satisfaction with all the benefits linked with the CoI decreases passing from frequent contributors, to frequent lurkers, to sporadic contributors and, lastly, to sporadic lurkers.

We employed the Tukey-B Test to show in case of significant F-Tests possible homogeneous subsets in the data (significance level 0.05). The Tukey-B tests revealed that we have not four different groups for all the significant variables, but sometimes the frequent contributors build one group and the others build a second group (like in the case of the relevance of external knowledge sources). Sometimes, three homogeneous subgroups where found - (1) frequent contributors, (2) frequent lurkers and sporadic contributors and (3) sporadic lurkers (e.g., variable: CoI fulfil own needs).

We furthermore asked the participants what they miss in their primary CoI. The results were analysed via a content analysis. We identified six different problem areas. Table 4 lists the most frequent answers and the number of people in parentheses that mentioned this issue. Two problem areas were indicated by all the groups and concern the need having more active participants and making the search of useful content easier. Frequent contributors recall the need to find more (and in a different format) topics; they also would even like to contribute more, if they would have time. Sporadic contributors totally agree with frequent ones but ask for more support from upper management and clearer strategy for all CoIs. Frequent lurkers get disappointed with old information and dead links, while sporadic lurkers are not motivated to use their CoI, because they find it easier to ask colleagues directly. They also complain about the limited time to participate in the CoI and, as similarly to sporadic contributors, the missing support from the management to integrate such activity in daily work.

Table 4: Missing issues in the primary CoIs (open answers analysis)

Problem area	Frequent contributors	Frequent lurkers	Sporadic contributors	Sporadic lurkers
User activity	• More active participants (18)	• More activity (2)	• Missing active people (2)	• Missing activity of other people (2)
Content issues	• More topics, not only questions and answers (7)	• More and more updated content (4)	• Missing updated content and links (3)	
Missing time	• More time to contribute (6)		• Missing time to use CoI (3)	• No time (3)
Finding relevant information	• Better search possibilities (6) • Access from outside the company (2)	• Easier overview about content that allows to follow a topic (2)	• Better ways to search for and filter relevant information (4) • Useful rating of articles (2)	• Miss focus on relevant information (2)
No motiva-tion		• Do not need CoIs for own work (1)		• Lack of motivation / better to ask colleagues directly (4)
Missing support from management			• Support from upper management / strategy for all CoIs, rewards for higher quality (2)	• Need more support from management to integrate in daily work (2)

5 Discussion

What illustrated in the previous sections provides some food for thought that deserves to be further discussed.

5.1 Characteristics of the user groups

The study was based on the assumption that it is possible, and better, to use a bi-dimensional taxonomy to classify ESM users, where the two dimensions are: frequency of use and kind of use. The results of the analysis seem to confirm such an assumption (all the four types include a not insignificant number of respondents); however, findings show that sporadic users and frequent lurkers are very similar in terms of cognitive needs and satisfaction with CoI, so that the statistical analysis sometimes indicated them as a single group. Rather, the latter ones are more satisfied that the former ones, which induces to think that frequency plays a more relevant role in explaining the different users' perceptions than the active or passive kind of use.

Furthermore, the study shows that different user types have different motivations for using the platform, that are connected to the need of information for their job (depending on which of this information can also be found in the CoIs), to how much the community, that is supported by the platform, fulfils their needs for finding useful and updated information and for collaborating with other colleagues. In general, it can be assumed that

the higher are the knowledge needs and the capability to find answers inside the community the more frequent is the use of the ESM platform.

5.2 Changing sporadic contributors and lurkers to frequent contributors

Taken for granted that is difficult to change a passive into an active user, the question is if and how to induce infrequent contributors to contribute more frequently, as well as infrequent lurkers to resort to CoIs more frequently. Our study shows that sporadic users do not find enough useful information in the ESM and miss the support of the management.

To face the first point, chairmen and key members should not only contribute new knowledge, but also take care that outdated knowledge is archived, and dead links are removed. In general, a better organised information allows its easier and faster retrieval, thus involving a more intense use of the platform as well as the community.

To address the second issue, managers should integrate the work with CoIs into daily work routines of employees, that means to encourage them to contribute and give them time to read information and provide answers. In doing this, they should consider the organisational position of the single employee. For instance, in the case company there are some factors that make project/engineering managers less frequent and active users of the platform, which need to be identified if project/engineering managers' participation is to be fostered.

6 Conclusions

Our study employed a bi-dimensional typology to classify and analyse how the employees of an engineering services company are using an ESM platform to access and interact inside their communities. Findings allow to answer the two research questions we posed; however, the answers are partially unexpected and provide thought-provoking indications.

6.1 Implications of the study

The paper has both academic and practical implications. Concerning the former ones, it confirms that such a bi-dimensional classification can help better identifying the different ESM user groups as well as understanding the factors that affect their behaviour. Furthermore, it allows highlighting more clearly differences and similarities that denote the various groups. For instance, in the analysed case, the study revealed that frequent lurkers and sporadic contributors share some common traits that distinguish them from the other two groups. The above paves the way for further empirical research aimed at employing the proposed classification in other contexts and verifying if the characteristics of the different groups might be linked to the organisational environment where the ESM platform is implemented. As regards the practical implications, the study provides some

useful indications to managers who intend to promote the use of an ESM platform inside their company. In particular, the analysis not only confirms the ineffectiveness of an undifferentiated approach, but it also suggests that mangers' efforts should be primarily directed to frequent lurkers and sporadic contributors whose participation can be more easily stimulated.

6.2 Limitations

The study is not without limitations. The most important is that results cannot be generalised, since only one company was analysed that belongs to an industry with specific knowledge needs and capabilities. An aspect that must be taken into account concerns the fact that the ESM platform operates inside a community-based context, which clearly influences its use. Furthermore, for the sake of quickness and simplicity, the survey was distributed through the ESM and not via email, thus reducing the reach. Thus, it is likely that the sample includes a larger share of more frequent users than the actual percentage in the company is. Lastly, the study is based on a self-assessment of respondents about the frequency and the kind of use they are making of the platform, and not on an analysis of log data and activity performed on the platform. However, researchers on this topic frequently use this method.

Despite the previous limitations, the findings of the study provide interesting insights that can be a basis for further studies aimed to better understand how the new social tools are employed in a business context.

Abstract

Nowadays information flow overload is typical for most of the companies, universities as knowledge organizations are not the exception. Little emphasis is placed on knowledge transfer efforts made by universities in passing knowledge to internal stakeholders (Chugh, 2013). The paper describes a sketch of a knowledge base for university research. The case of Graduate School of Management St. Petersburg State University is taken into consideration. The knowledge base in the form of ontology helps to create a big picture view of the different information pieces involved into research and improve understanding of research in general as well as its various research aspects (Gruber, 1993; Hahn, Chang, Kim & Kittur, 2016; Hammar, 2017).

This paper is consistent with design science research and systems thinking applied for generalization of the selected research domain (Dresch, Lacerda & Antunes, 2015). It is based on literature review, the systemic analysis of knowledge portals of several universities as well as semantic analysis and in-depth interviews. The paper is focused on the ontology development for research domain so methods of ontological engineering are used. The study considers knowledge base and ontology from knowledge management perspective. According to Ameen et al. (2012) the university ontology generally portrays an institution, representing the local reality of the entire educational process. The knowledge base in the form of ontology is designed considering various aspects: organizational structure, research activities and workflow processes, including administrative structures, research results and their dissemination.

The analysis of knowledge bases and literature review showed that existing university knowledge bases serve more like digital repositories (Koperwas, Skonieczny, Rybiński & Struk, 2013). But there is no survey devoted to university research domain. This research fills the gap.Proposed knowledge base is linked to the existing Pure Cloud Information System developed for a very specific application being a digital repository. The sketch of ontology of a knowledge base creates a big picture of decomposed comprehensive research aspects and tasks and their relationships; and allows the research data to be aggregated, filtered and delivered in a user-friendly way to the faculty and administrative staff.

Presented sketch of ontology of a knowledge base for university research may help researchers, managers and knowledge analysts to develop a big picture view, improve the navigation among different knowledge assets. The paper considers the feasibility of using the ontology for research data integration from relational databases and other information sources.

Keywords – research ontology, university knowledge base, visualization technique, domain-specific KM, case study.

Paper type – Academic Research Paper

1 Introduction

Nowadays information flow overload is typical for most of the companies and universities where organization of knowledge and information flows are decentralized, desynchronized in time and space. Universities take a lot of effort in knowledge transfer through commercialization of research and expert activities of the faculty but little emphasis is placed on the knowledge transfer efforts made by universities in passing knowledge to internal stakeholders (students, faculty and administrative staff) (Chugh, 2013).

It is an increasingly common practice within universities to use departments and schools as units of a big picture of research (Bourke & Butler, 1998). However the organisation of information flows among the information clusters and agents in the university is often hidden and invisible. Ontology-based approach can help to reveal the tacit knowledge structure of the university research landscape.

2 Research methodology

The paper describes a sketch of a knowledge base for university research. The case of Graduate School of Management St. Petersburg State University is taken into consideration. The knowledge base in the form of ontology is based on the use of modern visual knowledge codification (diagramming) techniques which helps with data integration and systemizing and managing knowledge on research (Banks, 2001; Sosnovsky, Gavrilova, 2006). The presented ontology of research (conceptual model) is based on competency questions including planning questions and temporal projections; and helps to create a big picture view of the different information pieces involved into research and improve understanding of research in general as well as its various research aspects and decisions (Gruber, 1993; Gruninger & Fox, 1995; Hammar, 2017; Hahn, Chang, Kim & Kittur, 2016; Wheeldon & Ahlberg, 2012). Systems thinking and visual metaphors are applied for generalization of the selected research domain. The conceptualization of university knowledge through visualization techniques serves to depict the results of research and to provide communicative tools for further discussions of the presented data.

The proposed ontology UNIVERRA (UNIVERsity Research Activity) is based on the extension of BIBO approach (Surla, Segedinac & Ivanović, 2012). The BIBO ontology (Bibliographic Ontology) is a conceptual structure to describe information defining the bibliographic things like papers, articles, or books (D'Arcus, Giasson, 2009). It uses RDF and is widely operated as a citation ontology or as a document classification ontology.

BIBO also semantically models publication review statuses, enabling to make a request for all items in the knowledgebase in a much simpler manner (Hammar, Lin, & Tarasov, 2010). Sometimes it is employed as a way to describe any kind of document. It has been originated from many modern document definition metadata formats and is widely employed as a common ground for converting other bibliographic data sources (Dimić, Segedinac & Ivanović, 2012). Figure 1 illustrates a piece of BIBO ontology.

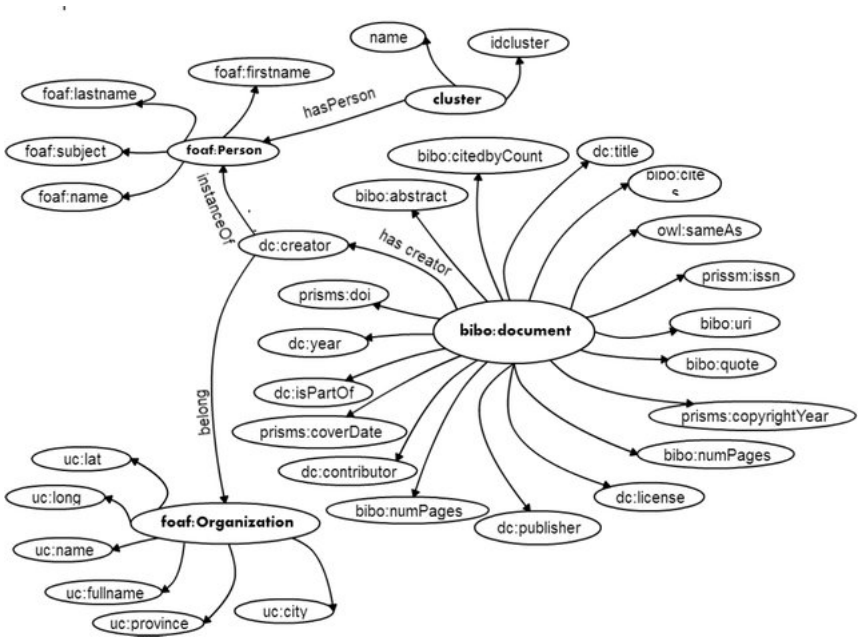

Figure 1 Fragment of BIBO ontology (Sumba et al., 2016)

There are a number of other ontologies describing the research activity, e.g. DoCO, the Document Components Ontology, most widely used for the description of document components (Constantin et al., 2016), FRAPO (Peroni & Shotton, 2018), SCoRO, the Scholarly Contributions and Roles Ontology(Shotton & Peroni, 2017), VIVO (Conlon et al., 2019). The basic concepts within the FRAPO and SCoRO models are shown in the following figures 2 and 3.

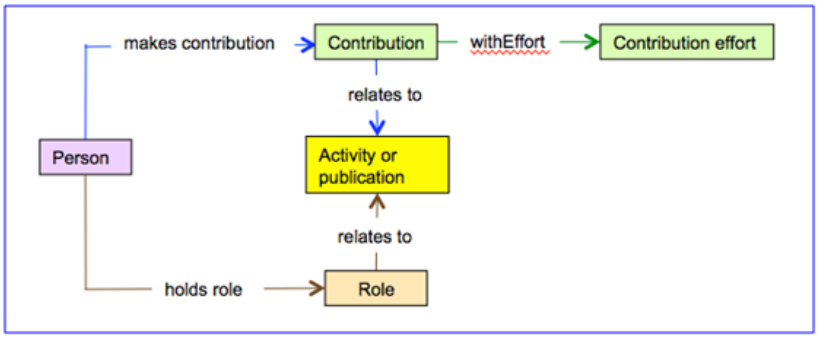

Figure 2 SCoRO ontology for Research Output concept

SCoRO ontology describes the contributions and roles of researchers, and the organizations of which they are members, concerning all types of academic activities depicted using FRAPO, and to the scholarly journal articles and other outputs that result from them.

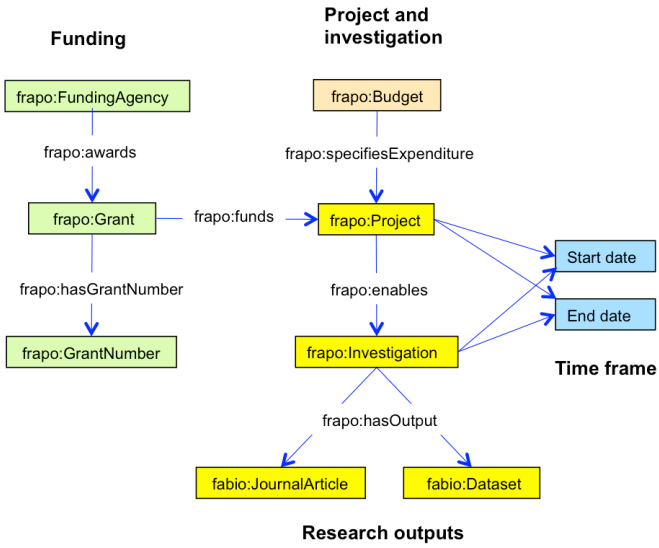

Figure 3 FRAPO ontology for PROJECT concept

FRAPO ontology also permits descriptions of various types of applications, funding programs, infrastructure entities (e.g. services and research facilities), and a wide range of financial entities (e.g. accounts, contracts, quotations, purchases, invoices and payments), and the relationships between them not shown in the diagram above.

Recent VIVO ontology supports recording, editing, searching, browsing, and visualizing different scholarly activities (Conlon et al. 2019). VIVO is member-supported,

company open source software and an ontology for representing scholarship. VIVO It encourages research discovery, expert finding, network analysis and assessment of research impact. It also may be easily extended to support additional domains of scholarly activity.

Our approach is consistent with design science research and systems thinking (Dresch, Lacerda & Antunes, 2015). It is based on literature review and the systemic analysis of knowledge portals of several universities as well as semantic analysis and in-depth interviews on the case of Graduate School of Management St. Petersburg State University. The paper is focused on the ontology development for research domain, so methods of ontological engineering are used. The study considers knowledge base and ontology from knowledge management perspective.

The analysis of knowledge bases and literature review showed that existing university knowledge bases serve more like digital repositories (Koperwas, Skonieczny, Rybiński & Struk, 2013). There are some works in this area devoted to information system of university and its problems discussing university ontologies for archives, studying process, human resource and financial issues as well as general management and administration processes (Bawany, Nouman, 2013; Malik, Prakash & Rizvi, 2010; Kyriaki-Manessi, Dendrinos, 2014). But there is no survey devoted to university research domain. The presented paper and the proposed design make an attempt to fill this gap. We use the visual approach in the ontology development that demonstrated its feasibility for several decades of deployment (Gavrilova, Voinov, 1996).

3 Ontology Design and Development

This research puts in evidence on the issue of development of knowledge base for research using ontology-based approach. The ontology in general can be defined as the "specification of the conceptualisation" (Gruber, 1993). According to Ameen et al. (2012) the university ontology generally portrays an institution, representing the local reality of the entire educational process.

However, we are interested in providing a big picture view of the research activity. So UNIVERRA ontology is put as a skeleton of a knowledge base aiming at collecting, organising and sharing each researcher's knowledge base. It allows to create self-service customer support content around recurring topics, issues, and themes. The knowledge base in the form of ontology is designed considering various aspects: organizational structure, research activities and workflow processes, including administrative structures, research results and their dissemination. This network of ontologies allows the creation of concepts independently or could be integrated for a specific application. We used the visual approach to the design as the most comprehensive one (Gavrilova, Voinov, 1996).

Designed knowledge base reuses another ontology (Read, Demetriou, Nenadic, et al. 2016). It is linked to the existing Pure Cloud Information System which was developed for a very specific application being a digital repository. It collects the information about

the published research results of the faculty and conference papers as well as the information on applications for grants and grants themselves.

Proposed knowledge base in the form of ontology creates a big picture of decomposed comprehensive research aspects and tasks and their relationships, friendly for navigation and search; and allows the research data to be aggregated, filtered and delivered in a user-friendly way to the faculty and administrative staff.

Knowledge base includes logical structure of the domain concepts and their relationships to one another. It was based on data sources that were made available: annual research reports, regulating documents and existing datasets.

Figure 4 illustrates the first version of the skeleton of the designed ontology UNIVERRA which describes the main actors and concepts of the modelled domain.

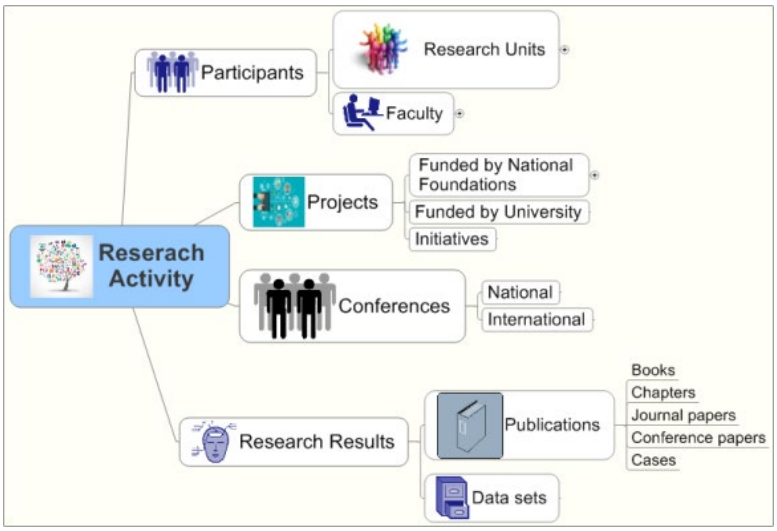

Figure 4 The sketch of the UNIVERRA ontology (upper levels)

Each of the concepts of this ontology can be presented as a set of more detailed pieces. We tried to develop the systems view of different research aspects at different scales and ensuring they all fit together. For example, the figures below show the conceptual structures of the research management domain as a whole and the aims of research activities.

Figure 5 presents the idea of management research on the case of Graduate School of Management, St.Petersburg University, with the most important concepts (key principles and objects, key activities) that radiate from the central idea of research management.

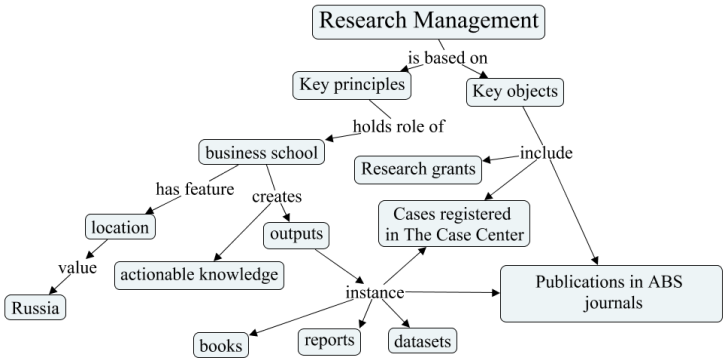

Figure 5 Concept map for principles and objects in management research at Graduate School of Management, St.Petersburg University (GSOM SPbU)

Figure 6 depicts the aspect of the aims of research activities.

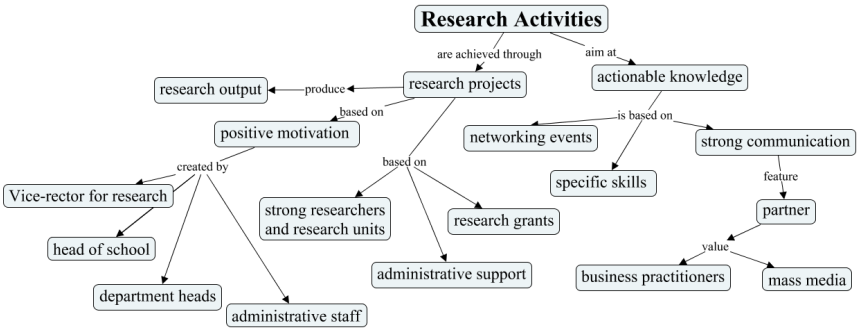

Figure 6 Concept map for the aims of research activities

The aims of research activities are closely connected with the faculty member profile, which concept is presented in figure 7 below.

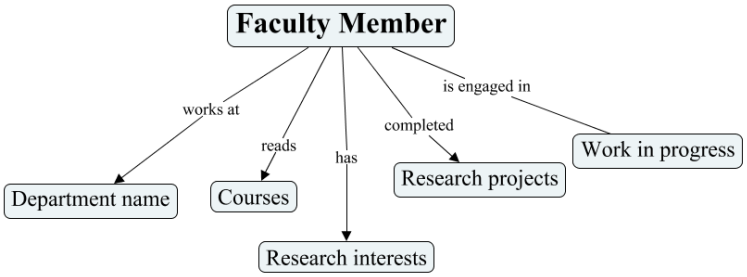

Figure 7 Concept map of the faculty member profile.

Figure 8 shows the conceptual structure of the information within "project" concept.

The designed knowledge base comprises not only classical domain ontology but also the knowledge management scaffolding information – rejected applications, failed projects, etc.

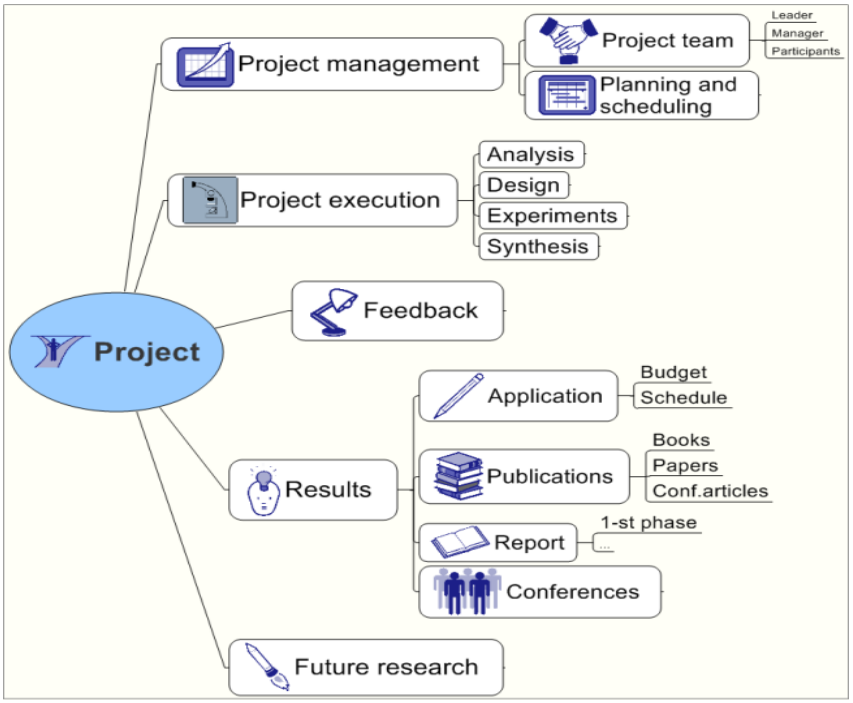

Figure 9 The sketch of the PROJECT ontology (upper levels)

4 Conclusions

In the era of Big Data the interest to generalising information is increasing dramatically. The researchers and educationalists look at ontologies with hope, trying to structure the increasing volumes of information mostly stored in computable form.

Presented sketch of ontology of a knowledge base for university research may help researchers, managers, and knowledge analysts to develop a big picture view and improve the navigation among different knowledge assets. We hope it becomes a sufficient model to represent the concepts of university research and the semantics.

Our UNIVERRA ontology is more modest than other ontologies describing research activities. The presented knowledge base for university research facilitates understanding of various research aspects and aims to serve as a self-service tool. It is developed for the purpose of enabling research knowledge sharing and reuse.

The paper considers the feasibility of using this ontology for research data integration from relational databases and other information sources. Now the UNIVERRA project is on the design stage.

Abstract

This paper investigates heterogeneity in Total Factor Productivity (TFP) of a sample of Knowledge-Intensive Business Services (KIBS) firms actively operating in Italy over the period 2012-2018. Business service industries can be defined as KIBS if they are private sector organizations that offer specialist professional, consultancy, and outsourcing services to other organization relying heavily on professional knowledge. On the basis of an ample literature, KIBS firms support the innovation process of organizations in different industry market, including, in particular, small and medium-sized ones, and of those operating in the public sector, through knowledge generation and diffusion. Starting from the underlying idea that KIBS firms differ from each other in several ways, whatever their location, and such heterogeneity in firm-specific characteristics is supposed to translate into heterogeneity in business performance, the main object of the present contribution is to analyze KIBS productivity heterogeneity on the basis of their localization and business sector. The empirical analysis is conducted at firm-level using a large sample of KIBS firms, obtained, as primary source, from the AIDA- Bureau van Dick database, which contains all Italian firms' disaggregated balance sheet and profit and loss statement information for the period 2012-2018. In particular, we consider the following Eurostat NACE Rev. 2 statistical sectors: 62-63 (information technology and communication sectors), 69-70-71-72-73-74 (professional, scientific and technical sectors). Based on the efficiency scores obtained from DEA (Data Envelopment Analysis), we

estimate the Malmquist Productivity Index for the period under investigation (2012-2018) to measure the variation of firms TFP. Moreover, in order to investigate if the source of productivity heterogeneity among the firm can be explained by firm specific features (geographic location, activity sector), a multilevel statistical modelling approach is used.

1 Introduction

Business service industries can be defined as KIBS (Knowledge-Intensive Business Services) if they are private sector organizations that offer specialist professional, consultancy, and outsourcing services to other organization relying heavily on professional knowledge (Wood, 2009; Hertog, 2000; Miles et al., 1995).

On the basis of an ample literature, KIBS firms support the innovation process of organizations in different industry market, including, in particular, small and medium-sized ones, and of those operating in the public sector (Windrum, 2013), through knowledge generation and diffusion (Ciriaci et al., 2015; Muller and Doloreux, 2009; Muller and Zenker, 2001; Hertog, 2000).

The process of "knowledge re-engineering" operated by KIBS, when interacting with other enterprises, causes KIBS to be identified as an important object for both innovation, regional policies (Brenner, 2018; Savic, 2016; Corrocher et al., 2012; Muller and Zenker, 2001) and regional development (Pino et al., 2016).

In recent years, there has been growing interest in the geography of KIBS (Brunow et al., 2019). Doloreux and Shearmur (2012) examine on the one hand the role of their location behavior in shaping the performance of the localities in which they operate, stimulating regional economic growth and potentially supporting regional structural change, and on the other hand highlight as their innovativeness, indirectly and more generally in determining enterprises' outcomes, is strongly associated with highly qualified socio-economic local environment, that play an active role in facilitating access to inputs (e.g. qualified employees and knowledge resources) and output market (e.g. interactions and collaboration with external partners).

Starting from the underlying idea that KIBS firms differ from each other in several ways, whatever their location, and such heterogeneity in firm-specific characteristics is supposed to translate into heterogeneity in business performance, the main object of the present contribution is to analyze KIBS productivity heterogeneity on the basis of their localization and business sector.

In particular, the paper investigates heterogeneity in Total Factor Productivity (TFP) of a sample of Knowledge-Intensive Business Services (KIBS) firms actively operating in Italy over the period 2012-2018.

The empirical analysis is conducted at firm-level using a large sample of KIBS firms, obtained, as primary source, from the AIDA- Bureau van Dick database, which contains all Italian firms' disaggregated balance sheet and profit and loss statement information for the period 2012-2018.

In particular, following the papers by Brenner (2018) and Skórska (2015), we consider the following Eurostat NACE Rev. 2 statistical sectors: 62-63 (information technology and communication sectors), 69-70-71-72-73-74 (professional, scientific and technical sectors).

Based on the efficiency scores obtained from DEA (Data Envelopment Analysis), we estimate the Malmquist Productivity Index (Färe et al. 1995; Caves et al. 1982) for the period under investigation (2012-2018) to measure the variation of firms TFP.

Moreover, in order to investigate if the source of productivity heterogeneity among the firm can be explained by firm specific features (geographic location, activity sector), a multilevel statistical modelling approach is used (Aiello et al., 2014; Fazio and Piacentino, 2010; Raspe and van Oort, 2007).

The next Section (2) describes the dataset and discusses the methodology. Finally, Section 3 points out the results and conclusions.

2 Materials and Methods

2.1 Analytical framework

Extending an our previous work (Campisi et al., 2019), the present analysis adopts a two-stage procedure to find answers to the following two questions.

RQ1: Does financial productivity of KIBS firms present different productivity pattern over time (2012-2018)?

RQ2: Is there or not a link or relationship among productivity behaviours over time and some firms' specific variables?

At the first stage, to assess and benchmark a large sample of knowledge-intensive business service organizations, a Constant Return to Scale (CRS) DEA based Malmquist Index Model (Färe et al., 1992) is developed. The productivity analysis is then used to characterize KIBS firms' financial performance through the definition of productivity patterns based on the Italian geographical region. In the second stage of our analysis, in order to evaluate the differentials in firms' productivity, we investigate the influence of specific firms' attributes (geographic location, and business activity sector) on the overall performance changes over time (i.e. Malmquist Productivity Index) adopting a multilevel statistical analysis.

2.2 Sample description

The quantitative proposed approach uses firm-level information about financial variables and some specific attributes.

The AIDA (Analisi Infomatizzata delle Aziende - Bureau van Dijk) database is used to carry out the analysis of this work. AIDA is a dataset that contains information filed at the Italian Chambers of Commerce by companies with at least one registered office in Italy and regarding comprehensive data about financial statements, activity, location, and ownership of small, medium, and large Italian firms.

A period of about 8 years, from 2012 to 2018, has been selected.

The sample extracted from the AIDA database is composed of 18.459 firms representative of the KIBS sectors, and defined on the basis of the next search strategy (applied for all the time frame used, 2012-2018): companies with legal status classified as active (i.e. actively operating during the period of analysis), firms with the complete availability of financial statements data, firms with a value of revenues from sales and services of 100 thousand euro or more, companies that employed between 2 and 250 persons, firms defined at the level of the NACE Rev. 2 Classification System representative of KIBS economics activities.

As private sector firms that offer specialist professional, consultancy, and outsourcing services with high intellectual value-added (Muller and Zenker, 2001) to other organizations (Wood, 2009), KIBS companies typically operate in the following sectors (Cabigiosu, 2020): software and computer services (ICT), strategy and management consultancy, auditing, accountancy, tax and legal service, marketing services, opinion pooling, technical services, engineering personnel training and headhunting.

According to a broader classification framework of KIBS firms proposed in some recent works (Hernandez et al., 2018; Skórska, 2015; Schnabl and Zenker, 2013) the next 2-digit NACE Rev. 2 branches were selected, comprising the following service industry segments: 62 (activity associated with software development and consultancy in the sphere of information technology and related activity); 63 (service activity in the sphere of information technology); 69 (law-related activity, accounting and book-keeping activity as well as tax consulting); 70 (activity of head offices; consulting associated with management); 71 (activity in the sphere of architecture and engineering; technical research and analyses); 72 (scientific research and development works); 73 (advertising, market and public opinion research); 74 (other professional, scientific and technical activity).

Table 1 provides a summary of the distribution of firms among Italian regional geographical areas and their relative grouping based on the adopted NACE Rev.2 activity codes.

2.3 Methodology

First, we calculate the Malmquist Productivity Index as a measure of firms' performance changes over time. The Malmquist Productivity Index is constructed as ratios of distance functions, which are estimated by DEA as a comparison tool. Then, the estimated value of overall productivity progress (or regress) and its components (technical efficiency change and technological progress) are mapped based on Italian geographic territorial units (region and/or province). Secondly, we carry out a regression of the estimated productivity patterns on various regressors, which are considered in this study as determinants of financial performance dynamics.

DEA is a mathematical programming methodology (non-parametric linear programming) that can be applied to measure the relative efficiency of a homogeneous set of Decision-Making Units (DMU) that produces outputs by combining inputs. The term relative is rather important since a particular DMU, identified as efficient in a given data set, may be deemed inefficient when compared to a different set of data.

With the objective to compare a selected sample of peer entities, such in our case KIBS firms, the DEA analysis allows to construct an efficient frontier, named best production frontier (or envelopment), which consists of DMUs with the highest ratio of output to input. The frontier surface is defined by the solution of a sequence of linear programming problems, one for each DMU. A DMU is said to be efficient if the ratio of its weighted outputs to its weighted input is larger than similar ratio for every other unit in the sample. DMUs located in the frontier are called "efficient units". For all other units, DEA measures the distance of the unit to the best practice frontier. The distance between this envelopment and the observed data point (representative of each DMUs) measures the

relative technical efficiency. Relative efficiency scores are defined in a range of [0,1] for each decision-making unit, allowing to rank the organizations on the basis of an increasing efficiency order (i.e. a score of 1 identify an efficient unit).

Since its introduction, by Charnes et al. (1978) adapting Farrell's proposal (1957), a variety of DEA-related literature has been published and applications of DEA models have been extensively used in performance appraisal in a wide range of business context and industrial sectors, becoming one of the most popular techniques for benchmarking analysis and a powerful quantitative approach to estimating and ranking a given decision making relative to other similar units subject to operation under similar input and output processes. In particular, the DEA has also been proposed as a model to evaluate the overall efficiency of small and medium-sized enterprises business (Fernandes et al., 2018; Marjanovic et al., 2014; Park, 2014; Chancharat and Chancharat, 2013; Mohamad and Said, 2012; Yang, 2006) and professional service firms (Hsiao et al., 2017; Hsiao et al., 2014; Wang et al., 2014) .

In our work, we applied DEA-based global Malmquist productivity analysis in order to develop a multi-period efficiency analysis model (Jianguo and Qamruzzaman, 2017; Majumdar and Asgari, 2017) and evaluate the productivity changes of each unit between two periods of time (t; t+1).

The concept of Malmquist Productivity Index (MPI) was first introduced by Malmquist (1953) and has further been studied and developed in the non-parametric framework by several authors. Caves et al. (1982) applied from a theoretical point of view the Malmquist's Index extending it as a productivity measure in a multi-input multi-output setting. Färe et al. (1992) made use of the connection between Farrel's basic measurement of technical efficiency (1957), DEA by Charnes et al. (1978) and MPI by Caves et al. (1982) to introduce the DEA estimation method for the MPI. In other words, the MPI is constructed as ratios of distance functions, which are estimated by the data envelopment analysis approach. Färe et al. (1992) further decomposed the index into two mutually exclusive and exhaustive components: changes in productivity over time (or efficiency changes - *Effch*) and shifts in technology over time (or technology changes - *Techch*). In general terms, the relative efficiency of a decision-making unit over time, defined by a relative distance using DEA, will depend on both its position relative to the corresponding frontier (technical efficiency) and the position of the frontier itself (technological change). The MPI compute firms' deviation of productivity in two different time periods, assuming common technological involvement.

Using an output-orientated model (i.e. to measure the maximal proportional expansion of the outputs given a set of inputs), the MPI between periods *t* and *t + 1*, can be defined as (Färe et al., 1995; Färe et al.,1992):

$$MPI\ {}^{t}_{t+1}(y_{t+1}, y_t, x_t) = \frac{D_{t+1}(y_{t+1}, x_{t+1})}{D_t(y_t, x_t)} \times \left[\frac{D_t(y_{t+1}, x_{t+1})}{D_{t+1}(y_{t+1}, x_{t+1})} \times \frac{D_t(y_t, x_t)}{D_{t+1}(y_t, x_t)}\right]^{1/2}$$

Where *D* represents the distance, *x* and *y* respectively inputs and outputs, and MPI is the Malmquist productivity index in time *t + 1* using the *t + 1* technology relative to the production in *t* using the *t* technology. The overall equation represents the Malmquist productivity growth of a firm between two periods. A value of MPI greater than 1 denote productivity growth from period *t* to period *t + 1*, while a value less than 1 indicate a decrease in efficiency relative to the previous year (i.e. productivity decline). An MPI equal to 1 represents no change in productivity over the periods.

The first term of the equation defines changes in technical efficiency (*Effch*) from period *t* and *t + 1* and the second expression, inside the brackets, indicates changes in technology (*Techch*). If a firm fails to achieve an output combination on its production possibility frontier and fails beneath this frontier, it can be said to be inefficient (or technological inefficient). Over time the level of output an organization is capable of producing will increase due to technological changes. These variations cause the production possibility frontier to shift upward, as more output are obtainable from the same level of inputs. Thus, for any firm in a specific industry, productivity improvement over time may be either technical efficiency improvement or technological improvement or both.

After estimating the MPI for each KIBS firm and in order to take into account differences in productivity across both geographic regions and business sector, we make use of multilevel statistical models to disentangle firm-specific effect from region-specific and sector-specific ones, that define the economic environment playing an important role in shaping productivity's heterogeneity observed at firm-level or instance, firms' performance may be affected by both the territorial conditions of the regions where they are located and the specific characteristics of the sector in which they operate. On the other side, firms from different sectors may be located in the same region and firms in different regions may operate in one given sector. From this point of view, sector and regions are not nested reciprocally but rather, the geographic areas in which firms are registered and the business sectors in which companies belong have a cross-classified structure (Aiello et al., 2015).

According to some relevant previous studies on firm productivity using multilevel methods (Aiello and Ricotta, 2016; Aiello et al., 2015; Aiello et al., 2014; Fazio and Piacentino, 2010; Raspe and van Oort, 2007) we apply a two-level cross-classified model (Mahlberg et al., 2013) where firms constitute the first level, and regions, sector or sector-by-regions (i.e. the interaction of region and KIBS industry) constitute the second level. A general specification of a simple cross-classified model can be expressed as follows:

$$y_{i(sj)} = \gamma_{000} + u_s + u_j + u_{sj} + e_{i(sj)}$$

Where the dependent variable, $y_{i(sj)}$, refers to the i-th firm from the (sj)th sector/region combination and that is equal to the overall mean γ_{000}, plus a random component u_s due to sector s, a random departure u_j due to region j, an interaction term

u_{sj} (interaction among regions and sectors), and an individual-level random departure $e_{i(sj)}$ (Aiello and Ricotta, 2016; Aiello et al., 2015; Aiello et al., 2014).

In order to interpret how much each different components (i.e. region, sector, region/sector) influence variance of the overall performance of each KIBS firm ($y_{i(sj)}$) is to compute the Variance Partition Coefficient (VPC). VPC statistics, computed as the ratio of each component variance (firm-specific attribute, region, sector, region/sector) to the total variance, report the proportion of the response variance that can be related to each level of the model hierarchical structure.

On the basis of the quantitative approach previously described, for each KIBS firm, operating in a specific Italian geographic area and belonging to a determined business sector, we first compute the MPI to define a total productivity measures and then try to evaluate of much of the difference in firms performance can be attributed to individual heterogeneity, how much of this difference reflects specific territorial conditions or business sector context.

2.4 Variables selection and data processing

According to the choice of inputs and outputs adopted, in some empirical studies that attempt to estimate firms financial performance on the basis of a combination of accounting-based income statement and balance sheet data (Oberholzer, 2014; Oberholzer, 2013; Ho et al., 2009; Lo and Lu, 2006; Tsai et al., 2006; Luo, 2003; Zhu, 2000; Seinford and Zhu, 1999), we collected for each KIBS company from 2012 to 2018 the following general and financial item: company name, CCIAA number (ID code registered at the Italian Chamber of Commerce), related two-digit NACE rev.2 branches, geographical region and province in which the firms are located (registered office address), number of employees (size), total assets, and value of revenues from sales and service.

To measure efficiency and productivity growth over time it is fundamental to choose a set of measures to use as inputs and outputs. In line with previously cited work, two inputs are thus identified, namely the number of employees and total assets, and one output, the value of revenues from sales and service. Total assets are defined as the year-end total amount from the balance sheet; the value of revenues from sales and service are computed as the year-end total amount of revenues income from the income statement.

Table 2 exhibits some descriptive statistics of data collected (inputs, outputs).

Table 2 – Some descriptive statistics of data collected (inputs, outputs)

ITEM OBSERVED	YEARS			
	2012		2018	
	mean	*sd*	*mean*	*sd*
Number of employees	11.9	19.4	15.4	25.3
Total assets (th EUR)	5,448.7	158,200.1	6,179.8	139,331.6
Revenues from sales and services (th EUR)	1,642.7	3,244.0	2,121.6	4,265.5

As previously stated, the linear programming model used assumed constant returns to scale and, because firms observed have a given amount of resources (employees and assets value) and have to maximize the final results (revenues), we adopt an output orientation (i.e. pursuing output maximization under given input). The results of DEA based Malmquist Productivity Analysis are obtained with FEAR (Wilson, 2008), a software package for frontier efficiency analysis that can be linked to the general-purpose statistical package R.

In order to validate the result of the overall DEA-based Malmquist Productivity Analysis to discover determinants of differentials in firms' productivity, we select the next two level for the application of the multi-level statistical model: level 1 (firms level variables: *Effch* and *Techch*), level 2 (geographic location defined by region-based groups and business activity sector groups represented by the selected NACE Rev. 2 codes).

3 Results and conclusions

We conducted the DEA-based Malmquist Productivity approach to address two primary issues in our computation over the sample period. The first is the financial productivity change measurement over the time frame selected; the second is to decompose changes in financial performance in what is generally referred to as a "catching-up" effect (*Effch* - efficiency change,) and a "innovation or frontier shift" component (*Techch* - technological change).

The former is generally defined as the diffusion of management and organization best-practices, and attributed to more focused investment planning, technical experience, and capacity utilization; the technological change is the consequence of innovation, that is, the investment and adoption of new technologies and methodologies, procedures, and techniques related to them, by best practice KIBS firms.

The values obtained for each KIBS companies are summarized for the period under investigation (2012-2018) and presented in Table 3 in the form of KIBS regional aggregation, and in Table 4 considering KIBS grouped into different business activities branches. Each summary presents the mean, median, Coefficient of Variation (CV%),

minimum, and maximum values for the MPI computed for the two grouping context, and its components scores.

According to the mean value, we can understand the average behavior in terms of productivity. The Coefficient of Variation and total range values (minimum and maximum) let us evaluate the fluctuations in terms of financial efficiency over time among alternatives.

The information in Table 3 can be used to compare the average performance of KIBS firms grouped in geographic regions (20 geographic areas), independently of the kind of KIBS activity that characterize firms' own core business. On the other side, Table 4 can be adopted to evaluate the productivity of KIBS companies based on their specific business activity and classified in eight business branches (defined by NACE rev. 2 codes) not depending on their geographic distribution.

According to the average values of the MPI, Table 3 shows the total productivity change score (the MPI presented in column 6) is higher than one for thirteen Italian regions, each one characterized by different percentage gains in total financial performance over time: Molise (+15,2%), Basilicata (+5,3%), Trentino Alto Adige (+4,1%), Friuli Venezia Giulia (+3,8%), Sicilia (+2,9%), Veneto (2,7%), Puglia (+1,2%), Valle d' Aosta (+1,1%), Piemonte (+0,9%), Toscana (+0,6%), Marche (+0,5%), Lazio (0,3%), Emilia-Romagna (+0,1%). These geographic areas contribute to 59,8 percent of the total KIBS sample (11.038 firms). With the exception of Lombardia (MPI equal to one, indicating stability or no change), the remaining regional territories suffer a decline in the financial productivity growth over the time period, with the worst financial performance scores obtained from Calabria (-4,4%) and Sardegna (-4,3%). It is also interesting to note that, for each region, the growth or decline behavior in terms of overall productivity appears to be driven by the role of the efficiency change component (column 6). In fact, every geographic area is characterized by an *Effch* score greater than one, which improvement is able to offset the generalized rate of the regress of the technological efficient component (column 8 - *Techch*) only in the thirteen regions mentioned above.

Looking at the average scores listed in Table 4, the only KIBS business sector that presents a growth in the total productivity index (column 5) are: 72 (+5,1% - scientific research and development), 71 (+ 3,2% - architectural and engineering activities; technical testing and analysis), 73 (+3,0% - advertising and market research), 70 (+1,7% - activities of head offices; management consultancy activities).

These four NACE Rev.2 branches represent only 38,9 percent of the whole firms' sample. The remaining industries show a decline in overall financial performance over time and, in line with the previous considerations and with regard of the NACE business branches aggregation form, the overall financial productivity behavior of the different KIBS business classes is related to the balance between the efficiency changes score (column 10) and the technological change one (column 12). In particular, the first is greater than one for all business branches, and the second presents a negative rate of growth (decline or regress) for every business context.

The final results of the multi-level model computation are displayed in Table 5 and obtained when running different regressions.

Regions	20		20	20
Sectors		36	36	36

In the first column, we consider the second level of the hierarchical structure composed by the 20 Italian regions. In column 2, regions are replaced by KIBS NACE sectors (n.

36). Column 3 presents estimations scores considering simultaneously regions and sector (n. 56 groups units) as components that may influence the overall productivity measures. Finally, column 4 takes into account the interaction among regions and sectors (n. 56 units). Using the VPC as a tool to interpret the magnitude of the variance component in each stage of analysis, the first one (firms-level variables plus regions) region-specific factors capture 64,8% of the total MPI variance, while the remaining is explained by firms MPI components. Introducing in the second level of the hierarchical structure the business sectors (firms-level variables plus NACE sectors), the variability of the productivity index for each firm is explained at 44,1% by the sectoral membership (column 2). When using the cross-classified specification (i.e. region and sector) we find that 26,1% the MPI variation lies at the regional level and 37,0% is related to the sectoral one (column 3). Finally, column 4 displays that the introduction of the interaction component "regions/sectors" captures 33,1% of the individual of MPI variability. Moreover, the explaining power of other components of the second level (region and NACE sector) decline respectively to 0,8% and 9,5%. These results show that MPI heterogeneity in the KIBS firms' sample analysed to present an important sensitive to the regional context in which firms operate, to the specific KIBS branches to which they belong and, in particular, to the interactions the arise from the economic environment defined from the coupling of regions and sectors. Giving this and in order to evaluate more deeply the role played from both the geographic context and the business sector-level characteristics, our analysis could be extended and complemented in two ways. First, in order to better estimate KIBS firms' changes in productivity over time, evaluate the use of other meaningful accounting-based income statement and balance sheet data; secondly, in order to better explain the measure to which the effect of the different components explains firm performance, augmenting the multilevel model application through a set of specific attribute defined at firm, region and sector levels.

Finding and Filling Lacunas in Linguistic Typologies

Abstract

Our study arose from a need to find and fill lacunas in knowledge systems supporting machine translation. The paper focuses on the challenge of developing a model that describes processes of goal-oriented enrichment of linguistic typologies as dynamic knowledge systems about language units and their translations. To describe the processes, we have developed a model of knowledge discovery for filling lacunas. The model is based on the idea of the spiral of knowledge creation and describes a process of populating a typology. The population process is based on conceptualizing potential sources of new meanings. In our projects, the potential sources are parallel texts. The conceptualization provides an opportunity to discover and describe new meanings of language units in question. The goal of the paper is to present the proposed model and scrutinize iterative stages of the discovery of new meanings of language units for filling lacunas in a typology. We develop a computer system to represent discovery outcomes and populate the typology. We give an example showing that new meanings could be discovered and used to enrich the typology.

Keywords – Conceptualization, Typology lacunas, Knowledge discovery, Individual meanings, Knowledge base.

Paper type – Academic Research Paper

1 Introduction

There is a large corpus of literature investigating the impact of artificial intelligence (AI) on the definition and solution of problems related to knowledge management (KM). The literature review by A. Zbuchea et al. (2019) provides a multi-faceted analysis of relationships between AI and KM, including:

- Applications of AI techniques advance KM (Liebowitz, 2001)
- Assuming the inability to formalize tacit knowledge as it exists in the minds of people does not exclude the possibility that computer systems might perform the same tasks using alternative representations; a richer model of cognition and knowledge representation is needed to study and build KM-systems (Fenstermacher, 2005)
- A strategic approach for solving the emerging challenges in KM (Anum, et al., 2018)

The goal of the paper is to present a model as a theoretical basis for AI-based creating new knowledge to fill lacunas in linguistic typologies. At present the spiral model of knowledge creation is one of the most popular (Nonaka, 1991; Nonaka and Takeuchi, 1995). The model is very often mentioned in discussions about knowledge discovery. Two categories of knowledge are determined in this model: individual knowledge and group knowledge. Each of these categories is divided, in turn, into two sub-categories: explicit knowledge and tacit knowledge. The spiral model includes the following four types of knowledge:

- individual tacit knowledge
- group tacit knowledge
- individual explicit knowledge
- group explicit knowledge

In the model, besides these four types of knowledge, the following four transition processes are defined: socialization, externalization, combination, internalization (SECI). By definition, each of the spiral turns of knowledge creation includes a sequence of processes: socialization → externalization → combination → internalization → socialization (as the beginning of the next spiral turn). According to Bratianu (2019), "The SECI model does not contain time as an explicit variable. <…> The model contains time implicitly since any transformation needs time, but it is a generic time without any possibility of measuring it". Therefore, in the SECI model, one can already see three dimensions of knowledge creation:

- The socialization dimension has two nominative categories (individual and group)
- The temporal dimension is implied in the spiral turns of knowledge creation
- The explicitness dimension has also two nominative categories (tacit and explicit)

There are models that describe the dynamics of knowledge with a larger number of nominative categories in the socialization dimension, as well as with one or two explicit temporal dimensions. M. Nissen (2006) extended the SECI model to integrate two temporal dimensions: life cycle and flow time. Life cycle with nominative categories refers to the kind of activity (e.g., creation, sharing, application) associated with knowledge flows. Flow time pertains to the length of time (e.g., minutes, days, years) required for knowledge to move from one person, organization, place, or time to another. The socialization dimension identifies three nominative categories (individual, group, and organization). All four dimensions (socialization, two temporal, and explicitness) for characterizing knowledge flows can be employed collectively to visualize the spiral turns of knowledge creation. One name is changed here for clarity (i.e., Nissen uses the term *reach* instead of *socialization*).

Another model with a larger number of nominative categories in the socialization dimension was proposed by Wierzbicki and Nakamori (2006, 2007). Like Nissen (2006), they also offer three nominative categories, but instead of organization knowledge, their

model (hereafter, the WN-model) includes conventional knowledge. They also subdivide each category into tacit and explicit knowledge, thus obtaining six types of knowledge, and define nine transition processes that contribute to knowledge creation, including socialization, externalization, combination and internalization.

Before describing our model for filling lacunas in a typology (hereafter, the filling model), we list here the principal features of the models briefly discussed above. All models explicitly or implicitly use three or four dimensions to describe the dynamics of knowledge. In the socialization dimension, two or three nominative categories are defined. For all models in the explicitness dimension, two nominative categories are defined (tacit and explicit). If we add conventional knowledge from the WN-model to the three Nissen's nominative categories (2006), then in the socialization dimension we get four nominative categories (individual, group, organization, and conventional). In all the models considered, the potential sources of emerging meanings are not defined.

2 The initial conditions

The initial conditions of the development of the filling model were obtained in the process of observing the work of linguists. They annotate language units along with their translations and simultaneously enrich a linguistic typology by new headings and their definitions if they discover new meanings of units or new semantic aspects of units in parallel text sentences (Tabl. 1). Linguists discover new meanings or aspects and describe each of them as an entirely new heading of the typology or add it to an existing heading. At the same time, they create a definition of the new heading or change the existing definition. Let's list the initial conditions obtained as a result of observing the work of linguists:

- Parallel text sentences which are stored in a database are potential sources of new knowledge discovered
- The discovery of new knowledge is a goal-oriented iterative process of annotating sentences
- To discover and describe new knowledge, a linguist conceptualizes sentences during their annotating and simultaneously changes a typology
- Annotations, including sentences and headings of the typology that linguists enrich, are stored in a database

Table 1. Sentence-aligned German-Russian parallel texts

German sentence	*Russian translation*
Don Quijotes sollen wir wohl alle sein, wenn wir nur ein wenig das Herz auf dem rechten Fleck haben und ein Körnchen Verstand unter der Schädeldecke.	Мы все Дон-Кихоты, если у нас честное сердце и под черепной коробкой крупица разума.

So sollen wir die Welt nicht zu retten suchen, sondern zu bestehen, das einzige wahrhafte Abenteuer, das uns in dieser späten Zeit noch bleibt.	В силу нашей ограниченности мы можем помочь только в отдельных случаях.

Note that any heading added to the typology represents a new concept of knowledge of only one linguist, that is, this concept and its heading are individual. In the general case, different linguists may create unlike individual headings that they formed during the conceptualization (=semantic analysis) of the same sentence.

A group heading concept is formed in the process of discussing individual headings and their definitions by the group of linguists who enrich the typology. The purpose of the discussion is to form a consensual definition within the group for the heading concept corresponding to the new meaning of the studied language unit or the new semantic aspect of the unit in parallel text sentences. Therefore, the proposed filling model covers two processes of typology enrichment:

- Discovering and representing individual concepts of new knowledge using headings and their definitions
- Forming and representing consensual new concepts

3 Two procedures and the filling model

The filling model allows to fix a time point of discovering each new meaning of studied language units in parallel text sentences. Suppose that at time t_1 one linguist discovers a new meaning of a language unit in an analyzed sentence, for which there is no corresponding heading concept in the typology. At time t_2, he/she externalizes this new meaning, defines a new heading concept and creates an annotation which includes a heading for this new meaning and a sentence as its source. At time t_3, another linguist also discovers a new meaning of the same language unit in the sentence and at time t_4, he/she externalizes this new meaning, defines a new heading concept and creates an annotation (Fig. 1). If these two linguists interpret the same language unit in the sentence differently, then these two heading concepts do not coincide in the typology. In this case, it becomes necessary to discuss them. Suppose that they have consensual concept of the new heading at time t_5 and its definition at time t_6.

In Fig. 1, which shows all three dimensions of the filling model: two quantitative ones (socialization and temporal) and the nominative one (explicitness), a consensual heading concept was agreed between two linguists. The process of agreeing on group concepts between any number of linguists is discussed below. For the example with two linguists, the time axis shows the first six time points (t_1 - t_6) in which six states of heading concepts are fixed for two group (tacit and explicit) and four individual (two tacit and two explicit) ones.

On the socialization axis, the number 1 indicates any of the two linguists who discovered new meanings of a language unit in question, and the number 2 corresponds to the two linguists which agree on a group heading concept and its definition. The

explicitness axis shows two nominative categories: “Tacit knowledge” for implicit concepts and “Explicit knowledge” for definitions of heading concepts.

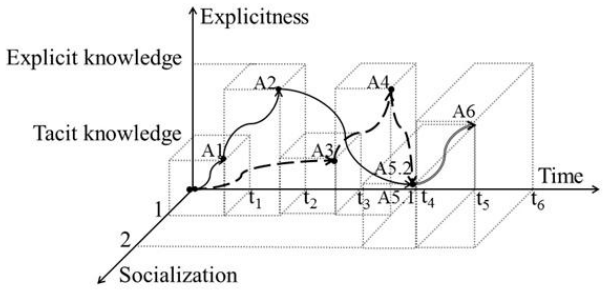

Figure 1. Three dimensions of the filling model and seven processes

In the Fig. 1, three solid, three dashed lines and one double line with arrows indicate seven following transition processes between the states of concepts at time points t_1 - t_6:

- A1 – analysis of a sentence by the first linguist and discovery of a new individual meaning of a studied language unit
- A2 – creation of an annotation with a typology heading of the new concept corresponding to the new meaning by the first linguist
- A3 – analysis of the sentence by the second linguist and discovery of a new individual meaning of the same unit
- A4 – creation of an annotation with a typology heading of the new concept corresponding to the new meaning by the second linguist
- A5.1 and A5.2 – agreeing on a group tacit concept of a typology heading between two linguists
- A6 – externalizing the group tacit concept and creating its definition

In order to describe the filling model, we consider these seven processes in more detail on the example of discovering new meanings of studied language units. The example shows how to determine the time points t_1 - t_6 of the completion of processes A1 – A6, respectively. In this example, two iteratively repeated procedures implemented in a computer system by our team are used. These computer-based procedures are designed to populate the annotation database and enrich a typology of a knowledge base. The first procedure covers four transition processes A1 – A4, supports discovering new meanings and defining new individual heading concepts. The second procedure covers three transition processes A5.1, A5.2 and A6 (Fig. 1) and supports linguists agreeing on a group concept of the typology heading and creating its definition.

3.1 The first procedure

The computer system supporting the first procedure consists of three parts (Fig. 2):

- The annotation database
- The knowledge base (hereafter KB) including the linguistic typology (KB typology) which describes the knowledge system about meanings of studied linguistic units
- The parallel sentence database (PSDB), which contains potential sources of new knowledge

The first procedure assumes that the initial state of the KB has been previously formed. Prior to the first procedure, the KB typology contains the description of the state-of-the-art conventional knowledge in the subject area under study. In addition, the PSDB was also populated in advance with the potential sources of new knowledge according to a linguists' goal. Linkages between sources and annotations, which include sentences and headings of the typology, are formed during the first procedure. Linkages are designated by dotted double-headed arrows in Fig. 2.

The first procedure is iterative and includes two transition processes A1 – A2 in Fig. 2 (the analogous processes A3 and A4 are neither shown in Fig. 2 nor described below). We are going to show that in the example of discovering new meanings of studied language units and defining new individual heading concepts, the process A1 can continue for several iterations, and the process A2 belongs to the same iteration where the process A1 is completed.

Each iteration includes the following steps

- Retrieving the digital data of a sentence containing the language unit in question from the PSDB (only one sentence is processed at each iteration; iterations and sentences are numbered from 1 to N in Fig. 2; it is assumed that at the iteration N the first new meaning was discovered)

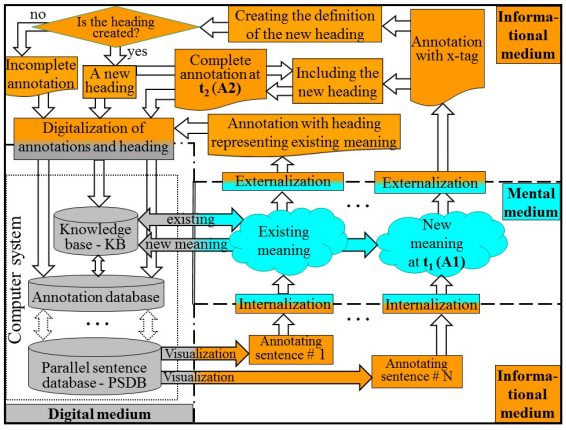

Figure 2. The first procedure supporting visualization, internalization, externalization, and digitalization

- Visualizing the digital data of the sentence, i.e., its transformation from a digital form to a perceptual one (this transformation is indicated in Fig. 2 by arrows “Visualization”), semantic analysis and annotating a meaning of the language unit by a linguist (if the linguist cannot interpret and analyze the sentence, then this iteration is terminated without generating any meaning)
- Internalizing an individual meaning of the language unit in the sentence
- If a meaning was generated, then the linguist compares it with each heading concept described in the KB typology
- If the generated meaning corresponds to any of heading concepts, it is not new (this case is indicated by the double-headed arrow "existing"); then the linguist adds the corresponding heading to the annotation (it is indicated by the left rectangle "Externalization" in Fig. 2); the annotation with the heading is digitalized and loaded into the annotation database
- If the generated meaning does not correspond to heading concepts, it is new (this case is indicated by the double-headed arrow "new meaning"); the time point when the new meaning was discovered is indicated in Fig. 1&2 as t_1; at this time point, the transition process A1 is completed (the new meaning notify that there is a lacuna in the KB typology)
- Then the linguist adds the incompleteness tag (=x-tag) to the annotation because the KB typology is incomplete (it is indicated by the right rectangle "Externalization" and the text "Annotation with x-tag" in Fig. 2)
- The linguist tries to create a definition of the new heading representing the new meaning of the linguistic unit in question
- If the linguist can create a heading and its definition representing the new meaning, the heading with its definition adds to the typology (this case is indicated in Fig. 2 by the rectangle "New heading"); then he/she can replace the x-tag with the heading in the annotation; the completed annotation is digitalized and added to the database (the time point when annotation is completed is indicated in Fig. 1&2 as t_2; at this time point, the transition process A2 is completed)
- There may be a case when the linguist cannot create a definition; in this case, he/she retains the x-tag in the annotation (the case indicated in Fig. 2 by the rectangle "Incomplete annotation"), then the incomplete annotation is digitalized and added to the database
- Linkages are established between loaded the complete and incomplete annotations and the sentences, on the basis of which the meanings were generated (these linkages are designated in Fig. 2 by dotted double-headed arrows)

Incomplete annotations require deeper investigation of the corresponding sentences by expert-linguists, which is beyond the scope of the filling model, but in any case, these annotations fix unfilled lacunas in the KB typology. To conclude the description of the first procedure, we note that the second linguist completes the analogous processes A3 and A4 at the time points t_3 and t_4.

The analysis of the listed steps makes it possible to formulate the key difference between the filling model and the spiral model. In the proposed model, the knowledge base is first iteratively filled with the headings for individual concepts of linguist's knowledge (the first procedure). Then on the basis of them, the consensual headings for group concepts are formed in the knowledge base (the second procedure). In the spiral model, each iteration (in the form of a spiral turn) includes the creation of both individual and group knowledge.

3.2 The second procedure

The description of the first procedure helped to reveal the content of processes A1-A4 and determine the time points t_1 – t_4 of their completion. Consider the second procedure, which includes the transition processes A5.1, A5.2 and so on, to reveal the content of these processes, which begin at time points t_2, t_4 and so on, respectively, and to determine the time points of their completion.

It is assumed that before the beginning of the second procedure, the first procedure has been performed by two or more linguists separately. There are cases when they generate new different individual meanings corresponding to the same sentence containing a language unit in question. In these cases, the second procedure is iteratively performed, which includes the following steps (Fig. 3):

- Retrieving the digital data of individual headings and their definitions from the KB typology which were created by different linguists but correspond to the same sentence # N containing a studied language unit with a new meaning (these headings and their concepts are numbered from # N.1 to # N.M in Fig. 3; it is assumed that M is the number of different individual headings created by M linguists which annotated the sentence # N; note, that M=2 in Fig. 1)
- Visualizing the digital data, i.e., transformation of the individual headings and their definitions from digital forms to perceptual ones
- Internalizing the individual headings and their definition
- Agreeing on a group heading concept # N between M linguists based on the individual heading concepts # N.1, …, # N.M (if it is not possible to agree on a group heading concept, then the second procedure is terminated for these individual headings)
- If they can agree on a group heading concept # N, then the processes A5.1, …, A5.M are completed at t_5
- Then the group concept # N is externalized and its definition is formed (the time point of its externalization is indicated in Fig. 1&3 as t_6)
- Changing individual headings # N.1, …, # N.M to the group heading #N in corresponding annotations (=reclassifying annotations)
- A digital form of the group heading and its definition are generated and loaded into the KB with the typology

- Linkages are established between the reclassified annotations and the group heading in the typology (these linkages are designated by dotted double-headed arrows in Fig. 3)
- The second procedure is repeated for a next group of individual headings until they are exhausted

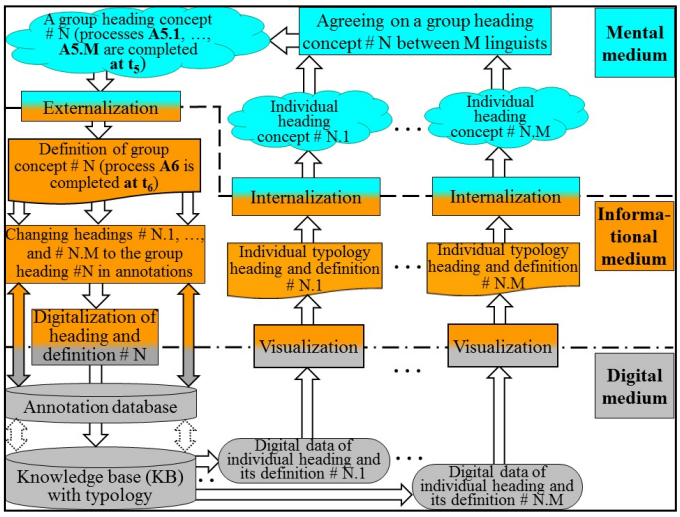

Figure 3. The second procedure supporting visualization, internalization, agreement on group concepts, externalization, and digitalization

3.3 The filling model

The first procedure of the filling model includes two transition processes (two out of the four transition processes that make up each turn of the spiral model): internalization and externalization, as well as two new processes: visualization and digitalization (Fig. 2). The second procedure includes three of the four spiral model transition processes (internalization, agreement on group concepts, externalization) and the same two new processes (Fig. 3). One name is changed here for clarity, i.e., Nonaka (1991) uses the term *socialization* instead of *agreement*.

Both procedures do not use the *combination* transition process, since individual concepts are outcomes of *semantic analysis* and *annotation* of sentences as potential sources of concepts of new knowledge. After considering two procedures of discovering and filling lacunas in linguistic typologies, we will describe the filling model in a generalized way using following hypernyms: *expert* rather than *linguist*, *ontology* instead of *typology*, *conceptualization* in place of *semantic analysis and annotating*, *semantic description* in lieu of *annotation*, and *knowledge source* rather than *sentence*. The filling model in a generalized way is based on the three following principal ideas.

First, the filling model covers three media of different nature: mental, informational, and digital (Zatsman and Buntman, 2015) and includes six transition processes: visualization, conceptualization, internalization, agreement (socialization), externalization, and digitalization (Fig. 4).

Second, three dimensions are defined for describing the outcomes of discovering and filling lacunas: two quantitative (socialization and temporal) and one nominative (explicitness) (Fig. 1).

Third, several different individual concepts of new knowledge can be created based on the same knowledge source. The Fig. 1 shows an example of creating two concepts, Fig. 3&4 illustrate the case of creating M different concepts.

Now we give a brief depiction of all the six processes of the filling model in a generalized way, which consists of two submodels. The first submodel describes the work of one expert discovering new individual concepts during conceptualization (see the left part of Fig. 4):

- The first found object for conceptualization is extracted from the database of knowledge sources which is converted into a perceptual form (the "Visualization" process)
- The extracted object is conceptualized, including putting existing ontology headings that characterize its semantics; if there is no relevant heading to reflect some semantic aspect of the object, then a lacuna in the ontology is fixed by the incompleteness tag (the "Conceptualization" process)
- An individual concept for the non-reflected semantic aspect is formed (the "Internalization" process) and an attempt is made to create a new heading of ontology, the concept of which would correspond to the non-reflected aspect
- If a new concept cannot be created, the semantic description of the object is marked as incomplete and a lacuna in the ontology is fixed; otherwise, the concept is created and its heading is added to the ontology and inserted in the description (the "Externalization" process) which is recorded in the description database (the "Digitalization" process)

Then the listed processes of the first submodel are performed for each knowledge source found. If these processes were repeated M times for the same source by different experts, then up to M different individual headings can be formed.

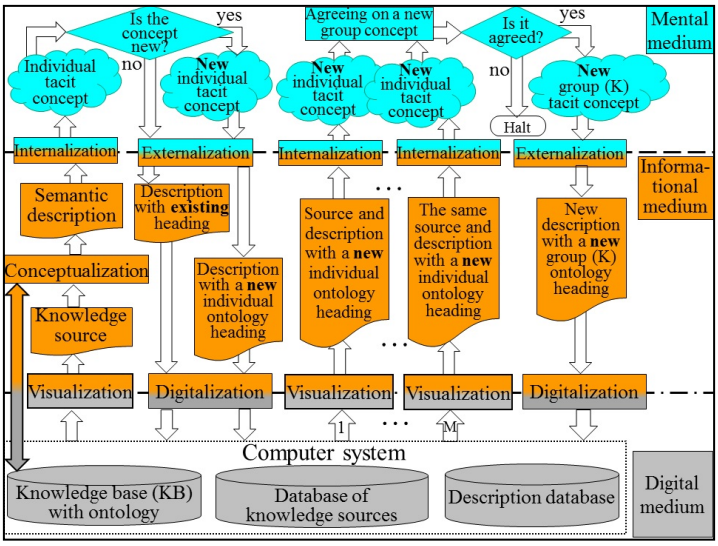

Figure 4. The filling model

The second submodel describes the work of L experts to form a single consensual concept based on M individual ones (see the right part of Fig. 4), created on the base of the same knowledge source:

- M descriptions with individual headings created by M different experts together with their source are extracted from the description database and converted into perceptual forms (M "Visualization" processes)
- Based on this source and M descriptions with individual headings, each of L experts creates their own individual heading concept for the non-reflected semantic aspect (the "Internalization" process) and an attempt is made to create a new group heading of typology, the concept of which would correspond to this aspect
- If experts cannot agree on a new group heading, the agreement process stops for these M individual headings (see the terminal «Halt» on Fig. 4)
- If a new group heading is created by K from L ($1 < K \leq L$) experts, then it is added to the ontology with a socialization index equal to K, and putted in a new description (the "Externalization" process), which is recorded in the database (the "Digitalization" process)

Then the listed processes of the second submodel are performed for series of individual headings formed for other knowledge sources.

4 Filling model implementation

On the basis of the filling model, our team has developed a computer system that allows to enrich the linguistic ontology about meanings of German modal constructions and their exemplary translations into Russian. For applying the computer system, a German-Russian dictionary that reflects the state-of-the-art level of knowledge about these studied linguistic units was selected. To show the feasibility of goal-oriented enrichment of the linguistic ontology, our team has designed a knowledge base with the initial version of the typology based on the dictionary.

The PSDB has been loaded with parallel texts of several dozen books totaling 2.6 million words. The downloaded texts of the books have been aligned so that one original sentence corresponds to its translation. Sometimes several sentences of the original text were put in correspondence with their translation, which may include one or more sentences. Thus, downloaded texts are divided into potential sources of new knowledge as shown in the example of the two pairs in Tabl. 1. For all books downloaded to the PSDB, 83190 pairs as potential sources have been formed by a computerized way.

As noted above, the subject of the study is the translations of German modal constructions. They include the verbs dürfen, können, mögen, lassen, müssen, sollen and wollen. Out of 83190 pairs, 16268 contain these verbs, and in 2041 of them the verb sollen is used. Tabl. 1 shows two examples of potential sources from 2041 pairs which contain the verb. The initial state of the ontology contained 12 meanings of the modal verb sollen, which correspond to the following headings: sollen-01, ..., sollen-12. The initial state of the typology includes headings only for those meanings that are described in the dictionary in a paper form. If the meaning of the verb in a studied source coincides with one of these 12 meanings, then, therefore, the source does not contain a new meaning and the typology heading with the corresponding number is written in the annotation with the source. If the meaning of the verb does not coincide with any of these 12 meanings, then the source contains a new meaning. Then a new heading representing the new meaning and its definition are added to the typology.

Up to 31.05.2020, 780 out of 2041 pairs containing sollen had been analyzed. During the analysis, two new meanings of sollen were discovered and their definitions were agreed between five linguists. The definitions of two group meanings with their headings were added to the typology.

5 Conclusions

Let's list the main differences between the proposed model (as a theoretical basis for computer-based discovering and filling lacunas in ontologies) and the spiral model (Nonaka, 1991):

- Two dimensions of the filling model are quantitative
- The lacuna filling process covers three media (the digital medium was added)

- The potential sources of new knowledge are added to the model, which correspond to the goal of the process of discovering and filling lacunas (it makes this process goal-oriented)
- The process "Combination" has been replaced by the process “Conceptualization"
- Two new processes on the border between the informational and digital media are added (visualization and digitalization)

The feasibility of the filling model was tested by adding new headings to the linguistic typology. However, there may be more complex types of changes, such as increasing or decreasing the meaning volume (=the semantic content) of existing headings of the typology. The current version of the model does not take into account such cases.

The filling model is planned to be developed by including the process of semantic analysis of incomplete descriptions of conceptualization objects (one of the main reasons of their incompleteness is the need to change the semantic content of existing headings rather than to add new ones to the ontology), as well as more complex cases of changing ontology headings and their definitions.

Abstract

Social software is becoming increasingly important in companies and has long since been used in organizations not only as an instant messenger but also as a collaboration tool. Therefore, this paper deals with the potentials and challenges for knowledge management (KM) in Enterprise 2.0 using the example of the social software Slack. Based on episodic interviews, new challenges such as "blurring of the boundaries between work and leisure" and "misunderstandings due to text-based communication" are identified. The implications derived from this should help companies to deal with the challenges of social software like Slack in Enterprise 2.0.

Keywords – Knowledge Management, Social Software, Enterprise 2.0, Slack, regulatory framework

Paper type – Academic Research Paper

1 Introduction

In order to deal with the challenges of a dynamic environment, well-conceived management processes of organizational knowledge are becoming increasingly important and make a systematic dealing with knowledge resources a core competency for organizations to enhance individual and organizational performance and to generate a sustainable competitive advantage (Mao, Liu, Zhang, and Deng, 2016). In addition to these changes towards knowledge-intensive processes, today's knowledge society is characterized by the emergence of numerous web-based technologies and Web 2.0, affecting people's interactions (Sarka and Ipsen, 2017). The rise of remote work and home office also contributes to the increasing importance of tools and applications for knowledge processing. Social Software itself can be described as "tools and

environments that support activities in digital social networks" (Klamma et al., 2006) and, thus, facilitate social connections and exchange of information (Chatti et al., 2007). In order to describe the usage and application of emergent social software within and between companies, the term Enterprise 2.0 was developed (McAfee, 2006). As previously mentioned, knowledge management in general is subject to major changes nowadays. Through the increasing use of social software, KM can be designed more cost-effective, cloud-based, ubiquitous, and standardized, but still contributing to meet individual needs and in this way fulfilling the purpose of social practice (von Krogh, 2012). The interaction and exchange of the group is promoted by allowing communities to form on the basis of the social software application. There are options for creating, exchanging, archiving, and organizing content (Haefliger et al., 2011). Thus, organizations can benefit from social software as it enables the development of many types of content through a variety of collaborative processes (von Krogh, 2012).

Especially, the instant messaging (IM) tool Slack enjoys great popularity. Slack represents the most frequently used IM tool worldwide and registers over 12 million active users per day. Slack itself serves not only as a pure means of communication in the classical sense, but also enables the integration of various applications and the sharing of documents within groups or between two individuals (Slack Technologies, 2020). To figure out to what extent this social software can represent a knowledge-promoting space and support a systematic KM, it is essential to understand and analyze the knowledge processes taking place within the organization and the integration of IM into these processes. Lin et al. (2011) describe the conceptual problems of proven knowledge management models in dealing with KM in Enterprise 2.0. For this reason, a framework model for a systematic knowledge management in Enterprise 2.0 has been developed, which will be hereafter examined and applied in the concrete context of the gaming industry. The aim of this paper is to analyze the application of Slack within the phases of the KM process and to identify potential challenges by means of a qualitative approach and by taking the IDEA framework (Lin et al., 2011) into account. The theoretical contribution of this paper is to review the theoretical model of Lin et al. (2011) in the context of the gaming industry, whereas the practical implications consist in the evaluation of the benefits as well as the challenges that social software can provide in dealing with knowledge.

Based on the factors discussed above, the following research questions will be considered: *How does the use of social software "Slack" affects knowledge management in Enterprise 2.0? Which challenges can be derived by using "Slack" for KM? Which interrelationships exist between people, technology, and organization?*

2 Social Software and KM

The rapid growth of IM in the workplace has attracted increasing attention from researchers around different aspects of IM. Previous studies have already dealt with the influence of instant messaging tools on the performance of organizations. Ou et al. (2010) concluded that IM tools support social networks, which in turn contribute to organizational agility. Furthermore, several studies investigate the negative effects of IM on performance, which may result from its interrupting nature (e.g. Isaacs et al., 2002; Rennecker and Godwin, 2003; Fox et al., 2009; Ou and Davison, 2011; Mansi and Levy, 2013). For example, Mansi and Levy (2013) investigated the role of IM and its impact on the task performance of knowledge workers. The results indicated that tasks with higher complexity may be performed more slowly, but simultaneously stimulate the exchange of information and thus can also contribute to time savings. The study of Ou and Davison (2011) on work interruptions caused by IM has shown that IM leads to more work interruptions, but does not negatively affect work results. However, other researchers found that IM can improve communication and productivity by supporting spontaneous reactions (Hersleb et al., 2002; Shaw et al., 2007; Saavedra et al., 2011) or by helping to build trust and facilitate cooperation between colleagues (Pazos et al., 2013). Further studies have investigated the direct link between IM and knowledge management processes. Ou et al. (2014) have examined to which extent IM tools are conducive to knowledge transfer in the workplace and in the course of this have an influence on team performance. The results showed that IM tools not only promote knowledge sharing but also knowledge creation among employees. Furthermore, Ajjan et al. (2014) found that the continuous application of enterprise instant messaging has a positive effect on the KM results (creation, retention and transfer of knowledge).

3 IDEA regulatory framework

Especially noteworthy is the study according to Lin et al. (2011), which explicitly deals with social software and the SECI model after Nonaka and Takeuchi (1994). Considering KM in the context of Enterprise 2.0 concept, Lin et al. (2011) have found that it is difficult to systematize knowledge-oriented activities in Enterprise 2.0 with the help of established knowledge management models. The study identified conceptual problems regarding implicit knowledge within the SECI model, which makes the SECI model appear unsuitable as a knowledge management model in the Enterprise 2.0 concept. This was followed by the construction of a framework for the systemic handling of knowledge in Enterprise 2.0, the IDEA regulatory framework. IDEA refers to processes which can have four characteristic moments: *interaction, documentation, evolution,* and *adoption.* These can be identified along work processes and facilitate the creation of a knowledge-promoting space, which in turn fosters the knowledge processes described by Lin et al. (2011): knowledge multiplication and knowledge innovation. In this way, value-creating work processes can be improved.

In this context, the IDEA moments are not to be understood as successive accomplished sub-processes. An analysis of the knowledge-intensive work procedures, taking into account the four IDEA moments, can help to identify the causes of possible knowledge problems and uncover optimization potential in order to initiate measures in the fields of technology, organization, and people. The moment of interaction describes the degree of mutual reference in the communication process, i.e. focuses the tailoring of the sent messages to the specific context or situation of the recipient. The process can be passive or active (Lin et al., 2011). The documentation describes the moment, which makes the knowledge-intensive work processes accessible for further use by active or passive mapping and recording of their course and results. Evolution is the moment that measures the extent to which the development of the organizational knowledge base is supported. The gathering of new experiences in work processes can lead to the further development of individual and collective knowledge. Depending on an organization's ability to learn, the new knowledge can be anchored in the organizational knowledge base. Adoption describes the moment that enables individuals to (re-)construct knowledge from existing data. The moment includes the steps of perception and interpretation of relevant data. The application and (re-)contextualization provides the opportunity to embed the new knowledge into the existing knowledge structure, and, thus to enhance it (Lin et al., 2011).

4 Methodology

4.1 Data sources

Research Setting. In order to answer the questions adequately a qualitative research approach is used. Semi-structured in-depth episodic interviews (Flick, 2000) were conducted, transcribed (Davidson, 2009), and analyzed using qualitative content analysis (Mayring, 2014). The data-collection was carried out at one of Germany's leading providers of online games. Nine interviews with a total amount of 477 minutes have been conducted with employees of different hierarchical levels in the IT, business, and product divisions.

Research Participants. Interview questions were based on the underlying research questions of the study. For example, the interview partners were asked about their individual user behavior with regard to social software as well as the consequent potentials and challenges. Of course, every participant was guaranteed that the interview is anonymous as well as voluntary. All nine interviewees have been working in the organization at least since the implementation of the Slack software. Participants from different business areas and hierarchical levels of the gaming company were deliberately selected (IT, business, and product areas). Every participant also shows a high level of user activity.

Semi-structured episodic in-depth interviews. According to Flick (2000), episodic interviews are based on the assumption that experiences of individuals are stored in the form of narrative-episodic knowledge on the one hand and semantic knowledge on the others. The procedure of episodic interviews can be outlined in nine phases, each represents a step towards the goal of analyzing the everyday knowledge of the interviewee about a certain topic or area in a way that enables the interviewer to compare the knowledge of respondents from different social groups - i.e. as social representation (Flick, 2000). Thus, we were helped to understand the experiences and perceptions as related to dealing with knowledge and Slack itself. All interviews were conducted between January to April 2019 exclusively face-to-face. They took between 39 and 75 minutes, they were recorded, and denaturalized transcribed (Oliver et al., 2005).

4.2 Data analysis

Qualitative content analysis. We started data analysis with an iterative coding of the interview transcripts based on the suggested procedures for qualitative content analysis (Mayring, 2014) using MAXQDA (Kuckartz and Rädiker, 2019), a software for qualitative research. First a deductive category finding was carried out by using the theoretical preliminary considerations to the IDEA moments as a starting point for the definition of the first-order themes (Mayring, 2014). The categories were briefly defined and for the purpose of illustration, anchor examples were given. To avoid delimitation problems between the categories, contingency rules were formulated. Subsequently, a first trial run was carried out in which the first interviews were analyzed with regard to relevant text passages in relation to the previously defined first-order themes and assigned accordingly. In this step, the category system was tested and revised in order to ensure the final unambiguous assignment of relevant text passages (Mayring, 2014).

5 Findings

Based on the conducted interviews, it can be concluded that using Slack can have positive and negative effects on KM within the examined context and supports knowledge multiplication as well as innovation according to IDEA regulatory framework (Lin et al., 2011). Nevertheless, the interviews also examined the success factors identified by Lin et al. (2011), which can contribute to the fulfilment of the respective moments. However, this analysis also identified challenges that arise when using social software Slack. The intentions of the actors and the interrelationships between people, technology and organization play a key role in this context.

Interaction: The results have shown that the moment of interaction is strongly emphasized.

> *"Slack is interaction. You use it to interact with people and give them information or ask them anything." (I.B)*

The moment of interaction can be divided into different second-order themes, which on the one hand can have a positive effect as success factors, but on the other hand can also cause challenges. One category describes the *cultivation of communities*. In the interviews, for example, topic-related communities were described which have a positive effect on the interaction through their dynamics, informal communication or the 'we-feeling'. At the same time, however, these can also bring challenges, such as the blurring of the boundaries between leisure and work or the increasing potential for conflicts.

> *"It can happen that I send various messages around Slack an hour before I go to work, just to answer people's questions or to look for information myself." (I.A.)*

Another factor that influences the outcome of the interaction is *relationship and collaboration management*. Slack simplifies the active establishment and search for contacts or a collaborative creation process through shared work or discussions. However, respondents have also highlighted negative aspects, such as the flood of information that can result from the simplified inclusion in various chats and discussions. A further success factor, the *robust knowledge networks* can promote interaction through the exchange of knowledge over large spatial distances or the development of communication across hierarchies and departments.

Documentation: The documentation of knowledge is largely supported by the use of slack.

> *"Documentation works too, you have a chat history. [...] Nothing gets lost or anything. [...] You can also search in Slack, that works great. You can even search in documents you once shared, as long as they are text documents. Insofar, Slack also covers documentation. However, it is sometimes difficult because many people can't use the search function properly. And I think in many people's minds it hasn't gotten to the point where it could serve as a knowledge base." (I.A.)*

According to Lin et al. (2011), the success factor *motivation of knowledge workers* is influenced both positively and negatively by the use of Slack. Active users describe that motivation is increased by the user-friendly interface and the added value gained through its use. Less active users criticize the lack of introduction and education concerning the use of Slack as a documentation tool on the part of the organization. Another subcategory *flexible wiki application modes* describes the active preparation or passive archiving of work processes or results. Work processes can be stored in the cloud of the organization or can be displayed in a processed form by integrated bots. However, the complexity, caused by hundreds of groups and conversation, can proved to be problematic, as the documentation is not archived in a structured way.

Evolution: The moment of evolution of knowledge was partially addressed in the context of social software. The subcategory *perpetual beta knowledge culture* describes the ongoing discussion and development of data, which can be fostered, for example, by threads or the possibility to comment, share or evaluate contributions.

> *"Especially in developer channels, there are also some posts where you say: 'Gee, that's really interesting. [...] I'll have a look on that.' I actually click on the link or*

I really look at it, which later broadens my horizon or teaches me something new." (I.A.)

However, the large number of groups and conversations can at the same time make the further development of the knowledge base more difficult. One respondent describes *creativity in the network*, which can be fostered by collaborative idea generation processes. The *collective objectification*, which depicts the objectification of the relevance of data, cannot be covered by Slack.

Adoption: According to the interviewees, the adoption of knowledge was encouraged by *contextualization*. Threads, commentary functions and specific naming of groups can support the contextualization and interpretation of comments according to some respondents. Challenges can arise within the category *contextualization* if discussions are not held in the designated threads:

"When people have arguments, it rarely happens in the threads, but in the main line, and that really wastes time and bothers me." (I.E.)

In addition, text-based communication itself is often a problem, as it is not possible to convey voice, feelings or emotion-based interactions, which in turn makes contextualization difficult. The subcategory *holistic awareness* describes the group perception or the perception of results and is especially promoted by the Slack notification system. Furthermore, Slack covers browsing, search and tagging functions, which are used by the majority of respondents and belong to the subcategory *navigation concepts*. This simplifies the search for information and documentation of past work processes or results. However, some interviewees describe the search function as suboptimal, since only their own communication processes are searched for keywords and it is more difficult to find specific content.

6 Discussion

Our findings show that the social software Slack represents a knowledge-promoting tool within the examined company and, due to the partially weaker or stronger support of the individual IDEA moments, provides a knowledge-promoting space that enables knowledge multiplication and innovation. Furthermore, different challenges could be identified, which result from the respective success factors and run along the IDEA moments. Whether Slack has a positive or negative effect on KM also depends on the extent to which the particular organization is able to deal with the various challenges and has a supportive effect on the employees. In this respect, the interrelationships between people, technology and organization were considered, which will be discussed in more detail in this chapter.

First, we will again take a closer look at the individual moments, the promoting, and hindering factors. The moment of interaction is supported in a concrete context by the social software Slack and its extensive functionalities. Slack enables a fast, easy, flexible, and broad exchange between employees and supports the creation of robust knowledge networks. However, the success factors outlined by Lin et al. (2011) also bring challenges

that have already been identified in the results. It can be confirmed that the moment of documentation is supported by using slack. Slack enables the documentation of various work processes and results through the existing chat history and the exchange in topic-related groups. The user friendly interface, the possibility to create specific or general groups, and the influence of the Slackbot as an assistance for the presentation and archiving of results are to be positively evaluated. However, challenges still appear, which are manifested in the flood of information by a confusing and unstructured documentation and the limited documentation ability of Slack itself. The moment of evolution is supported by the use of Slack. The open spaces created in various topic-related groups, the expandability of these groups, and the inclusion of several integrations and functionalities of Slack promote the further development of the organizational knowledge base. At the same time, the large number of existing groups and the lack of functionality on the part of the Slack software makes the collective objectification of relevant content more difficult. The last moment of adoption is also supported by the use of social software Slack. The use of threads, profile, and group information, together with a very individually adjustable notification system and various navigation concepts, enables a targeted and effective perception as well as interpretation of relevant data. Nevertheless, Slack is not fully capable of ensuring this, since the mere fact that text-based communication is used does not allow for the targeted communication of vocalizations or feelings. Furthermore, the contextualization of content is made more difficult by ignoring group information and by not perceiving or correctly using various features (e.g. threads), which can lead to unclear communication structures.

As already mentioned at the beginning, the interaction between people, technology, and organization plays a major role (Lin et al., 2011). The results have shown that people, technology, and organization are highly dependent on each other and that the interdependencies have a major impact on the way Slack is used. These interdependencies lead to both positive and negative effects. The interrelation between people and organizations can be of great importance when it comes to the handling and targeted use of Slack. The mutual interdependencies are expressed partly in company guidelines, but also in a lack of influence, which can lead to Slack not being used in a targeted manner and a lack of knowledge about the functions. A good balance of mutual influences, which lead to the goal-oriented use of the software, but also allow the employees sufficient freedom, seems to be especially important here. Considering the interrelation between people and technology, it becomes clear that the functional scope of social software is not or only partially known. In addition, many of the interview partners missed a mandatory and detailed introduction. Nevertheless, the interviewees also repeatedly mentioned the friendly user interface of Slack and presented the software as self-explanatory. The Slackbot or information material in form of blogs and videos were also used as an assistance in dealing with the social software. In this second-order theme, the usability of Slack is presented very clearly and positively, but concrete support from the company is missing. Considering the interrelation between organization and technology it becomes

clear that Slack is a very flexible, fast and versatile tool with the help of its extensive functions. Nevertheless, concerns are also expressed about data protection, as Slack is not an internal solution but a third party that has access to important company data. Furthermore, the organization's dependence on Slack is presented as both a strength and a weakness. Slack is able to create *"a kind of augmented reality" (I.F)* for an organization and its employees, which could make certain work processes even more effective. On the other hand, this dependency could also be negative if the boundaries between leisure and work become blurred, work processes and results are made dependent on others and sensitive data is transferred to third parties.

7 Conclusion

In the last years, the management literature has largely stressed the importance of knowledge assets for company's competitiveness. Grounded in the knowledge-based view of the firm, this paper, by means of nine episodic interviews, stresses the importance of a holistic view of a systematic KM through social software, taking into account the obstacles as well as the success factors. In summary, the IDEA framework offers a suitable basis for the evaluation of knowledge management in Enterprise 2.0. The interactions between people, technology, and organization play an important role, but must be considered separately in each specific context. In principle, Slack is able to support a systematic knowledge management in Enterprise 2.0. The challenges identified can help to improve the use of the software and, as a consequence, increase the perceived benefits. Especially, the transparent implementation and instruction of employees can contribute to a successful use. The steps taken to meet these challenges could be the design of concrete workshops for the company's employees and the creation of teaching materials for the correct use of social software. In order to promote the acceptance and use of the software, individual and organizational requirements must always be considered and included.

This study has several limitations. First of all, the number of interviews conducted is still very limited. The theoretical saturation has not yet been reached based on the interviews conducted, for this reason, this should be expanded in the future to get an even more comprehensive insight into the advantages and disadvantages of using Slack. Furthermore, the interviews were conducted exclusively in one company within the gaming industry, future research should investigate whether the results are comparable in other industries and contexts. The study refers to the concrete functionalities of Slack, in the context of other studies the transferability of the raised challenges and success factors to other tools could be examined. Furthermore, our investigation was conducted in the German context, the consideration of using slack within different cultures is required.

In conclusion, Slack has proven to be a suitable tool for knowledge transfer, generation and documentation. A prerequisite for generating positive effects of Slack, however, is the consideration of obstacles in implementing and using the social software.

Abstract

This paper aims to examine the value communication capabilities required in service development by proposing a way for value communication of a preventive maintenance solution. The research questions the paper aims to answer are, therefore, (1) how customer value of preventive maintenance services can be quantified, visualized and communicated and (2) what the implications of this value quantification and communication development to the wider MA capabilities development are.

The study is based on an interventionist case study in a manufacturing company and its hose assembly supplier. The researchers have worked with the case companies on development of a new production innovation eventually providing value potential also for the OEM's end users. In addition to supporting the service development, the MA researchers have worked on creating models for value quantification and visualization of this potential new aftersales service concept.

Customer value of preventive maintenance services can be communicated by quantifying and visualizing the cost behaviour of direct and downtime costs. The required capabilities can be accessed from the financial department requiring also effective knowledge management practices.

Value quantification and communication capabilities are in crucial role in also in the early stages of the servitization process and may warrant the help of the financial department. Value quantification and communication is needed early in development of a service offering in order to push the idea forward. Thus, these capabilities need to be developed to a sufficient level even before the development starts. The financial department can have a role in this as the value analysis requires certain skills and information to provide reliable estimations. The framework provided may also help manufacturers understand the value created by preventive maintenance solutions.

The paper answers the call for more practical tools for servitization. Moreover, the paper adds to the discussion about the role of MA in the servitization process and provides insights in the capabilities required in this process, especially in value quantification and communication.

Keywords – servitization, customer value, value quantification, value communication, MA capabilities

Paper type – Academic Research Paper

1 Introduction

For decades now, manufacturers have been engaging in the process of becoming a service provider, though with varying degrees of success. After Vandermerwe and Rada (1988) introduced the term servitization to describe this process, there has been extensive academic inquiry on the subject (see, e.g., Baines et al., 2009). Different drivers, such as competitive advantage, have been recognized as motivators for this change process (Vandermerwe and Rada, 1988). However, success in servitization is not given and manufacturers still face challenges (Brax, 2005) and, hence, the subject remains far from being mature (Baines et al., 2017).

Value communication is one of the recognized challenges in servitization in which management accounting (MA) capabilities could be utilized. Value communication is needed both in sales and internally to push the new service development (Kindström et al, 2012). However, in practice manufacturers find value communication challenging (Hinterhuber, 2008) and, thus, value communication has been recognized as a challenge in the servitization process (see e.g. Brax, 2005; Kindström et al., 2012; Parida et al., 2014). MA capabilities could aid in value communication especially in value quantification (Wouters and Kirchberger, 2015) which is needed in effective value communication (Eggert and Ulaga, 2018).

Therefore, the objective of this paper is to examine the value communication capabilities required in service development by proposing a way for value communication of a preventive maintenance solution. The research questions the paper aims to answer are, therefore, (1) how customer value of preventive maintenance services can be quantified, visualized and communicated and (2) what the implications of this value quantification and communication development to the wider MA capabilities development are?

To answer the research questions, this article takes advantage of a unique access to an industrial case on developing new technology that embeds customer value potential for preventive maintenance. The case companies are a mining equipment manufacturer and its hose assembly manufacturer who have jointly developed a production innovation which provides value also to the end customers as an aftersales concept. The case is based on an interventionist research project (see, e.g. Jönsson and Lukka, 2006; Suomala and Lyly-Yrjänäinen, 2012; Suomala et al., 2014; Lyly-Yrjänäinen et al., 2017) and the researchers have worked with the case companies in the development of the production innovation as well as polishing the same innovation into a new service concept. As interventionist MA researchers, they have also worked on creating models for value quantification and visualization at the early stages of the service development process.

The paper, therefore, provides a practical tool for value communication and adds to the discussion about the knowledge management aspects of the servitization process. First, the cost model and the framework created answer to the call for new tools and techniques to aid practitioners in the servitization process by Baines et al. (2009). Second, by

examining the capabilities required from the research team in the development of this model the paper provides more insights on the role of MA capabilities in servitization and more broadly on the knowledge management aspect of servitization. Both these concepts have gotten less attention in the literature (see e.g. Laine et al, 2012; Leoni, 2015), thus more inquiry on these subjects is warranted.

2 Literature Review

2.1 Customer Perceived Value of Preventive Maintenance Service

The customer's incentive to purchase the offering can be calculated as the difference of the total customer value and the price of the offering (Anderson and Narus, 1998). This difference between the total customer value and to total costs is also known as the customer perceived value (Eggert and Ulaga, 2002). As summarized by Eggert et al. (2018), over the decades our academic understanding has evolved from the exchange view on value to the current understanding of value-in-use and service dominant logic, in which customer is always a co-creator of value (Vargo and Lusch, 2004). However, the idea of customer perceived value as the difference of benefits and sacrifices has persisted. In one of the earliest instances Zeithaml (1988) defined customer value as: (1) a low price, (2) whatever the customer wanted from the offering, (3) the trade-off between the quality received for the price paid and (4) the difference between all the benefits received and all the sacrifices incurred. The fourth definition refers to the currently widely accepted and used benefits/costs model of customer perceived value (see e.g. Eggert and Ulaga, 2002; Khalifa, 2004, Kumar and Reinartz, 2016, Lyly-Yrjänäinen et al., 2019) shown in Figure 1.

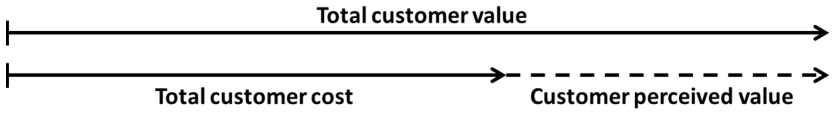

Figure 1. Customer perceived value

When evaluating the value of preventive maintenance, though in many cases increasing the direct maintenance costs, it usually lowers the total maintenance costs. Preventive maintenance has been used since the 1940's to avoid unplanned downtime (Garg and Deshmukh, 2006) and authors like Barlow and Hunter (1960) presented the first mathematical models for time-based preventive maintenance policies. Thus, the benefits of avoiding unplanned downtime has been understood for decades. However, when moving from corrective maintenance to more frequent preventive maintenance, the direct

maintenance costs and downtime costs have an inverse relationship, where the direct costs rise and downtime costs decrease (Woodward, 1997). Figure 2 shows this inverse relationship.

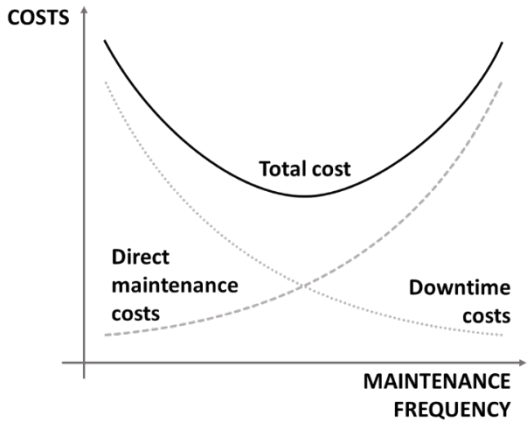

Figure 2. The relationship between the direct maintenance and downtime costs (adapted from Tempest 1976, p. 459).

Thus, the value of preventive maintenance is composed of lower total maintenance cost consisting of increased direct maintenance but substantially lower downtime costs. Direct maintenance costs include costs like labor and materials that are caused directly by the maintenance intervention (Pascual, 2008). Therefore, they are quite easy to measure and control (Vorster and De La Garza, 1990). On the other hand, the downtime costs are harder to quantify because they depend on different factors such as the production rate of the equipment (Pascual, 2008). If the downtime costs come down more than the direct maintenance costs rise, customer value is created from cost reduction in total maintenance costs.

2.2 Value Communication Capabilities in Servitization

Value communication capabilities are required in service development. It is well known that servitization process requires new capabilities for manufacturers to be successful (see e.g. Oliva and Kallenberg, 2003). This is also evident in the fact that not all manufacturers are able to provide profitable services (Malleret, 2006) or gain revenue growth but with lower profit margins (Neely, 2008). Value communication capabilities are important as to sell services, customers need to be made aware of their value (Malleret, 2006). Furthermore, value communication is needed also internally to push the development project (Kindstörm and Kowalkowski, 2014).

Effective service value communication necessitates value quantification and visualization capabilities. As concluded by Eggert et al. (2018) *"…value proposition quantification in business markets is a key consideration in effective value communication."*. Furthermore, value visualization capabilities are needed in service sales (Kindstöm and Kowalkowski, 2014) as customers struggle to understand the value of services in advance (Kindström et al., 2012). Thus, to market the service offerings, manufactures first need to quantify the value and then communicate it effectively.

However, these essential value communication capabilities seem to be underdeveloped in many organizations. Rapaccini et al. (2013) noted that tools and skills developed for service development were at the lowest stage of maturity compared to other aspects. Furthermore, in practice manufactures find value quantification and communication challenging (Hinterhuber, 2008). Lastly, manufactures struggle in value visualization when moving away from their traditional products to more intangible services (Kindström et al., 2012). Thus, the current struggles with value communication can be aggravated when a manufacturer moves to more intangible services where these capabilities are especially needed but not developed sufficiently.

2.3 Communicating the Value of Preventive Maintenance

Communicating the value of preventive maintenance is challenging as the benefits are not visible. When preventive maintenance is utilized, the maintenance is done proactively to avoid breakdowns and downtime (Ahmad and Kamaruddin, 2012). This increases the direct maintenance costs, but the total maintenance costs usually decrease, thanks to the reduced downtime (Woodward, 1997). However, these downtime costs are more intangible (Vorster and De La Garza, 1990) and, therefore, not so easy to quantify. Furthermore, the value is created in the long run, thus requiring understanding of the total life-cycle costs (Brax, 2005).

Thus, to successfully communicate the value, not only the quantification of the customer's direct maintenance costs but also a credible estimation regarding the downtime costs is required. In other words, in order to determine the customer perceived value when moving from corrective to preventive maintenance, the behavior of the two value components (the total customer value and total customer cost) needs to be known well. The preventive maintenance, however, does not change the value-creation logic of the customer and, therefore, it is possible to simply compare the costs with and without the preventive maintenance approach, taking into account these two cost components. Thus, the value quantification is focused only on the points of difference in value (Wouters and Kirchberger, 2015). Therefore, the increase in customer perceived value is created by decrease in total maintenance cost. In addition, as the decrease is created by a reduce in intangible downtime costs, effective value communication is also required.

The framework in Figure 3 explains the customer perceived value of preventive maintenance. As visible in the figure, the framework makes connection between (1) the

expected cost behavior of preventive maintenance compared to corrective maintenance (Figure 2) and (2) the definition of customer perceived value (Figure 1) explicit. In this framework, the 'cost lines', normally represented horizontally, are only rotated to vertical to illustrate how the graph showing the total cost of preventive maintenance can be used to communicate customer perceived value, too. In other words, the framework therefore explains and visualizes the increase in customer perceived value resulting from the reduced total costs enabled by investments in preventive maintenance.

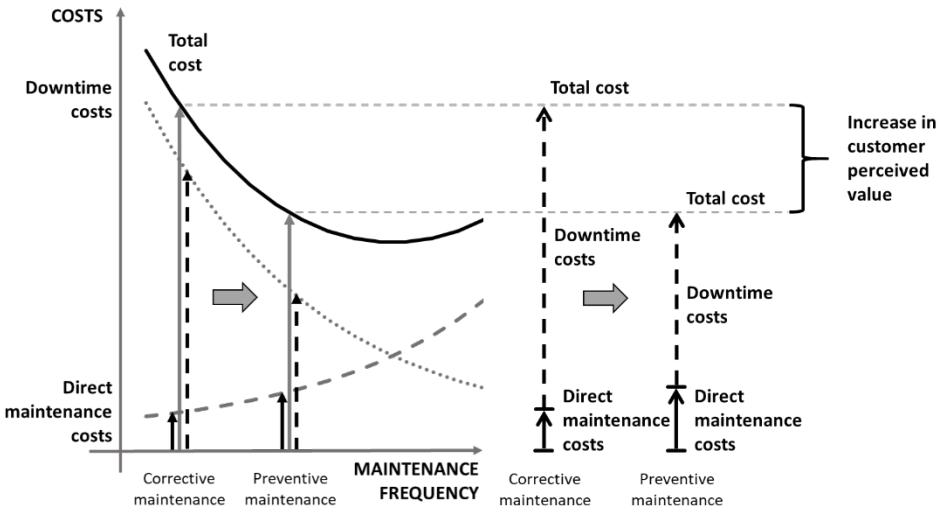

Figure 3. Customer perceived value of preventive maintenance framework

Therefore, to communicate the value of their preventive maintenance, service organizations need capabilities to (1) quantify their customers' maintenance costs and (2) visualize the cost reduction. Cost quantification requires knowledge about the customers processes (Wouters and Kirchberger, 2015) as well as cost calculation capabilities. Furthermore, to eventually communicate the cost reduction, visualization/communication capabilities are needed as the customer's understanding of these intangible costs might be limited.

Interestingly, MA function could be used to gain access to these required capabilities**.** Wouters and Kirchberger (2015) bring up the idea that especially customer value quantification can be very close to MA activities with the idea to show the benefits of the offering in monetary terms. The MA's role in servitization is also conceptualized by Laine et al. (2012). In their paper they discuss the different roles of MA in supporting the servitization process. Therefore, manufacturers could utilize the MA function's capabilities and resources, especially in value quantification as a part of the servitization process.

Thus, the servitization process requires also effective management of the manufacturer's current knowledge assets. The knowledge assets of an organization include intangible resources such as employee know-how (Moustaghfir, 2008) but also more tangible assets that enable the diffusion of knowledge (Linzalone, 2008). In the servitization process, knowledge management systems that support knowledge sharing should be in place (Leoni, 2015). Thus, from knowledge management perspective, effective service value quantification requires the development of both intangible knowledge assets (MA know-how) as well as more tangible assets (organizational routines for sharing knowledge).

3 CASE: Communicating Value of Preventive Maintenance Service

3.1 Hose Harness as a Production Innovation – Knowledge Transfer Emphasized

This paper is based on an interventionist case study with a company manufacturing mining equipment (OEM) and its hose assembly supplier. The mining equipment are powered with hydraulics and, therefore, hose assemblies are needed to transmit the power. A hose assembly consists of a piece of hose with fittings crimped (i.e. squeezed) at both ends.

The research collaboration started already 2011 with the development of a new digital production concept for manufacturing machine-specific hose assembly kits (Lyly-Yrjänäinen et al., 2016). However, as soon as the new hose assembly factory was up and running, the sourcing management of the OEM started to ask for a solution to reduce the installation time of hose assemblies.

A mining machine can have more than one kilometre of hydraulic hose or over 400 hose assemblies. When such mining machines have telescopic booms, the hoses going to the front end are built into thick bundles, bound together with plastic safety spiral. Especially these bundles are time consuming to build and, more importantly, work ergonomics are poor causing sick leaves. Figure 4 shows a worker building the bundle hose by hose and a finished, spiralled bundle on the other boom of a mining machine.

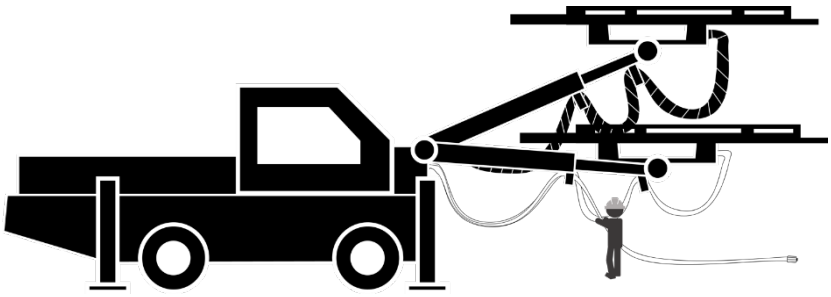

Figure 4. OEM assembly worker installing hoses into a 'bundle' on the machine boom

The sourcing manager wanted to purchase the boom hose assemblies as a ready-made, plug-and-play module similar to the wire harnesses used in the automotive industry. With wire harnesses, wires and cables are flexible; as long as they are all long enough, they can be connected. However, high-pressure hoses have several layers of steel wire in them, making the bending radius large and, as result, the hose ending points must be within a tight tolerance.

When the hoses were previously cut manually, the length tolerance was not that tight and, as a result, the OEM's assembly workers had to change hose routings inside the bundles to ensure that the hose end points are appropriate. Interestingly, the new digital manufacturing technology embedded in the new digital production concept improved the hose length tolerance, hence providing the starting point for the development of plug-and-play hose harnesses.

Because of the variation in the hose length, each hose bundle was somewhat unique and, hence, there were not much documentation on the assembly process either. Hose routing is difficult to document even with modern 3D solutions; instead, ideas for the knowledge transfer were tested using waste hoses and cheap plywood mock-ups. Eventually, after two years of development with the help of the research team, the supplier eventually invented a solution to handle the knowledge transfer needed to build the necessary jigs for both assembling the harnesses ergonomically at the supplier (left in Figure 5) and transporting them to the OEM assembly line for easy and fast installation (right in Figure 5).

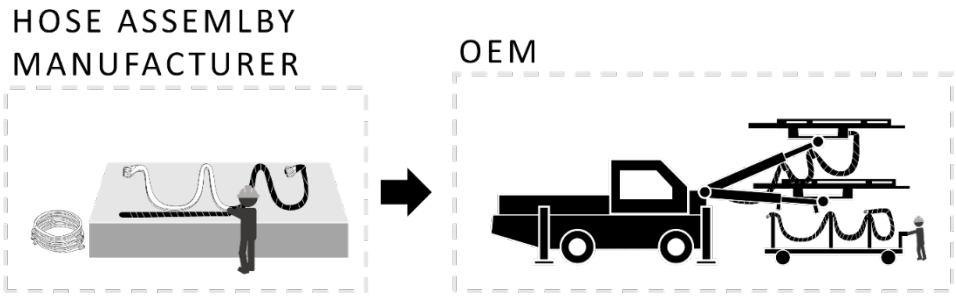

Figure 5. Supplier builds the bundle and the OEM installs it

Buses and trucks use preassembled hose harnesses for, e.g., brake hoses, though hose harness concept has never been applied to large, high-pressure hose bundles. As pointed out by the OEM Plant Manager:

> *"I have never seen nor heard about any manufacturer using preassembled harnesses similar to ours."*

Thus, new ideas were needed to manage the knowledge transfer and also how to build the assembly jigs and tool fast and with low costs; mining equipment volumes are measured in hundreds per year and such volumes simply do not justify high investments

in assembly tools. At the same time, many experienced professionals were convinced that outsourcing of the bundle assembly would never be possible. The development process, therefore, included both technology uncertainties and 'knowledge-management-related uncertainties' eventually solved.

When the uncertainties related to the process were solved, these ready-made, plug-and-play hose harnesses provided clear value in the OEM's final assembly. As stated by Sourcing Manager:

> *"Previously it took one worker three shifts to build the bundle for one boom. With this plug-and-play hose harness, the assembly time has dropped to three hours."*

Factory throughput time and asset turnover are important KPIs for the OEM. The hose harness concept impacts both these measures, appreciated by the top management. The core competence of the supplier is the fast and low-cost knowledge transfer process needed for ramping up new harnesses with limited amount of documentation available, a knowledge asset hard to copy. Furthermore, the innovative ways of knowledge transfer burden the over-burdened R&D and production engineering resources very little.

3.2 The Hose Harness Evolves in a Spare-Part Solution

Interestingly, the implication of the hose harness concept on the OEM final assembly sparked another potential application for it. As mentioned by Sourcing Manager:

> *"If the harness speeds up the assembly process in the factory, it has potential to reduce the maintenance downtime of our mining customers as well."*

When looking at the mining machines, the hose assemblies in drilling and tunnelling equipment are wear parts; pressure hammering and falling rocks eat hoses up fast; the replacement hose assemblies create a lubricative aftersales market for the OEM. At the same time, drilling and tunnelling machines are bottleneck resources, hence calling for new solutions for fast hose replacement. The comment of one of the OEM's engineers verifies the shared value potential:

> *"When I was younger and working on a tunnelling site, whenever a tunnelling machine had a broken hose, everyone was running. It is evident that customers would appreciate solutions that reduce the downtime of their bottleneck assets."*

Despite the shared value potential of services related to hose assemblies of mining and tunnelling machines, few OEMs have been able to successfully monetize it. As pointed out by the OEM's manager:

> *"We have not been able to compete with the local hose assembly suppliers. This is because the delivery time is of essence when selling replacement hose assemblies."*

With the hose failures in bottleneck machines, the impact of downtime on the mine productivity creates a need for fast replacement and, to shorten the lead time, a local hose assembly manufacturer typically operates inside the mine, illustrated in Figure 6. Typically, the same local supplier is then used for the scheduled, regular maintenance, too, hence keeping the OEM out.

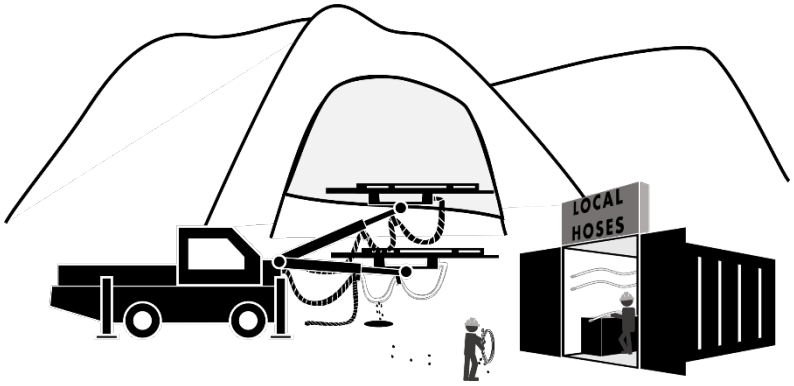

Figure 6. Replacement hoses.

The hose harness, however, may provide a solution that would help the OEM compete with the local hose assembly manufacturers. Since the drilling machines typically are bottle-neck resources in the mining operations, fast preventive maintenance solution on wear parts adds value to the customers. In the best scenarios, the hose harnesses can be changed down in the mining tunnels without driving the machine to the workshop, again saving valuable drilling time. Thanks to the hard-to-copy knowledge assets of the OEM's hose assembly supplier, it is not so easy for the local hose assembly manufacturer to offer similar value.

3.3 Modelling the Total Cost of the Proposed Preventive Maintenance Solution

The evaluation of the aftersales concept was initiated based on the value potential identified in the OEM production. The focus first was on building the sales argument for the cost reduction enabled by the complete hose bundle changeover with the plug-and-play harness concept. However, the MA research team built more complex cost analysis taking into account also the corrective maintenance. Table 1 shows the inputs used in the cost analysis with example figures.

Table 1. Inputs for cost analysis needed to evaluate customer value potential

	Hoses from a local manufacturer	**the OEM's hose bundle**
Cost of a single hose	€ 150	-
Cost of hoses for a complete changeover	€ 7 500	€ 6 000
Downtime when a single hose is replaced	1 hour	-
Downtime when complete changeover is made	15 hours	7 hours
Complete changeover interval	6 months	2 moths
Downtime cost per hour	€ 3 000	€ 3 000

First, when a hose breaks down, the hose is taken to the workshop inside the mine and, based on the sample, a similar one is manufactured. The wear-down hose assembly is used as a sample and depending on its condition, the new locally-made hose assembly does not always follow the factory spec.

Thanks to the local monopoly, the hose assemblies manufactured in the mine cost ten times more (150 Euros in the table above) than what the OEM pays for the hose assemblies Interestingly, as shown on the second row, the price of a complete pre-assembled, OEM-specified hose harness can be even less compared to the 'pirate' hose assemblies purchased locally.

Third, when a hose assembly breaks down, with the hose assembly workshop operating in the mine, the downtime is about one hour. Fourth, when comparing the time needed for building a new harness from loose hose assemblies or installing a plug-and-play hose harness, the time reduction was estimated about 60%:

> *"In a mine, the old bundle has to be disassembled before the new harness can be installed. In addition, there is usually a team of three to four people doing the work."*

Fifth, the hose assemblies in the boom of a new machine usually work for about two months without any breaks. After the two months, first hose failure occurs, and the hose failure frequency grows until it is time to rebuild the entire bundle. In the cost analysis, the boom hoses are completely changed in every six months while, to ensure error-free drilling, the hose harness should be changed every two months.

Finally, the bottleneck role of the drilling and tunnelling equipment makes the opportunity cost of lost sales the most important cost element. In this case, the opportunity cost is the gross profit the lost hour of drilling capacity. As pointed out by one of the managers:

> *"Depending on the mine, the cost of downtime per hour can be anything from 3 000 to 50 000 Euros."*

However, in order to make to make a conservative cost estimation, a downtime cost of 3 000 Euros per hour was used. Figure 7 visualizes the cost analysis for both the corrective and preventive maintenance policies based on the information discussed above. First, the graph on the top illustrates the cost behaviour with the hoses replaced at failure. The magnifying glass shows the 150 Euros of the replacement hose purchased locally and the downtime cost of one hour. As the graph illustrates, the hoses in the bundle start to fail after about two months with the failure frequency increasing until, after about six months, all the hoses are changed, and the bundle rebuilt in a workshop. The dashed line shows the accumulated costs, summarized in the pillar on the right. Second, the graph at the bottom illustrates the cost behaviour when the preassembled hose harness is changed in every two months to ensure failure-free drilling. Though the cost of hoses is a bit higher, the significant reduction in the downtime brings the costs down almost 50%.

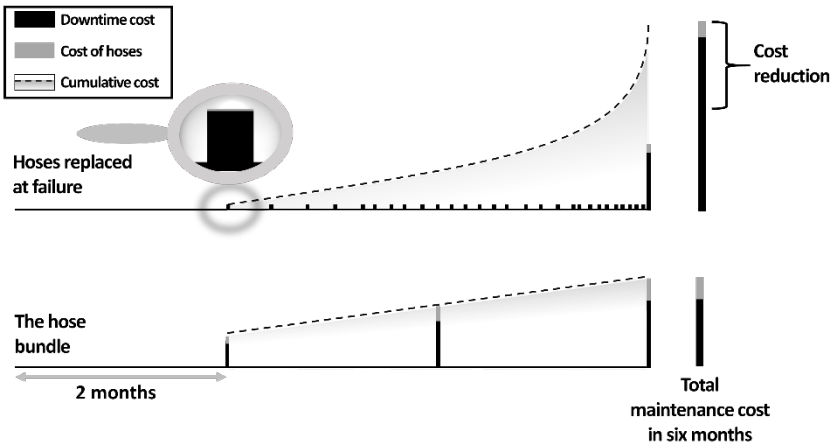

Figure 7. Total costs of hose maintenance in six months.

The figure aims to (1) visualize the significance of single hose failures to total maintenance costs, (2) highlight the predictability of costs with the hose harness, (3) show the amount of direct maintenance and downtime costs in both maintenance policies and (4) show the total cost reduction over the time period. The figure above provides a simple illustration of the key variables used for communicating the value potential within the organization. Naturally, in case the company wishes to push this service concept in the market, the figure can be used for communicating the value potential and the value drivers to the customers, too.

The figure above showed the cash-flow perspective of the two service approaches, with the total impact summarized on the right. However, the same summary can be shown using the illustration typical for preventive maintenance, as shown in Figure 8. The two arrows on the right show the total costs of the two service approaches, both split into the direct costs and downtime costs. When placed parallel, these two arrows make the total cost impact explicit. As the figure shows, the perceived customer value (i.e. 59 700 difference in the total costs) is shown in the same way typical to the benefits-sacrifices frameworks, though this time only vertically. However, Figure 8 makes it very explicit how the customer perceived value analysis follows the well-accepted idea of preventive maintenance, with the cost components coming from the framework illustrating the inverse relationship between direct costs and downtime costs.

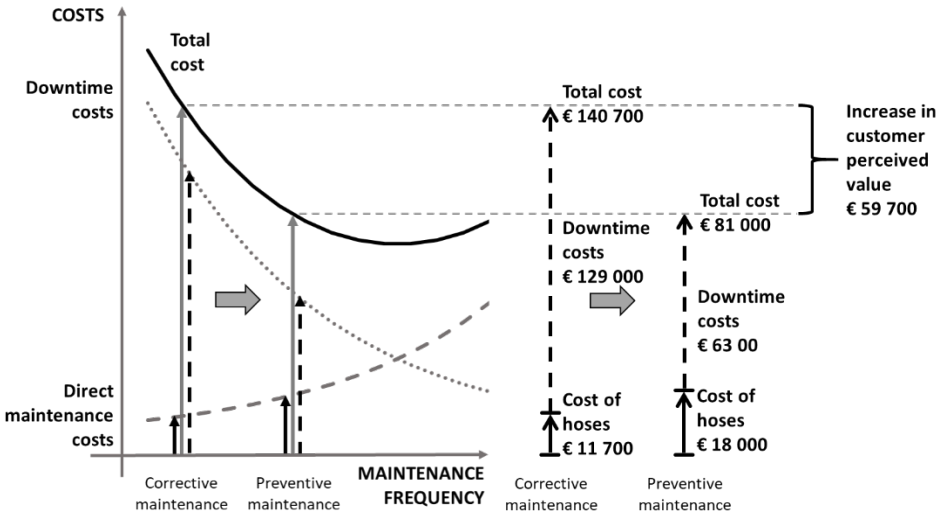

Figure 8. Increase in customer perceived value with the hose bundle in six months.

The cost analysis and the visualisations can, then, be used for building different scenarios educating both internal and external stakeholders. For example, to save on the direct costs, a mining company may be interested in accepting three to four hose failures during the third month to reduce the number of complete hose harness changeovers. However, with such a costing tool the sales organization can prepare an analysis showing that more than two hoses failures during the third month makes the customer's idea unprofitable. Such analyses introduce a totally new costing capability also for the OEM's front-line after-sales organization; value often is context specific (the downtime cost, for example, depends on the mineral customer is mining) and, therefore, it is important to use organization's MA knowledge to build MA competencies also in the front end.

4 Conclusion

The paper examined the value analysis and communication capabilities required in service development. Such capabilities are clearly required for building a shared understanding about the desired business development (Laine et al. 2012), and for identifying more detailed development activities based on such shared (continuously refined) understanding.

The first research question was how customer value of preventive maintenance services can be quantified, visualized and communicated. In response, Figure 8 shows a more detailed analysis of the customer perceived value using the framework introduced in this paper. The framework that was introduced and utilized in this paper holds several implications. First, it provides a promising basis for understanding and analyzing the longitudinal value of preventive maintenance activities. Second, it represents an example of an approach enabling a company interested in service development develop a

framework through which central value elements can be identified, further examined and communicated within and across organizational boundaries. As such, the framework represents a rare example of the tools and techniques that has been already a decade been called for in the servitization literature (Baines et al. 2009)

Regarding the second research question focusing on the capabilities required for these processes of customer value quantification, visualization and communication, one should note that external interventionist researchers are not always available. Instead, the company personnel need to hold those capabilities by themselves, within finance, services, R&D and other operations. MA (or finance function) should typically be there for actively supporting decision-making for business development. However, the information about the value and profitability embedded to servitization has been discussed so far in rather exploratory terms, and a more detailed, supportive role of MA in servitization could deserve substantial further examination (Neely 2008, Laine et al. 2012, Tenucci and Supino 2019). The development process around the case of this paper could be largely supported by the MA function of the company, which provides nice avenues for MA to truly become a business partner as discussed in the literature (see e.g. Järvenpää, 2007). However, MA is not working in isolation. Instead, cross-functional activities are desired in order to identify, further develop and manage the service business development.

The process, similar to the case presented in this paper, for developing the capabilities for quantifying, visualizing and communicating the customer value, is desired in companies aiming at service business development in a solid, knowledgeable basis. The process presented in this paper is related to increasing understanding about the value and business impacts of proactive maintenance services. However, there are several other avenues for developing new service businesses that could benefit from extended such MA capabilities. Thus, our paper holds implications for revisiting the role of the finance function and other experts in developing and utilizing their capabilities of MA supporting service business development and decision-making.

The study presented in this paper is not without limitations. The case represents an empirical illustration on for quantifying, visualizing and communicating the customer value, and has contribution in itself. However, wider implications presented in this paper regarding MA capability development in this context require further examination. Further research is encouraged to provide additional cases for extending the similar idea to different service business development contexts and for examining the need for and use of MA capabilities extensively in the servitization context. This would represent a major contribution in the research area, by providing new means for identifying and managing value of servitization.

Abstract

Even if the notion of knowledge management (KM) has been introduced more than three decades ago, the application of this concept in the context of small firms has still not been sufficiently explored. The relatively few contributions, however, agree on the fact that small companies do not manage knowledge the same way as their larger counterparts. In order to fill this gap, the present paper aims to the investigate the if and how different aspects of knowledge management in small enterprises offering knowledge-intensive business services (KIBS) – such as: type of adopted KM practices, barriers to KM implementation and use – are related with some characteristics of the companies such as: their size, the business sector they belong, the kind of adopted strategic knowledge approach followed. Specifically, paper examines some features of KM in companies belonging to various KIBS sectors (ICT, architectural and engineering services, professional services, R&D services and marketing and communication services) in Poland. The findings are based on a quantitative survey conducted among 104 small companies of this type. Investigated KM-related aspects were: the role played by knowledge and KM, the KM practices adopted, the factors that have hindered the adoption of such practices, the way they are used. KIBS companies were investigated because knowledge and its management are vital for their operations and they are perceived as intensive users of KM tools and practices. The findings of the survey show that the approaches to KM followed by small KIBS companies results to be rather differentiated. Concerning the factors that influence the KM approach adopted by the individual company, the size and the kind of followed strategy help in explaining the differences between companies more than the sector of belonging. In particular, the size seems to act as a constraint (in terms of number of adopted practice and of role of promoters) while the kind of strategy as an enabler (a more reflected strategy is connected with a greater number of adopted practices). The study offers food for thought about KM features in the KIBS sector and moreover, it contributes to a better understanding of KM in small enterprises. The knowledge presented in the paper may be of use to managers and owners wishing to better understand their KM practices and implement more suitable solutions.

Keywords – Knowledge Management, KIBS, SMEs, Poland

Paper type – Academic Research Paper

1 Introduction

Although the notion of knowledge management (KM) has been introduced more than three decades ago (Schwartz, 2007), the application of this concept has still not been sufficiently explored with relation to small- sized enterprises (Centobelli et al., 2017; Durst and Edvardsson, 2012; Massaro et al., 2016); furthermore the scarce research currently available on this topic offers rather fragmented results. The relatively few contributions, however, agree on the fact that SMEs do not manage knowledge the same way as their larger counterparts (Chan and Chao, 2008; Wee and Chua, 2013). With the aim to contribute filling this gap, the present paper intends to analyse if and how different aspects of knowledge management in small-sized enterprises are related with some characteristics of the companies such as: the business sector they belong, their size, the kind of strategic approach to managing knowledge they adopt. In particular the paper analyses some aspects related to the way small companies offering knowledge-intensive business services (KIBS) manage their cognitive assets, as follows: the degree of consideration that companies place to their knowledge and its management, the number and kind of implemented KM practices, the barriers they encountered when introducing the practices, the factors that facilitated their adoption, how such practices are used. KIBS companies where selected for a twofold reason. First, as their name recalls, such companies base their competitiveness on knowledge and therefore they must manage it at their best. Second, KIBS companies are very heterogeneous as far as their knowledge bases are concerned (Pina and Tether, 2016), which offers the opportunity to investigate if and how the sector to which the company belongs influences its KM approach.

The paper articulates as follows. Section two briefly summarises extant research about KM approaches and practices with a specific focus on small companies. Section three describes the research methodology and the sample used for the survey, while empirical findings are illustrated and discussed in section four. The last section is devoted to discussion, conclusions, suggestions for future research and limitations of the study.

2 Knowledge management approaches and practices

For some companies, KM can be a deliberate and planned activity; for others, it may *emerge* and develop progressively from the day-by-day practice. It is, therefore, possible to distinguish between two opposite approaches to KM: a *deliberate* or planned approach, and an *emergent* approach. To clarify this distinction, we can refer to the literature of *strategic management*, where we find a similar contrast between a deliberate vs. emergent approach to strategic planning (Mintzberg and Waters, 1985). Deliberate strategic planning refers to an explicit and rational formulation of goals, plans and means that

originates from precise intentions of the company. All is generally decided by the central management, progressively articulated in tasks for different parts of the organization, and backed up by formal controls, in a top-down logic. Conversely, a purely emergent approach to strategic planning is one where actions result to be consistent only over time, but in the absence of clear intentions, leadership, and rational predefinition of goals and plans. In other words, in an emergent approach, goals and plans of a company may even be established initially, but in the end, it is only the results of emerging actions and decisions that lead to an ex-post formalization and co-ordination of those actions and decisions that have proven to be more effective and beneficial to the organization. Maybe, as Mintzberg and Waters (1985) highlight, a purely emergent approach is impossible in real life, but there are situations that are (more or less) close to that abstract definition.

In accordance with the mentioned literature, we can introduce the two different definitions of deliberate and emergent KM approach (Zieba et al., 2016):

A deliberate or planned KM approach is an approach where practices, tools and methods of managing knowledge are linked to the general strategic orientation of the company and are deliberately designed at a top management level. KM goals are based on a rational analysis of company's needs, objectives and resources, and are later implemented and spread across the company with deliberate efforts and investments.

An emergent KM approach is an approach where practices, tools and methods of managing knowledge originate from the daily practices and learning processes of company's employees. Employees develop their own methods of learning, storing, retrieving and sharing knowledge in relation to their actual needs and practical problems to solve. The methods and tools that prove to be effective, useful and/or compatible with the daily business practice are later developed and become established practices, and later can be recognized as "the KM approach" of the company.

According to Zieba et al. (2016), companies of small size may especially follow the emergent approach towards KM. As a matter of fact, these companies have less resources to invest systematically in KM plans and appropriate organizational structures for a deliberate KM. Also, their management style is more oriented to flexibility and "entrepreneurial instinct". However, even if we limit the analysis to small companies, their approach is not standardized, and can develop in different forms, depending on the particular condition where they operate. The set of practices, tools, methods, and KM processes can vary from a company to another. This point still deserves to be researched. In particular, there is the need to characterize the possible content of the KM approaches followed by small companies, and to investigate why some companies introduce a certain KM approach. This is the goal of the present study, that aims to contribute filling such research gap by analysing the different KM approaches adopted by a group of small Polish companies.

3 Research methodology and sample

On the basis of what has been presented above, it can be stated that little is still known about the practices related to KM introduced by small companies and the factors potentially influencing their implementation. In order to fill this gap in, the authors of this paper have tried to answer the following research questions:

- Do KM practices implemented by small firms differ in accordance with the sector of the companies? If so, in which way?
- Do KM practices implemented by small firms differ in accordance with the size of the companies? If so, in which way?
- Do KM practices implemented by small firms differ in accordance with the strategic analysis performed before their implementation by the companies? If so, in which way?

In order to answer these questions, it was necessary to conduct a quantitative study among small firms in Poland. Companies from the KIBS sector were selected as they are knowledge-intensive and knowledge is their crucial resource (Miles, 2005; Miles et al., 1995; Zieba, 2013). Therefore, they naturally need to manage it properly, in accordance with their needs. The companies for the study were selected from the database containing such firms and purchased from a professional company offering data. The survey was distributed among the respondents via two means: a link to an on-line survey and a paper version of the survey sent via traditional post, together with the letter inviting to take part in the survey. In total, the survey was sent to 1000 firms via e-mail and 2000 firms via traditional post. The response rate from the e-mail survey was very low, so it was necessary to choose a different approach (traditional post). In total, 104 replied to the survey, which gives the return rate at the level of 3,5%. The study was conducted in two waves: the first one in 2018 and the second one – in 2019. The whole survey was devoted to KM approaches and practices, factors and barriers influencing their implementation, people responsible for KM, etc. In the next section, selected empirical findings (due to paper limits) will be presented, together with the discussion.

4 Empirical findings and discussion

We collected usable questionnaires from 104 small KIBS companies (i.e. with 50 or less employees), whose composition is shown in table 1. The sample is rather balanced in terms of sectoral and size composition, with the exception of professional services companies that are the 40% of the observed companies.

Table 1**:** Sample composition by company size and sector of belonging

	0 - 4	5-10	>10	Total
ICT	7	2	6	15
R&D	0	5	7	12
Technical	9	6	8	23
Professional	15	16	11	42
Marketing	8	1	3	12
Total	40	29	35	104

The surveyed companies have a relevant business history: only 11 have been active from 5 years or less (Table 2), and the average age of the sample is about 19 years. Hence, they have a consolidated experience which contributes to increase the significance of their responses.

Table 2: Sample composition by company age

Age	# companies
0 – 5	11
5 – 10	12
11 - 20	30
> 20	50
n. a.	1

The role played by the respondents further contribute such a significant: indeed, most of them are company owners or people occupying an executive/managerial position (table 3).

Table 3: Sample composition by role of respondent

Role	# companies
Owner	65
Board member	17
Manager	13
Specialist	9
Total	104

Coming to the analysis of the collected data, it must be recalled that for reason of space in the following pages only data concerning the KM-related practices applied by companies are analysed, linking them to the sector of belonging, the size and the fact that the introduction of the practices was preceded or not by a strategic analysis of the knowledge-related problems of the company. At this regard, we have subdivided

companies in three groups as follows: the first group includes companies that definitely (or almost definitely) did not make such analysis (and are indicated with "N") and represents around 23% of the sample; the second group includes companies that made some analysis but only partially (indicated with "I") and represents around 32% of the sample; and the third group contains companies that that definitely (or almost definitely) made such analysis (indicated with "Y") and represents around 45% of the sample. With reference to the literature about KM strategies, it can be said that companies of the first and the second group follow an emergent KM strategy and those of the third group a deliberate KM strategy. The composition of the sample confirms that among small companies, emergent strategies are more diffused than deliberate, also in the case of KIBS firms (Coyte et al., 2012; Wee and Chua, 2013). This implies that in most companies the introduction of K-related practices is the result of the necessity of satisfying working needs.

To begin with, it is worth noting that the sampled companies on the whole agree on considering knowledge as their most important competitive resources, which confirms previous studies about the role that such asset play for the competitiveness of the KIBS sector (Palacios-Marques et al., 2011; Lara et al., 2012; Mangiarotti, 2012). Furthermore, as it was logical to expect, responses indicate that companies with a deliberate KM strategy assign to knowledge a bigger competitive relevance in comparison with companies following an emergent KM strategy.

Table 4: KM-related practices applied by the company (average % by sector)

	ICT	R&D	Tech.	Prof.	Mktg	Total
Capturing and storing K in repositories or written documents	66.7	66.7	65.2	78.6	58.3	70.2
Email to share and transfer K	86.7	91.7	73.9	83.3	91.7	83.7
Social media to publish and access information	40.0	66.7	30.4	47.6	91.7	50.0
Building and maintaining employees' expertise and skills	60.0	66.7	82.6	85.7	75.0	77.9
Identifying and disseminating best practices	60.0	58.3	60.9	57.1	66.7	59.6
Creating a supportive environment for K sharing	66.7	66.7	34.8	50.0	58.3	51.9
Rewarding employees who share K	53.3	58.3	43.5	40.5	50.0	46.2
Organizing regular meetings to exchange information	53.3	83.3	52.2	61.9	75.0	62.5
Using ERP or CRM software as learning tools	40.0	50.0	26.1	21.4	33.3	29.8
Using communities of practitioners to share K	26.7	25.0	39.1	57.1	25.0	41.3
TOTAL (average number of adopted practices)	**5.53**	**6.33**	**5.09**	**5.83**	**6.25**	**5.73**

One of the survey's question asked respondents to indicate which KM-related practices (among ten listed) the company are using. As it can be seen in table 4, the surveyed companies on average use less than 6 practices each one. Some practices are widely diffused (particularly email that is used to share and transfer technical and market

knowledge by 83.7% of the companies), while others are rarely used (as ERP and CRM). Furthermore, table 4 groups the answer by sector: each value represents the percentage of the companies of the sector that are using the individual practice; the last row shows the average number of practices employed by a sector. Data denote the existence of significant differences between sectors: R&D companies are the most intense users of the practices, while ICT the least intense ones. This fact is quite surprising (there is a general opinion that ICT companies are at the forefront in managing knowledge assets) but it can be partially explained by looking at the single practices and taking into account that the use of a specific practice can be affected by the kind of knowledge base that denote each sector. For instance, marketing services companies make relatively little use of repositories, and this is congruent with the symbolic/cultural nature of their knowledge base; completely different is the case of professional service companies, that make use of administrative (document-based) knowledge. Similarly, the intense use of communities of practitioners by professional services companies can find reason in that they are more used to resort to professional associations (Hinings et al., 2016).

Table 5: KM-related practices applied by the company (% by size)

	0 - 4	5-10	>10	Total
Capturing and storing K in repositories or written documents	62.5	65.5	82.9	70.2
Email to share and transfer K	80.0	82.8	88.6	83.7
Social media to publish and access information	45.0	55.2	51.4	50.0
Building and maintaining employees' expertise and skills	70.0	86.2	80.0	77.9
Identifying and disseminating best practices	50.0	62.1	68.6	59.6
Creating a supportive environment for K sharing	37.5	51.7	68.6	51.9
Rewarding employees who share K	37.5	48.3	54.3	46.2
Organizing regular meetings to exchange information	52.5	62.1	74.3	62.5
Using ERP or CRM software as learning tools	22.5	20.7	45.7	29.8
Using communities of practitioners to share K	37.5	55.2	34.3	41.3
Total (average number of adopted practices)	**4.95**	**5.90**	**6.49**	**5.73**

As regards the number of applied practices, size results to be a very good explanatory factor: micro companies use less practices than the biggest ones (table 5). Only the use of communities of practitioners of practices diverges from this trend, but this is due to the fact that professional services firms (which make intense use of such communities) represent more than half of the "medium-sized" companies.

Table 6: KM-related practices applied by the company (% by strategic approach)*

	N	I	Y	Total
Capturing and storing K in repositories or written documents	68.2	56.7	79.1	69.5
Email to share and transfer K	81.8	80.0	86.0	83.2
Social media to publish and access information	40.9	43.3	62.8	51.6
Building and maintaining employees' expertise and skills	54.5	86.7	81.4	76.8
Identifying and disseminating best practices	27.3	60.0	72.1	57.9
Creating a supportive environment for K sharing	36.4	50.0	55.8	49.5
Rewarding employees who share K	18.2	60.0	51.2	46.3
Organizing regular meetings to exchange information	45.5	60.0	69.8	61.1
Using ERP or CRM software as learning tools	18.2	33.3	32.6	29.5
Using communities of practitioners to share K	27.3	36.7	51.2	41.1
Total (average number of adopted practices)	**4.18**	**5.67**	**6.42**	**5.62**

* Only 95 respondents

The results of table 6 confirm that the kind of KM strategic approach followed by a company is strictly connected with the effort it makes in managing knowledge. Actually, companies that have made a strategic analysis before introducing a KM-related practice are those that are applying more practices.

The last two aspects presented in this paper regard how the practices were introduces and who were the key promoters of the introduction.

Table 7: Introduction of practice (average by size)

	0 - 4	5 - 10	>10	Total
Practices were introduced after a strategic analysis of k needs (1 = definitely no – 5 = definitely yes)	2.87	3.77	3.35	3.27
Key promoters (1 = only employees – 5 = only managers/owners)	4.28	4.21	3.52	4.01

Findings of table 7 are as expected. Given the limited size of the sampled companies the key promoters could be especially executive/owners. It is also obvious that the role of employees increases with the dimension. Similarly, it is quite obvious that micro firms are those that more frequently adopt an emergent KM strategy. Furthermore, they are especially micro companies that follow an emergent strategy.

Table 8: Introduction of practice (average by sector)

	ICT	R&D	Tech.	Prof.	Mktg	Total
Practices were introduced after a strategic analysis of k needs (1 = definitely no – 5 = definitely yes)	2.69	2.90	3.99	3.73	3.33	3.27
Key promoters (1 = only employees – 5 = only managers/ owners)	3.79	4.00	4.05	4.12	3.83	4.01

Table 8 shows that there are some differences between sectors, that seems to be in line with what previously said about the different cognitive context that denote the various sectors. In particular ICT and Marketing services companies are those where employees play a more active role in promoting the introduction of the practices, which can be ascribed to the fact that in these sectors employees are more familiar with the information-related technologies.

5 Discussion and conclusions

The results of the analysis of the answers given to the questionnaires by the investigated firms allow to answer the research questions posed in section 3. First of all, the findings of the survey show that the approaches to KM followed by small KIBS companies results to be rather differentiated, which confirms previous studies about the fact that a single common way to implement KM cannot be identified (Alexandru et al., 2020). Concerning the factors that influence the KM approach adopted by the individual company, the size and the kind of followed strategy help in explaining the differences between companies more than the sector of belonging. In particular, the size seems to act as a constraint (in terms of number of adopted practice and of role of promoters) while the kind of strategy as an enabler (a more reflected strategy is connected with a greater number of adopted practices). Hence, it is possible to say that a deliberate approach towards KM can promote a more thoughtful and intense use of related practices and tools. An interesting result is that the sector of belonging does not seem to be a factor that helps in differentiating the firms' approach, even if it is logical to assume that different knowledge bases imply different ways of managing them. A possible explanation is that knowledge is such a complex matter and there are so many various practices that is difficult to bring everything back to a simple sectorial classification.

5.1 Academic and managerial implications

The study has both academic and managerial implications. As regard the former ones, it confirms the role played by having a deliberate strategy in the shaping the KM activities of a company, also in the case of the smaller ones. This paves the way to further studies aimed at deepening our knowledge about the factors and the conditions that favour the adoption of a deliberate KM strategy by companies of such a very limited size. Concerning the latter ones, our findings suggest that the adoption of KM-related practices

should be preceded by a careful reflection about their effective use, which can be really changing for smaller firms, where also owners or managers usually are directly involved in daily business activities.

5.2 Limitations of the study

The study presents some limitations. The first one concerns the sample that is not representative and regards only Polish small KIBS companies: hence the findings of the analysis cannot be generalised to small firms as such. Second, given the preliminary nature of the study, only a very limited part of the questionnaire was analysed, and the responses were not processed by means of specific statistical methods. However, this limitation can be overcome by the performing of a more sophisticated analysis in the future papers. Third, a greater number of factors could be identified and examined in the survey. All these limitations can set the field for the future research avenues and the forthcoming publications.

Abstract

The Copernicus Programme leaded by ESA (European Space Agency) has/is released/ing a huge amount of Earth Observation data and therefore firms operating in the Space Industry aim at getting most out of them. However, this is not straightforward in that, to be exploited, data need to be processed and interpreted and this, on its turn, requires to build on new digital technologies, and particularly Artificial Intelligence (AI). In this perspective, AI, while allowing data processing, can change the way firms create, deliver and capture value, and hence can be interpreted as a trigger igniting Business Model Innovation (BMI).
While understanding BM as a set of different components, our objective is investigating i) whether AI initially modifies a specific component of the BM, to be considered as epicentre of BMI, or if any of the BM components can be the epicentre of innovation, and ii) whether the innovation process spreads from the epicentre to other BM components and if this happens according to a common path.

Keywords –Artificial Intelligence, European Space Agency, Copernicus Program, Case study

Paper type – Academic research paper

1 Introduction

Nowadays, the European Space Agency (ESA), through the Copernicus Programme, has opened a vast amount of Earth Observation (EO) daily data to the world. Specifically, because of the increasing number of drones, satellites constellations and high-altitude platforms, Earth imaging is becoming increasingly affordable and available at higher resolutions.

Within this scenario, Artificial Intelligence (AI) is expected to play a pivotal role. Indeed, AI, through the availability of mature machine learning tools and the emergence of methods such as deep learning and appropriate hardware units for parallel processing (e.g. Graphic Processing Units - GPUs, Tensor Processing Units), allows processing these data and hence taking full advantage of them through the development of a vast array of new commercial downstream services related to climate, safety, security, surveillance, etc.

As a result, AI for EO large data volumes made available through the Copernicus Programme has changed considerably the Space Industry, where firms are reconsidering their Business Models (BMs) (Saebi and Foss, 2017) and searching for new ways for creating, delivering and capturing value (Parida et al., 2019; Warner and Wäger, 2019). In other words, AI for EO can be interpreted as a trigger for Business Model Innovation (BMI) in the Space Industry.

Given these premises, this paper aims at contributing to the research stream that investigates the role of AI in BMI with a specific focus on the possible paths of BMI through AI by looking at the component(s) BMI starts from and how changes spread to other components.

In the following section a general overview of the literature on AI and BMIs is provided. The third section outlines the methodology. The fourth and fifth sections present the results and their discussion, respectively.

2 Theoretical background: BMI and AI

The concept of BMI, despite the increasing attention received in the last years, is considered "a slippery construct to study" (Casadesus-Masanell and Zhu; 2013: 480) due to the associated proliferation of definitions (e.g. Mueller, 2014; Foss and Saebi, 2017).

Despite with different approaches and extents, BMI implies a change in business model (BM) components, according to the definition of BMI as the "designed, novel, nontrivial changes to the key elements of a firm's business model and/or the architecture linking these elements" put forward by Foss and Saebi (2017: 201).

Some authors look at BMI taking a process perspective and unveiling its dynamic, whereas others describe it as an outcome of an innovation initiative that renews company's existing BM (Mitchell and Coles, 2003; Foss and Saebi, 2017) or completely introduces a new one (Lindgardt et al., 2009). Considering what is being innovated, the transformation might involve one or more components of the BM (e.g. the channel, the

value proposition, the key relationships) or all of the components, thus modifying the entire architecture and the links among the activities underlying them. Moreover, BMI can stem from a single epicentre or several epicentres (Osterwalder and Pigneur, 2010). Overall, the debate on the "dimensionalization of BMI" (Foss and Saebi, 2017) is still open and further studies are needed to better investigate the interdependence among the different components.

The possibilities of adapting or innovating the different components of the BM or even introducing an entire new and disruptive BM have dramatically increased thanks to the opportunities offered by the digitalization (Kiel et al., 2016; Rachinger et al., 2019), leading off the development of a young stream of literature. The new digital technologies, such as (AI, big data, or internet of things (IoT), allow changing the processes of creating, delivering and capturing value and the relationship with customers and other actors as well (Parida et al., 2019; Warner and Wäger, 2019). At the same time, new service and product offerings might be developed, using digital solutions for satisfying unmet customers' needs. Even though it is evident that digitalization enables BMI, contributions are still dispersed (Parida et al., 2019); in particular, while there are some papers that investigate the impact of IoT and cloud computing on BMI (Coyle and Nguyen, 2019), there are very scant contributions that examine the role that other digital technologies, have in BMI.

Considered the recent estimates forecasting that 75% of business applications in various sectors will employ AI by 2021 (Crews, 2019), as well as the evidence of well-known top companies (e.g. Airbnb, Uber, Tesla, Google, Alibaba and UPS) having introduced completely new business models thanks to the use of AI, this study focuses on this specific technology.

The concept of AI, which was coined in 1956 by John McCarthy and his group, is defined as a set of "theories and techniques used to create machines capable of simulating intelligence. AI is a general term that involves the use of a computer to model intelligent behaviour with minimal human intervention" (Wamba-Taguimdje et al., 2020). As said above, AI allows rebuilding, revising and completely changing companies' BM, to the point that Valter et al. (2018) sustain that, in the future, BMs will be a result of an interaction of humans and machines with the latter taking over more and more tasks. Despite the tremendous impact that AI might have on businesses, which have started attracting the attention of scholars, there are only few studies that explore the connection between AI and BMI (Lee et al., 2019).

So far, on the one hand, some articles investigate the influence that AI capabilities might have on organizations performance improvement (Wamba-Taguimdje et al, 2020). On the other hand, some others focus on how AI applications might modify the different components of BM or create an entirely new BMs (Garbuio and Lin, 2019), or how an organization might be able to exploit the potentialities offered by AI. In the latter stream, the article by Garbuio and Lin (2019) distinguishes three main ways through which businesses can or will use AI: assisted intelligence, that allows improving what is

currently in place by increasing the value of the current activities, augmented intelligence, which makes available new capabilities and thus requires modifications in the company's business model, and finally autonomous intelligence, which is the advanced stage of AI that acts on its own and chooses its action on the basis of business goals.

In order to have an organization ready for the AI challenges, Lee et al. (2019) and Reim et al. (2020) present a set of recommendations managers might follow to prepare their company to catch the multiplicity of possibilities offered by the AI (Lee et al., 2019). In particular, both contributions insist on the need to develop internal AI competences, as well as an adequate culture that is also open to collaborations since multiple companies are part of digital ecosystems.

Based on these premises, considering the paucity of research on the role of AI in BMI and the need to further investigate the interdependence among the different components of BM through the BMI process, the aim of this article is to explore possible paths of BMI through AI by looking at the component(s) BMI starts from and how changes spread to other components.

3 Methodology

The research methodology adopted in this paper is multiple case studies. We relied on a multiple case study approach analysing three cases (case A, B and C) operating in the Space Industry and engaged in changing their BM for tapping into the opportunities AI offers.

We followed Osterwalder and Pigneur (2010)'s BM framework which allowed the definition of the variables at play (Eisenhardt, 1989): respondents were asked to describe how AI impacted the company's four areas of the BM over time (the description of the areas/components is provided in section 3.3).

Data were collected in a four-month period and included primary (the CEO of the firms) and secondary sources (firms' websites and documents provided by the informants) according to a multiple data collection method (Eisenhardt, 1989). In carrying out the three case studies, we followed several steps (Barczak, 2015): case selection, identification of the unit of analysis, definition of the reference research framework, data collection, data elaboration, and data analysis.

3.1 Case selection

We selected three case studies of firms operating in the Space Industry, which engaged in changing their BM with the aim of tapping into the opportunities offered by AI technologies.

Table 1. Main characteristics of the firms

Firm	Founded	Country	Size	Industry	Products/Services	Funding	Type
A	2014	IT	~ 10, spin-off	Computer Hardware (mainly aerospace)	Design, development and commercialisation of Electronics Systems, Informatics Systems and innovative services	Private and Public	Privately held
B	1994	IT	~ 50 employees, SME	Defense & Space	Private Geographical Information Services (GIS) and Earth Observation consultancy company, which focuses on information land management	Private and Public	Privately held
C	2008	SL	~ 50 employees, start-up	Computer Software (mainly aerospace)	Enterprise-level solutions for managing spatial data, especially for support in land administration and agriculture processes	Private and Public	Privately held

Firms A, B and C (whose names will not be revealed for sake of anonymity) are European Small and Medium Enterprises (SMEs) operating in the Space Industry. Their main characteristics are reported in table 1.

3.2 Identification of the unit of analysis

As unit of analysis, we address the process the firm followed to change its BM, either explicitly defined or emergent.

3.3 Definition of the reference research framework

We relied on the BM framework provided by Osterwalder and Pigneur (2010), composed of four main areas, each encompassing different components: Offer (Value Proposition), Customers (Customer Segments, Customer Relationship and Channels), Infrastructure (Key Resources, Key Activities and Key Partners) and Financial Viability (Revenue Stream and Cost Structure) because it is a widely accepted conceptualisation of a BM.

The above research framework served as a starting point to conduct interviews as it allowed the definition of the variables at play (Eisenhardt, 1989). Indeed, respondents were asked to describe how the BM was conceived before and after it was innovated. However, according to an exploratory approach, we avoided thinking about specific

relationships between the constructs, so striving to maintain a neutral position when asking firms to explain how the BMI took place.

3.4 Data collection

Table 2: Topics, information sources and supporting tools

Investigated topics	Primary sources	Supporting secondary sources	Supporting Tools
Description of firms; identification of key informants for the case studies	CEOs, Marketing Officers, AI experts of firms A, B and C	Firms' website; slides presented at conferences	Interview guide, part I
Detailed description of the BM components and architecture for the analysed firms before AI was used to			Interview guide, part I
New BMs configuration, in terms of components and architecture, aimed at taking advantage of AI			Interview guide, part II
Final verification of the case studies validity		—	—

Data were collected in a four-months period and included several primary and secondary sources (Table 2) according to a multiple data collection method (Eisenhardt, 1989) in order to enhance the validity and reliability of the data provided by the informants.

As primary sources, the first contact point was the CEO, who allowed us to access two sets of information: i) the detailed description of the initial BM(s) and ii) the detailed description of the new BM(s) configuration. Semi-open questions were used for direct interviews. Semi-open questions allowed gathering all the necessary data, at the same time leaving interviewed people the opportunity to enrich the context description and to enlarge the set of variables investigated. The interviews lasted about one hour and a half each.

As secondary internal sources, we analyzed the firms' website. Other secondary sources were provided by the interviewee and used to triangulate information gathered during the interview (e.g. slides presented at International Congresses and Conferences, company presentations).

3.5 Data elaboration

The interviews were recorded and transcribed my means of a software tool (Dragon Professional v.15). All the information gathered by means of interviews and secondary sources were elaborated with data categorization, using the categories/variables suggested by the literature on BMI. For each variable, information collected by the different sources was compared. For each investigated variable, the triangulation of data was guaranteed: data from the direct interviews were integrated with the secondary sources in order to ensure construct validity and to limit post hoc rationalization.

3.6 Data analysis

Data collected and categorized were used according to the reference models on BMI in order to answer the research questions. Specifically, we analysed possible paths of BMI through AI by looking at the component(s) BMI starts from and how changes spread to other components by means of tables and schemes to facilitate the emergence of evidences from the cases.

4 Results

In the following we first analyse each case separately, and secondly, through the cross-case analysis.

4.2 Within-case findings

Firm A's Case study shows that the epicentre of the BMI process is the Infrastructure: Firm A is indeed striving to increase its knowledge and competences to take full advantage of AI and hence to be acknowledged by ESA (which is showing an ever increasing interest towards AI for the elaboration of Copernicus data) as capable to design electronic systems endowed with AI algorithms which can work on board of satellites. The final aim is that of offering ESA a Value Proposition consisting in the possibility of using AI for selecting images directly on board, getting rid of those images that, while being of low quality, are useless. This, on its turn, will allow resources optimisation, which indeed is one of the main concerns for space missions.

For strengthening its own human resources on AI algorithms, Firm A is implementing two strategies: on the one hand, training qualified personnel to be in the next future at the forefront of AI space applications, and, on the other hand, tapping into the knowledge of Key Partners such as ESA Labs and universities, by means of part-time contracts, collaborative contracts, and contracts by projects with academics. In addition, the path between Firm A Infrastructure (Key Resources and Key Partners) and the Value Proposition is not direct: providing ESA with the above Value Proposition, entails Firm A to build strong Customer Relationship with ESA, by growing in credibility at ESA's eyes and being recognised by ESA among the first companies to be qualified for such a use of AI. This is being achieved by participating to i) a pilot project funded by ESA, intended to provide an in-orbit demonstration of AI algorithms on a CubeSat, and ii) workshops/conferences organised by ESA on the topic. If being a credible partner at the customer's eyes is a key factor in general, in the space industry this is essential: in a niche market as the space one is, being credible and reliable on edge technologies creates loyalty from customers which is much more important than in other sectors. In the words of the CEO "Customer loyalty in the space sector is essential". The Financial Viability of the new BM will be impacted too. In fact, the new Value Proposition offered to ESA

requires investments for training human resources (also supported by means of EU projects) but will grant Firm A a new Revenue Stream deriving from consultancy activities addressed to both ESA and national agencies, as well as participation as expert contractor in open calls etc.

Figure 1 depicts the BMI path.

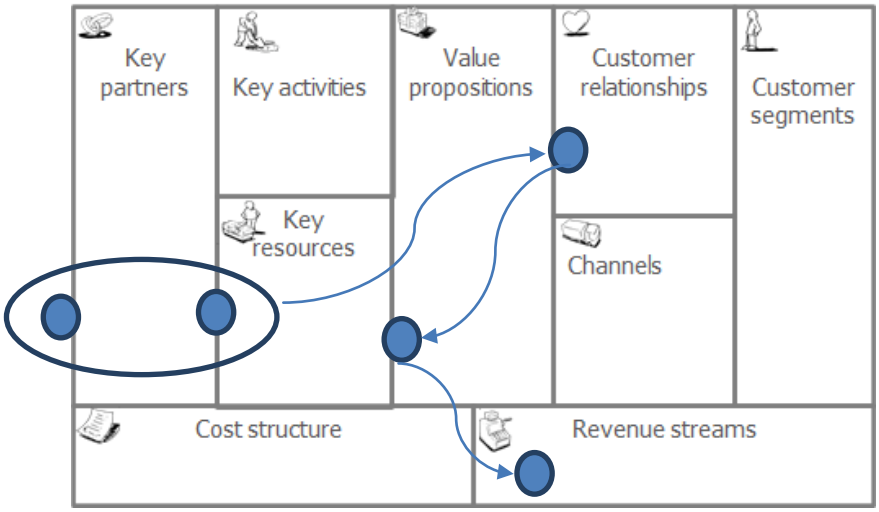

Figure 1: BMI path in Firm A

Firm B has recently innovated its business model in order to offer its Customer Segments (firms in the transportation/oil&gas industries), previously addressed with geo-information, a new Value Proposition in terms of ready-to-use knowledge (geo-analytics) obtained through joining together many diverse data sources (e.g. social media, satellite imagery, mobile phone telemetry, and weather sensors) into a single, unified model able to expose the relationships between apparently unrelated data elements. In other words, the new Value Proposition consists of offering geo-analytics, i.e. info-as-a-service software that, while being scalable in both time and space, is able to provide Customers with the very knowledge they need. This new Value Proposition entails catering to two customers' needs: not only customers can access relevant knowledge to perform their business as a continuous service, but also they can change their cost structure, from CAPEX (capital expenditure) to OPEX (Operating expense), i.e. from an investment in a desktop software to an operating cost connected with software subscription. Such shift determined, from Firm B point of view, a change in its Revenue Stream - from sales revenues to revenues from subscriptions – which, in turn, required an innovation in the Customer Relationship for enforcing customer retention and hence sustaining annual cash flows connected with subscriptions. Firm B underpins the Customer Relationship by continuously improving the offered products and applying the pre-commercial

procurement approach that entails the engagement of the customer in the design of new and innovative applications. The viability of Firm B Value Proposition builds on a bundle of enabling Key Resources in terms of data and technologies, Key Activities in terms of managerial approaches to design, and Key Partners. This bundle allows keeping Firm B Cost Structure affordable; in the words of the CEO: "*info-as-a-service to be sustainable must be scalable, must have from 90 to 70% of gross operating margin, small influence of direct costs on the application*". Despite its BM is not classifiable as purely cost-driven, for Firm B, which is an SMEs, succeeding in creating and maintaining the leanest possible Cost Structure is crucial. Key Resources, Key Activities and Key Partners are of paramount importance for overcoming cost issues connected with the liability of smallness. Key Resources are represented by the huge volume of EO data unleashed for free by ESA on a daily basis through the Copernicus Programme, according to free open data policy. Key Resources are also the enabling technologies supporting the Value Proposition at affordable costs such as: the cloud computing and the consequent possibility of distributing scalable software-based services to customers via a single server, the HPC (High Performance Computing), and the AI. More in particular, Info-as-a-Service, as one of the main applications of cloud computing, is used by Firm B to distribute software-based services to customers via a single server, owned by external partners. Specifically, concentrating the provision of software on a centralised server saves time and money, and eases the problems of scalability (capacity of the software system of scaling up or down application resources to only consume for the resources that are really required at some point in time) that instead occur when software is distributed via physical media. The words of the CEO underpin this point: "*If you consider a large part of traditional services, it has this scalability problem; so you cannot increase production without increasing costs, and since we are essentially talking about value-added activities, they are personnel costs – besides, it is not personnel who you find on the street corner, because you have to train these people. Our answer to this problem is to try to have the ability to make applications and services as scalable as possible with a large automation contribution within the processes*". When introducing the concept of automation, the CEO explains the prominent role of AI, on which Firm B has been working for four years. Specifically, in order to keep costs affordable, it is essential to employ AI for automating the interpretation of satellites images, avoiding to "*enrol the services of a multitude of image interpreters.* […]. *The same need arises if you start doing things on board, for example starting with the constellations of thousands of satellites and thinking that this can be done by a human operator like coordinating their acquisitions or using the resources on board in a smart way. In addition, there is a bottleneck in all missions which is the data transmission channel, you can improve it by using laser communications and systems of this type but in essence there is a great way of transforming things by transmitting to the ground not all the acquired data but only the information you need and therefore having activities on board and therefore these activities must be automated. That is, we cannot send a photo interpreter on space to*

work on things". Examples of managerial approaches aimed at developing the new Value Proposition (Key Activities) at affordable costs are dev-ops methodologies, adopted in the development of the software applications for facilitating communication and fostering flexibility in the context of evolving requirements. Key Partners are ESA which has offered for free the data from the Copernicus Program and the supplier of the servers enabling cloud computing.

Figure 2 depicts Firm B BMI path.

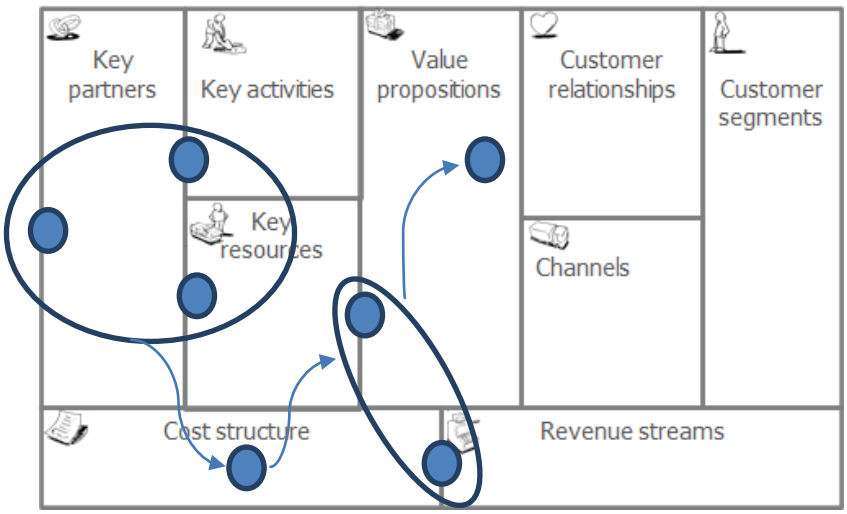

Figure 2: BMI path in Firm B

Firm C case study shows that the Copernicus Programme and the AI have dramatically affected its BM. Specifically, the availability of good quality, consistent and globally available data and, at the same time, the development of the capability of extracting meaningful information thanks to machine learning AI show that the epicenter of the BMI process is on the Infrastructure and in particular on the Key Resources. Firm C has in fact created a new organizational unit, called 'machine learning R&D team' in order to introduce AI machine learning in the company. This allowed enlarging the Value Proposition to products based on machine learning: an example is Sentinel 2 (S2) Cloudless, a cloud detection algorithm for satellite data. These products are addressed to new Customer Segments especially in the agricultural sector where clouds create most of the problems. In addition, Firm C is now working on the development of completely new products that, while mapping natural phenomenon such as floods, earthquakes, and hurricanes, are addressed to a range of Customers Segments: from agriculture to real-estate, from water resources monitoring to insurance industries. In order to improve customer retention, Firm C had to innovate the Customer Relationship, supporting the

customers, helping them, answering their questions, solving their problems in a timely manner.

Figure 3 depicts Firm C BMI path.

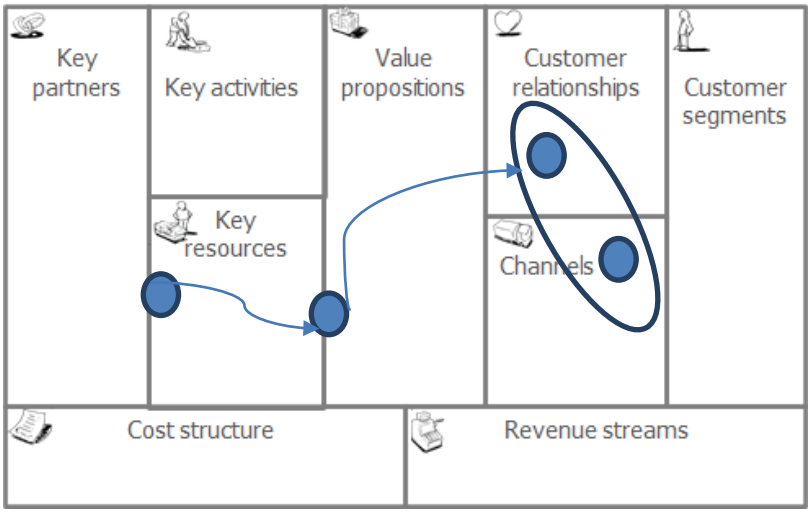

Figure 3: BMI path in Firm B

4.3 Cross-case findings

Following Eisenhardt (1989), we conducted the cross-case analysis selecting categories or dimensions, and then looking for within-group similarities coupled with intergroup differences.

Preliminary evidence suggests that BM changes have found the innovation trigger in 4.0 technologies such as AI, cloud computing, becoming largely available at affordable costs. Specifically, AI is a trigger that in case A acted singularly, while in cases B and C in combination with other 4.0 technologies.

As an addition, the innovation wave seems to affect all the components BM with dynamic patterns that share some common aspects, but also present differences.

As regards the common aspects, it is interesting to note that in all the cases, and prominently in firm A, AI is interpreted not only as a technology enabling new Value Propositions, but a value in itself to be offered to customers, which indeed in the Space Industry are attributing increasing importance to AI. In addition, the paths followed by the three companies show that technology (and particularly AI) is the trigger of the BMI process. Specifically, firms aiming at taking full advantage of AI need to acquire this technology as a Key Resource. Hence, Key Resources and assets play as the epicentre of the BMI process, with Key Partners (although different: universities and ESA's Labs for firm A, and technology providers for firm B) having a supporting role.

As for the differences, the epicentre of the BMI evolved into different paths. Concerning Firm A, the path evolved towards Customer Relationship that enabled the possibility to offer ESA a Valuable Proposition. Such new Proposition in its turn seems to affect also the Revenue Streams, the Customer Channels and Relationship.

While for firm B a new Cost Structure for the company can emerge thus making alternative Value Proposition possible. Finally, for firm C the BMI path evolved towards a new Value Proposition to be offered to new customer segments, thus impacting the revenue streams.

5 Discussion and conclusions

This paper aims at adding to the nascent and growing debate in the extant literature which investigates if and how digital technologies, and particularly AI, impact the processes of creating, delivering and capturing value (Parida et al., 2019; Warner and Wäger, 2019). Specifically, we aimed at investigating if AI triggers similar paths in the BMI process. Open scientific issues are: i) whether AI initially modifies a specific component/area of the BM, to be considered as epicentre of BMI, or if any of the BM components/areas can be the epicentre of innovation, and ii) whether the innovation process spreads from the epicentre to other BM components/area and if this happens according to a common path.

As regards i), our preliminary results confirm the recommendations provided by Lee et al. (2019) and Reim et al. (2020): to take full advantage of AI, firms are firstly required to prepare the ground, developing internal AI competences (Key Resources and Key Activities), as well as an adequate culture that is also open to collaborations with external Key Partners. This means that the Infrastructural area seems to ignite the BMI.

We add to the literature a couple of results that concern ii). As a first result, case studies seem to indicate that the innovation process, initially stemming from the infrastructural BM area, spreads in other parts of the BM, involving all/most of the components of the BM. This means that AI-driven BMI is not modular, but rather is architectural (Foss and Saebi, 2017) in that it regards the general structure and the interactions between the components. As a second result, it emerges that the path stemming from the Infrastructure is dissimilar in the case studies. This seems to be due to the different objectives the firms have: if AI is to be interpreted for instance as a technology enabling the reduction of costs (Firm B), or a mean to strengthen the Customer Relationship with important Customer Segments (Firm A) who attribute AI a pivotal role.

This evidence suggests that innovation drivers and perhaps also other contextual factors to be identified might have a role in the innovation diffusion within the BM.

This research is not exempt from limitations that also point out directions for future improvements. The most important are related to its explorative nature and the initial stage of the work. Drawing on few case studies, results might be affected by the specific application context. This is a common issue that limits the generalization of results.

Further evidence going more in depth into the investigated cases and extending the research to new ones, should be collected.

Abstract

The present research aims at providing an overview on the new approaches adopted in the definition of a business model, paying particular attention to the role of new technologies. In detail, we investigate the business models configuration in the cultural sector starting from the model provided by Osterwalder and colleagues (2005) and proposing a new framework defined on the basis of the most significant evidences emerged from the scientific publication and the practical experiences.
As it concerns the contribution, the research outlines how the business models are being transformed by new technologies and provide a framework within which to understand how digital business models can be built onto concepts and practices of cultural heritage service.

Keywords – Business models, digitalization, digital tools, cultural heritage

Paper type: Academic Research Paper

1 Introduction

In recent years, considerable research has been conducted into "business model" in the age of digital transformation (Berman, 2012) As the technology evolves, both researchers and policymakers are forced in dealing with rapid changes in daily operations, as well as in the development and restructuring of business models (Giones and Brem, 2017; Langley et al., 2020). The digital business transformation involves new processes of integrating the growing body of digital technologies and the resulting customer, product, and operational data (insights) into an organization with results of increasing the value creation capabilities (Normann, 2001). Businesses are undertaking their own digital transformations, rethinking what customers value most and creating operating models that take advantage of what's newly possible for competitive differentiation. Additionally, these new ways of framing business models is permeating several industries, especially service-based ones, since digital transformation affects value perception (Adrodegari and Saccani, 2017), therefore digital instruments may increase the value promise addressed from businesses to their customers (Algar, 2007, Hamari et al., 2016; Fadda et al., 2019).

However, when it comes to business models in cultural heritage, the academic literature and applied empirical research is less developed, if not scarce and this paucity is stressed by scholars (e.g., Li, 2018) calling for further research. Indeed, few contributions dealt with the changing business models in cultural industries, since due to the novelty of the ongoing digital transformation, some authors focused on how the governance of cultural-based firms should take care of the impacts on business models (e.g., Baraldi and Ferri, 2019), while others stressed the suitability of the traditional business models in a context with new entities emerging and changing the design and provision of cultural services. (Adie, 2017).

Due to the aforementioned debate, this paper aims at addressing the calls for research and at shedding some light on the novelties affecting business models in cultural heritage in digital age.

This paper contributes to literature by framing a digital business model in the cultural heritage. The model is depicted through a set of assumptions about how a cultural-based organization, by relying on new technologies create value in a new way, deliver it to a customer – namely a visitor – and other stakeholders, and how value is framed in terms of economic, social and cultural outcomes. Consequently, the remainder of this paper is structured as follows: First the theoretical session presents literature on business models and recent contributions on digital business models; then, the methodology section introduces our research process, the section on findings presents the framework and details and empirically illustrates the key elements of the framework, while the last section presents the main conclusion and discusses the further research.

2 Literature review

2.1 The evolution of the business model

In the last two decades considerable research has been conducted into "business model"; the attention paid by scholars led to the provision of multiple definitions, determining significant challenges for understanding its essential components.

In general, literature contributions focus on economic aspects depicting the business model as a tool to describe the rationale of how an organization creates, delivers, and captures value (Amit and Zott, 2001; Osterwalder and Pigneur, 2010; Mandrella et al., 2020). According to other perspectives, the business model is the representation of a firm's strategy; in line with this, a terminological confusion is detected as *''business model, strategy, business concept, revenue model and economic model are often used interchangeably"* (Sharma et al., 2012) as Shafer et al. (2005) outlines, stating that *"business model is a representation of a firm's underlying core logic and strategic choices for creating and capturing value within a value network"* (2005: 204). The business model has also been referred to *"as architecture, design, pattern, plan, method, assumption and statement*'' (Morris et al. 2005: 726) that make the strategic choices explicit, through an ecosystem approach (Foa, 2019).

More general approaches (Johnson et al. 2008; Frank et al., 2019; Zhao et al., 2020) stress the relevance of shaping a business model to keep a competitive position on the market, as it is considered especially useful when new opportunities and threats indicate a need for reinvention. In this regard, Dudin et al. state that "*the management concept business model canvas is designed for managing the strategic sustainable and competitive development of the enterprise structures in the context of the turbulent and unpredictable changes in the market environment*" (2015: 887);

However, most of scholars describe the business model as a set of interrelated activities that transcends the boundaries of the firm into its wider environment (Zott and Amit, 2017), highlighting its multi-sided nature (Rumble & Mangematin, 2015; Parmentier and Gandia, 2017; Zhao et al.,2019). To express the new multi-sided approach, some scholars talk about the "crowd actor" (Bigham et al., 2015; Raj and Kar, 2015) tracing a path from customer to community to crowd, an evolution mainly due to the new technologies interventions and the new methods to favour participation (Yoo et al., 2019; Siquiera et al., 2020). Bigham et al. (2015) describe the crowd as *"a dynamic group of individuals* (that) *collectively form a single actor that responds to real-time performance tasks, e.g., controlling an on-screen character, driving a robot, or operating an existing desktop interface"* (p. 101).

As it concerns the application of the model, Osterwalder et al. (2005) provide a framework known as business model canvas (BMC) for practitioners, and in their more recent value proposition canvas, Osterwalder and colleagues (Osterwalder and Pigneur,

2014) take a feature-based approach, suggesting the importance of infrastructure, offering, customers, finances, and resources.

The canvas outlines the value exchange between the company and the actors, as well as its network of partners for creating, marketing, and delivering this value to generate profitable and sustainable revenue streams (Osterwalder et al., 2005; Osterwalder and Pigneur, 2014). As suggested by Dudin and colleagues (2015), to achieve an efficient and effective performance, an entity should set its own customer priorities, in particular, allocate a pool of the key customers, as the most important customers, namely those allowing the generation of the basic enterprise income, and a common pool of customers, the ones that generate the residual enterprise revenue. The costs and revenues streams are fundamental in the structure of the business model canvas, as, when shaping the canvas, the authors aimed at stressing the fact that *"the cost streams generate the product value for the enterprise entity itself, in turn, the revenue streams determine the product value for the consumer"* (Dudin et al., 2015: 893).

The BMC consists of nine building blocks to be perceived as an ontological framework for define relationships between the components of the company; in the right-hand side the canvas emphasizes the role of actors grouping the 'customer' in three blocks (customer relationships, customer segments and the channels) that result in a revenue stream for the company; in the left-hand side the elements that are necessary to actually create the product (or service) are grouped (partners; activities to be undertaken and resources to make a product or create a service).

2.2 Digital business model in cultural heritage

More recently, a new perspective has been adopted, as scholars started to talk about "digital business model" in line with the increasing embeddedness of digital technologies in products and services highlighted by scholars (Bharadwaj et al. 2013; Markovich et al., 2019). One of the first contributions stressing the way new technologies can favour the emerging of new business models was proposed by Demestichas et al. (2013), who framed new technology-based business models, more focused on the management of relationships as a way to create and share value (Gati et al., 2019).

Technologies as IoT are changing companies daily activities (Hussain, 2017; Belli et al., 2019) and the effects are self-evident in several industries; one of the most all-embedding approaches is the service-bases business model (Kindstrom, 2010), since customers and firms are expected to cooperate towards the achievement of value creation and IoT is something to elaborate on in order to lever on all the assets available (Trabucchi et al., 2018; Casais et al., 2020); data are one of these assets and they can favour a better service provision. For example, business models based on Artificial Intelligence (Corea 2017) take the focus of the mutual influence between these two elements, as business models are changed because of Artificial Intelligence, as well as Artificial Intelligence is affected by business models. This mutual impact depends on the

differences emerging along time, since, actors' behavior is even more affected by Artificial Intelligence and new technologies in general (Bostrom 2016).

According to the reshaping of the global market through new technologies, and how the digitalization process affected also the cultural sector, it has to be noted that new technologies have also favoured and allowed the configuration of new kinds of services starting from the target segmentation process (). Scholars show that digitization of cultural heritage is growing up together with the improvement of the quality of digital tools, creating new and more personalized kinds of services and experiences (Lanzaretti & Sartori, 2016; Rantala et al., 2019; Fissi et al., 2020). Anyway, companies in this kind of industry are still far from reaching a standard in business models (Schiuma & Lerro, 2017; Zhao et al., 2020), as a purely economic logic cannot be applied in cultural heritage industry (Klamer et al., 2013; Towse & Hernández, 2020). Nevertheless, many cultural organizations are currently reframing both their language and behavior, tracing paths towards new business models.

3 Methodology

To address the aim of this paper we adopted an abductive research approach (Dubois and Gadde 2002) as it seemed most suitable, given the nature of the research objective. Unlike inductive and deductive reasoning, abductive research can explain, develop or change the theoretical framework before, during or after the research process. Accordingly, abductive reasoning consists of a pragmatic approach to advancing the social sciences through a process of "systematic combining" in academic research as depicted in Dubois and Gadde's approach. Thus, we moved back and forth between inductive and open-ended research settings to more hypothetical and deductive theories attempt.

The main components of the proposed conceptual framework were defined by an iterative process that enriched theoretical arguments via a context-specific empirical analysis (Flyvbjerg 2006).

To collect data we considered some of the most innovative evidences in cultural heritage domain reacting to the new digital era. Google search and institutional web site (i.e. NEMo) were used to scrutinize among cases; the selection of the seven cases considered included those that have implemented – or are about to implement – innovative way to transform their service settings, both in situ and online. The data collection took place by combining different sources on museums, namely information from the official websites, messages posted by the organization on social media, as well as the content of specialized magazines and reports issued by supranational institutions dealing with arts; this combination of data is in line with the methodological suggestions by Smith et al. (2006). Indeed, this process favoured an understanding of the phenomenon from different angles, namely based on what curators, IT firms, end-users, as well as local institutions state about the new cultural services offerings. All in all, empirical evidence supported the analysis of the recent literature depicting the ongoing changes in business

models. In conclusion, theoretical and practical evidences let us to interpret business model canvas pillars through a wider perspective and in a view based on digital technologies as elements of disruption with the past, leading towards the proposal of a conceptual framework.

4 Findings

The key findings of this research observed from a new angle the elements of business models as observed in the canvas (Osterwalder and Pigneur, 2010) and theorized by several scholars (e.g., Zott and Amit, 2010). Indeed, collaboration can now be seen as integration, in line with how partners are parts of digital ecosystems instead of being just related one another. Consequently, resources are not just owned but the notions of density and liquidity (Normann, 2001) make them available in the entire ecosystem, thus content better represents what digital transformation can offer to the actors integrating their efforts in digital business models. This content is offered through multiple interactions taking place in various context, thus there is not a single channel that can frame the whole process, but an omnichannel approach is needed; therefore, an omnichannel strategy is properly representing firms' approach in a digital ecosystem domain.

Due to the change above the value proposition too changes, since it depends on additional elements shaping the entire set of activities actors perform, shaping an experience for customers with multiple consequences. These consequences are framed in different ways, since the wide context is affected by the new interactions, thus the outcomes are social, apart from economic and cultural.

The evolution of market dynamics changed the role of all the actors that is now more active and pivotal; new forms of interaction have been developed, moving from collaboration, or cooperation, to integration of sources of knowledge and resources in line with Osterwalder's key partners definition (Osterwalder & Pigneur, 2010). More complex ecosystems are emerging, and the need for partnerships is further amplified and made possible thanks to new technologies and consumers' behavior leading to a demand for highly customized experiences (Kastelan, et a., 2017; Rantala et al, 2019). Innovation is indeed a key issue in the integration of resources to shape more valuable services; for example, processes based on resources/capabilities and new technology are often the result of the involvement of research institutes as universities or scientific institutions, with the aim to develop new businesses through technology and knowledge transfer.

However, has to be underlined that capabilities/resources integration produces positive results only if the consequences are beneficial for all participants leading to continuous value creation and delivering (Fuchs et al., 2000; Mandrella et al., 2020).

In this regard, an example is the Europeana Network Association (ENA), an association grouping experts and practitioners involved in the field of digital cultural heritage. Europeana provide cultural heritage institutions with value by sharing and promoting the collections of museums taking part of the initiatives providing people of all the world with an extensive experience that they can personalize As stated in the official

website *"Europeana supports all cultural heritage institutions to create good quality digital assets in standardized formats, allowing them to share, explore, interrogate and use their collections in ways that fulfil their institutions' own 21st century missions", and adopting strategies* in line with EU policies operating in areas such as inclusiveness, online accessibility, reuse of public information, promotion of EU research, in order to develop cultural sector and create more emphasized experiences.

In a technology-driven perspective resources are still crucial, but what is being exchanged among parties through digital technologies is content. Content is a resource itself and also the result of resources and knowledge combination; indeed, Yoo et al., (2019) referred to user innovation as a key feature of new business models and users' participation as the activity leading to user-generated content. The advantage of favouring new content generation stands on creativity and on the emerging of a unique mix in the combination of efforts performed by multiple actors, as claimed by Trabucchi et al. (2018); indeed, new sources of information are relevant, particularly in traditional businesses to move from the well-established activities to new ones. Additionally, Casais et al. (2020) stressed some more the role of a multitude of actors contributing to the creation of new content with a focus on sharing economy, as it is already evident in the changed business models in tourism industry. Therefore, not only resources are changing, but activities too, since the combination of knowledge and resources and the content generation are the new ways towards digital business models.

An example featuring the considerations above is offered by one of the most famous museums in Europe, namely the Tate Gallery in London (United Kingdom). Tate proposed a digital strategy in 2013 to get the most from the digital transformation; the interactive comment walls are one of the key changes brought to Tate Museum, since customers are allowed to contribute to the museum activities through social media. Additionally, the digital activity and skills developed at Tate favour the creation and nurturing of an arts community, namely a huge community consisting of online actors to offer new and enriched content to visitors. In this way, a virtuous cycle is activated, since new visit experience will lead to further chances to reshape the content and create new one with effects on the upcoming service experience.

In a digital-oriented vision, the service context has become more competitive and customers are more demanding, since elements as memorability, emotions, and feelings are now at the centre of marketing activities. As a consequence, customers look for something new compared to traditional value promises and firms aim at offering experience, due to the cognitive and emotional involvement of consumers, with wider effects in terms of value creation and future purchases. For instance, Foà (2019) opted for ecosystem as the most suitable way to describe service contexts; the perspective on ecosystems is more appropriate since it involves also the activities and outcomes before the visit and after the visit itself. This shift is supported by digital technologies as proposed by Ruhl and Zurdo (2020), with customers at the centres of all activities a firm performs, not only the ones strictly related to service provision. In the same vein, Fissi et

al. (2020) stated that the experience offered to a customer is a crucial element in the business models, since it drives value and all its related dynamics, in terms of benefits for the firm, satisfaction for the consumer, and the improvement of the image as a competitive lever to challenge the increasing competitiveness of market.

The British Music Experience offered a concrete example of such an approach. A great variety of content and music is offered to offer the best from the global scene in last sixty years. Some attractions are physical resources offered by singers and bands, while others have been created on purpose to recreate an era or to track back the history on one of the world-famous artists. The British Music Experience is offered in Liverpool and includes galleries, zones for interactive services, audio and visual experiences and even holograms. The experience may be further enriched with the participation – both on-site and offline – to educational workshops and guided tours, as well as film screenings and private events.

Customer experiences are even more participation-based, with special reference to the involvement of various categories of actors, including other customers. However, to provide satisfying services, customer segmentation is still remaining the starting point in shaping and implementing marketing strategies. Thanks to new technologies companies are now able to study the target more in-depth, to identify in the best and most efficient way possible customers preferences and expectations.

Furthermore, through the digital tools and the so-called multi-sided platforms, customers' engagement is amplified as companies are now able to satisfy several categories of consumers leading to the concept of community. Customers are now able, thanks to new technology and digital tools, to occupy their own "persona segment", adopting the most suitable technology (An et al., 2018), participating also to the target segmentation process.

Obviously, the involvement of a larger number of actors requires the adoption of techniques to make them interact and contribute to service shaping and value creation through online and offline activities.

A fitting example is represented by the #FutureMuseum Project an "experience-Driven and People-Centered" initiative aiming at promoting the idea that *"the future museum will assume the role of an intermediary between local communities, the state and the international community",* namely based on the concept that cultural organizations are even more community oriented, as also stated by La Plata Museum of Buenos Aires' managers talking about democratising museums. Indeed, *"through their capacity to network museums will be in a position to translate the grim realities of their communities into international platforms",* bridging the between the local context and the international context particularly on cultural and social issues.

Taking care of customers is a not-to-be-missed task for a firm, even more when competitive arenas become more complex due to the presence of several actors; technologies represent both the cause and the solution to the problem of interacting with customers in more competitive markets. Indeed, technology has opened the doors to new players on the market, but it offers also new solutions to describe what firms can do to

take a proper care of their customers. Consequently, the literature on business models offer some recent advances addressing this vision.

New media favour additional opportunities to take care of customers and manage relationships with them; in this vein, Gati et al. (2019), while recognizing the advantages in taking care of customers in an almost ubiquitous way with no time and space constraints, stressed the negative effect of an excess of communication, since customers may be soon tired of too much of communication.

The online interaction may turn in something hard to be managed for firms too; indeed, a recent study (The Art Newspaper, 2020) calculated the number of total followers of the Museum of Modern Art in New York and an astonishing number emerged: 12.4 million followers, namely almost the same as the inhabitants of Los Angeles or Moscow. The relevance of this number is confirmed even by the number of followers of the second-ranked museum in this special standing, namely Metropolitan Museum of Art – again in New York – with 9.8 million followers. The online communication activities of the Museum of Modern Art are several, since everyday there are pictures of artworks, inspirational messages, contests stimulating visitors attention, as well as the interpretation of arts in line with society events and news, as it was recently with the pandemic and the anti-racism manifestations.

The above mentioned development of new communication channels as well as the chance to experience cultural heritage in multiple contexts led to the emerging of the so-called omnichannel strategy; indeed, authors focused on this topic even with reference to business models, as Siquiera et al. (2020) described as hard to be separated the on-site and online markets since they are mutually influent; additionally, they state one of the markets may increase the popularity of a firm, while the other may perform more operational tasks. Anyhow, they agree with previous studies describing the markets as featured by an increasing complexity and with demanding consumers, since the availability of information makes consumers more aware of what they can get from an offering and increases the chances they have to compare offerings in the decision-making process previous to an offer.

An example of omnichannel service offerings is given by a museum in the United Kingdom, namely “The Hastings Contemporary”, situated in East Sussex. This museum is mainly centered on modern and contemporary art created by local artists; the gallery is known in the United Kingdom for the focus on paintings and on Modern British art. The gallery was awarded a prize in two contests. The board of administration of the museum decided to borrow a robot from a laboratory and unleash it into the empty rooms of the museum during the pandemic. The robots moved among the artworks and filmed the inner of each room, broadcasting a visit to people at home through an online channel. The success of this idea, named as “robotours”, has been so wide that the museum had to limit the number of online visitors in order to ensure quality in streaming the content; sessions were limited to half an hour and took place frequently during the day to offer the same chance to a wide number of visitors.

In summary, the role of companies in society is greatly changed in the last decades due to the new technologies and the new and pivotal role acquired by actors – especially customers and partners (Osterwalder et al., 2005). New technologies and the multi-actor (or multi-sided) approach amplify the impact of companies' businesses as no more only economic but also social and cultural; for example, scholars as Algar, 2007, Hamari et al. (2016) and Fadda et al. (2019) outlines the new goals of cultural organizations, namely creating, sharing and delivering value both for the society and the company itself.

The evolution of the role of customers from single actors to crowd actors, as previously mentioned, turned customers into co-designers of service, going beyond economic goals and taking into account the social and cultural role of companies and of all the actors interacting with it.

For example, the Western Australian Museum, together with Morris Hargreaves McIntyre, developed a community engagement tool called the 'Spectrum', useful "*to analyze, plan and evaluate how people engage with the Museum and its programs. This is seen as vital to the ongoing development of the Museum, especially in the context of the development of the New Museum in Perth and its impact on the whole of Western Australia".*

The significant number of initiatives and programs co-created and co-curated with community partners is also determining changes in the ordinary activities of the museum, with special reference to the introduction of new Aboriginal trainee programs for the members of the staff.

The WAM approach influence the business model in terms of making the value proposition realistic and relevant to a range different actors and categories of customers, also because the organization "*has reprioritised its expenditure to make more investment into community and education work, regional engagement and into its work with Aboriginal and Torres Strait Islander people".*

Building on insights and categories from the existing literature and based on empirical evidences led as to propose a new framework that captures the challenges of new business models within the contemporary landscape of cultural heritage digital transformation. In the following figure, the 9 blocks identified by Osterwalder have been adapted to the cultural context on the basis of the theoretical and practical evidences.

source: authors' elaboration

5 Conclusion

This research effort of the present work is devoted to captures the challenges of new digital transformation within the contemporary landscape of cultural heritage business. The research interest is twofold: (1) to understand conceptually how the business models are being transformed by new challenging of digital transformation (2) to provide a framework within which to understand how digital business models can be built onto concepts and practices of cultural heritage service. Building on insights and categories from the existing literature and exploiting them empirically, the paper identifies some issues that are integral to the proposal of new framework addresses the opportunity for cultural heritage to furthering research discussion and practical implications on digital business models.

The proposed framework aims to add to the efforts of scholars in developing new ideas, concepts and tools that more deeply explicate the complex and multifaceted nature, structure and processes of business models in a digital era.

First our research contributes to studies on business models, by advancing the understanding of the ongoing changes due to the implementation of digital tools (Giones and Brem, 2017) and offer a detailed analysis of how each of the element of a business model ay change when digital transformation affects the choice of a firm and the ecosystem it is part of. Additionally, this research contributes to research in cultural heritage, as called for by Li (2018), by combining empirical evidence with theorizing, leading to understand how digital business models are changing in cultural services. Consequently, this contribution may support the activities performed by curators and museum managers in challenging digital transformation as a way to further enhance their offering.

Further research may involve practitioners in order to better understand which are the issues affecting the implementation of digitalization in these firms, and how they are concretely reacting to the main features of a digital-driven context.

Abstract

Decision Supports Systems (DSS) are computer-based systems which are characterized as interactive systems, used to help decision makers to utilize data and models to solve problems and support activities linked to their decision making process by enhancing it (Ali, et.al, 2017). Until now most of DSS are developed and implemented for business sector depending on the company/organization perspectives, still there are few done within the area of sport. With those premises, the objective of this paper is to assess the current state of art implementation of new technologies - in the specific the Video Assistant Referees (VAR) - and the impact that it has in supporting the referees in their decision making process during soccer matches. In this paper, we propose a review of literature, starting with the online database through specific keywords in order to assume the current state of analysis.

Keywords – V.A.R., Decision Support Making, Referee, Football Match, ICT; Literature review.

Paper type – Academic research paper

1 Introduction

In today's digital age the technological advances have further pushed the need for knowledge management to the forefront, and XXI century organisations are facing and exploiting the data "explosion", by navigating into an ocean of information coming from different sources, sites and stakeholders (Gavrilova et al., 2017).

Indeed, the proliferation of data and the development of advanced technologies are transforming the way organisations manage, integrate and deploy their competences, take strategic decisions, operate their businesses models, drive value creation mechanisms to meet diversified stakeholders' wants and needs.

Nowadays, people are getting more and more involved in adopting new technologies, which provides them with new ways to communicate, investigate and support decisions. Information and Communication Technology (ICT) has gone through innovations and every aspect in every day's life of people around the world has changed as a coincidence to the changes of society.

The required harmonization of information and communication technologies (ICTs) with operational decision-making demands new alignment software techniques. The subject of using modern technologies as a support to decisions becomes an interesting topic for a large number of researchers in organization studies. Decision Supports Systems (DSS) are computer-based systems which are characterized as interactive systems, used to help decision makers to utilize data and models to solve problems and support activities linked to their decision making process by enhancing it (Ali, et.al, 2017). Until now most of DSS are developed and implemented for business sector depending on the company/organization perspectives, still there are few done within the area of sport.

With those premises, the objective of this paper is to assess the current state of art implementation of new technologies - in the specific the Video Assistant Referees (VAR) - and the impact that it has in supporting the referees in their decision making process during soccer matches. The VAR team is located in a centralised video operation room.

The VAR team can access to all relevant broadcast cameras and two dedicated offside cameras. The VAR does not take any decisions, but it supports the referee in the decision-making process and the final decision can only be taken by the referee.

In this paper, we propose a review of literature, starting with the online database through specific keywords in order to assume the current state of analysis.

The contribution of the document will be to develop a greater awareness of the contribution of the VAR in supporting sport decisions.

2 Methodology

The International federation of football took the approval on the use of video in order to provide support to football refereeing. The federation a claimed this technology as an effective aid in decision making. The Use of Video Technologies in Refereeing Football

and Other Sports analyses the capacity of audio-visual technology from different perspectives to help understand the best implementation of the Video Assistant Referee (VAR) system in football. This paper addresses the opportunity of the implementation procedures regarding how to use it, considering that it could lead to important changes. For this reason, a review of literature was conducted in April 2020 by the author. The systematic review was completed in accordance with the Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA) guidelines (PRISMA, 2009). However, this protocol was modified by incorporating the article screening process as each article was identified, rather than as a single solitary stage later on in its process. The search strategy used a series of specific keywords. A primary keyword (I.C.T. n° 1). was used in direct combination with a second (Decision Support Making n°2) and third keyword (V.A.R. n°3), and Keyword n° 4 Sport. In the paper considered the system football.

Four inclusion criteria were established to exist as a specification for relevance once any sources were identified. The four criteria were:

1. The years considered must be a through 2009 and 2020.
2. Must be peer reviewed based literature.
3. English language.
4. Open access.

Four relevant bibliographic databases were used for this purpose. These included the Scopus, Sport discus, Science Direct, and Medline bibliographic databases. Furthermore, as per the PRISMA protocol, additional records were identified through other sources. These sources included the use of article reference lists identified through the primary search stage and use of Google Scholar. Once the duplicates had been removed, the remaining publications were then filtered using the inclusion criteria.

Table n°1:

Number of articles from first search	8.725
Number of articles removed due to article duplication/application of eligibility criteria	7.592
Number of eligible articles from first search	1.133
Number of eligible after the reading the abstract	362
Number of eligible after the reading the full paper	36
Number of articles identified by other means	2
Total number of eligible articles	38

Subsequently, 38 publications met these conditions and were included in this review.

3 ICT and Decision Making

Managers are saddled with the responsibility of leading their organizations to achieve objectives and stated goals. This does not only require versatility and prowess, but more adequate knowledge management with excellent decision-making. Knowledge management is a meticulous approach toward the optimization of a organization's knowledge economy. It involves several elements like human resources practices,

technology, culture and organizational structures (Du Plessis, 2007). Several knowledge management models propose that knowledge management framework should include knowledge management enablers and processes. Knowledge management framework should have a basic understanding of knowledge operations and infrastructures to support the organizational operations. In Lee and Choi's (2003) opinion, knowledge management enablers are mechanisms employed by organizations to foster consistent knowledge usage. The Information Technology plays a central role in eliminating the communication barriers in organizations. Enabling collaborative learning, knowledge seeking, and communication are the important role of information technology (Ngoc, 2005). According to Davenport and Prusak (1998), information technology is a crucial enabling factor and has a dynamic role in knowledge management. Gold and Arvind Malhotra (2001) opined that there must be comprehensive investment in technological infrastructures to aid various systematic activities within the organization and that to increase the success of knowledge management projects and applications, investing in information technology is unavoidable.

The implementation of technology has a significant impact (Haake, 2009; Balmer et al. 2011; Dyer 2015; Foster et al. 2012; Stefani 2012) on the performance, this require adequate knowledge management with excellent decision-making.

Scott and Bruce (1995) defined decision-making style as the habitual, learned response pattern an individual exhibit when tackled with a problem or situation.

The central nature of the decision-making process in economic-business studies has been highlighted by broad and influential doctrines. The decision can be defined as an answer to a situation characterised by three elements: the possibility of assessing more than one course of action (alternative); the presence of expectations that results connected with each course of action can truly create; the presence of consequences associated with possible results that can be assessed according to the personal values and objectives of the decision maker (Hastie & Dawes, 2001). Decisions are the result of a complex decision making process, including several subsequent yet logically-connected phases: 1 identification of the problem to be solved or specification of the objectives to be achieved 2 collection of information regarding the external and internal environment in order to establish and define the problem or clearly highlight the objective 3 development of alternative courses of action 4 identification and assessment of consequences associated with alternatives according to the assessment system of the person making the decisions 5 choice of the very best alternative. This process has not been included in a univocal interpretation within a doctrine, but it has generated heated debate that has resulted in the creation of two different schools. Behling, Gifford and Tolliver (1980) associated decision-making style with cognitive style, because it is believed that those who gather information intuitively are more likely to be “feeling as information evaluators” while those who gather information systematically are more likely to be “thinking as information evaluators”. A classification scheme for decision-making style proposed by Harren (1979) includes two opposing

categories in regard to information gathering and evaluation: intuitive and rational. Intuitive Decision-Making Style is also referred as "holistic thinking, immediate insight, seeing the answer without knowing how it was reached" (Thorne, 1990).

Decision-makers might sense patterns, feelings and objects in seemingly unconnected facts. Intuition is often perceived by people as a sudden awareness of information (Ritter & Dijskterhuis, 2014, Sauter, 1999). Intuition also provides the decision-makers with relationships and facts without understanding why such relationship or facts existed. Thus, resulting to higher individual and organizational performance (Zander et.al., 2016). Sauter (1999), Hodgetts et al. (2017), have been hypothesized the role of intuition in decision-making as a two-step process: (1) explicit decision – made by the use of emotions; (2) implicit decision – made by referencing previous decisions (Bierman, Destrebecqz, & Cleeremans, 2005). Patton (2003) identified three sources of intuition used by decision makers: (1) general experience – the learning that occurs during the normal process of accumulating and aging of experience (2) innate response – the instinct that brings subconscious but appropriate reactions to situations. It is usually inborn not learned; and (3) focused learning – the learning that originates from deliberate efforts to cultivate habits and attain intuitive responses. A study by Açıkgöz, et.al (2014) found that intuition enhance project success and corporate performance. Different is the rational Decision-Making Style – causes decision makers be obliged to consider a number of alternative scenarios and probabilities for each alternative before making decision (Busari & Spicer, 2015, Oliveira, 2007). According to Dean and Sharfman (1993), rationality is "the extent to which the decision-making process involves the collection of information relevant to the decision, and the reliance upon analysis of this information in making the choice." Rational procedures help decision makers establish relevant decision criteria, identify a comprehensive set of alternatives, and evaluate the individual alternatives objectively (Kaufmann, et.al., 2012). In contrast to intuitive decision-making style, rational decision-making style encompass cautious and methodical thoughtfulness of all conceivable decision choices (Baird, 1989). Scrutinizing the available options by means of rational decision-making style necessitates the decision maker to deliberately appraise options and their relevant probable consequences. Through this approaches, the managers, seen as expert decision makers, are not immune to systematic errors that can generate a poor level of accuracy in assessments, instability in predictions (Smith & Kida, 1991) and a lack of logic in estimates (Frederick and Libby, 1986), connected, among other things, by an indiscriminate use of intuition to the detriment of careful and rational thought (Isenberg, 1988). On the other hand, managerial doctrine has for years highlighted that the myth of the thoughtful and systematic programmer-manager is destined to crumble due to a reality that sees high level managers characterised by short-term, varied and discontinuous activities, with a decisive inclination towards action and poor inclination to thought (Mintzberg, 1991).

4 Decision support making and Sport

Some authors focus on how to implement decision making in the sports world, in this regard, Tur-Porcar, et al. (2020) have as main objective to create a hierarchy of emotional and motivational factors that sports organizations can use to increase commitment athletes. The analysis in this study was performed using the Analytical Hierarchy Process (AHP). This structured decision-making process has made it possible to demonstrate that motivation and the regulation of emotions are the most important criteria for generating this commitment within sports organizations. In addition, the work of Defruyt, et al. (2020) was set up as a perspective to study, investigate athletes' perceptions before they begin a double career (DC) in Higher Education (HE). An optimal dual career balance (DC) - defined as a "combination of sports and studies that help student-athletes achieve their educational and athletic goals, live satisfying private lives and maintain their health. A qualitative methodology was used, with the two relevant theoretical models that guide data collection (i.e. semi-structured interviews) and data analysis (i.e. thematic analyzes). The results showed that many different considerations related to different levels of development (e.g. athletic, psychological, psychosocial, academic / professional, financial), can influence the decision-making process of athletes to start a DC in HE.

Finally, Collins, and Collins (2019) examine the coping strategies used by sports professionals to manage their cognitive loads of decision-making. A mixed approach based on a quantitative questionnaire and a structured qualitative interview was employed. The study found that coaches' knowledge and behavior focus on their ability to set goals. First, it's about self-regulation, driven by the goal. Coaches have clearly established goals that focus and prioritize their actions and therefore their cognitive load. Male coaches focused their goals on the outcome, while female coaches focused their goals on the process. According to the authors, an intermediate position seems optimal. The experience of the coaches grows and the ability to move between the process and achieving results also becomes optimal.

Secondly, there are the authors who focus their studies on how to adopt decision support tools, including technological ones, within the various sports organizations.

In this context, we recall Calder, and Durbach, (2015) who developed a decision support tool, called stochastic multicriteria acceptability analysis (SMAA), to assist the evaluation of rugby performance. The method considers the player's performance on a number of attributes and resolves uncertainty in both performance evaluation and preferences for some aspects of the game over others. This system addresses the uncertainty that exists both in evaluating player performance and in preferences for some aspects of the game over others. It emerged from the study that the SMAA model cannot replace the decision-making process itself but aims to support the process by helping coaches better understand the players available to them and the preferences that favor each player.

Furthermore, Nasiri, et al. (2019) present an integrated approach that combines multi-criteria decision analysis and mathematical programming to support the decision maker

through the selection process of a football team's players. First, the analytical network process is applied to assess the meaning of the different performance criteria for each position in the field. An integer programming model was designed to assess the transfer status of players. Finally, data envelope analysis is used to identify the most efficient solution that determines the status of each player.

Instead, Marquez's research, et al. (2020) provides information on consumer behavior regarding the use of technology that can assist the decision-making process of sports managers. Through a survey on paper and pencil of American high school football spectators (N = 523) on 12 games, the study examined the perceived ease of use, the perceived usefulness, the trust of the digital ticket, the willingness to pay convenience the fees and their effects on the intention of the spectators to use the digital ticket. The results show that confidence in the issue of digital tickets, the willingness to pay a convenience fee and the perceived ease of use have influenced the perceived usefulness of the technology. The willingness to pay taxes also had a direct effect on the intention.

Also, Petrović's study, et al. (2015) aims to review the type of decision support offered by emerging information and communication technologies (ICT) in sport. The research used an exploratory approach to data collection due to the fact that the topic is new, and that the data is difficult to collect. The topic is analyzed using the case study method. Research has found that an emerging market exists to extend the reach of digital technologies adapted for the sports industry and sporting events. Increasingly, developers are exploring and exploiting the vast potential of ICT to create value in the field of sporting events. The development of emerging technologies creates new opportunities that the sports industry requires a growing range of innovative solutions for decision making to be tested and accepted in the near future.

Thirdly, other authors focus on the supports in the decision-making process of the referees in soccer or rugby.

In this regard, the main focus of the work of Samuel, et al. (2019) was to test the usefulness of a new decision simulator designed for qualified soccer referees. The challenge was to create a simulator that, on the one hand, simulated the referee's task (i.e. numerous sequential episodes of decision-making under physical effort) and, on the other hand, verified the convenience of the simulator (i.e., it can be easily applied by referees on a regular basis). Expert soccer referees (N = 22, age = 27) were tested on a new simulator decision making during the active part of the season. They ran on a treadmill for 60 minutes at different rates while watching two video sections describing real matches, in context and in mixed order, and calling out their match decisions aloud. Decision accuracy levels were higher for simple decisions, such as offside than for careless fouls or yellow / red cards. The results support the use of simulator as a potentially innovative method for referee training in sequential decision making.

In contrast, Dawson, et al. (2019) analyze the impact of technology support and the subsequent role extended by the referee of the TV match in the decision-making process and on the assignment of sanctionable offenses for players in games played in the group

stages of the European Rugby Cup (ERC) and European Rugby Champions Cup (ERCC) in 15 seasons from 2000/01 to 2015/16. The main finding and contribution of the research is that the introduction of the official of the television match influenced the impact of the sanctions issued for both teams. However, the increase in the number of yellow cards awarded to away teams implies that home injury has increased since the official's introduction to the TV game. This suggests that the referees may have consciously or unconsciously tried to avoid contributing to internal bias before the introduction of an additional official who is remote from the effects of the crowd. Recognizing that this adjustment is based on circumstances is important information for the training of officials; in particular because an official of a TV match may not be present in all the matches he will referee.

Instead, Harding, at al., (2016) focus on the concept of attitudes (e.g. referees, athletes and coaches) towards a proposal for technological innovation that calculates the transmission time and rotation of each athlete. In-depth cross-sectional qualitative data were used to explore the assessments of the components of the assessment protocol. Email correspondence and an online survey platform were used to collect data. The participants assessed the freedom, individuality and progression of the performances approved by the current subjective evaluation protocol. The attitudes of the participants towards the proposed innovation varied based on whether it was used to calculate the final scores of the athletes or to assist the referees in the decision-making process.

Another interesting topic in this area is that studied by Van Quaquebeke, and Giessner, (2010). The authors aim to investigate whether the cognitive association of height and dominance of people and, specifically, of players influenced sports judgments by football referees. In particular, the authors hypothesized a distortion of attribution in the "foul" calls, since respectively taller people are more likely to be perceived as perpetrators and their smaller opponents respectively as victims of foul. This is the phenomenon known as "attribution bias", understood as an asymmetric cognitive association that systematically influences bad decisions about players. As a demonstrator, this association was acquired data on professional football arbitrage (i.e. all fouls recorded in the last seven years of the German Bundesliga, in the last seven years of the Champions League of the Union of European Football Federations (UEFA) and in the last three cups of the FIFA world). The investigation shows that the referees are not processors of objective and perfect information, but human and therefore also subject to cognitive associations learned socially and evolutionarily trained that sometimes influence their decision-making process.

Finally, Schnyder, et al. (2017) aim to reconstruct subjective theories on the decision-making process of football referees in offside situations. 16 Swiss male referees were interviewed using a combination of semi-structured interviews. Contrary to the hypothesis, the results identify the need for further research, in particular as regards the determination of the moment of the decisive passage and the psychological basis for judging offside situations.

5 First result: The V.A.R. in the football match

In recent years, there has been an increasing use of technology in a number of areas of sport to support the referee's decision making; this also happens in football. A football match lasts 90 minutes and is equally divided into 2 45-minute periods separated by a 15-minute half-time recovery in which both competing teams change sides. At the end of each half, the referee can allow extra time to recover any time lost during the play. The referee represents the maximum authority in the field, and his main objective is to guarantee that the Laws of the Game are respected (Mallo et al, 2008). In making decisions the referee is supported by VAR technology (Sabag et al, 2020). VAR is a kind of technology that helps the referee through assistant referees, who watches the live streaming of the game. VAR watches the match in the video operation room (VOR) assisted by an assistant VAR (AVAR) and replay operator (RO).

VAR follows the progress of the action on a series of screens. When he realizes that the referee on the pitch has made a wrong decision, he communicates it via radio so that he can correct it. VAR can intervene, only in 4 categories defined as game-changing situations (Mather et al, 2020; Kapil, 2018); they are:

1. Establish the regularity of a goal
2. Awarding of a penalty kick
3. Expulsions that require the direct extraction of the red card
4. Identity error (exchange of the player to be warned or expelled with another)

Analysing the literature concerning the VAR, it has been noted that the experiments conducted on video technologies have led to several advantages for the decision-making process of the referees:

- videos from different angles allow you to capture the physical and tactical information of different players (Meng et al, 2020);
- the use of instant replay allows the referees to make more accurate decisions (Salomon et al, 2011). V.A.R. have access to the replays of the videos in real time and in slow motion. The impact of the speed of the video on the decision-making process of the referees showed that the slow-motion footage increases the accuracy for the referee's technical decisions (no foul, indirect free kick, direct free kick or penalty kick), in particular for corner situations. However, the impact of video speed depends on the type of decision and the type of situation that need to be assessed (Spitz, 2017; Spitz et al, 2018).

According Pina et al (2018), V.A.R would allow certain refereeing decisions made on the field (goal, penalty, red cards and incorrect identity in assigning a card) to be examined by an individual located in a video operating room where the referee can analyze multiple angles of the camera provide input on those decisions.

In their study, Carlos et al (2019) showed how the introduction of the VAR system influenced the play in soccer. They used a generalized linear model and a pairwise z-tests

to compare seasons before and after the implementation of the VAR. They found that there was a significant decrease in the number of offsides, fouls and yellow cards after the implementation of the VAR and there was an increase in number of minutes added to the playing time in the first half and the full game. VAR plays an important role in enhancing the quality of the refereeing. These findings may help coaches, players and managers to better understand the effects of the VAR system on professional soccer and to identify strategies to improve refereeing during matches.

Undoubtedly, video technology allows the referees to assist in their decision-making process, on decisions such as establishing whether a goal has been scored or which player has actually committed a foul. Video technology can provide more objective information and be valuable for decision making. It was introduced precisely to assist the referee's decision-making process and avoid wrong decisions. The hope is that they can reduce or eliminate the errors that can occur during the game. The main criticism of real-time video-replay devices like VAR is the possible disruption to the flow and pace of the game due to the stopping and starting, which might be especially disruptive in matches played in cool weather (Dyer,2015;Svantesson,2014). Several studies have shown that referees 'decisions can be influenced by several factors such as crowd noise, social pressure, match status or the strength of the teams (Boyko, Boyko, & Boyko,2007; Dohmen,2008; Garicano, Palacios-Huerta, & Prendergast,2005;Riedl, Strauss, Heuer, & Rubner,2015; Sutter & Kocher,2004; Unkelbach & Memmert,2010).

6 Conclusion

A professional referee must have excellent decision-making ability, excellent making ability to problem solving, he must be an excellent broker and have excellent skills communicative with both own colleagues who with players on the field. He Needs to have good anxiety and stress management skills trying to above all, keep his confidence, self-esteem and high charisma after a possible mistake; he must not be too conditioned by external situations to himself as criticism, protests, insults or screams. It is therefore important not be conditioned by the surrounding environment but seek however to increase its capacity of internal "locus of control". The role of the referee is certainly not simple, his decisions are always under the eyes of everyone, from the fans, to the players, to the coaches and just for this subject to many criticisms. The VAR system wants facilitate the work of the referee and ensure that his decisions are consistent with what is seen objectively on the pitch and not conditioned by external situations. In addition to this, it allows the referees to be more confident and allows you to put them in the best conditions to make the most decisions corrected during the game (Ugondo et al, 2019; Nerboldi E., 2018).

But in many ways trying to use VAR to make the game fairer has led to difficulties. Using technology one problem is that the interpretation of the rules of the game has highlighted the fact that these rules are often too subjective. There are also limitations: even with a video replay, it is not always clear whether a player has stumbled or dived.

Therefore, while VAR has improved the accuracy of many decisions, on the other hand the technology has also highlighted the difficulties of being a neutral referee of a football game, apparently increasing people's expectations without always satisfying them. Additionally, decision making can be time consuming and cumbersome. This is almost bearable in a stop-start game like cricket, but not in a sport that should be in an almost constant flow like football.

By analysing the reference literature, an attempt was made to verify how the scholars of the case have addressed the contribution that the Video assistant referee technology (known as VAR) can make to supporting sports decisions in football match. The soccer referees are required to keep up with play at all times to ensure optimal positioning in making key decisions, and VAR intended to correct egregious mistakes, has taken close calls to a place beyond the abilities of humans to perceive them, a matter of centimetres measured by a computer. Despite the potential benefits of VAR, the implementation of this technology faces with barriers and restrictions, technical limitations, standardization limits, attitudinal constraints-behaviour of individuals, and organizational constraints.

The second step will be the interviews at the professionals by the understanding the role of the VAR in the decision making. Trying to understand if the VAR is a decision support tool or a tool to be endured because it is envisaged at governance level.

Abstract

Cultural tourism constitutes an interesting business opportunity for many companies. Recent advances in mobile-based technologies open new ways in offering value to cultural tourists, driving some tech companies to enter the cultural tourism market at full steam. These companies offer the opportunity to exploit benefits new technologies, providing users with a set of services that are more responsive to their new expectations and information needs, supporting them along all the tourism experience lifecycle. Although there are countless mobile apps aimed to assist tourists with their everyday practices, little research has been devoted to investigate the impact of these technologies on the management cultural tourism services. This research constitutes a first attempt to fill this gap. We reviewed a set of 80 mobile apps providing services for cultural tourists, in order to design a bi-dimensional framework to position the offering of app based cultural tourism services.

Keywords – cultural tourism, app-based services, value proposition, tourism experience lifecycle,

Paper type – Academic Research Paper

1 Introduction

Cultural tourism is widely recognized as a major element of international tourism consumption. Cultural tourism is characterized by a set of emerging niches (such as gastronomic tourism, arts tourism, heritage tourism, film tourism and creative tourism) giving a significant boost to the growth of this industry (Richards, 2018).

Information and Communication Technology (ICT) has been the backbone for innovating many processes in cultural tourism industry, both on demand and supply side.

From a tourist perspective, ICT based solutions are able to help the decision-making process along the tourism experience lifecycle, can support the performing of travel related activities, and enrich the cultural experience of the travel. The chance to taste in advance a trip (thanks to virtual reality, videos, photos, opinions and storytelling of other users), the opportunity to compare offers through fare aggregators and meta search engines, the immediate delivery of a set of tourism services (e.g., reservation or booking) and the possibility to enjoy availability of contextualized services (location-based services, context-aware mobile tourism guides, augmented reality) are among the features that make technologies and cultural tourism an absolutely winning combination (Ammirato, Felicetti, & Della Gala, 2015). Digital technologies can support the cultural tourist with plenty of functionalities also to respond to specific and contingent constraints, like epidemic risk (i.e. Covid-19), thus becoming a strategic asset for global tourism relaunch.

Recent advances in the convergence of ICTs (e.g. "internet of things) led to the development of new services for tourists. By leveraging on context-awareness, ubiquity, pervasiveness, and mobility features, mobile-based services are suitable for an effective and efficient service provision, providing value to the tourist.

Tourists contribute to the creation of a massive flow of data generated by sensors, devices and cameras distributed on cultural tourism destinations. All these data represent promising basis for enhancing the tourism firms' capability to personalize their offering of products and services (Ardito, Cerchione, Del Vecchio, & Raguseo, 2019).

In this sense, the increasing role of technologies in *prosumption* of cultural services paved the way towards new ways in offering value to tourists, enabling new business models and driving some tech companies to enter the cultural tourism services market at full steam. These companies offer the opportunity to exploit benefits new technologies, providing consumers to manage cultural tourism services that are more responsive to new tourists' expectations and needs. In particular, these emerging trends make possible to conceive new business models where stakeholders of cultural tourism industries interact to create value for tourists.

In fact, from a business oriented perspective, web and app-based solutions enrich the value proposition of cultural tourism companies, acting not only as a support for traditional businesses in tourism sector but also as core business enabler for marketplaces and other tech companies interested in providing tourism information based services (Schneider et al., 2019).

If, on the one side, cultural tourism can be boosted by digital technologies, on the other side, there are countless mobile-based services aimed to assist tourists along the tourism experience lifecycle. Little research has been devoted to investigate the characterization of such services business models and their value proposition to consumers of cultural tourism services. Our work tries to fill this gap by proposing a framework to characterize, classify and assess, the extant offer of mobile app for cultural tourism. Namely we provide an answer to the question: how current smartphone apps can support the cultural tourist? That is, what functions do smartphone app provide to the cultural tourist to best perform a travel?

Based on a review of smartphone apps, this paper intercepts and evaluates the functionalities available to a hypothetic cultural tourist, and highlights where the next major developments lie. This framework can be used as marketing tool to position the offering of the above-mentioned services in the cultural tourism market.

2 Theoretical Background

2.1 Cultural tourism

Cultural tourism is becoming a major source of business and employment in today's economy. Internet and the digital technologies have radically changed the approaches and processes to managing and experiencing a cultural travel.

Cultural tourism is nowadays recognized as one of the most important forms of tourist traffic in the world (Niemczyk, 2013).

Cultural tourism can be viewed in a narrow and traditional definition, or according to a wider and modern one. According to this latter, cultural tourism entails the consumption of a cultural past and historical product, but also those contemporary, like cultural way of life of the people and/or region (Richards, 2001).

Cultural tourism can be defined as a form of travel, characterized by the voluntary departure from one's place of residence, during one's time off work, for a continuous period of not more than 12 months without any break (Niemczyk, 2013), for at least 24 hours (Ercole, 2008), with the intention to gather new information and experiences to satisfy their cultural needs (Richards, 1999).

Cultural tourism involves the participant being aware of the place where he or she is visiting, in which culture becomes the core element of the tourist product, and is key driver of planning of the journey (Niemczyk 2013). Cultural tourism is not just visiting and knowing, but also and overall becoming "*acquainted with new places, their*

communities, cultures, their interest in art, architecture and history, participation in cultural and artistic events, a "return to one's routes", and contact with the sacrum; during which a tourist experiences the reception and cultural wealth of a given location" (Niemczyk 2013) (p. 24). Cultural tourism is not just about visiting sites and monuments, which has tended to be the 'traditional' view of cultural tourism, but it also involves consuming the way of life of the areas visited. Both of these activities involve the collection of new knowledge and experiences.

Actually, the narrow and wider perspective on cultural tourism, appears to reflect not just the traditional and modern view, but also the distinction between the so-called "high" culture and "popular" culture (Williams, 1983). "High" culture refers to artistic expressions such as literature, poetry, painting, sculpture, music, while "popular" culture is understood in a sociological and anthropological sense, with its intangible component (values, norms, models of behavior) and material (customs, traditions, lifestyles) of a people or a social group (Ercole 2008).

All-in-all cultural tourism covers not just the consumption of the cultural products of the past, but also of contemporary culture or the 'way of life' of a people or region (Richards 1999).

Managing a cultural travel to maximize the traveler's satisfaction, from its inception to the ex-post consumption, is not as easy. This basically requires to integrate knowledge, information, travel products, pertaining to two dimensions: the travel (transportations, accommodations, subsistence) and the cultural experience (monuments, exhibits, gastronomy, etc.).

(Ammirato et al., 2019) effectively modelled a travel as a complex integration (travel package) of travel products. An effective integration of travel-logistic products and touristic experiences provide the traveler a satisfying (cultural) travel. In fact, a good integration of transportation and accommodation result into an efficient travelling, while a good integration of touristic offers (i.e. cultural goods) results into a coherent experience. A successful cultural travel can be seen as a fitting integration of travel-logistic products ('horizontal integration'), and of cultural touristic ('vertical integration') (Ammirato et al., 2019).

Cultural tourism products can be identified in: a) cultural heritage tourism, b) museum tourism, c) industrial tourism, d) cultural events tourism, e) historical-military tourism, f) religious-pilgrimage tourism and g) culinary tourism (Niemczyk 2013).

As much as the traveler is a 'digital enabled' traveler, the success of cultural tourism and of cultural touristic products depends strategically by the capacity of the digital technology to integrate complex travel information, in any place and time, to the needs of the traveler. Thus, smartphone apps rise as strategic for the success of a cultural travel, and in general for cultural tourism. It can be seen as a cluster of usability, creating a set of goods and services and thus facilitating travel taken for cultural purposes (Ammirato et al. 2019; Niemczyk 2013).

2.2 The Cultural tourist.

Bearing in mind the importance of culture in the decision to visit a destination and the experience sought, (McKercher and Du Cros, 2002) distinguishes five types of cultural tourists according to the 'experience sought (shallow or deep), and the importance of culture in the decision to visit a destination (low or high): purposeful, serendipitous, sightseeing, casual, incidental.

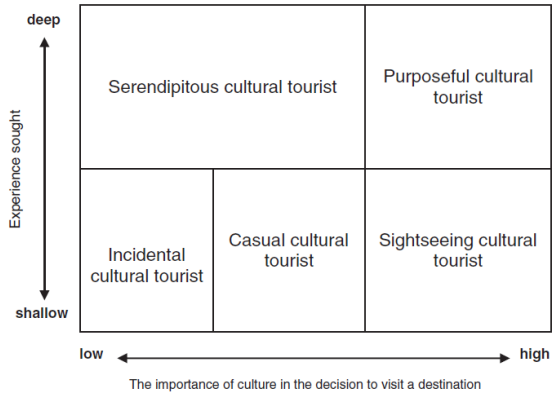

Fig. 1 – The five typologies of cultural tourist according to (McKercher and Du Cros, 2002)

A widespread approach in the definition of tourist experience consists in the adaptation to the tourism sector of some generic models to describe consumer behavior in the purchase of products or services. In Ammirato et al. (2015), a model characterized by the following phases is proposed:

- *Dreaming*: the process begins with the emergence of a need, a desire to travel. In this phase, tourists look for inspiration for their vacation. While in the past, most of the ideas came from photos, stories and memories of friends' past experiences, or brochures of travel agencies (TAs), or tour operators (TOs), today the internet greatly simplifies this step. The dream of holiday is fed by an overabundance of photos, videos, or maps on the web, allowing users to gain virtual previews of the holiday, explore places, identify the location, refer to opinions and recommendations published by travellers who already had an experience and then prospected tourists begin to 'dream' their vacation.
- *Planning and booking*: once the tourist identifies the potential destination and the type of holiday he intends to do, he proceeds with the detailed planning of the trip. After establishing the details of the whole holiday, all that remains before travel is to make reservations of transportation, accommodation and any additional services (car rental, excursions, events, etc.) that will complete the tourism package. Until a few years ago, planning and booking activities were generally carried out by TAs and TOs, who had to book transportation,

accommodations, and activities or to create complete packages for the customer whose only concern was to pay the broker. Nowadays the availability of web services based on comparison, recommendation systems, and booking services, leads consumers to make self-service reservations with increasing frequency, allowing them to enjoy lower costs related to the absence of intermediaries, to book at any time from everywhere.

- *Experiencing*: this phase is mainly related with the in-place tourism activities: the tourist overnight stays in hotels, make excursions, enjoy meals, visit local attractions etc.. The main difference with the past at this stage is the availability of contextualised information and additional services (maps, location-based services, context-aware mobile tourism guides, augmented reality etc.) offered to the 2.0 tourist through mobile devices as well as the opportunity to share location-based multimedia contents. Based on location, user profile (preferences), time, and pre-stored trip information, a user get recommendations about points of interest, plan personalised tours, get informed on open nearby restaurant according to his time, be advised where to eat on the basis of his food preferences, get public transport information, etc. (Karanasios et al., 2011)
- *Recollecting*: After experiencing the holiday, the tourist comes back home and remembers the experience through photo albums, souvenirs and storytelling. At this phase of the tourism 2.0 lifecycle, the main ICT tools are those based on sharing services, as in the dreaming phase. The meaning of using specialised portals to share photos, videos, stories and opinions on visited places is to collect some snapshot of the vacation in order to recall its memory and to give tips and advices on the experienced Tourism Destination.

Fig. 2 The tourism experience lifecycle

As much as the traveller is a 'digital enabled' traveller, the success of cultural tourism and of cultural touristic products depends strategically by the capacity of the digital technology to integrate complex travel information, in any place and time, to the needs of the traveller. Thus, smartphone apps rise as strategic for the success of a cultural travel, and in general for cultural tourism. It can be seen as a cluster of usability, creating a set of goods and services and thus facilitating travel taken for cultural purposes (Ammirato et al. 2019; Niemczyk 2013)

2.3 Cultural tourism and smartphone apps

In order to best meet this challenging requirements of the cultural travel management, cultural tourist adopt and self-support with Information and/or Digital technologies, namely web-based services (Akoumianakis et al., 2011; Ammirato et al., 2019; Runfola et al., 2013) and smartphone apps (Dickinson et al., 2014; Gupta et al., 2018).

Based on its advanced computing capabilities and ubiquity, the smartphone has rapidly been adopted as a tourism travel tool. With a growing number of users and a wide variety of applications emerging, the smartphone is fundamentally altering our current use and understanding of the transport network and tourism travel (Dickinson et al. 2014).

A wide variety of smartphone apps are available to the contemporary traveller able to provide a wide spectrum of services like transport planning (Uber, Skyscanner), travel planning (TripIT, Tripadvisor), accommodation planning (Booking.com, Expedia), tour guide (DETOUR, NY Travel guides) and directional services (Google maps) (Gupta, Dogra, and George 2018).

The value proposition of tourist and in particular of the cultural tourist, becomes crucial for positioning a touristic strategy and make competitive a destination or a travel product, by developing smartphone travel apps around their value proposition (Samy, 2012) or simply marketing a travel product, or a destination, through the most value-added and used apps.

Smartphones are defined by (Verkasalo et al., 2010) (p. 243) as "*devices that can be used both as a mobile telephone and as a handheld computer*". Thus, what separate smartphones from mobile phones are the features of a computer, such as the applications (apps) (Andersson and Frost, 2013). Smartphone apps can be defined as small programs that run on a mobile device and perform tasks ranging from banking to gaming and web browsing (Taylor et al., 2011) which make smartphones possible to use for as many purposes as possible, even included plan, manage, and archive cultural travels and related experiences.

With regard to value for cultural traveller, the utility gained from an app is a crucial concept. Then, before considering what the user perceives of an app, one should consider the utility an app provides.

(Dickinson et al. 2014) analysed the App functions in the tourism travel domain. They identified 5 basic functions, and several uses: information (information only or

information plus search function), two-way sharing (two way implicit and/or explicit sharing, that is users specifically provide information back to the app.

This may build on social networking capabilities to share information with selected friends, a social network of users embedded in the app, the wider Internet community (eg blogs) or the app provider), context awareness (services based on the smartphone's contextual sensors; the most prominent of these are current temporal and spatial location), internet of things (ability to communicate with everyday objects such as vehicles and parcels), tagging (ability to leave messages on places and objects for future visitors) (Dickinson et al. 2014).

2.4 The role of smartphone apps in the cultural tourist lifecycle

Over recent years, the rise of mobile app-based service allowed to consumers the opportunity to access to in-time, in-place and in-context information services.

The term mobile app-based service refers to services that can be accessed by means of mobile devices (e.g. tablet, smartphone, PDA,). Today's smartphones and tablets have acquired richer functionalities (embedded sensors enabling augmented and situated information, internet connection and easy portability), developing a huge potential to provide personalized, in-time and in-place information services. Mobile applications (or apps) are downloadable programs designed to run on mobile operating system (e.g. iOS, Android O.S.). They require installation on a device and run locally on it. An app-based service interacts with a consumer and his/her surrounding environment thanks to some user's mobile device resources, such as built-in device sensors and local databases, or may be connected to external sensor systems (Volpentesta, 2015), they can access also remote databases and API to extend their functionalities and dynamically update their content.

Based on the above-mentioned issues and theoretical concepts, we are interested in understanding what services do smartphone apps provide to the cultural tourist along the whole phases of a cultural travel. In other words, our research question is: what functions do smartphone apps address to a cultural tourist to improve cultural travel performance (both from cultural and logistic-operational point of view)?

App-based services offer to cultural tourists the opportunity to access complete and detailed information when and where they make their tourism related choices, but their information provisioning has limited chances of success as it is not affected by changes in tourist's situation (unless the consumer is explicitly involved in service demand and configuration).

Some characteristics of mobile app-based services have a major impact on the characterization of mobile-based information offerings, since they play an important role in providing tailored, high-quality and contextualized information and, thus, in satisfying cultural tourism information needs. Extending the concept of "fitness for use", related to information value and information quality (Eppler et al., 2004; Borek et al., 2014), we

consider the value of an app-based service as the overall utility that the user receives when using the information service. In the case of app-based services for cultural tourism, the user is a tourist who requires some information necessary for his/her decision-making or learning process, as he/she is involved in cultural tourism activities in some situations.

Value proposition is defined as the implicit promise a company makes to its customers to deliver a particular combination of values (Sweeney and Soutar, 2001). Several authors (Walters and Lancaster, 1999) agree that business value proposition of an information service leverage on three main components: content (i.e. the product or service to be purchased), context (i.e. the environment in which content is offered) and infrastructure (i.e. the way content is delivered). From the supply side perspective, the value proposition refers to the ability to facilitate a better tourism experience for users and it reflects service performances influencing the consumer's judgement about the utility the user receives when using the service. From a user perspective, the service value is the ultimate trade-off between benefits and costs a tourist perceives as the result of his/her interaction with the app-based service. Benefit/cost assessment varies from a consumer to another as it is affected by consumer's attributes (knowledge, cultural related values, experiences, attitudes). In what follows, we present a set of components affecting tourist perceived value:

Utility benefits. They refer to the overall utility of the information that a user acquires when interacting with an app-based service. Here, we refer to this utility as a measure of the impact on tourism-related decision-making. Two entities play a crucial role in determining utility benefits:

a) *Content*: a set of information 'cues' that are exchanged between the consumer and the service. The main value factor is the **content relevance** that establishes how much impact the "what" is exchanged has on a decision process. Content relevance sub factors are topicality, accuracy, depth, scope, clarity, organization, and format of the information exchanged (Nocella et al., 2014).
b) *External Context:* a set of characteristics of the situation (place, time, activity, social relations, etc.) in which the user interacts with the service. The main value factor is **situation relevance** that establishes how much impact the "how", "when", and "where" of the interaction has on a decision process (Volpentesta et al., 2017). It may be defined as the extent to which information content is required to be specified to practical matters of the current situation.

Sociocultural benefits. They concern with the satisfaction of consumer's sociocultural needs through the user participation in a community. Participation at the community brings a wealth of cultural knowledge (including beliefs or practices), social norms, literacy:

a) *Sociability*. It affects satisfaction of user's needs of personal connectedness and relationships with other tourists and cultural tourism stakeholders;
b) *Trustworthiness* of information sources. It affects user's assessment of the reliability of the information content provided by the service.

Costs. They refer to consumer's physical and cognitive efforts of users while interacting with an app-based service. These efforts may be of two types:

- *Personal burden*. It refers to the amount of efforts a user has to put into interacting with a service to get information for personal use;
- *Collaborative burden*. It is the overload of efforts due to the participation to a collaborative process.

3 Research Methodology

Methodology used in this study consists of the following phases:

Phase 1: ***Identifying the domain.*** We selected IOS App Store and Google Play as mobile apps databases where to perform our search, since they are the two leading mobile app stores, in terms of numbers of apps and downloads (Chergui et al., 2016).

We initialized a list L of search keywords with English and Italian terms related to the cultural tourism domain. We performed a search on the above mentioned databases. The list L was possibly extended with new relevant keywords retrieved in the apps description. We carried out a systematic research in order to provide an exhaustive set *U* of mobile apps in the Cultural tourism domain. The process ended when no newer keywords or apps were found. The research was performed from 1 to 31 May 2020.

An app of this set is included in the analysis domain if:

the app description is written in English and/or in Italian;

the app preview (or associated website, if available) claims that the app provides tourism related information or service supporting the user in cultural tourism activities or learning process;

the app is not an old version or edition of another one in *U*

At the end of the process, the set U was constituted by 80 mobile apps.

Phase 2: ***Defining the analysis framework.*** Data were mainly sourced from the app description obtained from the store apps preview and associated web sites (if available). Moreover, in most cases, apps were downloaded and were analyzed in more detail to verify data extracted from the app description, or to generate data that were difficult or impossible to extract from the app description.

Subsequently, we analysed the selected mobile apps in order to identify which types of utility value are delivered to users. We assumed that utility components can be identified considering the motivations, expectations, needs and attitudes of consumers of cultural tourism services. The reason for this approach lies in the fact that the more the content of the service adapts to the specific motivations and expectations of the consumer, the higher the value of the service. The detection was carried out through empirical observation of the characteristics of the APP identified. In particular, for each app in the sample we gathered app data with respect to the Information Content, i.e. data on information categories used in the interaction between the tourist/user and the app-based service.

Information content were categorized in a set of utility component, basing on semantic similarity criteria.

Phase 3: App Analysis. Each author separately analyzed the mobile apps belonging to *U* by means of the framework defined as output of phase 2. At the end of that process, we verified that all the authors have classified the apps in the same way. We decided to consider a dichotomous scale to assess the presence (or not) of a utility dimension impacting on the consumer's perceived value.

4 Findings

The analysis of the apps led to the identification of the following utility components:

- ***Convenience***: Some apps aim to facilitate tourism experience providing services addressed to reduce efforts, time and cost in enjoying a cultural tourism experience. These apps facilitate the tourism experience by allowing tourist to find the lowest prices, take advantage of discounts and promotions, keep budget under control.

  The cultural tourist wants to save money, without having to give up quality. For this purpose, some apps (like Virail and Piratinviaggio) suggests offers for flights and accommodations. Other apps (e.g. Tiquets and Google Trips) allows tourists to compare offers of different websites, while Tripify helps the user to keep under control the expenses during the trip. Applications such as Tiqets and Virtlo allows the user to book tickets directly from the smartphone, skipping the queues and saving precious time.
- ***Risk reduction***: some features are addressed to reduce the likelihood and severity of an adverse event or to mitigate its impact. In this sense, mobile apps provide emergency contacts, indicate the least dangerous routes, real-time notifications during the experience, information on weather conditions, read reviews and advice from other users, guarantee quality and reliability of contents.

  Before booking a restaurant or hotel, visiting an attraction or simply before choosing the destination of the next trip, most tourists rely on the reviews and suggestions of those who before them have been in the place of interest. Several applications offer the possibility of inserting and reading reviews, reassuring the traveller about his future destination. Some apps offer reviews by locals or experts, as in the case of Spotted by locals or Mesmo. Other apps (e.g.EatnMeet or HostelWorld) offer travel insurances or free booking cancellation. Some apps guide tourists through less dangerous routes (e.g. women who travel alone and move at night) offering the opportunity to easily access to emergency contacts.
- ***Enhancing Experience***: some apps provide features aiming to improve and reinforce the quality of a cultural tourism experience. These features leverage on hedonic aspects of travellers, increasing their desire and pleasure to be involved

in a journey. For example, apps like Monugram and CicerosGet offer the opportunity to recognize monuments, piece of art and famous places from photos taken by the tourist, offering immediate information, according to a "Shazam-like" approach. Playtrip and Apptripper accompanies the cultural tourist to discover works of art, monuments, etc., making the trip even more interesting. To increase the fun, some apps offer quizzes about the places the tourist is visiting. Other apps leverage on augmented reality or "near to me" functions.

- ***Sociability***: apps for cultural tourism offer the opportunity to enjoy tourism attraction and to satisfy tourist's needs of personal connectedness and relationships with other tourists and cultural tourism stakeholders. Some apps allow the cultural tourist to share experiences with local people: apps like Withlocals-Tour & Viaggi, Cool cousin offer offering the opportunity to contact, chat, meet in person locals, as well to be guided on the journey by a local expert. Sharing is becoming an integral part of the experience, that's why applications like City Maps to go and Monugram allow integration with other platforms (e.g. social networks), while others like Modify and Geotourist create a network that connects users of the same application, allowing them to share with the community photos, travel notes, itineraries etc.
- ***Practicality:*** some apps offer the opportunity to better manage the tourism experience lifecycle. In this sense, features as customer profile management, search functions, instant multi-language translation, ticketing management, and all-in-one functions represent a valid opportunity to reduce user's effort while travelling. Other apps allow offline use and in advance content download. These features are useful in specific contexts where connection is not available or roaming charges are expensive.

The following table summarizes utility dimension and utility components arisen from app analysis.

Table 1. Utility dimensions and utility components of app-based services for cultural tourism

Utility dimension	**Description**	**Utility Component**	**Apps**
Convenience	Find the lowest prices, reduce booking times, take advantage of discounts and promotions, keep budget under control, manage more services in a single app.	Budget monitoring	Tripify (2017)
		Prices comparison	GoogleTrips (2019), Cultural Places (2017), TourScanner (2018)
		Time saving	Musement (2013), Tiqets (2014), Virtlo (2018) , Palmipedo (2017), SmartFy (2016), Tourist Office (2016), AnyTour (2018), GPSMyCity (2018), Piratinviaggio (2011), RoadTrippers (2011), Tripwolf (2008), Il mondo intorno a me (wam) (2013), GetYourGuide (2013), HostelWorld (2011), AllTrails (2010), Virtlo (2018), AroundMe (2017), Viator (2012)

		Economic convenience	Virail (2017), Piratinviaggio (2011), Couchsurfing Travel (2012), Mesmo (2019)
Risk reduction	provide emergency contacts, indicate the least dangerous routes, real-time notifications during the experience, information on weather conditions, read reviews and advice from other users, guarantee quality and reliability of contents	Security	W-her (2017), All Trails (2010)
		Reviews	Tripadvisor (2000), W-her (2017), WithLocals-Tour&Viaggi (2013), Pronatives (2016), Monugram (2018), AllTrails (2010), Viator (2012), GetYourGuide (2013), HostelWorld (2011), Eatnmeet (2019)
		Warranty	Touchnote (2010), EatnMeet (2019), Viator (2012), HostelWorld (2011), GetYourGuide (2013)
		Alert messages	Tripcase (2015), Monument tracker (2010), Ti porto io (2016)
		Certificate information sources	Foursquare (2009), Spotted by locals (2008), GoogleTrips (2019), Cultural Places (2017), Minube (2010), Anytour (2018), Jitt.travel
Enhancing Experience	Recognition of the place through an image, use of augmented reality, games to encourage learning processes, create your own personal gallery, keep the chronology of the places with annotations and photos, audio guides.	Recognize point of interest (shazam effect)	Google goggles (2010), Monugram (2018), GetCoo (2015), Tours&Travel (2018), Ciceros (2018),
		Near to me	Tripadvisor (2000), HostelWorld (2011), Klook (2015), GetCoo (2015), AroundMe (2017), Runnin' City- GPS&Audioguide (2016)
		Itinerary proposal	Yamgu (2014), Myeasyroute (2017), Klook (2015), Apptripper (2013)
		Storytelling	Playtrip (2017), Palmipedo (2017), Geotourist (2014), Smartify (2016), Izi travel (2012), Anytour (2018), Apptripper (2013)
		Augmented Reality	Playtrip (2017), Google Arts & Culture Open Heritage (2015), Virtlo (2018)
		Memories collection	Foursquare (2009), GetCoo (2015)
		Entertainment	My Wowo (2017), Esplorazioni (2016)
Sociability	Chat and / or receive suggestions from locals, meet locals, connect the profile to their social networks, enter the community, get awards, interact with community members, upload and share your experiences (videos or photos, travel notes, itineraries, etc.),	Interaction with locals Social Networking	Cool cousin (2015), Musement (2013), EatWith (2016), Izi Travel (2012), Tripify (2017), Civitatis (2017), Minube (2010), WithLocals-Tour&Viaggi (2013), EatnMeet (2019), CouchSurfing Travel (2012)
			City Maps to go (2014), Monugram (2018) Foursquare (2009), Ti porto io (2016), Touchnote (2010), Modify, Mapify (2018), Packpoint (2014), Geotourist (2014), Roadtrippers (2011), Polarsteps-Travel tracker (2015), GetCoo (2015), Mesmo (2019), ViaggiAmoItaly (2016), Voice Map Audio Tours (2015), Ciceros (2018), GetCoo (2015), AppTripper (2013), Couchsurfing Travel (2012), Tours&Travel (2018), Mapstr (2014)
Practicality	instant translations in multiple languages, content download for offline use, profile customization, integrate many services in a single	Multi-language interaction	Google goggles (2010), Google Arts & Culture Open Heritage (2015), ProNatives (2016), HostelWorld (2011)
		Offline use	Cool cousin (2015) , City Maps 2 go (2014), Sygic Travel (2008), Polarsteps-Travel Tracker (2015), Google Trips (2019), TripAdvisor (2000), Tripcase (2015), Yamgu (2014), Monument tracker

	app		(2010), Tiqets (2014), My Easy route (2017), Google arts&Culture Open Heritage (2015), GPS My City (2018), AllTrails (2010), Jitt.Travel (2015), Culturetrip (2011), Spotted by Locals (2008), Tripwolf (2008), Cultural Places (2017), Izy travel (2012), Zonzofox (2014), Tourist Office (2016), Packpoint (2014), Tripify (2017), Smartify (2016), My wowo audioguide (2017), Esplorazioni (2016), Virtlo, Apptripper (2013), Runnin' City-GPS&audioguide (2016), Ciceros (2018), HostelWorld (2011), GetYourGuide (2013), VoiceMap AudioTours (2015)
		User's profile customization	Monument tracker (2010), Foursquare (2009), Touchnote (2010), Google Trips (2019), Izi travel (2012), Tourist Office (2016), Tourscanner (2018), Packpoint (2014) , Zonzfox, GPSMycity (2018), WithLocals-Tour&Viaggi (2013), Pronatives (2016), Jitt.Travel (2015), Piratinviaggio (2011), OpenTable (2019), Sygic travel (2008), ViaggiAmo Italy (2016), Alltrails (2010)
		All in one	Tripcase (2015), Google Trips (2019), Artplace Museum (2016), Culture Trip (2011), Tripwolf (2008), Viaggiart (2014), Golsreal, Rome2Rio (2016), Il mondo intorno a me (wam) (2013), Tours&Travel (2018), Virtlo (2018), AroundMe (2017), Viator (2012),

The identification of relevant utility dimension for cultural tourists allowed us to characterize some aspects of the value proposition delivered by app-based services in that context. The value proposition of cultural tourism services refers to the ability to facilitate tourists to better satisfy their needs along the tourism experience lifecycle and it reflects service performances impacting on the consumer's judgement about the utility the tourist receives. According the following dimensions, namely *utility* and phases of the *tourism experience lifecycle*, we built a framework to characterize and map the value proposition of app-based cultural tourism services.

Table 2. Value propositions map of app-based services for cultural tourism

	Dreaming	***Planning***	***Experiencing***	***Recollecting***
Convenience	Find, select, filter places according some criteria	Find special offers; compare rates; save time in finding travel solutions; book tickets; tourist services reservation.	Keep your budget under control; fast-line / skip-the-queue services; real-time monitoring of overcrowding; real-time fares; last-second deals.	Costs and fares tracking
Risk reduction	Learn about threats, dangers,	Know the safest routes; read	Direct use of emergency	Users can provide suggestions and

	contraindications related to specific places	reviews; having the opportunity to cancel without repercussions; buy insurance	contact, real-time notification of adverse events, real-time meteo	advice about some security and safety related issues
Enhancing Experience	Virtual reality services, inspiring video, photo and storytelling campaigns.	Proposal of personalized itineraries and possibility to integrate activities with customized experiences	Receive context-based information. Take advantage of augmented reality, shazam-like and near-to-me services	Create a collection of memories with photos and personal notes
Sociability	Be inspired by the stories and images of those who have already lived the tourist experience or by those who live in that place	Receive suggestions and advice on which services to book; which suppliers to contact; which periods of the year, days, hours, are best for visiting the tourist attraction	Receive real-time support from other travelers who are on the spot at the time or meet locals willing to act as a tour guide	Share memories, experiences, emotions, opinions with other users.
Practicality	Save favorite places, favorite reviews, customize the weights of other users' review criteria	Save and manage quotations, reservations, calendars; plan itineraries.	Manage tickets and travel documents, receive information in real time	Manage and archive photo, video, souvenirs of their own holidays.

5 Conclusions

Cultural tourism represents a significant chance for many destinations, since it provides the opportunity to present a snapshot of the image and history of a region, symbolize the identity of a community and increase the liveliness of the local economy (Chen, Peng, & Hung, 2015; Hou, Lin and Morais, 2005; Wansborough & Mageean, 2000). Tourism destinations have the potential to become popular attractions, because travellers are increasingly interested in cultural tourism and related activities (Cuccia, Guccio and Rizzo, 2016; Gnoth & Zins, 2013).

The current market paradigm that shift towards a digital consumer society is leading new digital businesses to enter the market of tourism related services (Volpentesta et al., 2017). New technological advances on mobile-based technologies and IoT have made possible the development of new services providing value to cultural tourists along the tourism experience lifecycle. Although there are countless mobile apps aimed to assist tourists all along their experience, little research has been devoted to investigate the impact of these technologies on the management cultural tourism services.

This exploratory study attempted to provide a methodological approach and a multidimensional framework to position the offer of app based cultural tourism services.

We reviewed mobile apps that provide services for cultural tourists, by analyzing their functions and the information flow that occurs in the interaction between the user and the

service, in order to identify value dimensions of app-based cultural tourism services. Although several studies addressed the concept of information value, the available research lacks in defining an approach capable to analyze the relevance of information provided to targeted audiences by cultural tourism services. Our paper proposed a framework that, from a marketing related perspective, could represent a valuable tool for positioning cultural tourism information offer, with the twofold objective to analyze the value proposition of app-based services according to a consumer perspective and to understand gaps of current offering.

Moreover, the practical implications revolve around informed and effective action based on current knowledge and learning about the design of IoT based solutions. In fact, results could be used to suggest some direction to the design a new generation of services and to identify potential service delivery improvements within the IoT domain.

Abstract

In a context of continuous technological change and rapid market growth, companies must necessarily implement changes to remain competitive on the market, otherwise they risk to lag behind and not be able to survive (Wang et al.,2013). Many scholars consider innovation, especially radical innovation, as the solution companies must adopt to deal with such an unstable environment (Ettlie et al.,1984; Sood and Tellis, 2005). Radical innovation, in fact, is a product, service or process with both familiar and completely new features that significantly improves costs or performance and completely transforms the market or even creates a new one (Leifer, O'connor and Rice, 2001). Anyway, developing radical innovation within a firm is not so straightforward due to internal barriers like rigid organizational structures (Lyu et al., 2020). To overcome such organizational rigidity organizational unlearning is required (Leal-Rodríguez et al., 2015; Morais-Storz and Nguyen, 2017), as it is defined as "the process of discarding of old routines to make way for new ones, if any" (Tsang and Zahra, 2008, p.1437). Thus, the aim of our conceptual paper is to investigate the relationship between organizational unlearning and radical innovation through a critical analysis of contributions in the literature to date.

Keywords – Organizational unlearning, radical innovation, organizational change, entrepreneurial orientation

Paper type – Academic Research Paper

1 Introduction

In a context of continuous technological change and rapid market growth, companies must necessarily implement increasingly rapid changes to remain competitive on the market. The inertia of organizations with respect to substantial changes in the surrounding environment and their lack of adaptability can jeopardize their survival (Wang et al.,2013). Many scholars agree in considering innovation, especially radical innovation, essential for dealing with such an unstable environment (Ettlie et al.,1984; Sood and Tellis, 2005).

Radical product innovations can be defined as new products made from a new technology or a significantly innovative idea that will bring about revolutionary changes in existing markets (Chandy and Tellis, 2000; McDermott and O'Connor, 2002). A radical innovation allows the firm to gain a significant competitive advantage, in some cases creating a completely new market in which it is the leader (Lyu et al., 2020). In spite of the recognized importance of radical innovation, its development is not so straightforward due to firms' barriers like rigid organizational structures (Lyu et al., 2020). Researchers have noted that to overcome such rigidity organizational unlearning is necessary since it is considered an important condition to adapt to environmental changes (Leal-Rodríguez et al., 2015; Morais-Storz and Nguyen, 2017).

A firm that wants to acquire new knowledge, needed to implement a radical innovation, must unlearn obsolete and misleading knowledge and beliefs (Hedberg, 1981). Since a radical innovation involves moving away from the past routines and beliefs to facilitate the entry of new knowledge, carrying on an organizational unlearning is mandatory (Buchen, 1999). If a company remains anchored to the knowledge base it already has, without the intention of questioning it to develop new knowledge, then the possibility of implementing a radical innovation is drastically reduced.

Putting into practice, organizational unlearning promotes and supports the emergence of radical innovations. In order to implement such a practice, however, it is necessary that someone within the organization understands its urgency. Unlearning, in fact, provides for cognitive activities that lead the members of the organization to realize that some routines are obsolete (Starbuck and Hedberg, 2001). Although organizational unlearning has been shown to favour the process of adaptation to changes in the surrounding environment, allowing the company to change its internal dynamics, its relationship with the innovation process has not yet received much attention from scholars (De Holan and Phillips, 2004b). In particular, the relationship between organizational unlearning and radical innovation is under-investigated, although the concept of radical innovation has been extensively discussed in the literature. With this in mind, the purpose of this conceptual paper is to analyse the contributions in the literature dealing with the relationship between organizational unlearning and radical innovation in order to sustain this line of research and propose potential future developments.

2 Theoretical background

2.1 Organizational unlearning and forgetting

The concept of organizational unlearning gained considerable importance in the early 80s thanks to the study conducted by Hedberg (1981) "How organizations learn and unlearn". Although this concept has been widely debated in the years to come, scholars never agreed on a unique definition to describe the phenomenon. For this reason, Tsang and Zahra (2008) collected and analysed the main definitions proposed for organizational unlearning and assessed their common elements. What all definitions have in common is the emphasis on the process of getting rid of something within the organization. What is discarded are outdated beliefs, routines, norms and habits and in most cases the focus is on replacing them with new ones. It follows that the discarding and the replacement aspect are the two cornerstones of organizational unlearning. The discarding dimension implies that the company is clearly aware of which knowledge is no longer useful and must therefore be forgotten. Hence, the concept of organizational unlearning has been studied in parallel with the concept of organizational forgetting (De Holan, 2004).

In the management and organizational literature organizational unlearning has been studied considering two different meanings: voluntary, therefore intentional; and involuntary, therefore accidental. Accidental unlearning happens when a company loses part of its knowledge due to an unforeseen event, such as the involuntary deletion of data or loss of system memory, due to knowledge transfer both outside and inside the organization or to a change in the organizational life cycle (Wang et al., 2013). In this case the company loses valuable information and is impoverished (Cegarra-Navarro et al., 2016). This situation can cause the company to lose competitiveness in the market, so it must invest time and resources to recover forgotten knowledge (De Holan, 2004). Instead, we talk about intentional organizational learning when the process of discard obsolete knowledge is conscious and driven by a voluntary effort (Cegarra-Navarro et al., 2013). This process occurs when there is an awareness that current behaviours, actions, knowledge structures, assumptions and routines are obsolete and no longer appropriate and consequently there is a need to replace them with new ones (Lei, Slocum and Pitts, 1999).

At the hearth of voluntary organizational unlearning there is the intention to prepare the ground for acquiring new knowledge, therefore it is to be considered as the preparatory stage of the organizational learning process (Wang et al., 2013). Although learning is crucial to achieve a successful organizational performance, it is often hampered by barriers within the organization that appear in the form of rigid behaviours and obsolete knowledge (Starbuck and Milliken, 1988). Therefore, scholars agree that it is difficult for a firm to establish new routines because the previous ones and the already established cognitive structures hinder the absorption of new knowledge. It follows that organizational unlearning is required in order to change the status quo (Cegarra-Navarrol,

Cepeda-Carrion and Jimenez-Jimenez, 2011; Morais-Storz and Nguyen, 2017). In fact, Tsang and Zahra (2008) define organizational unlearning as a process in which obsolete knowledge, norms and routines are discarded in order to make room for new ones.

It is important to underline that organizational unlearning cannot be detached from the process of unlearning at the individual level. The organization, in fact, is made up of a group of individuals, so collective learning is derived from individual learning (Hislop et al., 2014). When the organization decides to discard previous routines it must necessarily involve the individuals in the organization, ensuring that they are all aligned with the decision and that they no longer apply such routines (De Holan and Phillips, 2004a; Wang et al., 2013). According to Tsang and Zahra (2008) it is more difficult to eliminate the practices which are socially rooted, such as those related to human resources management. Therefore, in order to facilitate the unlearning process, the organization needs to strive to create a stimulating environment and a context that allows individuals to get rid of what is no longer needed, encouraging openness to new knowledge and counteracting resistance to change.

Although the literature on organizational knowledge recognises the interconnection of the concepts of organizational unlearning and organizational forgetting, there is no clear distinction between them. If we adopt the definition of organizational unlearning from Tsang and Zahra (2008, p.1437), i.e. "the discarding of old routines to make way for new ones, if any", we note that many scholars attribute the same meaning to organizational forgetting (Huang et al. 2018; Klammer and Gueldenberg, (2019b). It follows that the meaning of the two concepts overlap and are considered as synonyms.

According to some scholars, however, what distinguishes organizational unlearning from organizational forgetting is the intentionality of the process of discarding obsolete knowledge (Klammer and Gueldenberg 2019). According to this approach, organizational forgetting refers to the involuntary loss of information (Wang et al., 2013). Organizational unlearning, on the other hand, intends that this loss occurs intentionally (Cegarra-Navarro et al., 2013; Hislop et al., 2014).

De Holan, Phillips and Lawrence (2004) extensively investigated the concept of organizational forgetting and proposed a framework from which it derives that unlearning is a mode of forgetting. Specifically, the framework is divided into two main dimensions: the mode of forgetting, whether intentional or accidental, and the type of knowledge, whether pre-existing or new. According to the authors, organizational unlearning is an intentional process that involves the dismantling of the extant body of knowledge, once it is understood that it has become ineffective in pursuing the business in a successful way.

2.2 Organizational unlearning and innovation process

The survival of companies is constantly threatened by an increasingly dynamic environment. This continuous change represents a major challenge for companies that need to address it by developing a strong innovation capability in order to remain

competitive in the market (Damanpour and Gopalakrishnan, 1998; Wang et al., 2013). A fundamental point to produce innovation, whether radical or incremental, is that the company must necessarily acquire new knowledge and get rid of obsolete one. As a result, if the company is persistent in relying on current beliefs, routines and procedures within the innovation process, it will not be able to respond positively to changes in the environment, so it will hardly be able to develop innovation. For this reason, organizational unearning is closely linked to the concept of innovation (Akgün et al., 2007; Wang et al., 2013). Many scholars have analysed the relationship between organizational unlearning or forgetting and innovation.

Assink (2006) asserts that inability to unlearn is one of the barriers preventing the company from developing innovation. According to the author, the inability to abandon outdated beliefs and start thinking in an unconventional way negatively affects the way information from the market is collected, interpreted and used, and thus disadvantages the production of innovation. Becker (2008) highlights the importance of questioning policies and procedures developed within the organization as soon as they are no longer able to contribute to the development of innovation by the company.

The development of innovation by companies is mainly due to their ability to adapt to a constantly changing environment and to exploit the opportunities that this change offers. In order to best embrace change, it is reasonable that the company should modify the current routines by implementing a process of unlearning or forgetting (Yang et al., 2014). The literature shows that many companies have not been able to abandon the old ways of working and thinking and consequently have not been able to recognise important changes in technology and the market, falling behind their competitors (Akgün et al., 2007). The willingness of companies to keep their cognitive structure and their institutional rules and practices unchanged limits their innovation behaviour and consequently reduces their innovative capacity (Huang et al. 2018). The core competencies possessed by companies in most cases are not sufficient to exploit and benefit from changes in the surrounding environment. Many companies, in fact, run into the so-called "competency traps" (Levitt and March, 1988), i.e. they mistakenly believe that if the practices adopted so far have always led to successful results then they should not be changed because they will guarantee the same positive results in the future (Srivastava and Gnyawali, 2011). Without being aware of this, companies develop internal obstacles that negatively affect their innovation performance.

2.3 Radical innovation

The concept of radical innovation is of great interest to both scholars and practitioners, as they recognize the fundamental role it can play for companies. Although there are multiple classifications of innovation, one of the most widely used counterposes radical innovations and incremental innovations (Dominguez Escrig et al., 2016; Gatignon et al., 2002), even if the distinction between these two concepts is not always clear (Assink,

2006). Incremental innovations arise from an already known knowledge base and consist of a series of small improvements to a company's products, services or processes. Even though these improvements involve a certain degree of novelty, they do not substantially change the existing product, service or process (Veryzer, 1998). On the contrary, the goal of radical innovations is to develop revolutionary technologies, products, processes or business models that completely disrupt the existing market (Thomond and Lettice, 2002; Verganti, 2008). Leifer, O'connor and Rice (2001) define radical innovation as a product, service or process with both familiar and completely new features that significantly improves costs or performance and completely transforms the market or even creates a new one. Radical innovation attacks existing businesses and offers great opportunities for growth and profit for the companies that introduce it (Assink, 2006). On the one hand, such innovations represent a great opportunity for organizations, which can gain a significant competitive advantage and become market leaders (Baker and Sinkula, 2007), but on the other hand they represent a threat if not promptly exploited. When an organization introduces a radical innovation, the products made by competitors become immediately obsolete and the market begins to be dominated by a new standard (Verganti, 2008). As a result, companies must adapt quickly to avoid the risk of lag behind and fail (Dominguez Escrig et al., 2016; Nijssen et al., 2005).

3 Organizational unlearning and radical innovation

Scholars recognised that the unlearning process can pave the way for innovation (Yang et al., 2014), but little has been studied about the relationship between organizational unlearning and radical innovation. This section will try to bring together what has been argued so far about the relationship between organizational unlearning and radical innovation in order to create a solid basis for further researches.

Yang et al. (2014) argue that it is worth exploring how the different dimensions of unlearning can have an impact on radical innovation. Specifically, the authors consider the two dimensions of unlearning: "changes of routines and beliefs" and "forgetting". This distinction is based on studies by Akgün et al. (2007) who argue that in order to produce substantial organizational change it is necessary to change the organization's routines and collective thinking, as well as to voluntarily lose or forget previous knowledge. According to Yang et al. (2014) it is appropriate to study these two dimensions of organizational unlearning separately. In fact, the former is internally oriented as it is mainly related to the employees of the organization who have to change the current procedures and modify the internal processes, while the latter is externally oriented, as organizations can eliminate the memories that have involved external stakeholders without them resisting it. The authors found that the change and forgetting dimensions have different impacts on the development of radical innovation.

Changing routines and beliefs, meant as expectations towards market, processes and technology (Akgün et al., 2007), allows the organization to increase the ability to produce radical innovations through the injection of new ideas, tools and procedures. This positive

relationship is further strengthened by the presence of slack resources, which is based on resource-based view (RBV) theory. According to RBV, the resources owned by a company influence the company's strategy and the results it can pursue (Barney, 1991). Slack resources are the resources that the company possesses in excess of those that are needed to conduct the business, consequently they allow the company to take more risks, investing in projects that do not represent a certainty and therefore feel freer to produce innovation. As argued by Yang et al. (2014), the presence of these resources favours the implementation of changes in routines and beliefs and, as a consequence, positively contributes to the emergence of radical innovation.

In parallel, the forgetting dimension is found to have a negative impact on the production of radical innovation. Yang et al. (2014) argue that companies need the support of a variety of external stakeholders, such as cooperative partners, customers or suppliers to successfully carry out an innovation process. It is unlikely that companies have sufficient internal resources and expertise to produce innovation in a completely autonomous way. Forgetting, either voluntarily or due to an unfortunate event such as the loss of memory of the systems, can cause a loss of interest by external stakeholders towards the company. The lack of their support may hinder the production of radical innovation.

Wang et al. (2013) contribute to the study of the relationship between organizational unlearning and radical innovation by recognizing the role of organizational flexibility as a mediator between the above-mentioned constructs. Organizational flexibility represents the ability of a company to deal with uncertainties arising from changes in the surrounding environment, responding promptly to them by allocating resources to different courses of actions.

A company characterized by rigidity and resistance to change will not be reactive to a changing external environment. Instead, through organizational unlearning, the company abandons procedures that it considers obsolete, adopts new practices and changes beliefs, enhancing the opportunity to acquire new knowledge and promoting organizational flexibility. The authors believe that organizational flexibility contributes to positively influence a company's ability to produce innovation, both incremental and radical.

According to Lyu et al. (2020), organizational unlearning moderates the relationship between environmental turbulence and radical innovation and between entrepreneurial orientation and radical innovation. In a constantly changing environment, companies are requested to change their beliefs structures, knowledge sets and procedures in order to keep up with external changes. In this scenario environmental turbulence refers to an external environment that changes quickly and in an unpredictable way. This leads companies to review their strategies, skills and knowledge as they may have become obsolete and ineffective. It follows that organizational unlearning is a powerful tool the firm can use to make the necessary adjustments to adapt to an ever-changing environment.

Lyu et al. (2020) stressed that being flexible is a fundamental characteristic that companies must have in order to survive and remain competitive. According to Wang et al. (2013), through organizational unlearning the firm abandons ineffective beliefs, procedures and routines, increasing its flexibility and being more reactive to change. Lyu et al. (2020) recognize entrepreneurial orientation positively associated with organizational unlearning. Entrepreneurial orientation concerns the strategic orientation of a company that includes methods and practices of decision making (Wiklund and Shepherd, 2005).

Entrepreneurial orientation is associated to the firms' tendency to change traditional routines, thus fostering the process of unlearning outdated knowledge, beliefs and procedures. It has been studied that companies with a high entrepreneurial orientation are more prone to change, as they question previous knowledge. As a consequence, they tend to be more innovative (Miller, 1983).

Based on contingency theory, Lyu et al. (2020) then explored how firm size moderates the relationships between the antecedents and organizational unlearning. According to contingency theory, the success of an organization derives from the combination of intrinsic characteristics of the organization and contingent variables. This theory is grounded on the idea that no unique and winning strategy for every company exists, but rather, the same strategy can be more or less effective if applied under different environmental conditions (Morton and Ho, 2008).

One of the variables widely investigated in contingency theory is the firm size. Lyu et al. (2020) assert that the larger the firm size the less positive impact environmental turbulence has on organizational unlearning. In fact, a small company can benefit from less bureaucratic inertia which makes it more adaptive to change. A turbulent environment requires a quick replacement of routines, beliefs and knowledge as they rapidly become obsolete. In a large, multi-layered company, the unlearning process is slowed down by stricter rules that govern its business operations, making it more difficult to replace values and habits that conflict with the ever-changing environment. On the contrary, the larger the size of a company, the greater the positive effect of entrepreneurial orientation on organizational unlearning. This happens because large companies have access to larger financial resources that they can use to implement entrepreneurial orientation activities.

4 Conclusions, limitations and future research direction

The aim of our conceptual paper is to investigate the relationship between organizational unlearning and radical innovation through a critical analysis of contributions in the literature to date. First of all, this study highlighted that although the single concepts of organizational unlearning and radical innovation are widely discussed in the literature, little is yet known about the relationship between them. Therefore, our conceptual paper aims to understand the underlying dynamics currently investigated and

to identify potential research gaps that future research could address to deepen the understanding of this relationship.

4.1 Contingency theory

Adapting to the constantly changing environment is a prerogative for companies that want to remain innovative and competitive in the market. Even more so, in order to introduce radical innovation, the company must adapt as quickly as possible to changes in the surrounding environment, so as to be the first to understand its potential, exploit it and achieve a significant competitive advantage. As the literature shows, organizational unlearning is a key factor in leading a company to introduce radical innovation (Lyu et al., 2020; Wang et al., 2013; Yang et al., 2014).

The literature so far demonstrates that contingency theory has only been used to better understand the company's ability to undertake an organizational unlearning process. In particular, Lyu et al. (2020) studied the variable of firm size to assess the impact of environmental turbulence and entrepreneurial orientation on organizational unlearning. Some of the most important contingency theories of organizational structures define three main contingent variables: environment, strategy and company size (Donaldson, 2001). As the impact of firm size on organizational unlearning has already been studied, it might be interesting to understand how other variables influence organizational unlearning and how they indirectly impact the production of radical innovation.

Contingency theory has been widely used in the literature to explain the dynamics of the organizational learning process (Cyert and March, 1963; Gnyawali and Stewart, 2003), as according to it organizations are depicted as open systems that continuously adapt to the environment (Romme and Dillen, 1997). Gnyawali and Stewart (2003) stated that organizations must adapt the learning process to the surrounding environment and in particular to the different environmental conditions they may face. Following the same logic, it would be appropriate to study how the nature of environmental changes affects the unlearning process and the consequent production of radical innovation.

4.2 Individual unlearning, organizational flexibility and radical innovation

The study of the literature revealed the fundamental role of organizational flexibility in triggering radical innovation within an organization. Wang et al. (2013) recognized the necessary mediating role of organizational flexibility between organizational unlearning and radical innovation. Sanchez (1995) decreed that the flexibility within an organization is to be understood in terms of resource flexibility and coordination flexibility. Both concepts of flexibility imply a direct involvement of the individual within the organization. In fact, in a turbulent environment individuals adapt by seeking new ways to manipulate the available resources (Wang, Qi and Zhao, 2019). Joint efforts by all the individuals in the organization to unlearn obsolete knowledge result in unlearning at the

level of the organization (De Holan and Phillips, 2004a; Hislop et al., 2014), which in turn discards the old routines replacing them with new ones and improving the overall flexibility of the organization. As the connection between individual unlearning, organizational flexibility and radical innovation is clear, the relationship between these constructs should be further investigated.

4.3 Limitations

Although this conceptual paper has contributed to prepare the ground for future researches concerning the relationship between organizational unlearning and radical innovation it has one main limitation. As this relationship is still poorly researched there are not yet many contributions in the literature, therefore our paper uses a rather limited number of papers to investigate and discuss such relationship.

Managing Knowledge to Counter Climate Change

Christopher Søren Shann Turnbull

International Institute for self-governance
PO Box 266, Woollara, Sydney, Australia 1350

Abstract

The purpose of this paper is to apply existing knowledge to counter climate change. The contribution to knowledge is to ground institutional analysis, individual behaviour, political science, economics, management and the management of global sustainability in the practices and science of governance found in nature. This is achieved by using bytes as the unit of analysis to explain how nature governs complexity on a more reliable and comprehensive basis than achieved by humans. Tax incentives could encourage organisations to adopt elements of ecological governance found in nature and in social organisations identified by Ostrom and the author. Ecological governance can provide benefits for all stakeholders as desired by CEO's of the US Business Round Table. Corporations then become a common good to allow them to promote global common goods like countering climate change, pollution and inequalities in power, wealth and income. Democracy is enriched bottom-up.

Keywords – Bytes, Climate change, Common good, Ecological governance, Tensegrity.

Paper type – Academic Research Paper

1 Introduction

The purpose of this paper is to present existing knowledge of how society might better counter climate change. The causes and solutions of climate change are widely understood and accepted. The difficulty is how to motivate nations of the world to take collective action. To understand how society might better counter climate change widespread knowledge is required on how to constructively manage wicked problems described as "the tragedy of the commons" (Hardin 1968).

These tragedies arise when different individuals or groups promote their self-interest by over exploiting life-sustaining resources to eliminate them for everyone. The extermination of humanity on Easter Island is an example. Climate change introduces the risk of exterminating humanity on the planet. For the first time the tragedy of the commons has become a global issue of human and institutional behaviour. Countless examples of such wicked problems and their solutions have arisen over millenniums in the context of excessive hunting, fishing, grazing and irrigation. But their solutions have yet to be taught in graduate schools.

Political scientists Elinor Ostrom and her husband Vincent spent their lives studying how since pre-modern societies knowledge exists on how individuals or groups could

avoid tragedies of the commons. In pre-modern hunter gathering societies the solution did not depend upon either markets or hierarchy but forming special types of network relationships that introduce checks and balances on power elites whose actions could destroy the common good for everyone.

The Ostrom's used the language of political scientists to describe the nature of these networks as "polycentric republics" (Ostrom 1987, 1990, 1993, 1998a 1998b, 2010. 2012, Ostrom & Allen, 2008, Ostrom, Walker & Gardner 1992). The communication and control architecture in such "polycentric republics" is also found in the communication and control networks existing in our brains (Kelso, Dumas, & Tognoli 2013). For this reason, this form of governance is described as "ecological" (Turnbull, 1991a, Marston 1992: 39). This makes the knowledge on how to counter climate change subjected to the natural science of governance (Turnbull 2000b, c, e, 2002b; 2005, 2008a; 2012b, 2013c, 2014b, 2015a, b, 2018a, Turnbull & Guthrie 2019a, b, Turnbull & Myers 2017).

The science of governance is grounded in natural laws identified by Neumann (1947), Shannon (1949) and Ashby (1957). These laws explain how to improve the reliability of data processing in respectively: decision-making, communications and control. Knowledge of the science of governance in turn explains why and how nature creates complexity and how best complexity can be managed (Kurzweil 1999, Pirson & Turnbull 2011a, b, 2012, 2015, 2016, Turnbull & Guthrie 2019a; Turnbull & Pirson 1919).

Governance science uses data as its unit of analysis. Data is now routinely metered in bytes. Bytes are eight units of data called "bits". Bits are represented by perturbations in matter and/or energy that make a difference. To minimise the materials and energy for living things to be created, developed, survive and reproduce in unknowable dynamic complex environments, evolution has developed processes for minimising the material and energy required.

Factbook (2019) reports: "The brain makes up 2% of a person's weight. Despite this, even at rest, the brain consumes 20% of the body's energy"! The human brain is thousands of times more efficient than the most advanced computer chips that cannot match its performance even ignoring their dependence on external power sources (*The Economist* 2020: 9).

Unlike the social science of economics that seeks to minimise the undefinable social construct of cost, the science of governance is based on minimising materials and/or energy. In this way Transaction Byte Analysis (TBA) subsumes and extends the Transaction Cost Economics (TCE) developed by Coase (1937) and Williamson (1975) for analysing only hierarchical organisations. TBA provides a method for analysing any type of organisation and so any type of collective activity by humans or any other specie. This is because no collective action can occur in society or nature without data processing within and between coordinating entities.

Managing wicked problems like climate change requires knowledge of how to manage complexity. This is common knowledge with natural scientists designing self-governing automobiles and space probes. An introduction to this knowledge for social scientists is

presented in the following sections. This knowledge provides a framework for understanding why current forms of markets and hierarchy are ineffectual to counter climate change. Section four suggests how tax incentives can introduce ways to introduced ecological forms of organisations and different types of markets to counter climate change.

2 Language, knowledge and the architecture of complexity

Words are the tools of thinking and special words are required to communicate special concepts to explain the complex communication and control architecture of ecological organisations. Mathews (1996) identifies a number of special words in a review of the literature. But Mathews omitted an overarching concept of complexity called "Tensegrity" that drives evolution. Evolution arises from the possibility of Tensegrity being challenged in way to allow novel improvements to arise to create a new entity that is better suited in a new context while also reproducing Tensegrity to maintain evolutionary processes. A process inhibited by hierarchies.

Buckminster Fuller (1961) coined the word "Tensegrity" by combing the words "tension" and "integrity". This concept has since been recognised by natural scientists but largely neglected by social scientists. One exception is Pound (1992, 1993: 11) who recognised its need but not its name in stating: "always have an opposition viewpoint" and at p.18 "There must always be an opposition party and the prospect of insurgency". Natural scientists like Harvard biologist Ingber (1996) described tensegrity as "The Architecture of life" and quantum physicist Bohm (1980) described the concept in different words as the architecture of the universe. Its relevance to social organisations was identified in the PhD dissertation of the author (Turnbull 2000f: 8, 69, 134).

The science of governance explains why the laws of nature found in the physical world apply to individuals, society and its institutions. This explains the similarities noted between biology and economics tabulated in Turnbull (2000f: 68). Ashby (1957: 1) explains why identical phenomena arise in both social and natural science by observing "*The truths of cybernetics are not conditional upon them being derived from another branch of science*. Cybernetics has its own foundations." The remit of cybernetics is "The science of communication and control in the animal and machine" (Wiener 1948). The science of governance has subsumed the science of cybernetics by being the science of communication and control in the animal, machine and social organisations.

Mathews (1996) identifies a key type of structure for creating or governing complexity that Koestler (1967) called a "Holon". However, Hock (1999) invented his own word "Chaord" from combining the words "Chaos" and "Order". In 1970, Hock became the founding CEO of the credit card company Visa International Inc. He created an organisation that meets the test of being composed of "polycentric republics". Visa was owned by its member banks with each bank having its own board of directors within a common legal entity. Each geographic board possessed the power to issue and manage its

own Visa cards to create hundreds of "polycentric republics". Each "Republic" cooperated ~ competed with each other in their mutually owned legal entity.

Koestler (1967) coined the word "Holon" to describe an entity that is both a "Whole" of sub-systems and component of a larger system made up of Holons that he called a Holarchy. The Greek word for "whole" is "Holo with the suffix "on" being a component, like protons and electrons being components of an atom. Holons were what Smuts (1925) and Simon (1962) were describing in a different language.

Holons possess quite different properties from hierarchies as revealed by Hock's (1999:30) description of a Chaord that he described in two different ways:

1. Any self-organizing, self-governing, adaptive, nonlinear, complex organism, organization, community or system, whether physical, biological, or social, the behavior of which harmoniously combines characteristics of both chaos and order.
2. An entity whose behavior exhibits observable patterns and probabilities not governed by the rules that govern or explain its constituent parts.

Hock (1999) described "chaordic" in three ways:

1. The behaviour of any self-governing organism, organization, or system, which harmoniously blends characteristics of order and chaos.
2. Patterned in a way dominated by neither chaos nor order.
3. Characteristic of the fundamental organizing principles of evolution and nature.

Beer (1959) pioneered the application of cybernetics analysis to management. He developed the Viable Systems Model (VSM) to describe any organizational structure that can produce itself and survive in a changing environment (Beer 1995). Because of their cybernetic heritage a number of VSM features are found in Holons, but the reverse does not apply.

Beer developed VSM before the concept of "corporate governance" became a discipline recognized by social scientists[1]. This made VSM subject to the discretion of management. It was not hard wired into organizational constitutions as found in organizations governed by polycentric subsystems in VISA, The John Lewis Partnership in the UK or the Mondragón Corporacion Cooperativa (MCC) in Spain.

Crucially VSM does not include the concept of tensegrity that is a defining feature of Holons. While Mathews (1996: 52-53) does not use the word tensegrity, he recognizes its existence and its special beneficial attributes by describing their contrary ~ complementary characteristics as a defining feature of a Holon. As examples, Mathews (1996: 41-44) refers to Holons as possessing: "Centralisation ~ de-centralisation", "Bottom-up ~ Top-down", "Autonomous ~ integrated", "Order ~ ambiguity",

[1] *Beer met the author in Toronto on August 3, 1996. After reading a version of Turnbull (1997) he advised that he had not extended his cybernetic insights to the governance of firms. Beer had been President of the World Organization of Systems and Cybernetic since 1987. He encouraged the author to publish in the Systems Science literature as undertaken in Turnbull (2005, 2007, 2012b, 2013c, 2014b, Turnbull & Guthrie 2019b).*

"Management ~ leader". This last feature does not communicate a contrarian relationship like the others. A better description would be to use the words: "Subordinate ~ leader" as arises for a Holon within a Holarchy.

Tensegrity naturally arises in mutual organizations from the conflicts arising within and between stakeholders. Tensions can arise between similar stakeholders, like the member banks of Visa, and/or between different stakeholders classes. Examples of the latter are: customers, distributers, suppliers, contractors, employees, executives, shareholders and host communities. Tensegrity is mostly extinguished in centralized command and control hierarchies. This could explain why management scholars and practitioners promote collegiate and cooperative relationships that obscure even further how tensegrity is hard wired into human behavior who represent an organizational Holon. Some scholars are aware of the benefits of contested relationships like Pound (1992, 1993), and Jensen (1993: 852) who reported on "The failure of internal control systems".

Different types of stakeholders may possess different interests in the firm that can create tensions, but the interests of such stakeholders are not typically formerly integrated into the governance architecture of firms. When they are, they like unlikely to possess meaningful power and/or influence to create serious tensions.

The MCC is an exception with multi-stakeholders interests participating in cooperative supervisory boards (Turnbull 1995b). How these potential tensions can be organized to create internal challenges for continuous improvements and adaptations to new risks and opportunities are raised in the next section. This begins by considering the systemic problems inherent in simply hierarchies involved in complex activities.

3 Why transform simple hierarchies to polycentric republics?

The imperative to transform existing dictatorial command and control business hierarchies into polycentric networks of stakeholder republics arises from simple hierarchies:

1. Possessing excessive exploitative powers that can corrupt their directors, managers, the business and society, (Jensen 1993: 852, Turnbull 2000f: 115; Monks & Sykes 2002: 9;) and,
2. Humans possessing limited physiological and neurological capacity to receive, process, store, process and communicates bytes, data, information, knowledge and wisdom to cope with complexity, (Williamson 1975: 21) and,
3. Cybernetic laws of requisite variety that state it is impossible to:
    a) Reliably communicate complexity up or down a hierarchy either simply or reliably without a requisite variety of independent cross checking channels, (Shannon 1949) and,
    b) Reliably directly amplify control of complex variables without supplementary co-regulators providing a requisite variety of regulation (Ashby 157: 265).

The above problems means that corporate governance codes supported by the World Bank, OECD, UK, US and around the world are promoting a system of exploitative governance, that is subject to failure because business and political leaders lack knowledge of the science of governance. The problems are not limited to publicly traded entities but also to private firms, government owned firms and even non-profit organizations.

How ecological governance can mitigate twenty systemic problems inherent in enterprises organized as simple command and control hierarchies are outlined in Table 1. "How mimicking nature can mitigate systemic problems in hierarchies". Details are provided in the authors PhD dissertation (Turnbull 2000f) and in Turnbull (1991a, 1997, 2000b, c, 2001, 2002b, 2005, 2007, 2008a, 2012b, 2013b, c, d, 2014a, b, 2015a, 2016a, 2018a, b, c, 2019a, d).

The practicality of firms transforming to polycentric republics is supported by their existence without any special laws in leading jurisdictions like the US, UK and Europe. A survey of the internal architecture of stakeholder-governed corporations around the world by Bernstein (1980) revealed that a common feature was a distribution of power to a number of boards and/or control centers. This suggests that the inherent conflicts of interest that can arise when workers can dismiss bosses and bosses can dismiss workers without a separation of powers do not allow such organizations to become sufficiently sustainable to be identified.

Table 1. How mimicking nature can mitigate systemic problems in hierarchies

	Toxic problems of hierarchies	Mitigation by mimicking nature
1	Society assumes top-down control is natural	Nature uses bottom/up control & top/down guiding
2	So no education about ecological governance with distributed control to simplify complexity	Complexity simplified with almost self-governing sub-systems dependent upon contrary guiding
3	Unitary boards obtain absolute power to identify and manage their own conflicts of interest to allow absolute corruption of directors, the business and society	Shareholders appoint one board to manage the business and a second to govern the corporation to establish tensegrity benefits for all stakeholders and society
4	Group think arises from directors captured by CEO to hide risks, misconduct & malfeasance	Governors/guardians of stakeholder voices obtain contested "requisite variety" of data for checks and balances
5	Corporations can lie and/or mislead themselves about director independence	Directors independence becomes irrelevant as Governors control minimized conflicts
6	Directors capture auditors who judge their accounts	Governors control auditors who judge directors accounts
7	Auditors lie that they are independent	Auditors kept independent by Governors
8	Accounting doctrines hide how investors get overpaid beyond their investment time horizons with surplus profits creating hidden sources of inequality and stakeholder exploitation	Ownership of surplus profits distributed by corporations issuing shares to citizen stakeholders that democratizes wealth and power. Reduces the need for corporate taxes and welfare programs
9	Directors control advisors to shareholders	Shareholder advisors controlled by Governors
10	Directors nominating themselves for election	Director nomination by shareholders & Governors
11	Directors control their own pay after setting and marking their own "exam papers" aka KPIs	Governors determine director pay from Stakeholder Key Performance Indicators (KPIs)
12	Directors control reports about corporate impact on the environment, stakeholders and community welfare and their own governance	Stakeholders provide guardians with reports for shareholders on Governors pay, corporate impacts on: stakeholders, the environment and society.

13	Directors control how they are held accountable to shareholders at AGMs and control the voting processes on own election and remuneration.	Stakeholder nominee controls conduct of AGMs. Governors determine AGM agenda, location, acceptance of proxy votes, vote counting, etc.
14	Directors ignorant of shareholder identities, etc.	All ultimate owners and/or controller made public
15	Share trading relationships and price manipulation hidden from directors and public	No shares traded without prior disclosure of any related derivatives and identity of counter parties
16	Shares traded covertly by third party exchanges and in "Dark pools"	Corporations directly execute all share transfers
17	Directors not held to account by various stakeholder groups who may have conflicting interest but on who directors rely upon to improve the quality, reliability, and efficacy of continuous operational improvements	Each common interest stakeholder group obtains rights to form their own non-profit associations to appoint advocates-supplementary regulators/ management mentors that avoid directors and shareholders being kept in a cocoon of ignorance
18	Directors of simple command and control hierarchies lack systemic process to cross check management actions and misreporting	Directors obtain stakeholder communication and control channels independent of mgers to cross check integrity of operations and outcome reports.
19	Impossibility of controlling complexity directly	Complexity controlled indirectly by stakeholders
20	Self-regulation/governance is impossible	Self-governance shrinks costs & size of government & compliance costs.

Such separations of powers need not necessarily produce polycentric republics as possessed by Visa Inc, The John Lewis Partnership or the MCC. These organizations, and especially the MCC and the Citizen Utility Boards (CUBs) established by Ralph Nader (Givens 1991) in the US provide working models for constructing Figure 1. Figure 1 does not represent any existing firm with polycentric republics. It is generic discussion model to illustrate some critical elements for introducing ecological governance.

A crucial essential feature is to introduce contestability and so tensegrity into the governance architecture of business by introducing a requisite variety of a separation of powers. This also eliminates a number of systemic toxic conflicts of interest while at the same time decomposing decision-making and communications overload of directors. Such outcomes are supported by the groundbreaking work of Persson, Roland, and Tabellini (1996). They showed how an appropriate separation of powers provides net advantages to all constituent stakeholders.

A complete separation of powers requires that no director who possesses the power to manage the enterprise is also involved in governing the corporate entity. The European two-tiered board would appear to achieve this objective but is compromised by supervisory boards also being accountable for management. Shareholders in Figure 1 are shown electing two boards and in different ways. The author has introduced this arrangement in two public companies he has founded (Turnbull 2000a, 2002c).

A separation of the power to manage from the power to govern is typically introduced by Venture Capitalists (VCs) as a condition for their investment. This arrangement is also introduced in Leveraged Buy-Outs (LBOs). Jensen (1993: 869) states that they are "proven models of governance structure" and "LBO associations and venture funds also solve many of the informational problems facing typical boards of directors." Legal scholar Dallas (1988, 1997) has presented arguments and proposals for a separation of corporate powers, as have Diermeier & Myerson (1999).

Senator Murray (1998) recommended to the Australian Parliament that all publicly traded companies should be required to separate the power to manage from the powers to govern by establishing the arrangements shown in Figure 1. Murray renamed the "Corporate Senate" described in Turnbull (2000a) that only had veto power over conflicts of directors interests to be come a "Corporate Governance Board" with executive powers over any conflicts of directors interests that included managing the AGM. Figure 1 suggests that the "Stakeholder Congress" appoints the chair of the AGM to avoid directors or governors being conflicted in their accountability to shareholders and other stakeholders.

This allows shareholders to exercise control over the appointment and remuneration of both directors and governors with information provided independently of them as indicated in Figure 1. Shareholders obtain access to alternative views on the ability of the enterprise to provide benefits for all stakeholders (BRT 2019). Such contestability introduces Tensegrity into the conduct of AGMs.

There is no ethical commercial reason for managers of an organization to become both over-worked and conflicted by also being involved in the political process of governing the organization. US company director consultant, Ralph Ward promoted his business by publishing Turnbull (2012a) that identifies how the arrangement described in Figure 1 can provide win-win outcomes for shareholders, directors, mangers, auditors, non-executive directors or governors and stakeholders.

Figure 1 describes, "A new way to govern: Organizations and society after Enron" (Turnbull 2002a) commissioned by the UK "Think and do tank" the New Economics Foundation as a public policy pocket book to identify an alternative to Thatcher privatization or State ownership. Columbia law professor Katharina Pistor (2015) prescribed the pocket book for a course module at the Swiss International Law School (Turnbull 2015a). The pocket book describes "A new model of corporate governance" (Fink 2018) sought by the largest asset manager in the world to allow companies to provide "benefits for all stakeholders" (Fink 2018). Fink is one of the 181 CEOs of the US Business Round Table (BRT 2019) that have made a similar commitment.

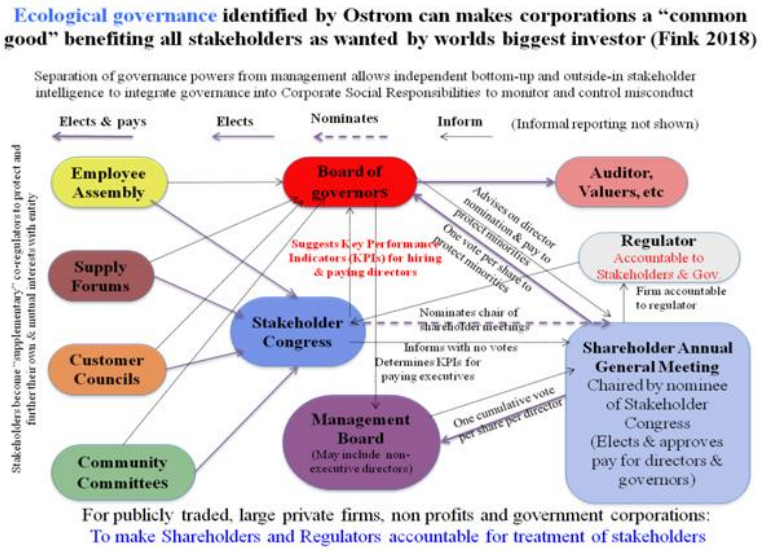

Figure 1

However, the BRT made no mention for the need to also introduce "A new model of corporate governance". CEO's accountable to all stakeholders can become accountable to no one. This led some commentators like Pistor (2019) to state that: "America's corporate leaders believe they can decide freely to whom they serve." A careful review of Figure 1 reveals that while stakeholder interests are represented in an influential manner, shareholder primacy is maintained to make shareholders accountable for protecting and furthering the interest of all other stakeholders. Achieving this objective would make corporations not only a common good but align their purpose in promoting the common good both locally and globally.

Figure 1 allows corporations to be become ethical as detailed in Turnbull (2019d). It creates the solutions identified in the right hand column of Table 1. In these ways ecological governance also directly increases the wellbeing of individuals by allowing them to constructively use their embedded instincts to introduce checks and balances for spreading organisational self-regulation and self-governance (Ostrom, Walker & Gardner 1992, Turnbull 2018b). How such transformation might be achieved is next considered.

4 How might corporations become a common good?

Elements of ecological governance could be introduced in various ways and stages to publicly traded corporations or other types of organizations in the private, public and/or non-profits sectors. These could arise from:

1. Governing bodies of organizations establishing a requisite variety of stakeholders advisory panels as shown in Figure 1 with any supporting geographical sub-units that besides increasing the depth and density of cross checking data from managers could also be used to promote Just In Time supplies, Total Quality Control for customers, Innovations by lead customers and/or users, employee voice (including anonymously to facilitate whistle blowers) and host community environmental and other feedback advice. Executives would be become accountable for making the entity a common good entity as proposed by the US BRT (2019).
2. Governing bodies establishing the above processes in formal regulations of the organization to facilitate the establishment of contestability, challenged, feedback and organizational tensegrity to promote continuous evolutionary improvements. Directors would become accountable for making the entity a common good entity.
3. Shareholders and/or members changing the constitution of their entity to introduce the arrangements outlined above to make shareholder and/or members accountable for transforming their entity to promote the common good with a "new model of corporate governance" such as proposed by Fink (2018).
4. Regulators mandating changes in corporate constitutions as above and/or
5. The government providing tax, and/or other incentives to implement the above processes with and/or without ecological ownership to create common good enterprises that also reduces inequality by democratizing the wealth and control of nations bottom-up.

Ecological governance enriches democracy by directly engaging with broad constituencies of voting stakeholders. This is why it is important that only voters are recognized as stakeholders, not corporate entities with who they may be associated as employees, contractors or agents. It creates a supplementary political process for individual voter to directly engage and participate in influencing institutions in the private, non-profit and government sectors. While Figure 1 maintains shareholders primacy, this can be extended to all *stakeholders* by introducing an ecological form of capitalism (Turnbull 2015b) that transfers ownership from shareholders to stakeholders after the time horizon of investors.

My first book, Turnbull (1975a) on *Democratising the wealth of nations*, was not about governance but ownership. It introduced the idea of Ownership Transfer Corporations (OTCs) as a way of creating an economic and political incentive for individual voters to become engaged in reforming capitalism. The book was published by the politically right Company Directors Association and launched and reviewed by a socialist Dr. Jim Cairns (1976) who had a PhD in economics and at the time was the Deputy Prime Minister of Australia. His favoraboe review was published in the Journal of Australian Stockbrokers providing evidence of the books bipartisan appeal. The publisher of the book had added

an alternative title for their members being “New money sources and profits motives”. Copies were sent to all members of parliament with a different covering letter that used the title most suited for the views of the recipient.

At the suggestion of the founder of the UK conservative Think Tank Respublica I changed the name OTC to the more politically nuanced language of “Endowment Corporation” in Turnbull (2014a). A short summary of the book was published by a politically left Australian Think Tank forty years after its publication (Turnbull 2015c). Academic presentations of the idea of replacing exclusive, static and perpetual property rights with inclusive, dynamic and time limited rights are presented in Turnbull (1973a. b, 1997, 1998) with the 1997 article republished in the Corporate Governance volume of *This History of Management Thought* (Turnbull, 2000d).

The Central Research Institute for National Economy in Prague translated articles for a visited they hosted me in 1991 and 1992 (Turnbull 1990, 1991b, d, f). In 1992 the State Commission for Reform of the Economic System hosted me in Beijing for lectures to their Cadres on using employee ownership as a technique for privation (Turnbull 1990). Some more notable practitioner and reform presentations are: Turnbull (1974, 1975b, 1980, 1983a, 1993a, b, 2002a, 2004, 2014a).

The majority of all business investments are time limited. Time limited property rights are not an alien, nor a provocative concept for venture capitalists and professional investors. A fact illustrated by the many Build Own, Operate and Transfer (BOOT) projects around the world. All intellectual property rights are time limited. A major intellectual problem is created by accountants assuming all business remain a “going a concern”. So unlike professional investors, accounting doctrines do not have time horizons. This means that investors can get overpaid receiving a cash return back after their time horizon. Any such return is by definition in excess of their incentive to invest to create a “surplus” profit. This is different and additional to any “super”, “excessive” or “monopoly” profit that may be received and reported before their time horizon. This makes them subject to measurement, reporting and taxation.

What is not reported is not managed, let alone taxed. As reported in my earlier writing surplus profits can be many times greater than the value of the original investment. However, economists assume that there is no limit to greed. This denies them possessing a concept or word to describe profits in excess of the incentive to invest.

Surplus profits have become an invisible and insidious systemic source of the inequality created by capitalism not considered by economists like Picketty (2014). As surplus profits cannot be measured, the best way of making the economy more efficient and fairer is to introduce dynamic property rights to democratize the wealth of towns, cities, regions and nations. Turnbull (1975a: 65-70) includes techniques for democratizing urban commons described in a subsequent literature archived by the New Garden Cities Alliance (NGCA 2020).

As corporations are typically taxed at a lower rate than many citizens and have ways to shift profits to tax havens, the transfer of corporate equity to individuals can generate

increased tax revenues and votes for political leaders. As shown in Turnbull (1975a, 2000d) tax incentive to provide investors with a bigger, quicker and less risky profits in return for gradually giving up ownership over the twenty year life a patent is relative small.

The endowment process can occur by shareholders agreeing to change their corporate constitutions to create a new class of Stakeholders shares. There is not limit to how many stakeholders shares can be issued but the percentage equity endowed each year can be constant. A process is established for any type of stakeholders shown in Figure 1 to become shareholders in a company that maintains shareholder primacy. My book suggests a proportion of stakeholders shares are reserved to fund a minimum universal wellbeing income described as a "Social Dividend".

Endowment corporations would payout all their profits each year like many cooperatives. Business growth, management and investor succession could be provided for through dividend re-investment in "offspring" enterprises. Giant corporations would become replaced with nested networks of locally owned and controlled enterprises of human scale as illustrated by the MCC. Investors "fading out with a profit" (Turnbull 1974, 1975b) would retain pre-emptive rights to continually be a shareholder in such networks of their choice.

Any incentive introduced to democratize the wealth of nations could also be used to democratize the control of corporate capitalism as indicated in Figure 1. This would enrich democracy on a bottom up basis with ecological governance. This would make self-governance practical to provide an additional way to reduce the size, cost and influence of governments (Ostrom, Walker & Gardner 1992).

Perhaps the most challenging problem in countering climate change is educating both democratically elected leaders and those leading other nations in self-perpetuating command and control hierarchies that neither markets nor hierarchies are sufficient, or even necessary. This problem requires a compelling proportion of the general population to demand changes as outlined above. The challenge for universities it to initiate educational courses at all levels of society to facilitate decision-making.

The economics Nobel Prize Committee have done their part in recognizing Elinor Ostrom in 2009 for sharing the knowledge of organizing collective action to avoid tragedies of the commons. It is ironic that she shared the award with Oliver Williamson who spent his life researching "Markets and Hierarchies" (Williamson 1975).

Markets are the cause of the problem as noted by a former Chief Economist of the World Bank. As Lord Stern he reported to the UK government that: "climate change is the result of the biggest market failure the world has ever seen" (Stern 2006). This is because markets did not price the pollution cost of burning carbon. Carbon taxing and trading provide a way to counter market failure but stop markets creating counter productive messages. To avoid markets creating messages to exacerbate climate change the definition of economic value needs to become by defined by the degree each bioregion of the world becomes sustainable for eternity. In other words the value of

money in each region needs to be tethered to a Sustainable Index for each region (Turnbull 1983b, 2011, 2016b, 2018b, 2019b, 2019c, 2020).

Hierarchies inhibit countering the problem of climate change as educational institutions and monotheistic religions unwitting reinforce the belief, that hierarchies are the natural of things. The opposite is the truth. As described by Hock (1995: 7):

> *Industrial Age, hierarchical command and control pyramids of power, whether political, social, educational or commercial, were aberrations of the Industrial Age, antithetical to the human spirit, destructive of the biosphere and structurally contrary to the whole history and methods of biological evolution. They were not only archaic and increasingly irrelevant; there were a public menace.*

Action research is required to test how best to introduce elements of ecological governance to institutions in the private, government and non-profit sectors. The immediate limitation is that no known graduate schools provide education in how to become a governance architect to lead implementation action. The biggest challenge is to disseminate this knowledge of how to sustain humanity on the planet.

Abstract

The following paper aims to establish a strategic understanding of design by examining different approaches to quantify the value design can add in a business context. The approach of strategic design is based on the understanding of design as an integral part of the corporate strategy which can be derived from corporate culture as well as from a firms' mission. The paper intends to contribute to the subject of what economic value design creates for companies. Therefore, systematic approaches of how to quantify the value design may add in a business context have been juxtaposed with six structured in-depth expert interviews with firms from different sizes and branches in order to gather individual perceptions on the role of design in management. The study examines, how can a strategic understanding of design be established in a business context and to what extent does this lead to an added economic value.

Keywords – Strategic Design, Value Creation, Innovation, Understanding of Design, Design and Economics

Paper Type: Academic paper

1 Introduction

Design, it seems, is now everywhere. In fact, design is no longer only the professional scope of just product designers or interior architects. The use of design has already proven itself in a wide range of contexts and is becoming increasingly relevant, especially in innovation management (Micheli, 2014). Design is more and more integrated into business strategies and innovation processes of companies from various industries (Brown, 2009; Brunner, Emery & Hall, 2009; Martin, 2009). An increasing number of companies is seeking ways to turn design into a strategic resource for their organisation (Topaloglu & Er, 2017).

Design is undergoing a transition in the ways it is considered and used inside the companies. The traditional understanding of design inside business has been largely limited to the creation and development of products and services. More recently, the character of design has broadened towards a wider range of activities and responsibilities concerning the general business strategy and management. Designers and design-like methods, such as design thinking are increasingly considered to contribute in formulating new services and business models, restructuring a company's strategy, as well as in driving cultural change (Deserti & Rizzo, 2013; 2014; Lee & Evans, 2012; Lockwood, 2011; Buchanan, 2008; Junginger, 2008; Smith, 2008; Ravasi & Lojacono, 2005; Borja de Mozota, 2003; Turner, 2013). From a practical perspective, a growing number of design agencies (IDEO, Frog, NOSE) get involved in strategic services such as innovation strategy, technology strategy, business design.

However, the percentage of companies that have firmly integrated design into their business strategy is still relatively low (Wolf, 2009). Even if design is discussed a lot these days, it is still in need of a new image depart from pure shaping or implementing to enable a real strategic view. It is obvious that sending employees to design thinking workshops, hiring design graduates, and setting up interdisciplinary teams is not sufficient for an organisation to strategically benefit from design. To really make a difference, design needs to become an integral part of the organisation's strategy and management quite naturally. Knight, Daymond, and Paroutis (2019) call the strategic implementation of design, across marketing, sales, and operations a 'Design-led Strategy'.

Nevertheless, design investments and design activities have to prove and justify themselves (Rae, 2013). A prevalent problem can be seen in the inability to measure the economic value design creates for companies. The lack of a design measurement model leads to a requirement of representatives on top management level who are convinced that design can have much more impact to corporate performance if it is not only understood as a process of form-giving. Depending on the history of each individual company and the personal conviction of the management, the relevance of design is assessed differently.

Irrespective of the increasing number of articles highlighting the role of design in management and innovation, there are important gaps in the body of knowledge. Research is lacking on many important issues regarding the strategic value creation by design. There are still uncertainties regarding the term 'strategic design' and the general understanding of design as part of a firm's business strategy. Research is lacking on approaches how to integrate design in departmental structures, economic value chains, and the corresponding activities. Moreover, the predominant approaches to measure the value contribution of design in business contexts are still vague. Research is also lacking on the main challenges when design is anchored in a corporates' strategy.

This paper aims to provide qualitative empirical results in order to partly close these research gaps. Therefore, the research consists of two parts. Starting with a theoretical survey, based on the ability to classify the current state of design use within a company, several approaches to measure design value have been juxtaposed subsequently. The

scholarly part is followed by a qualitative research consisting of six in-depth expert interviews to examine the huge difference in the use of design in various companies to show overall aspects of design practice. Finally, the paper ends with the study's limitations and conclusions.

2 Theoretical review

The following sub-sections briefly present a synthesis of existing literature with regard to the general understanding of design, the integration of design in business value chains, the approaches to measure value contribution of design in business contexts, and main challenges of design management.

2.1 Understanding of design

A fundamental challenge in dealing with design is about the divergent understanding of design, which is both favoured and caused by low research activities making it difficult to clearly assign the areas of application, the way of organising design within a company as well as the stage at which design is included in the value chain (Viladàs, 2009). This lack of allocation leads to design being misunderstood and having to justify itself (Rae, 2013). As long as there is no common understanding of what design is, how it should be used and organized, it is hardly imaginable to establish a strategic understanding of design in an economic context. The almost 30 years old quote from Blaich & Blaich (1993) still holds its rationale: *„I have often wondered if any other discipline devotes as much time to define itself as design does."*

The necessary interlocking of the two disciplines management and design is well explained by Boland & Collopy (2004), where managers are told how to operate with a design attitude towards problem-solving oriented decisions. Besides that, also Nobel laureate Herbert Simon advocates new methods of management theory which should fundamentally internalize design (Simon, 1996).

Buchanan (1992; 2001) defines different levels of design usage in the 'f*our orders of design*' model. According to the author, design is about 'the human power of conceiving, planning, and making products that serve human beings in the accomplishment of their individual and collective purposes' (Buchanan, 2001). Based on that model, the first domain of *symbolic and visual communications* is the typical work of a graphical designer. It deals with the nature, shape, and meaning of *symbols* such as typography, illustration, photography, and print (Harland, 2011). The second order *material objects* includes the design of 3D-objects comparable to the work of an industrial or product designer, which is concerned with tangible, physical artefacts – with *things*. Since every product needs to be designed to be used, therefore there can be no 'non-designed' product. The third domain *activities and organized services* covers user experience and interaction as well as management tasks and strategic objectives for the first time. Here, the focus is on *action* and designing experiences rather than objects. In the fourth order of

complex systems or environments for living, working, playing and learning, Buchanan (2001) refers to the opportunity of design in integrating people into a broader ecological, social or cultural environment, which is to be adapted to human needs by designing environments. Design is understood as an 'idea or a *thought*' that organises the 'integration of information, physical artefacts, and interactions in environments of living, working, playing, and learning' (Buchanan 2001). This model helps to understand the wide range of design challenges ranging from symbols (graphic design), things and devices (industrial design), action and user experience (interaction design) and finally thoughts and strategies (environmental design).

Strategic design can be defined as the economic application of design to long-term strategic problem solving, which can only be defined individually on the basis of situational requirements by the problem solver and its context. Strategic design is therefore the basic orientation of all design aspects towards the same sense and purpose getting even more meaningful in a global and digital environment (Best, 2011; Zec, 2011). Strategic design helps companies to implement innovation strategies and becomes essential in increasing strategic challenges.

2.2 Organisational anchoring of design in a business context

How Design is situated in a business context, highly depends on its corporate understanding. The main difference in dealing with design is whether the business disposes of an own design department or working with an external design agency.

Operating with design is hardly successful when it's isolated from other disciplines, as it only works in conjunction with other departments (Best, 2011). Design does not create value as a stand-alone activity. It has to be able to work company-wide to overcome the silo organization and meet customer expectations (Rae, 2016). Every touchpoint of user and company has to meet the customer expectations. This requires a greater collaboration of departments (Micheli, 2014).

Using design as a way of product differentiation is also publicly known in economics, even if design was not included in internal economic dynamics for a long time. Design creates additional benefits for consumers that the product is given a value that is not defined by its price. Especially in times of technical convergent products, design is attributed an increasingly important role as a purchase argument (Zec & Jacob, 2010).

However, design needs an organisational anchoring. This can be seen as the activity of grounding and aligning design aims and goals in the organisation's structure, culture, needs, and aims. On one hand, the way of organising design within a company often defines how design can be used. On the other hand, how design is organised in a company is significantly influenced by the understanding of design. Very rarely design gets as much attention to be able to influence strategic decisions on management level. It requires certain organisational structures for design to operate as an element of corporate strategy.

2.3 Measuring the business value of design

There are several studies trying to examine the value added by design, showing that there is a positive correlation between the use of design and improved economic performance (Sheppard et al., 2018; Wescott et al., 2013). Research shows that managers feel a desire to quantify the value of design to prove the advantage of strategic design scientifically (Best, 2011). However, none of the existing approaches about the quantifiability of design contains a real key figure to show the value added (Rae, 2016).

The significance of these approaches trying to examine the value of design remains questionable as long as the criteria for determining an average to design-led company are not openly defined. In view of the inability to define design, how can it be measured and how can something be managed without it being measurable? For quantifying the value of design, it seems to be necessary to integrate design in a corporate understanding while convey design's success (Zec, 2011).

The use of design depends largely on the importance that is attached to design in the company. Therefore, different approaches as the Design Ladder (McNabola, 2013) have been analysed during the research to classify the maturity levels of design usage. The surveyed companies were asked to classify themselves into one of the four different steps of Non-Design, Design as Form-Giving, Design as Process and Design as Strategy (Danish Design Center, 2016). The Design Ladder is a useful tool to classify the current state of design in the company and is widely known in literature and practice (Wolf, 2009). The basic assumption is that a positive correlation between design and economic performance occurs (Danish Design Center, 2016). This relationship has been confirmed by Baars (2018), showing that some success criteria such as market position and return on invest increase with a higher position in the Design Ladder. However, a study by the British Design Council (2008) reveals that almost 70% of the companies surveyed do not measure a Return on Design Investment (RODI).

2.4 Challenges of strategic implementation of design

There was a movement to integrate design within the slogan „Design is a boss' job" into *top management and leadership positions* in the early 1990s (Topalian, 1990; Topaloglu & Er, 2017). The concept of Design Management has already attracted some attention in the 80's. If design is understood as a "bosse's job" it is directly connected to the beliefs and opinions of the management team and is therefore very dependent on just a few individuals in a firm. Designer as leaders need to be visionaries, as Otl Aicher or Steve Jobs once showed in an exemplary way. Designers need to be able to work interdepartmental speaking one language with other departments to advertise design internally (Micheli, 2014). A well realized design leadership improves the experience of each individual with the company (Dawton, 2011).

Another fundamental challenge in dealing with design is the *clash of two cultures* in form of economy and design (Best, 2011). While the university environment already

separates business economists and designers, it is extended to the working environment. The cultural peculiarities may cause the huge differences within firms in terms of views and perception of design as value creating. While some are degrading design as a simple form-giving process, others understand it as a differentiated way of organizing customer needs, as a process or even as a strategic tool (Best, 2011). The more design is integrated into corporate culture and the whole process of product development, the more effect it possible (Micheli, 2014). To use design as a resource, it needs to be omnipresent (Dawton, 2011).

Moreover, designers lack the ability to justify and communicate the added value of design, as there is no possibility of quantification and designers mostly lack the economic references. Unfortunately, the result is a devaluation of the design profession and a reduced appreciation of the design process.

Companies recognize that breaking down disciplinary barriers leads to innovation and to a higher customer orientation. In contrast to this, traditional corporate value chains and the strict division of labour in an organisation places the customer not in the heat but at the end of the chain (Baars, 2018). A diversified form of organization has to develop in such a way to enable an integration of the customer. In addition, the organisation of individual silos has to be abolished so that a project-specific cooperation of all departments is possible. Usually, internal design departments or external design agencies are entrusted with design-relevant tasks, regardless of the value-added process of the product (Baars, 2018). Thereby, design is often considered as a downstream activity. Design-led companies where design is well integrated into the process of product development are still the exception (Avore et al., 2018).

The supposedly new method of design thinking offers a solution approach to product development in which products and corporate structures are developed in a customer-centered manner, which can provide companies a decisive competitive advantage considering saturated markets. Design can only be used interdepartmental and interdisciplinary to gain customer centricity and a strategic design application.

Designing the social, economical and cultural environment towards human requirements using the approach of human centered design results in a long-term improved business performance. Through the changing economy where experiences are becoming a distinct economic value, user experience designers (UX) are transforming the human-machine-interaction to create new customer experiences which are more and more becoming the product itself (Gruber et al., 2015). In this context, design is the essential tool to build an overall and consistent customer experience by designing each touch point of customer, product and company. Companies such as Google, Amazon or Samsung are best practice examples in creating vast consumer experiences.

Research Questions

According to these given assumptions and challenges the main research questions of the present paper are:

- How can a strategic understanding of design be developed in business contexts?
- How can design be fully embedded in economic value chains and the corresponding primary and secondary activities?
- What are predominant approaches to measure the value of design in business contexts?

3 Methodology

3.1 Research Design

To get information on the research question a qualitative study is undertaken, including structured in-depth interviews with firms from different branches and sizes in order to gather individual perceptions on the role of design in management (Kuckartz, 2016). We chose this qualitative approach because of its strengths in analysing contemporary and unique phenomena with little theory (Yin, 2003).

3.2 Data Collection

Data were collected mainly through semi-structured interviews, and wherever possible internal documentation. We conducted 6 interviews between October and November 2019. In the study focused on how the interviewees perceived design and its strategic role within their company. The interview questions revolved around the core issues of this paper, the companies' understanding and definition of design, the anchoring of design in an organisation, the applying of design in the value chain, the ability to quantify the business value of design, and the main challenges related with strategic design.

Two interviews were conducted face-to-face, while the others were guided by phone. The interviews lasted between 42 and 78 minutes and were recorded and later transcribed. Multiple perspectives were gathered (Eisenhardt & Graebner, 2007) from interviewees from different functions such as design management, brand management, corporate communications, product design, and strategy. Table 1 summarizes the six companies and the interviews.

3.3 Data Analysis

The interview transcripts were subjected to a content analysis for systematical examination being structured and analysed in six main categories. The following table (table 1) gives an overview of the interviewees and their main understanding of design. Currently six interviews are completed, differing in their use and understanding of design.

Table 1: Overview of interviews and companies included in case study

No.	Size of company (No. of employees)	Year of foundation	Branch/ industry segment	Products/ services	Position of interviewee	Gender of interviewee	Duration of interview	Type of interview
1	14.000	1923	Engineering	Equipment for sheet metal processing	Head of Design Management	f	42 min.	phone
2	216.000	1995	Telecommunication	Software, hardware, services	Head of Design, Team Manager	m	78 min.	Face-to-face
3	16.000	1862	Security industry	Access -, door-, lock systems, room systems	Head of Strategic Product Design	m	45 min.	phone
4	1.049	1950	Sanitary industry	Flow regulators for showers and washbasins	Leading Expert Scouting and Foresights	m	57 min.	phone
5	90.000	1870	Financial industry	Range of financial services	Head of Brand Communications and Corporate Social Responsibility	m	43 min.	Face-to-face
6	360	1930	Office supplies	Writing implements	Head of Brand and Product Strategy	m	59 min.	phone

4 Results

4.1 Understanding of design

It has been discovered that the definition of the term design is highly dependent on personal adjustment of which nobody can be convinced externally. Design is able to generate additional benefits and to influence purchase decisions in an important manner. The results underline the assumption, that there is no ’non-designed’ product. Especially in technic centered companies design is understood as form-giving, mostly without any strategic use. The understanding of design must detach itself from the image of pure product design in order to be recognized as a strategy. The changed definition of design can be seen as a shift in meaning from product design to the design of a scenario, which explains the transformation to an experience economy (Gruber et al., 2015).

Table 2: Main assumptions regarding the role of design

No.	Branch/ industry segment	Main assumption
1	Engineering	Design is important, but not fundamental to an engineer-led business.
2	Telecommunication	Design is the most important instrument for customer centricity.
3	Security industry	Uniform product design is most essential.
4	Sanitary industry	The understanding of design must evolve with the spirit of the times.
5	Financial industry	Design can influence everything and is much more than just product design.
6	Office supplies	Every human decision is influenced by design. Design needs to be evaluated in its very own context.

4.2 Organisational anchoring of design in a business context

Most companies within the survey did not have an own design department but are working with external design teams, notwithstanding the fact that they are mostly design centered companies. The findings show that the organizational anchoring of design is not necessarily an indicator of a strategic design use. Furthermore, participants report that design is used in marketing and sales department, recognizing a strong connection between design and the technology development, in which above all methods of design thinking are used. Strategic design requires interdisciplinary cooperation and needs to be supported at management level to have strategic impact. The study approves the assumption that design needs to be established in the corporate strategy, but the greatest relevance is assumed in convincing employees – especially middle managers – of the added value of design and affect the corporate culture accordingly. In addition, a design manager could facilitate in guide design centricity.

The respondents argued, that design is mostly used as a factor to differentiate in Marketing and Sales, or to develop an own Corporate Identity. Apart from that, Design Thinking is widely known as a tool for product and technical innovation. The Human Resource Management uses design as a competitive advantage for Employer Branding within the War of Talents.

4.3 Measuring the business value of design

One of the main assumptions is, that the management level needs to be convinced of the value through design by (financial) metrics. However, design cannot be distinguished from other disciplines due to a lack of a uniform understanding of design and is therefore difficult to measure (Micheli, 2014). Participants see a positive correlation between design and business success, but none can quantify the share of design in the company's success, as there are many factors having an impact on business performance. The meaningfulness and thus the persuasive power of an indicator for the representation of added value through design remains still questionable. The results do not clearly answer the question if key performance indicators may or may not contribute to a changed perception in dealing with design. In fact, there is some evidence, that tangible examples

have a comparable effect to performance indicators if they are both meaningful and emotional. For example, when the company can record a substantial decrease of complaints or product returns simply by modifying the design of products and processes.

5 Limitations

The study followed a qualitative empirical approach including six in-depth interviews with long durations. One major limitation of our study is, that we were only able to picture a very limited excerpt of branches and company sizes. Therefore, the study is not representative, as we could have shown numerous of more examples of how design is used. Furthermore, the positions of the surveyed were limited for the same reason. Future research could try to counteract this limitation by a quantitative research. We rely on our participants telling the truth without being prejudiced by their companies view.

6 Conclusion

Strategic design not only contributes to product appreciation, it also enables companies to achieve a customer focus as well as a holistic customer experience that has to be the main aspect of every business. From a managerial perspective design is able to interlink different abstraction levels in a firm, when connecting the corporate vision and sensemaking with product development and customer service.

Designers are taught to understand the customer as the starting point of each problem-solving process. Therefore, the 'image problem' of design should be tackled. This can only be solved by establishing a new understanding of design and thus a new design culture. Managers should also strive to establish a common understanding of what design is, for example through an individual, company-wide definition. This may prevent that designers constantly have to defend themselves when collaborating with other departments.

With regard to the measurement of design value, the establishment of a strategic understanding of design in a business context depends on individual and personal attitudes and therefore can barely be justified by a simple number. Nevertheless, a figure representing the added value of design could contribute to the conviction of some people, managers in particular, but it can hardly provide the decisive argument. Managers should be aware, that design is and will remain an emotional subject, which importance could best be illustrated by success stories and not only by key performance indicators.

Saturated markets require a constant measure of innovation, which is fundamentally promoted by design. While management directs internal processes and strives for continuous optimization, strategic design enables the fundamental value creation of a company. The optimization of processes and the general management of the company is limited, so strategic design is needed to generate an added value (Baars, 2018). Only a collaborative approach of design and management leads to a perfectly balanced problem-solving process. Especially technology-driven companies may benefit from a more

strategic understanding of design, given the fact that holistic user experience and not high-level functionality only becomes distinctive in global competition.

Abstract

Companies are burdened under information flow overload. The knowledge maps can support the knowledge workers and decision makers in this situation. Knowledge map as a term has been used with various meaning in several different scientific communities: not only in knowledge management, but also in education studies, in organization studies, in decision analysis, in artificial intelligence etc. To generalize the variety of the definitions (e.g. Eppler or Leibovitz) one can use the term of knowledge map as a description of the sources, flows, constraints and sinks of knowledge within the organisation. The current study considers knowledge maps from knowledge management perspective and is devoted to the generalising the numerous scattered knowledge mapping research and practices. It aims to identify and generalize the contents of knowledge maps - what are the main concepts, which are represented in knowledge maps, and relationships between them. The discussed research results in an ontology (or conceptual model, as it was defined by Gruber) for knowledge maps. Existing types of knowledge maps are associated with fragments of this ontology, so typical views and templates will are also highlighted. Such an ontology may help to select the necessary elements for knowledge mapping in specific company and situation. The research methodology is based on literature review, semantic analysis and ontological engineering.

[1] *The research is partially supported by grant 20-07-00854 by Russian Foundation of Basic Research*

The paper helps to clarify the content of knowledge maps, its' meaning and possible components. It provides building blocks for creating company-specific knowledge mapping templates and practice.

Keywords – Knowledge maps, Templates, Ontology, Semantics, Knowledge management systems

Paper type – Academic Research Paper

1 Introduction

Companies are burdened under information flow overload. Knowledge Map can help as it describes what knowledge is used in the company, and how it flows around the business processes. It is the basis for determining knowledge commonality, or areas where similar knowledge is used across multiple process (IBM, 2004). The knowledge maps as a graphical "description of the sources, flows, constraints and sinks of knowledge within the organisation" (Leibowitz, 2005) can support the knowledge workers and decision makers. Knowledge map as a term has been used with various meaning in several different scientific communities: not only in knowledge management, but also in education studies, in organization studies, in decision analysis, in artificial intelligence etc. (Eppler, 2008).

The current study considers knowledge maps from knowledge management perspective and is devoted to the generalising the numerous scattered knowledge mapping research and practices. It aims to identify and generalize the contents of knowledge maps - what are the main concepts, which are represented in knowledge maps, and relationships between them. "Knowledge management perspective" means that we do not include into the term "knowledge map" different knowledge diagrams – like mind maps, concept maps, flowcharts, etc. that just depict the main relations between the pieces of knowledge body.

The discussed research results in an ontology (conceptual model) (Gruber, 1993) for knowledge maps. Questions are associated with fragments of this ontology, so typical viewpoints and templates are also highlighted. Such an ontology may help to select the necessary elements for knowledge mapping in specific company and situation.

Research in knowledge mapping is not so young and started in late 90-ies. There are some generalizing works in this area, for example, overview of the concept (Wexler, 2001), classification of knowledge maps using different criteria (by purpose, by format, by content) (Eppler, 2008), systemic survey of knowledge mapping research (Balaid et al, 2016). There are also some methodologies and frameworks with knowledge maps structure and templates (Harper, Trees, 2018; Hubert, Trees, 2018). But there is no surveys devoted to the content ("what") of knowledge maps, which analyse examples and templates of knowledge maps in order to identify possible components and building blocks of a knowledge maps. This research fills an aforementioned gap.

2 Research methodology

Our research methodology is based on literature review, semantic analysis and ontological engineering. Existing templates and examples of organizational knowledge maps from literature are analysed using semantic analysis – the main concepts, which are represented in knowledge maps, and relationships between them will be extracted. Methods of ontological engineering (Suárez-Figueroa et al, 2012) are used for establishing a unifying ontology (conceptual model) for knowledge maps. Such ontology development represents an example of design science research, which "extends the boundaries of human and organizational capabilities by creating new and innovative artifact" (Hevner et al, 2004).

The research process is represented at Fig. 1.

Research start from the analysis of existing types of knowledge maps and their classifications (section 3). This analysis helps to select knowledge map examples and templates for further specification. Literature review is the main method at this step.

Ontology development in section 4, on one hand, follows classical logic (requirements specification, knowledge reuse, conceptualization etc.), but, on the other hand, is mostly driven by the idea of pattern-based ontology design (Presutti et al, 2012). Specifications of content for the selected knowledge map examples and templates – information models or metamodels – can be considered as content ontology design patterns ("content patterns) for creating an ontology of knowledge maps.

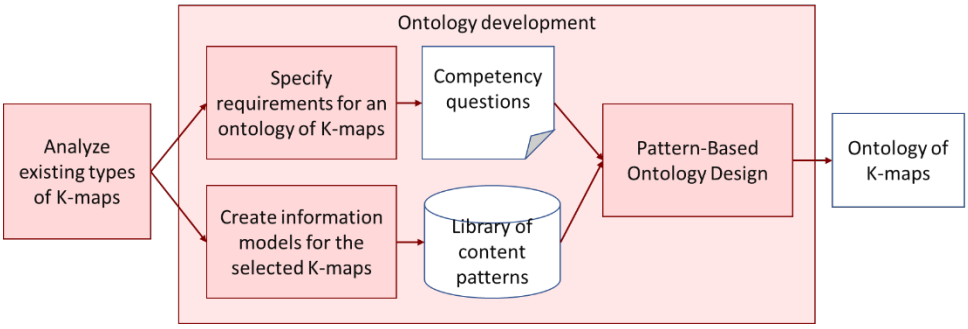

Fig. 1. Research process of the study

3 Analysis of existing knowledge map types

A number of different typologies of knowledge maps have arisen during the last two decades. The early developed ones have inconsistent classification parameters or describe only small part of the knowledge maps variety. Further we focus only on several mature classifications, namely (Eppler 2004), (Eppler 2008), (Hubert 2018).

The classic of visual approach to knowledge management Martin J. Eppler proposes several extensive classifications of knowledge maps. One of the most practical ones is (Eppler, 2004) which includes:

1. Knowledge source maps (where the knowledge is),
2. Knowledge asset maps (what kind of knowledge we have),
3. Knowledge structure maps (how the knowledge is interconnected),
4. Knowledge application maps (which knowledge is needed for the certain process),
5. Knowledge development maps (how certain competence is developed).

It can be noticed that only the set of the mentioned maps tells a convincing story about the organizational knowledge. Moreover, this set is not complete and priority of a certain map over the other may be defined only in the organizational context. In his later work Martin Eppler criticized this classification: "The main problem with this classification is that it is not comprehensive, versatile, or precise enough to be of general use in knowledge management" and suggested a new one (Eppler, 2008) – more precise, rigid and formal.

New Eppler's classification of knowledge maps is multi-faceted (Eppler, 2008) – it includes several simple classifications, which are created based on different classification principles or facets:

A. by intended purpose or KM process (''why?''), which includes knowledge identification maps, knowledge assessment or audit maps etc.
B. by content, which is represented in the map (''what?''): by *content format* (blogs, books, repositories, online courses, etc.) and *content type* (methods, experts, processes, departments, lessons learned, concepts, events, skills and competencies, patents, knowledge flows, and knowledge needs);
C. by graphic form for representing the map (''how?''): includes all spectrum of visuals from matrixes to metaphors
D. by their creation method (''how?'' and ''who?'') - from community generated maps that are constantly revised and refined by map users to automatically generated maps;
E. by the level, at what the map is applied (''who?'').

Facet A (by purpose) includes types, which intersects with the first Eppler's classification.

Facet E (by the level) is common for Eppler's and APQC's classifications what distinguish the organizational level at which the map is applied: personal, dyadic, team, departmental, community, organizational, inter-organizational levels in (Eppler 2008); enterprise, cross-functional, process- and role-based levels in APQC (Hubert 2018). At the enterprise level APQC recommends focusing on fit between strategic goals and organizational knowledge using Strategic Overview Map and on knowledge at risk in Expertise Overview Map.

At the next level, the maps help to identify knowledge (Expertise tacit map) and to understand potentials and gaps (Technical/Functional knowledge map). Lastly, at the process- and role-level APQC suggests identifying needs and sources of knowledge via Process-based map and Job/Role-based map. Another type of knowledge map at this level

is Competency/learning needs map. As the title implies, this map outlines learning needs for a certain task.

Another typology of knowledge maps is suggested by Novins (1997):

a) pointer models (points to the correct source, usually a person),
b) linkage models (adds some meta information on the sources),
c) solution models (relates knowledge areas to business problems).

Table 1. Some examples of knowledge map types and their content

Name of the map	Content	Source
Knowledge application map	knowledge, processes or steps	(Eppler 2006)
Knowledge source map	experts, competency areas, business areas, geographical location	(Eppler 2004)
Knowledge assets map	stock of knowledge; an individual, a team, a unit, or a whole organization	(Eppler 2004)
Knowledge assessment or audit map	knowledge asset, current ability, future importance	(Eppler 2006)
Knowledge identification map	experts, patents, practices and their location/coordinates	(Eppler 2006)
Knowledge assets map	location of important knowledge assets	(Gilbert et al. 2000)
Cross-functional knowledge map	functional or technical knowledge, expertise in tacit knowledge	(Vestal 2005)
Process-Based Knowledge Map	process, activity, knowledge needed, format of knowledge, knowledge gap	(Hubert 2018)
Job / role based map	Jobs, roles, specific knowledge	(Hubert 2018)
Expertise overview map	knowledge in various parts of business, knowledge at risk	(Hubert 2018)
Knowledge assets value creation map	knowledge asset, performance objective, general objective	(Carlucci 2007)

4 Ontology of knowledge maps development

4.1. Competency questions

The analysis of different types of knowledge maps helped to specify questions, which may be answered using knowledge map. These questions can be considered as competency questions, which define functional requirements for ontology engineering:

A. What kind of knowledge company have?

- What are the (main) knowledge assets?
- What are the (main) topics/areas of company's knowledge?

- What are the types of company's knowledge?

B. Where knowledge is used and what knowledge is needed?

- What knowledge is required for performing certain activities?
- What knowledge is required for producing certain products and services?

C. What are the sources of knowledge?

a. Which person or role owns knowledge?
b. In which organizational unit knowledge can be found?

D. How necessary and current knowledge can be assessed?

a. What is the level of importance of any specific knowledge?
b. What is the size of the gap in any specific knowledge?
c. What is the level of expertise in any specific knowledge?

E. How knowledge is exchanged?

a. What knowledge is exchanged between persons?
b. What knowledge is exchanged between organizational units?
c. What knowledge is exchanged between information systems?

F. How knowledge will be created/acquired/developed?

a. What are the stages of knowledge development?
b. What is the learning path or a roadmap?

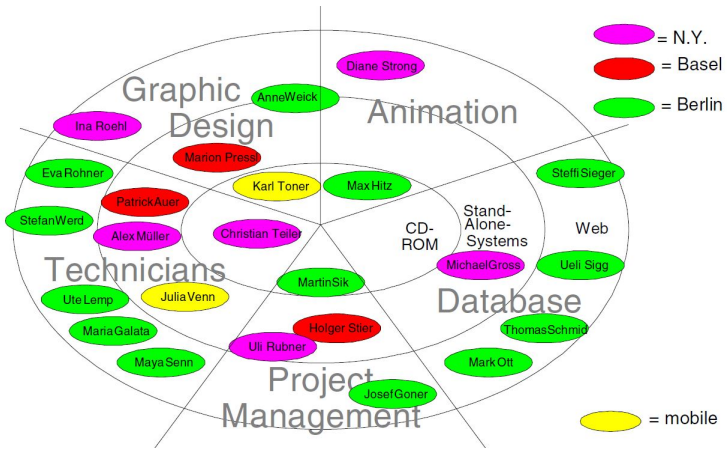
4.2. Specification of knowledge maps content

Specifications of content for the selected knowledge map examples and templates – information models or metamodels – can be considered as content ontology design patterns ("content patterns) for creating an ontology of knowledge maps.

Figure 2 demonstrates an example of information model, which specifies the contents of knowledge source map.

a) Example of knowledge source map

Source: (Eppler, 2004)



b) Information model (metamodel) for the knowledge source map

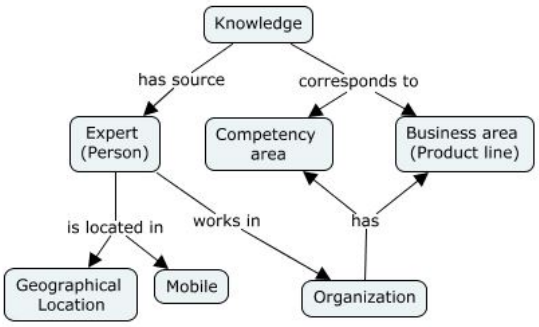


Figure 2. Example specification of knowledge maps content

4.3. Ontology of knowledge maps

According to (Presutti et al, 2012) the idea of pattern-based design implies that "the ontology project is divided into the problem and solution spaces. The problem space contains a set of requirements (see Competency questions), while the solution space contains a set of ontology-design patterns. The two spaces are compared in order to identify patterns matching the requirements." Then relevant patterns are selected and combined.

Fig. 3 shows the preliminary version of an ontology of knowledge maps. High level groups of concepts are aligned with competency questions.

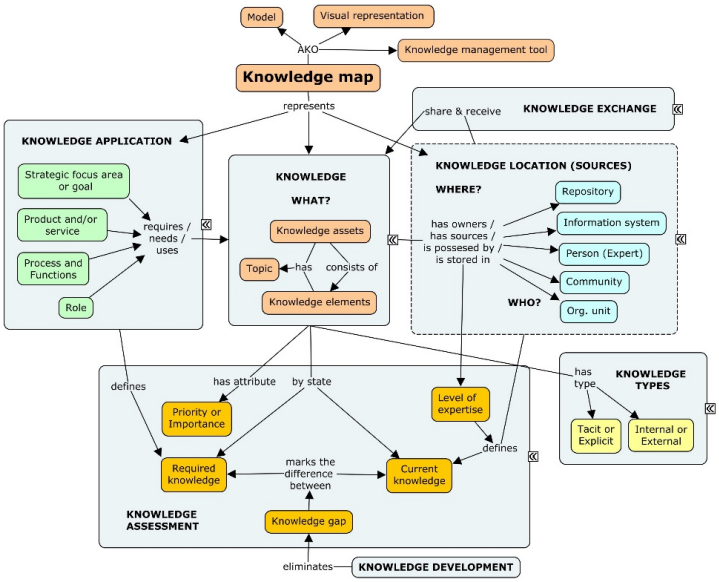

Figure 3. Ontology of knowledge map

Figure 3 generalizes the above described features and classifications of different knowledge maps into the skeleton of the ontology. This ontology gives the broader and deeper understanding of knowledge mapping techniques

5 Conclusion

For the last twenty years knowledge maps take into account the who, what and why of the knowledge mapping process. Best professional knowledge maps help identify intellectual capital, socialize new members, enhance organizational learning and help anticipate impending threats and opportunities (Wexler, 2001).

Knowledge mapping helps in the process of the continuously evolving organizational memory, capturing and integrating strategic explicit knowledge. This process takes place within a company or institution and between it and its external environment (Wexler, 2001). K-mapping may also support the learning within the company as it enhances and enriches the visibility of knowledge structure.

This paper and designed ontology helps to clarify the theory and practical content of knowledge maps, its' meaning and possible components. It provides building blocks for creating company-specific knowledge mapping templates and practice. In the context of digital era the created ontology may improve the design of information system for knowledge mapping and integration of this system into overall organizational IT architecture (Oberle, 2014).

In the context of digital era the created ontology may improve the design of information system for knowledge mapping and integration of this system into overall organizational IT architecture (Oberle, 2014). In addition, it ultimately enhances the cognitive comprehension and the deeper understanding.

Abstract

This research will show the value chain profiles of microenterprises in emerging countries in the dimensions of planning, installed capacity, maintenance, research and development, and procurement.
The sample used included 120 microenterprises from various productive sectors in the south of Ecuador. Data collection was carried out in 2019, by means of an online questionnaire, sent by e-mail through the Business Observatory of the UTPL to the managers and/or directors of the microenterprise. To identify possible groups of microenterprises, cluster analysis was used; a technique that allows identification of groups with similar characteristics, previously used to study configurations in microenterprises.
The present authors hope that the findings will contribute to the resource-based view (RBV), by characterizing the profiles of microenterprises according to value chains, in the particular context of an emerging economy such as Ecuador.
The determination of the number of profiles, characteristics, and needs of microenterprises will serve public managers for decision-making, helping to more efficiently target the resources and efforts needed to develop local microenterprises.

Keywords – value chains, business performance, cluster analysis, SMEs, Ecuador.

1 Introduction

Currently, Ecuadorian microenterprises compete at a disadvantage against global companies, with regard to innovation, human capital, knowledge, and technology development. Compared to other Latin American countries, Ecuador has an incipient degree of innovation, ranking 99th after Chile (51), Uruguay (62), Brazil (66), Colombia

(67), Peru (69), Argentina (73), and Paraguay (95); surpassing only Bolivia (Global Innovation Index 2019).

To reduce such competitive gaps, microenterprises need to take action to improve value chains and develop competitive capacities. The analysis of these chains enables identification of the main activities that develop value for customers and company, in order to contribute to the improvement of the activities in an efficient and effective way (Porter, 1985). Understanding the situation and the need of the customer together with the right supply enables improvement of the joint demand chain, leading to higher efficiency of the demand chain, and high customer satisfaction (Heikkilä, 2002).

Analyzing value chains, the present study recognizes that not all companies are equal. The existing differences in productive activities, marketing channels, and types of leadership require specific analysis and solutions; therefore, it is not possible to build a proposal and solution for all, with the priority being to characterize microenterprises.

Analysis of the value chain as a strategic planning tool aims to maximize value creation and minimize costs through the classification of the activities that generate value in an organization being the "primary activities", including inbound logistics, operations (production), outbound logistics, marketing and sales, and services (maintenance). The "support activities" include infrastructure, administration, human resources, research and development (R&D), and acquisitions.

Several studies have analyzed the components of the value chain and their impact on performance. For example, the empirical study conducted by Baihaqi & Sohal (2013) of 150 manufacturing industries in Australia analyzes the influence of supply chains on organizational performance through the following four variables: internal integration practices, information technology, information quality, and cost-benefit sharing. Additionally, by using the structural equation model, it demonstrates that technology and information quality positively influence the intensity of information exchange, while internal integration and costs are not related to business performance. On this theme, the study by Perona & Saccani (2004) analyzes how to manage the processes of the value chain in customer-supplier relations for the household appliances industry in Italy. This descriptive study, carried out with the application of questionnaires, in-depth interviews, and the use of integration techniques in three domains—operation management, technology management, and strategic planning—qualitatively verified the level of integration in customer-supplier relations for four household appliance industrial groups. Green management in the supply chain was analyzed by Holt & Ghobadian (2009) in their study applied to 60 companies in the UK manufacturing sector, where the authors identified three factors influencing the supply chain—legislative pressures, leadership committed to the environment, and the social factor.

The previously stated studies focused on a single segment of the value chains of companies: backward (suppliers), during the process, and forward (marketing); including, analyzing a single sector of productive activity, as observed in the research by Perona & Saccani (2004). Therefore, there is a great opportunity to work with all of the activities

for a country not yet properly explored. Additionally, in a preliminary search carried out in the preparation of the present study, no relevant work on the profiles of value chains in microenterprises in Latin America and Ecuador were found.

To close this gap, the present study seeks to answer the following questions: What are the profiles of microenterprises in southern Ecuador according to the behavior of value chains? What are the most frequent value dimensions in microenterprises based in Loja? And finally, what are the value chain configurations in competitive companies?

To answer the questions posed, the theory used will be the resource-based view (RBV) (Barney, 1991), suitable for this type of study and unit of analysis (microenterprise). This theory has been used in similar research, such as that developed by Rosca & Bendul (2019) and Parast (2019).

2 Conceptual background

2.1. Ecuadorian microenterprises' challenges for productivity

Productivity is the main creative force of prosperity. In a globalized world, competitive advantage prevails as a means for businesses to grow and position themselves in the markets. Productivity determines the degree of efficiency with which resources are used in organizations and countries *(Cooper, 2004)*.

An increase in productivity is largely explained by technical progress and knowledge development. Improving productivity in Ecuador is one of the main objectives of the productive sectors and is a major factor in determining the economic growth and development of countries.

In Ecuador, the degree of productivity and innovation of microenterprises is low compared to the rest of the world and Latin America, and there is currently high pressure to improve productivity levels due to competition and the internationalization of economies. Therefore, organizations plan and define both short and long-term strategies to be, and remain to be, competitive in domestic and international markets. *(*Global Innovation Index 2019*, s. f.)*

Ecuador, ranking among the last places (99) in the Global Competitiveness Index (*Global Innovation Index 2019*, s. f.) pursues a great challenge of reducing these gaps, which may in principle seem unattainable due to the unequal competition between small, medium, and large companies.

The Ecuadorian business network is predominantly made up of microenterprises (94%), and the cost of acquiring raw materials, production, and marketing is high compared to larger companies. It is therefore necessary to improve productivity, considering that not all companies need the same measures to grow and conquer local and regional markets because they are different.

Today, planning, technology, and innovation play an important role in global business management, becoming fundamental tools for companies to be effective, efficient, and

competitive. Ibujés Villacís & Benavides Pazmiño (2018) point out that the use of technology has increased the productivity of small and medium-sized enterprises (SMEs) in the textile industry in Ecuador, hitting quality standards and being more competitive in the global market.

2.2. The role of value chains in business competitiveness

In Ecuador, analysis of value chains has not been considered as a planning tool for microentrepreneurs to increase levels of competitiveness. Microenterprises cannot survive alone in a globalized world, and even more so, close relationships and coordination between the different activities of the value chain are required to be competitive (M. Lewis & Slack, 2003). To achieve greater growth, companies must coordinate effectively in the development of new products and strategic planning (Perona & Saccani, 2004).

Analysis of the value chain as a strategic planning tool aims to maximize value creation and minimize costs, through classification of the activities that generate value in an organization as "primary activities", which include inbound logistics, operations (production), outbound logistics, marketing and sales, and services (maintenance); and "support activities", which include infrastructure, administration, human resources, research and development (R&D), and acquisitions (Porter, 1998).

Reducing costs, increasing the quality of products, and being more competitive must be the result of making decisions based on the analysis and evaluation of all activities that involve the production process that generate value. Studies such as that carried out by Bayhaqi and Sohal (2013) of 150 Australian manufacturing firms show that considering only a part of the supply chain is not enough—the exchange of information is essential, but insufficient by itself to achieve significant improvements in the performance of the company. On this theme, the study by Perona & Saccani (2004) analyzes how to manage the processes of the value chain in customer-supplier relations for the household appliances industry in Italy.

However, most microentrepreneurs are not prepared to identify, plan, and manage the main activities that develop value for customers; they often start business activities ignoring many of the key dimensions of managing a business and must obtain the necessary skills to survive (Shepard et al., 2000). The importance of entrepreneurial skills, such as innovation and risk-taking, should not be overlooked as essential ingredients for the success of SMEs, according to Nieuwenhuizen and Kroon (2002) and cited by Urban & Naidoo (2012).

Ecuadorian microenterprises need to develop managerial skills that allow them to be more innovative and thus more competitive (Diaz-Villavicencio et al., 2016), but not in isolation. Collective learning and relationships of trust can also reinforce the growth and development of clusters, and businesses within them (Niu, 2010).

Hence the need to characterize microenterprises according to the criteria of planning, installed capacity, maintenance, research and development, and procurement. By grouping together, companies appear to be able to draw from a common and accessible set of resources, information, and demand for innovation in order to improve skills and create global competitive advantages (Niu, 2010).

3 Research methodology

3.1 Sample

The information was obtained in the city of Loja, capital of the province of the same name, located in southern Ecuador. The region has 442 microenterprises (Superintendency of Securities and Insurance Companies, 2017). The microenterprises considered were those that met the criteria of an annual sales volume less than US$100,001, while the number of persons employed being equal to or less than nine workers (regulation of the Trade and Investments Production Code, 2010).

Ecuador was chosen as it is an emerging market, highlighted by low individualism, high uncertainty, and high power of hierarchy expressed in the degree to which the less powerful states in a society accept and expect that power is distributed unevenly, whilst also accepting and respecting a hierarchical order in which everyone has a place (Hofstede, 2011).

For the identification of microenterprises, the present authors were supported by the Business Observatory of the Private Technical University of Loja (UTPL), who provided the database for this research.

Data collection was carried out during the months of September and November 2019, with an online questionnaire used as the data collection instrument, sent by e-mail through the Business Observatory of the UTPL to the managers and/or directors of the microenterprises. The link for the survey was accompanied by a message to encourage participation, with the present authors committing to publish the final results. Participation was encouraged through telephone calls and personal visits to microentrepreneurs. One hundred and twenty surveys were collected from 442 microenterprises in various sectors, representing a response rate of 27.15%. Then, 40 responses were excluded for presenting incomplete information, resulting in a total of 80 useful surveys for analysis.

The industries best represented were wholesale and retail (20%), information and communication (17%), administrative and support services (17%), manufacturing (8%), real estate (7%), teaching (7%), and others (24%), reflecting the significant productive sectors in the city of Loja.

3.2 Measures

To measure the value chain planning variable, five items were considered. Three of them related to production, materials, and demand forecasts, taken from Robinson & Pearce (1983) and Richbell et al., (2006). The fourth item related to demand flexibility by, Vickery et al., (1999) and the fifth to quality and competitive costs Bowersox D, Closs D, & Cooper B., (2002).

Installed capacity was measured with four items related to planning, maximum capacity, customers, and costs; the same items that were taken from Porter (1985).

The maintenance stage consists of four items related to preventive and corrective maintenance of microenterprises, according to Baihaqi & Sohal (2013). For the measurement of items, maintenance training, and an insurance system against fires or other incidents, the work of Ambulkar et al., (2015) was considered.

To measure technology in microenterprises, five items related to human talent, marketing, administration, finance, and service delivery were taken from Ernst, Hoyer, & Rübsaamen (*2010*), while for innovation; service, processes, marketing, and organization were taken from Dávila et al., (2019), Ibujés Villacís & Benavides Pazmiño, (2018) and Weerawardena & Julian (2006).

Finally, measurement of the four items of supply or raw materials and services supply chain was carried out considering the new trends that seek to reduce the costs of logistics and supply chain as described by Bowersox d, Closs D. & Cooper B., (2002).

All items used in the survey have a Likert scale of 5 points, with values of 1: totally disagree, 2: disagree, 3: neither agree nor disagree, 4: agree, and 5: totally agree.

3.3 Method of analysis

To identify possible groups of microenterprises, cluster analysis was used; a technique that allows identification of groups with similar characteristics which have previously been used to study configurations in microenterprises, (Weijland, 1999). The procedures and best practices described by Ketchen and Shook (1996) were followed. Calculations were supported with R studio software.

For the grouping, the variables of planning, capacity, maintenance, technology and innovation, and procurement were used, followed by the comparison of business performance.

First, hierarchical grouping was applied to determine the appropriate number of groupings. Then group centroids of the hierarchical procedure were used as initial grouping seeds to perform the k-means grouping procedure.

To explore the differences of the identified groups, the usual unidirectional ANOVA and a post hoc criterion (Tamhane T2, at $p<0.05$) were used, since the sizes of the groups were unequal (Moder, 2010).

4 Results

To identify microenterprise groups, the present study followed the two-step clustering procedure recommended by Ketchen & Shook, (1996) and Hair, Black, Babin & Anderson, (2010). First, hierarchical clustering was performed to determine the appropriate number of groups. In this study, Ward cluster and complete linkage solutions were applied, as suggested by Ketchen & Shook, (1996). Both methods suggested four cluster groups as being optimal.

Then, group centroids from the hierarchical procedure were used as initial grouping seeds to perform the k-means grouping procedure.

Table. Microenterprise groups according to analyzed variables

	Cluster averages			
	1	**2**	**3**	**4**
Cluster variables				
Planning	3.87	1.00	3.81	4.41
Installed capacity	2.74	1.00	3.27	4.11
Maintenance	3.34	1.00	3.92	4.41
Technology	4.27	1.00	2.75	4.53
Innovation	4.18	1.00	2.84	4.31
Dependent variable				
Business performance	3.56	1.80	3.39	3.99
Cluster size (N)	23	3	24	30

The solutions were consistent, which shows that the grouping was robust. The analysis of selected variables is presented below.

Significant differences between the four groups of microenterprises analyzed were found, as evidenced by the F test: F (3.76) = 38.43, p= 0.000 for planning; F (3.76) = 31.84, p= 0.000 for installed capacity; F (3.76) = 21.21 , P= 0.000 for maintenance; F (3.76) = 56.21, p= 0000 for technology; and F (3.76) = 42.14, P= 0000 for innovation.

4.1 Relationship between the analyzed clusters and organizational performance

After verifying that the microenterprise groups were statistically different, the study verified whether or not the performance of the clusters was statistically significant for the groups. The F test F (3.76) = 5.451, p= 0.0018 was employed for the performance level. Table 2 shows the results of the *post hoc* analysis which confirms that Group 2 was statistically smaller than Groups 1 (p=0.01), 3 (p=0.02), and 4 (p=0.01). Group 4 was greater than Group 3 (p = 0.02). There was no significant difference between Group 1, and Groups 3 (p=0.17) and 4 (p = 0.07).

Table 2. Comparison of performance averages of the analyzed clusters

Cluster (i)	Business performance (annual average)	Cluster differences (i-j) (p-values in parentheses) Cluster (j) 1	2	3	4
1	3.56	-			
2	1.8	1.76 (0.01)	-		
3	3.39	0.24 (0.17)	-1.58 (0.02)	-	
4	3.99	-0.42 (0.07)	-2.78 (0.01)	-0.58 (0.02)	-

4.2 Interpretation of identified clusters

Figure 1 shows the differences between the clusters. To facilitate the comparison and interpretation of the data in this study, the clusters were identified as Cluster 1 *"value chain medium*", Cluster 2 "*value chain deficient*", Cluster 3 "*value chain low", and* Cluster 4 *"value chain high*".

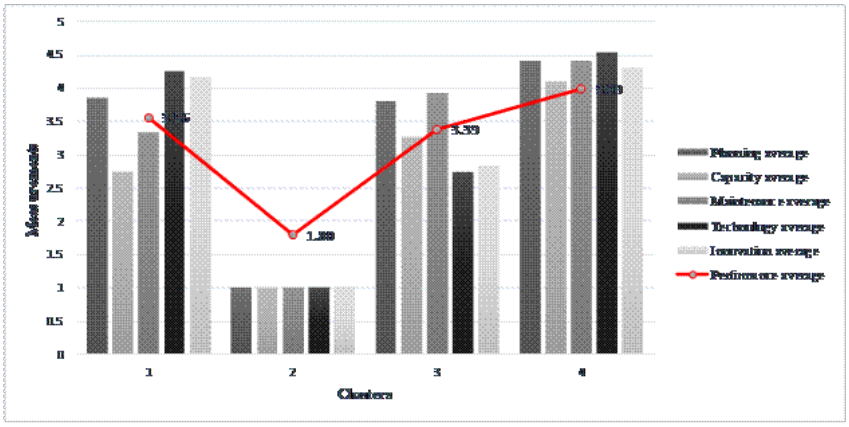

Figure 1. Cluster attributes

Cluster 1 ***"value chain medium"***—microenterprises in this group had the second highest scores in planning (3.86), technology (4.27), and innovation (4.18), after Cluster 4. Regarding the capacity (2.74) and maintenance (3.34) variables, Cluster 1 was in third place after Cluster 4 and Cluster 3. However, it was the group with the second best business performance (3.56). The productive activity of this cluster focuses on the following four sectors: wholesale and retail trade (26%), information and communication (22%), education (3%), and administrative services (3%).

Of the cluster, 22% is characterized by being made up of family-owned enterprises. In addition, the managers are partners or shareholders of microenterprises in 74%, and have a high level of higher education, also in 74%.

Cluster 2 **"*value chain deficient*"**—the microenterprises that made up this group had the lowest scores of the six variables analyzed with an average of (1). For performance, it scored (1.8). The productive sector is focused on professional, scientific, and technical activities; information and communication; and wholesale and retail trade.

Family businesses account for 33% of the group and the managers have a higher education level of 66%. Like Cluster 1, managers are partners or shareholders of microenterprises (67%).

Cluster 3 ***"value chain low"***—the 24 microenterprises of this group were positioned third when considering performance with 3.39, and were characterized by high planning (3.81), capacity (3.26), and maintenance (3.93) values. The cluster also ranks third for technology (2.75) and innovation (2.83). The productive sectors in this group were dispersed, highlighting administrative services, information and communication, health care, and manufacturing all with 17%, and wholesale and retail with a 13% share.

Family-owned enterprises accounted for 16%, managers were partners or shareholders of microenterprises in 83% and the level of higher education was (66%).

Cluster 4 ***"value chain high"*** consisting of 30 microenterprises was characterized by high levels of performance (3.99), derived from the correct use of administrative tools such as planning (4.41), capacity (4.11), maintenance (4.41), and use of high levels of technology (4.53) and innovation (4.31). Productive activity was divided into administrative services (27%), wholesale and retail trade with 20%, real estate (10%) and information and communication (10%).

Family businesses accounted for 6.67%, and 83.33% of managers are partners or shareholders of microenterprises, with 73% being trained at higher education level.

These results lead to the following two important findings:

The first is related to innovation which is not a competitive differential for the microenterprises analyzed, although it is necessary to explain aspects of competitiveness. Innovation is widely recognized as a key factor in the competitiveness of nations and enterprises (Galia & Legros, 2004). Madrid-Guijarro et al., 2009 note that small enterprises which do not adopt innovation in productive activities run the risk of becoming uncompetitive, because their processes and products could become obsolete. The authors state that innovation management could be affected by barriers associated with costs or resistance from the manager or employees.

Empirical evidence from Madrid-Guijarro et al., (2009) and Kotey & Sorensen, (s. f.) conducted in SMEs in Spain and Australia identifies the barriers that prevent companies from accessing innovation, limiting them from remaining competitive.

Madrid-Guijarro et al., (2009) studied the relationship between product, process, and innovation management, and the obstacles to innovation; the most significant barriers were associated with costs, while the least significant were associated with the resistance

to change of the manager or employees of companies. The results in their study show that the impact of costs is greater in small businesses than in large organizations. Kotey & Sorensen, (s. f.) identified poor infrastructure, poor staff skills, limited access to finance, and political uncertainties as barriers that prevent innovation in the companies analyzed.

Therefore, SMEs in southern Ecuador, having small structures, have not assertively promoted the management of innovation as a necessary factor to improve competitiveness. High production costs, poor infrastructure, limited support from governments, and being located away from the main development centers of Quito and Guayaquil remain as possible limitations for this differentiation between business clusters.

A second finding is the existence of different configurations in the value chain that can lead to the same performance, as is the case with Cluster 1 and Cluster 3. In Cluster 1, the strategies focused on innovation and technology. The microenterprises in this cluster focused their strategies on learning the market, thus generating innovative activities that create superior value for the customers served (Weerawardena et al., 2006) in addition to technological innovation in the microenterprise operating environment (Chege et al., 2020).

However, Cluster 3 had a value chain of flexible capacity with the market, and a certain degree of resilience in maintenance to supply chain change as its strategies, allowing it to achieve similar performance to Cluster 1. These results are similar to those from studies by Vickery, S. N., Calantone, R., & Dröge, C. (1999) on the flexibility of production chains; they are also similar with a study by Ambulkar et al., (2015) on the degree of resilience to supply chain change. However, the two clusters have a good level of value chain planning in common, this being an essential link in the performance of the two clusters. Perona & Saccani (2004) showed in their study in Italy that adequate coordination in the development of new products with strategic planning enables companies to achieve greater growth and thus better performance.

Finally, education and previous experience are elements to be highlighted in the four business clusters of southern Ecuador for good business performance. Richbell et al., (2006) point out that there is a significant association between education and previous experience of small business owner-managers who explain the presence or absence of a business plan within the small business.

6 Conclusions

This research enabled the identification of microenterprises according to the value chains of emerging countries according to planning, installed capacity, maintenance, research and development, and procurement, contributing to the RBV theory.

In light of this analysis, in Loja, four profiles of microenterprises from southern Ecuador were identified according to the behavior of value chains, whose results show that innovation is not a differentiating factor in business performance, although it is a necessary requirement to explain aspects of competitiveness. There are also different

strategies available to achieve similar performance. Therefore, once the profiles of microenterprises were identified, knowledge and good performance could be enhanced with the help of universities and observatories.

The present research identified some limitations such as the distrust of microentrepreneurs to provide information, which decreased the number of observations and limited territorial reach to the city of Loja. It is therefore recommended to extend this research nationally and to other emerging economies, and to conduct research on the value chain and its impact on competitiveness.

Abstract

The objective of this paper is to explore the characteristics of a knowledge management system supporting an Engineer-To-Order manufacturing strategy in the context of small and medium-sized enterprises. For this reason, after the identification of a preliminary set of requirements, three in-depth case studies of Italian SMEs are discussed. The paper introduces an IT-based tool to support the knowledge management to enhance the performance of Engineer-To-Order manufacturing. The results of the paper could provide valuable guidelines for managers adopting a knowledge management system to foster knowledge management practices in the Engineer-To-Order business.

Keywords – Knowledge management, ETO, Information Technology, SMEs, case study.

Paper type – Academic Research Paper

1 Introduction

Engineer-To-Order (ETO) is a manufacturing mode for highly customised products which need to be designed and engineered in detail according to customer's specifications (Pandit and Zhu, 2007). Some of the common problems associated with the ETO processes resulting from high customisation are difficulties in estimating costs, lead-times and delivery dates, expensive rework due to late realisation of errors, material wastage, conflicts between project and manufacture schedules (Pandit and Zhu, 2007).

Most of the abovementioned problems have inefficient or ineffective information management and the difficulty of synergising the various parties involved in the process as the predominant causes (Pandit and Zhu, 2007). Therefore, there is the need to support better the generation, analysis, sharing and reuse of specialised and domain-oriented knowledge required by ETO information-intensive business processes (Pandit and Zhu, 2007). For this reason, Knowledge Management Systems (KMSs) can be adopted as a managerial platform to deal with the challenges involved by ETO. Indeed, due to the peculiarities of the ETO manufacturing strategy, the methods and supporting tools to handle the information flows from order receipt to product delivery and commissioning need to be carefully tailored (Adrodegari et al., 2015; Rahim and Baksh, 2003).

The necessity of knowledge-based solutions that can be translated into bespoke knowledge management tools is even more relevant when focusing on small and medium-sized enterprises (SMEs) adopting an ETO strategy. Research by Jami Pour and Asarian (2019) suggest that to enhance business performance, SME managers must define policy and practices to manage organisational knowledge. However, while there are many studies that analyse the processes of dissemination of knowledge and highlight the adoption of KM in large companies, as regards SMEs the framework of knowledge is still fragmented (Cerchione et al., 2016). In addition, the body of literature as well as the availability of commercial KM tools focusing on SME are relatively sparse and do not draw a picture of maturity and completeness (Kramer et al., 2017).

In order to overcome these gaps in the literature, this paper aims to explore the characteristics that a KMS should present to address the needs of an ETO manufacturing strategy in the context of SMEs.

2 Engineer-to-order and knowledge management

There is no general consensus in the literature on the definition of ETO. According to the definition by Willner et al. (2016), for the scope of this paper we will consider as part of the ETO category all those products ranging from the traditional "low volume, highly-customised" product to the product that requires limited order-specific engineering.

The ability to reduce lead times and costs, while providing high levels of customisation and flexibility are key components to ETO firms' competitiveness (Gosling et al., 2015; Birkie and Trucco, 2016; Cannas et al., 2018). ETO companies reply to invitations to

tender from potential customers. The tender includes information on product performance, price, delivery lead-time and commercial terms. Typically, 85-90% of cost is committed at the tendering stage (Hicks et al., 1999). The tendering success rate is often less than 30% (Konijnendijk, 1994; Hicks et al., 1999). The tendering process consumes engineering resources since it requires the preliminary development of the conceptual design and the definition of major components and systems (Hicks and McGovern, 2009). After the contract has been awarded, a detailed project planning would be required in order to ensure that jobs are completed in a timely manner. However, several authors highlight that among the main challenges ETO projects have to face there are the lack of planning and monitoring of design and engineering activities, while production is typically planned in detail, and the lack of an integrated approach to the management of all processes (Adrodegari et al., 2015). One critical issue is to accurately determine the engineering due date, and thus the order delivery date (Grabenstetter and Usher, 2014). Setting these dates represents a challenge also at this stage, since it would assume full knowledge of the product and the associated design, which is not available because the design for the ETO product has not yet been completed (Grabenstetter and Usher, 2014; Zennaro et al. 2019).

In ETO firms, the engineering process is the largest controllable consumer of lead time, using one-half of the total (Grabenstetter and Usher, 2014). The engineering process is a bottleneck core process (Amrani et al., 2010). Errors, ambiguities or misunderstandings in requirements definition at the design stage can commit substantial costs, which are realised during manufacturing and later stages of the product life cycle (Hicks and McGovern, 2009).

ETO manufacturing environments are very complex (Barbosa and Azevedo, 2019). Digital technologies are emerging as promising means for managing complexity. However, there is a lack of approaches focusing and addressing the needs of ETO environment (Adrodegari et al., 2015; Barbosa and Azevedo, 2019), and this is true also for the knowledge management domain. In particular, Adrodegari et al. (2015) identified a lack of IT support in particular for the two fundamental tasks of project management and planning.

Some authors have proposed IT tools for automated knowledge management. Among these, Kłos (2016) developed a KMS for ETO manufacturing companies based on ERP systems. Elgh (2011, 2014) developed a conceptual framework for modelling and management of product knowledge of systems supporting the design and manufacture of highly customised product variants. According to Elgh (2014) a KM tool for ETO should satisfy the following requirements: facilitate capturing, support structuring, enable storage, facilitate retrieval, support visualisation of text, figures and tables, include querying functionality, enable versioning control, include authorisation control, support relations to supporting documents, preferably reside upon an existing available tool. Mourtzis et al. (2014) developed a methodology for fast and accurate knowledge-based estimation of maintenance time for complex engineered-to-order products, based on Key

Performance Indicators (KPI) monitoring. Li et al. (2011) provided a review of knowledge-based systems that could support product knowledge identification, capture, representation and reuse during the processes of One-of-a-Kind product development. Among the most popular knowledge-based systems the authors identified Web-based, ontology-based, STEP-based, and case-based approaches.

3 Methodology

The methodology adopted in this research consists in a literature review followed by multiple in-depth case studies. The literature review presented in the previous section enabled the identification of a preliminary set of characteristics and needs of ETO companies. The following case studies empirical research had the objective to confirm, refine, and integrate literature findings. Therefore, we combined deductive reasoning with inductive theory building (Eisenhardt, 1989; Yin, 1994; Sousa and Voss, 2001). Three ETO manufacturers from different industry sectors participated in the study. Data collection was primarily based on a series of in-depth semi-structured interviews supported by observations, archival sources related to project documentation, and facilitated workshops over a period of approximately two years. Facilitated workshops had the objective to present the knowledge management needs and consequent IT tool requirements identified during interviews, and to collect feedback on possible refinements. The evidence emerging from interviews and meeting was contrasted with the existing body of knowledge from the literature, and integrated by discussions between the research team, and with practitioners. Based on the identified requirements, an IT tool to support KM in ETO organisations was developed and then implemented in the three case study companies. Training session were organised both to train the companies' personnel on how to use the tool and to sensitise them on the importance of the knowledge management process supported by the IT tool. A final workshop was organised to collect feedback on the benefits or limits of the tool experienced during the first months of use.

4 Case studies

In this section the three case studies are presented. Since this paper focuses on the non-physical information flow in ETO firms, the tendering, planning, and engineering design processes of each company will be analysed.

4.1 Case A

Case A is a company designing and producing machines and modules for the automation of assembling processes. Each machine is composed by several assembling stations in a line and usually includes feeding groups, handling tools, mechanical processing, and controls. Each machine is designed based on the specifics of the item to be assembled. On average, 60% of the modules of each machine are standard modules,

while the remaining 40% are fully customised. The ETO process starts with one or more meetings between a sale officer and the potential customer. The customer provides a sample of the item that the machine should assemble, and technical documents summarising the specifics of the product and assembly process. The following stage is the development of the offer. The tendering stage is highly critical. The offer is developed directly by the sale officer, but support from the technical office is often required to understand how the non-standard modules would impact lead time and costs. Tendering is a costly activity and all the effort is lost if the order is not eventually won. For this reason, the company would like to introduce a sales configurator tool to automate the elaboration of tenders. The configurator should enable the selection of standard modules and already developed variants from a database containing descriptions, and cost and time estimates updated based on the lesson learned by past projects. It should also facilitate the tendering of new modules. Also in the case the order is not confirmed, all the documentation produced for the offer is stored in the knowledge repository for future reuse. If the order is confirmed, it is necessary to plan in detail all the activities, from design, to production, assembly, testing, and commissioning. All the plans (activities, deadlines, responsibilities) are summarised in a textual document called "minutes". The documents is updated all throughout the development of the project and is shared with the customer. Case A laments the difficulties in monitoring the progress of the project using such a document, that could contain hundreds of pages, and the lack of a proper project management tool to plan the activities and have an overview of all ongoing projects.

4.2 Case B

Case B designs and realises single piece electrical systems and control panels for specific applications. Each system is composed by sub-systems that could be completely configured and personalised according to the specifics of the machine to cable. The first stage is the meeting with the customer and the collection of the electrical system requirements by a sale officer. The customer provides the officer with technical data sheets and drawings of the machine to equip. All these documents are analysed by the technical office that selects and dimensions the components to integrate. The operational research office estimates the number of person-hours required, while controlling and business administration offices define the price. Therefore, the tendering stage involves several offices and represents a highly time-consuming activity. Finally, a design review is organised with the customer to identify further needs for corrections and improvements; this is the last step before the order confirmation by the customer. Actual engineering of all the components of the electrical system could finally start. The design activity requires constant exchange of documents between the electrical designers and the mechanical designers of the machine at the customer's site. Many design changes are required not only during the design stage, but often also during the manufacturing stage.

Case A laments a lack of communication and collaboration with customer's designers. Therefore, electrical designers often lack the information needed to find the most suitable design choice, and adopt temporary measures, thus postponing the identification and solution of problems. Currently, the sharing of documents between the company and the customers is managed in an informal way, mainly through file sharing platforms like Dropbox and Google Drive, that require long times both for upload and download, and expose to the risk of loss of information. Furthermore, due to the lack of a shared project plan the customer often does not provide the required documentation on time, thus leading to delays and longer lead times. All the documentation of past projects is currently paper-based. Therefore, the retrieving of past knowledge takes long times and it is mainly based on the memory of single designers. This hinders the ability to reuse past solutions in different contexts and take advantage of the modularity of the systems.

4.3 Case C

Case C designs and manufactures special tools and profiles for machining chip removal of single-spindle lathes, multi-spindle, transfer and work centres. Each special tool or profile is designed based on the specifics of the piece and the material to work.

The first contact with the customer is by a sale representative. The representative collects information regarding the needs of the customer, and usually the order of tools is confirmed directly during the first meeting. Differently from big size high value ETO products, in the case of small size low value ETO products the tendering stage is less critical, and often completely neglected, as in the case of Company C. The customer will know the price only after the product will be manufactured. Therefore, the relationship with the customer needs to be built on trust and loyalty. One of the main difficulties at the order confirmation stage is the definition of a delivery date, due to the lack of a planning tool. Before starting the design activity, the designer always searches the knowledge repository of the company for any information available related to that family of tools or the specific customer. The repository is based on Microsoft SharePoint Designer and looks like a web site with a tree view menu. One of the main criticalities pointed out by Case C, is the fact that searching functionalities are not available, and in order to retrieve information the user has to navigate the menu guided by his intuition. Only one person in the company is in charge of adding new information to the repository and deleting obsolete one, but a clear procedure for the approval of the content is not defined. On one side, this causes delays in making useful information available to the personnel, on the other side it exposes to the risk of sharing outdated information. In addition, there is the risk of inconsistency between multiple instances of the same piece of information, since none automatic control is operated during the input phase and a tracking of previous versions of the same data is not available. Moreover, currently differentiated access profiles are not defined and it not possible to make only a certain type of information available according to the roles in the company.

5 The developed IT tool

Based on the knowledge management needs collected from the literature and from the analysed ETO cases, an IT tool have been developed and tested in the three case study companies. The tool consists of a web-based platform integrating three different modules: Sales configurator, Project management tool, Knowledge repository. The Sales configurator enables the semi-automatic preparation of an offer based on the information collected from past projects. All the standard modules of a product are catalogued together with the possible variants. To each standard module a set of parameter related to costs and lead time is associated. The update of these parameters is automatically required by the tool whenever a project including such module ends based on the final balance of the project. For all non-standard modules, a blank form to complete is available. Each new module after completion is included in the catalogue of standard modules of the configurator. The tender documents is easily composed by the tool based on the modules selected. The tool provides also the total cost and time required for the development of the project, thus facilitating the definition of the price and the delivery due date. If the order is confirmed, all the data from the tender are automatically imported by the project management module, and a draft Gantt chart is developed. The draft can be modified as needed. The module includes a timeline of the project, with alerts for intermediate deadlines and milestones. This module provides also a document sharing space with versioning to facilitate file sharing among designers and to gather all project documentation, and a discussion space in the form of a forum to improve communication and collaboration among project partners, avoiding the use of e-mails. Finally, the knowledge repository module collects all projects documents and data, along with other information relevant for the company, and makes them easily accessible thanks to advanced tag-based search functionalities enhanced by Natural Language Processing machine learning algorithms. The repository offers differentiated access profiles and manages a workflow for information input and deletion approval.

The developed IT tool has been implemented in the three case study companies. Training sessions have been organised in each firm to explain the use of the tool. In addition, a general hands-on workshops was held to raise awareness on the importance of knowledge as a key asset for ETO companies. Six months after implementation a feedback was collected from each company. Case A reported several benefits connected to the use of the IT tool. One advantage of the sales configurator is the possibility for the sales representative to provide the customer with an estimate of price and delivery time already during the first meeting. This is a key competence for competitiveness since it reduces the time needed to win a new order. Furthermore, on one side, less time is necessary to elaborate the final offer document, thus increasing the tendering capacity of the company, on the other side, the majority of activities needed to prepare an offer do not require highly skilled human resources that could be devoted to more value-adding activities. The project management modules has replaced the old “minutes” and

automated the workflows, thus improving the planning and monitoring of all project activities.

Also Case B reported a positive feedback, especially with reference to the design phase. The forum and the document sharing functionalities have improved the collaboration with customer's designers, and reduced both the time spent for re-design and the total time required to complete the design of the electric system. The compression of time is a consequence also of the possibility of retrieve knowledge and solutions developed in past projects through a quick search of the knowledge repository.

Case C reported that the main benefits came from the new knowledge repository module that provides advanced searching functionalities with respect to the one previously available. That reduces the time needed for information retrieval. In addition, the presence of a formal procedure for approving the update of recorded data, guarantees consistency and validity of the information retrieved. It also enables every user to propose the insertion of new knowledge, thus minimising the loss of knowledge while ensuring its trustworthiness. Complete past project documentation, that previously was stored in a separate database, now is available among the information searchable in the repository, and this facilitates knowledge reuse since information is less fragmented.

6 Final remarks

Although each company has to develop its own approach to KM and one-fits-all solutions do not exist, based on the results of this research, it is possible to outline some common traits related to KM specific for the ETO context. These traits could also be easily translated into requirements that an IT-based tool should satisfy in order to support KM in ETO organisations.

The knowledge domains which appear to have the greatest value to ETO, and to which the knowledge management system should be applied, are those related to tendering, project planning and engineering design processes. According to ISO 30401, in order to effectively manage knowledge through its stage of development, the KM system should cover the following activities: acquiring new knowledge, applying current knowledge, retaining current knowledge, handling outdated or invalid knowledge. Due to length constraints an extensive discussion of all the requirements related to each activity with a detail for each ETO process is not possible in this paper. Therefore, a summary is provided in Table 1.

Table 1. Summary of ETO KMS requirements

Process / **KM Activity**	**Tendering**	**Project planning**	**Engineering design**
Acquiring new knowledge	- Facilitate collection of customer requirements and their timely storage in the knowledge repository to	- Foster lesson learning and post-project assessments - Facilitate communication with the customer	- Facilitate communication and collaboration among designers to foster innovation

	make them immediately available		
Applying current knowledge	- Use standard cost and time parameters based on past experience for modular products to facilitate the creation of a tender	- Use standard cost and time parameters for modular products to facilitate the planning of the project - Facilitate project monitoring to enable improved actions and decision making	- Facilitate searching of past design solutions to foster knowledge reuse (e.g. through tagging) - Facilitate documents sharing among engineering teams
Retaining current knowledge	- Keep records of all tenders, also unsuccessful ones. - Document new product modules and include them among standard modules for reuse in future tenders	- Enable the storage of all project documents in a single repository. - Enable documentation and communication of all project activities, deadlines, responsibilities and milestones	- Enable classification and storage of all design solutions - Keep records of the motivations of design choices
Handling outdated or invalid knowledge	- Foster the regular update of standard modules documentation at the end of each project.	- Foster standard cost and time parameters update at the end of each project	- Implement a formal approval process for information input and deletion in the knowledge repository

Abstract

The emotional intelligence of leaders is a critical component of being able to lead self and others effectively. The qualities of emotionally intelligent leaders have been linked with transformational leadership abilities. Though current research in leadership shows correlations between Emotional Intelligence (EI) (Goleman, 2015, Mayer & Salovey, 1997), Transformational Leadership (TFL) (Bass, 1985, 2000), and Self-Actualisation (SA) (Maslow, 1961, 1963, 1971, Hall, 2008, 2009), there are no existing studies showing how, or if, Neuro-Linguistic Programming (NLP) can influence transformational leadership ability and correlating self-actualising behaviours.

A qualitative thematic analysis approach, including four (4) in-depth case studies, interviews, and participant observations will be undertaken to provide insight into the factors influencing transformational leadership ability through an EI and correlating NLP lens. Case studies specifically will be used as a methodological approach to explore and advance theoretical foundations and highlight new knowledge and themes emanating from the research (Corley & Gioia, 2011; Eisenhardt, 1989; Gehman et al., 2017; Gioia, Corley, & Hamilton, 2013; Whetten, 1989; Yin, 2003).

This study will explore how EI and NLP influences TFL ability. Current studies in EI and TFL show correlations between both in terms of inherent behavioural dimensions. This research will uniquely contribute to the existing body of knowledge by using an NLP lens to demonstrate correlating self-actualisation behaviours and investigate the impacts of transformational leadership ability on self-actualising leaders.

Purposive sampling will be used to select four (4) highly emotionally intelligent participants, who are recognised as Leaders in their fields and in respective organisations in Australia. Case studies will be developed with an in-depth focus on the background, context, and career development path of the four leaders, the aim being to provide insight into factors influencing transformational leadership ability through EI and the NLP model.

Keywords – Emotional Intelligence, Neuro-Linguistic Programming, Transformational Leadership

Paper type – Academic Research Paper

1 Introduction

1.1 Approach

There are a vast number of leadership and leadership development theories, practices, models and styles, such that attempting to provide a single definition of leadership is problematic. Despite the lack of a common definition, the understanding and practice of leadership and leadership development are experiencing fundamental changes (Avolio, 2007; Bennis, 2007; Day and Antonakis, 2012). These changes require the traditional types of leadership, or what Bennis (2007) calls "tripod" leadership forms, and even the more recent theories including; transformational, charismatic, and authentic leadership practices, need to advocate for a fuller, and more integrative focus on a multi-level, multi-component and inter-disciplinary approach to leadership. Leadership is a function of the leader, the led, and the complexity of the emotion context (Avolio, 2007).

Studies in EI treat emotions as a unitary and predictable stable construct, and as such does not address the granular aspects of emotion leadership (Kaplan, Cortina, Ruark, LaPort & Nicolaides, 2014), such as what is happening *within* a leader moment-to-moment (Jordan & Lindabaum, 2015) in the workplace.

As emotions are fleeting and ephemeral in nature (Weiss and Cropanzano, 1996) such that Jordan & Lindabaum (2015) refers to them as "the curse of the emotions". An overview of emotion management will be briefly discussed to provide grounding for the research. Management of one's emotions is a key part of the process of self-actualisation (Maslow, 1971; Hall, 2009), a process this research suggests can be promoted using NLP.

1.2 Research Gap

Though current research shows correlations between EI, transformational leadership and self-actualisation, there are no studies that examine the long-term impacts of transformational leadership on leaders. This research will contribute to understanding the long-term effects of transformational leadership style on leaders by employing EI and an NLP lens as a mediating technique to measure correlating self-actualising principles and behaviours.

There is currently no research linking NLP to EI. It will therefore explore the following sub-research questions during the thematic case study analysis approach; (i) how EI mediates the relationship between transformational leadership and self-actualisation (ii) how NLP influences transformational leadership ability, and (iii) how NLP promotes self-actualising leaders. By so doing, the correlation between NLP and EI will become prevalent, and be significant for this research.

Further, present multi-level leadership studies in EI and transformational leadership typically focus on the *individual-to-group/follower-leader* affect-effect impact of transformational leadership (To, Tse, Ashkanasy, 2015; Hur, Van de Berg, Wilderom,

2011; Cote, Lopes, Salovey, Miners, 2010; Griffith, Connelly, Theil, Johnson, 2015). There is limited research exploring the self as part of a within-person dynamic in a multi-level leadership study (Jordan & Lindabaum, 2015). This research will explore the *self* from a self-actualisation impact perspective (Maslow, 1961; 1962; 1971; Hall, 2008). It will add to the within-in leadership variance using the NLP model to explain self-regulation and emotion management behavioural practices (Jordan & Lindabaum, 2015) aligned to self-actualising leaders.

Finally, there is a dearth of research literature into NLP despite its application and use across countries for 30 years (Kong, 2010). This research will contribute to bringing the impact of NLP in leadership into the academic mainstream, and contribute to providing an explanation, and model of leadership practice that can be used to develop self-actualising, peak performing leaders that have the capability to lead themselves and others, and to transform and transcend predetermined environments and accepted social constructs that limit human potential.

1.3 Limitations

There is limited academic literature on NLP, meaning the findings of this study cannot be generalised.

This study will involve a select small sample of 4 case studies including interviews as part of a qualitative approach. It lays the foundation for a further longitudinal study.

2 Literature Review

2.1 Theoretical considerations

This literature review is based on the following theoretical frameworks:

- Emotional Intelligence (EI) (Goleman, 1998, 2008, 2015; Mayer, Salovey, Caruso, (2004) Freedman (1998, 2019) – EI is a theory about the ability to actively understand, process, and influence one's own emotions and those of others to guide behaviours.
- Transformation Leadership (TFL) (Bass, 1985, 2000) – TFL is a theory about a leadership style that transforms followers' attitudes, values and behaviours and inspires them to pursue higher-order and organisationally relevant goals.
- Neurolinguistic Programming (NLP) (Perls,1954, Satir, 1988, 1991, Erickson, 1982, 1983, 1985, 1986, Bandler & Grinder, 1975, 1976, 1979, Hall, 1997, 2003) – NLP is a model of communication, a coaching technique, and an attitude, that focuses on individual internal learning to improve self-awareness, develop greater skills in self-management, communication, and interpersonal awareness.

2.2 Emotion and the workplace

Work is an emotional experience. For followers, it can be a source of anger, distress, frustration, and embarrassment, but also a spring of pride, belonginess, fulfilment and excitement (Ashforth & Humphrey,1995; Boudens, 2005). Leadership is primarily a relational process, an interaction between the leader where leader behaviour affects the performance, well-being, and creativity levels of their followers (Jordan, Lindebaum, 2015). For this reason, managing one's own emotions, and those of followers is a critical managerial function akin to managing markets or finances (Leavitt & Bahrami, 1988).

Like Leavitt and Bahrami, Rafaeli and Worline (2001) argue that the job of management has become the management of emotion. This thinking is re-affirmed by Goleman (2015), who from an emotional intelligence and Leadership perspective, posits that it is the primal task of a Leader to manage their own emotions first, prior to others.

The role of emotion and leadership in the workplace remains a subject of scholarly interest; ranging from early leadership studies that sought to articulate the effects of charismatic leaders on followers' hearts and minds (Weber,1947), to understanding how transformational leadership ability inspires and instils hope and optimism in followers (Bass,1985).

Similarly, there is growth in the area of leader emotion management (LEM) with the aim of furthering understanding into leader impact on the work-related emotions and feelings of followers (Ashkanasy & Tse, 2000; Humphrey, 2008' Humphrey, Pollack & Hawver, 2008; Pescosolido, 2002). For example, Koning & Van Kleef, 2006, explored the effects of leader anger displays on organisational citizenship behaviours (OCBs), with a focus on demonstrating the adverse effects.

Though literature in this area is scant, it raises opportunities for further research into the type of emotion displays linked to transformational leadership ability.

2.3 Emotion management

Emotions can be defined as acute, intense, fleeting, ephemeral reactions to an event (Weiss and Cropanzano, 1996). Often used interchangeably with moods, whilst they are both affective (or feeling) states, moods are more diffused and longer lasting. People generally feel their emotions whilst the mood runs in the background without triggering conscious awareness of it (Watson, 2000).

Emotion and moods tend to be intertwined temporarily as moods such as "feeling let down", can develop into full blown emotional experiences, such as "feeling depressed". That being said, Ekman and Davidson (1994) argue that the distinction between emotions and moods are not entirely clear both from an experiential perspective and in terms of functions. On the contrary however, Bandler & Grinder (1975); Bandler, (2008), Grinder, (2013) argue that emotions are a great resource for choosing resourceful states and breaking chronic mood patterns that can spiral out of control.

Jordan and Lindebaum (2015) separate the display of emotion into 2 parts; emotion experience (or felt emotions) and emotion expression (or displayed emotions). Suggestibly, Watson's (2000) "full blown emotional experience" sits in the latter category. Lawrence et al (2011) argue that transformational leaders characteristically use strategies to manage their emotional experiences (or feelings) in response to specific situations in the workplace, including interpersonal interactions. Correspondingly, Jordan and Lindebaum suggest that a transformational leader is one who uses emotion management practices to decide how they experience their emotion (Jordan and Lindebaum, 2015). The experience of emotion for the transformational leader does not need to equate to the chosen strategy for display. The chosen strategy is chosen because of a deep understanding of 'self', and how emotions operate and pertain to self, termed as self-management, which is a dimension of EI (Goleman, 2015).

Whilst there is research connecting EI, which includes self-management, to Transformational Leadership, (Ashkanasy & Tse, 2000), it is not clear if both Jordan and Lindabaum (2015) and Lawrence et al (2011) are suggesting that only transformational leaders are best able to manage their experience emotions.

Hall (2008), thinks differently. Arguing, from a human development perspective, self-management of mind, body and emotions is an activity for people striving to achieve excellence, in any field. The striving, or what he terms as "self-actualising" (2008), is a term borrowed from Maslow's self-actualisation psychology (1961, 1963, 1971) and includes managing emotional experiences.

This is a unique approach to current models of self-management given its focus and intrinsic connection to the self-actualisation psychology of Maslow, and its re-interpretation of the term leadership as concerning not just organisational, but personal outcomes.

Self-regulation and within-person leadership

Self-regulation is a leader's ability to manage emotions within their person (Jordan & Lindabaum, 2015). The within-person model enables leaders to display and use a range of emotions consistently across several situations in the workplace (Ashkanasy and Jordan (2008). The adjudication of the choice of emotion displayed by the leader is, however, dependent on how the emotion is perceived as situationally appropriate by followers (Jordan & Lindabaum, 2015).

In terms of how the within-person leadership variation occurs, Gioia & Poole (1984), key proponents of the within-person model suggest that the leader experiences situational cues which trigger responses by way of 'discrete emotions' in the leader. The leader is confronted by a series of strategies from which they can select. The selection warrants a decision on a 'script', or schematic knowledge structure held in memory that specifies a behaviour that is appropriate for specific situations. The leaders memory bank includes case based knowledge (Schmidt & Rikers, 2007), heuristics, (Abe & Izard, 2009), knowledge about the group and the personal norms of an organisation (Hertel & Kerr,

2001) and followers' expectation of the situation to select the appropriate script through which the emotion will be displayed.

Whilst the emotion chosen in the within-person leadership variance is driven by memory scripts based on multiple experiences, the veracity of action taken by a leader is questionable, given the adjudication of leader action and choice of script, is determined by the response of followers. Arguably, what is a within-leadership centred approach is equally externally driven and determined. This presents some challenges signalling opportunities for further development and expansion of the theory.

2.4 Emotional Intelligence

There is a growing body of research that suggests that a leaders' ability to understand and manage their own feelings, moods and emotions, as well as those of their followers, contributes to effective leadership performance across a variety of organisations (Gardner & Stough, 2002, George, 2000, Kerr, Garvin, Heaton & Boyle, 2006). In the workplace particularly, managing one's own emotions, and those of employees, is as much a critical managerial function as managing markets or finance (Leavitt & Bharami,1988). It is arguable to suggest therefore that the emotional intelligence of leaders is a critical component in being able to lead effectively (Jordan & Lawrence (2009). Importantly, there is research linking the qualities of emotionally intelligent leaders to transformational leadership abilities (Bass, 1985; Barling, 2000)

As a subset of social intelligence, emotional intelligence (EI) includes the ability to monitor self and other's feelings and emotions, to discriminate between them, and to use the information to guide one's thinking and actions (Mayer & Salovey,1997). Further, it involves the capacity to reason about emotions, to use emotions to enhance thinking, to accurately perceive emotion, to access and generate emotion to assist thinking (Bandler and Grinder, 1975, 1976, 1979), to understand emotion and emotional knowledge, and to reflectively regulate emotion to promote emotional and intellectual growth (Mayer & Salovey, 2004). Salovey's definition of EI, including the Salovey-Mayer EI model (2000), and key mainstream EI models, including Baron (1997) Cooper and Sawaf (1998), Goleman (2008), and Six Seconds (1997), are similar in approach with a common focus on self and other.

Whilst agreeing with two-fold approach of EI, Hall (2002) argues from a neuro-semantic perspective that the ability to guide the emotions of self and others includes understanding the meta-correlations between thinking, feeling, speaking (or languaging) and behaving, as part of the interplay of the movie-mind. As a mind-body-emotion system (Hall, Bodenhamer, 2009), the way we think determines how we feel, which informs what we speak (or language), and how we then behave (act). Thinking directly determines behaviour (Hall, Bodenhamer, 2009).

The meta-correlations between thinking, feeling, and behaving, is a key experiential addition of NLP to the theoretical EI approaches of Mayer & Salovey (1997, 2004); Bar-

On (1997), Goleman, 1998), with the exception of Freedman, whose Six Second model (1998) moves EI into the sphere of experiential practice.

In exploring the meta-correlations, NLP borrows from, and employs the principles of hypnotherapy (Perls,1954, Satir, 1988, 1991, Erickson, 1982, 1983, 1985, 1986) as a means of working with the unconscious mind, part of the mind-body-emotion system, to facilitate individuals' (including leaders) capacity to connect with their own abstract mental reality or intra-personal awareness. The ability to guide the emotions of self and others requires engaging with the vast reservoir of learning that is the unconscious mind (Erickson, 1982). 'Patterns' (Bandler and Grinder, 1975, 1976, 1980; Dilts, 1999, Hall, 2008, 2009, 2010) for working with the unconscious mind, as part of NLP's mind-body-emotion system, is a critical part of self-management and self-regulation, and a self-actualising behavioural prerequisite. This is a current gap in traditional EI models, discourse, and leader emotion management (LEM) approaches.

2.5 Management of emotions

Management of emotions involves the management of one's own personality. From the context of the individual leader, this includes their leadership perspective, goals, self-knowledge, and social awareness (Averill & Nunley, 1992; Gross,1998; Parrott, 2002). For example, small children are often taught to count to 10 before getting mad, or to smile at grandpa. As they grow older their means of emotional self-management increases and become stronger. There is now the ability to avoid feelings, or to intentionally re-frame situations to reassure themselves to achieve calmness and self-composure (Erber,1996; Larsen, 2000, Tice & Bratslavsky, 2000; Wenzlaff, Rude & West, 2002).

Similar to using emotions, management of emotions uses emotions toward greater self-improvement. The skill for both areas of EI improve as one develops psycho-socially and physically.

In EI literature, research suggests that there are five mainstream emotional intelligent models, each with a varying slant or focus (Kewalramani, Agrawal, Rastogi, 2015).

Fig 1 below shows correlations between the five models (Kewalramani, Agrawal, Rastogi, 2015) classified under four headings: (i) understanding self, (ii) understanding others, (iii) managing self, (iv) managing others. The analysis is an attempt to demonstrate the intrapersonal and interpersonal nature of EI, which given the theoretical underpinning of some models, arguably requires further study.

EI Model Type	Understanding Self	Understanding Others	Managing Self	Managing Others
Salovey-Mayer-Caruso (2000)	Perceive emotions (Branch 1) Understanding emotions (Branch III)	Understanding emotions (Branch III)	Facilitating Thought (Branch II)	Managing emotions (Branch IV)
Bar-On (1997)	Intrapersonal General Mood	Interpersonal	Adaptability Stress Management	Social skills

Cooper and Sawaf (1998)	Emotional literacy (Sense)	Emotional fitness and Emotional Depth (Understand)	Emotion Alchemy (Apply)	Emotional Alchemy (Apply)
Goleman (1998)	Self-Awareness	Empathy	Motivation Self-Regulation	Social skills
Joshua Freedman (1998)	Know Yourself	Choose Yourself	Choose Yourself	Give Yourself

Fig 1: Indian Journal of Positive Psychology, 2015

2.6 Transformational Leadership

Current research in Transformational leadership (TFL) suggests consistency in definitions of TFL. TFL is a process in which leaders use emotions to communicate a vision, elicit responses from followers, and ensure they are emotionally motivated to perform beyond their expectations (Humphrey, 2002, Brown & Moshavi, 2005). This is consistent with Bass (1985), a founding scholar of TFL. Bass defines TFL as a form of leadership that through transformation of followers' attitudes, beliefs, values, and behaviours, intends to inspire followers to pursue higher-order and organisationally relevant goals.

Traditionally, TFL constitutes 4 dimensions:

1. Raising others to a higher level of achievement or idealised influence,
2. Motivating followers to transcend their personal interests for collective welfare, or inspirational motivation,
3. Developing followers' abilities to facilitate their own personal growth (individualised consideration), and
4. Developing followers' intellectual capability to approach problems in new ways, or intellectual stimulation (Bass, 1998, Avolio, 1999).

Taking the 4 dimensions together, Wang and Howell (2010) and Wu et al (2010) argue they should be collapsed into two categories:

1. Idealised influence and inspirational motivation - This is where a transformational leader displays similar behaviours toward the group. For example, communicating a compelling vision to the whole group; and
2. Individualised consideration and intellectual stimulation – This is where the same leader display different behaviours in addressing the individual uniqueness of each person in the group. For example, the provision of personalised coaching for each member of the group.

Both TFL dimensions are consistent with the 'self' and 'other' focus of traditional EI models (Salovey-Mayer, 2000) and self-actualisation principles and practices (Maslow, 1961, 1963, 1971; Hall, 2008).

2.7 Emotional Intelligence and Transformational Leadership

A growing body of research has shown that emotional intelligence is inherently associated with TFL (Barling, Slater & Kelloway, 2000; Leban & Zulauf, 2004). Similarly, EI and TFL scholars (Gardner and Stough, 2002; Barbuto and Burbach, 2006) suggest that the ability to monitor and manage the emotions in self and others correlates with the inspirational, motivational and individualised considerations of TFL(Hur, Van den Berg, Wilderom, 2011). Of interest to this study, are the influences self-actualising behaviours have on transformational leaders' ability viewed through an NLP lens.

TFL theory highlights the importance of leaders' impact on the emotional state of others, and several studies have provided emotion-type insight into the transformational leader-follower link with emotional intelligence (Ashkanasy & Tse, 2000). The qualities of empathy, motivation, self-awareness, trust and emotional stability, are qualities of a transformational leader that are directly associated with emotional intelligence (Goleman, 1998, Bar-On, 1997, Mayer & Salovey, 1997), and self-actualising behaviours (Maslow, 1971).

2.8 Emotional intelligence and self-actualisation

Similarly, emotional intelligence has been linked with the theory of self-actualisation (Maslow, 1961, 1963, 1971; Hall, 2008; Gilligan, 1997, Gilligan and Dilts, 2011), through its association with the positive psychologies of Maslow and Jahoda (Bar-on 2010).

Similar to the within-person leadership model, where a leader is self-challenged to choose a mental script that is contextual to managing an emotion in the workplace (Jordan & Lindabaum, 2015), so too is the ongoing process of self-actualising about becoming more fully aware of ones' emotions, choosing which emotions to listen to and which ones to nurture (Hall, 2007).

However, there is a further aspect to EI, one that concerns the depth of intelligence within emotion, involving an intentional and experiential move to find out who we really are deep down below as a member of the human species, and as an individual (Maslow, 1962) leader. This aspect of EI is not often referred to in traditional EI theory and practice. Arguably therefore, the connection between EI and self-actualisation is in the actual process of becoming aware (Hall, 2007), and using emotion to facilitate thought (Schwartz, 1990) particularly in terms of the meanings we give experience, and how we understand the difference between "the map and the territory"(Korzybski's,1933).

Interestingly, using emotion to facilitate thought is an EI dimension that Mayer et al, (2004) argued should be removed from EI theory. On the contrary, this study embraces it as a key component of the unfolding process (Francis, 1992), a process that is characteristic of self-actualising transformational leaders.

2.9 Neuro-Linguistic Programming (NLP)

NLP is a model of communication a coaching technique, and an attitude (Hall, 2008), that focuses on individual internal learning to improve self-awareness, develop greater skills in self-management, communication, and interpersonal awareness (Bandler & Grinder,1975, 1976, 1979). The principles of NLP appear consistent with the emotional intelligence theoretical framework.

A recent longitudinal study (Tosey, Mathison & Michelli, 2005) demonstrated that NLP is a structured and systematic means of mapping subjective experience and constructed reality of people experiencing transformative development (Linder-Pelz & Hall, 2007). This study will leverage this characteristic NLP tool to explore and provide insight into transformative behaviours of a small sample size of emotionally intelligent and self-actualising leaders in Australia.

Kohn (2010) posits that within the NLP model, subjective experience is broken into three main representational systems (Bandler & Grinder,1975, 1976, 1979):

1. **The Visual representation system:**

Includes external images, and remembered or constructed internal mental images

2. **The Auditory representation system:**

Includes external images and remembered or constructed internal sounds and internal dialogue, such as a person talking to themselves on the inside. This is also referred to as 'Auditory Digital' (Bandler and Grinder, 1979)

3. **The Kinaesthetic representation system:**

Includes tactile sensations caused by external forces acting on the body and emotional responses.

Some NLP practitioners suggest that individuals prefer one representational system over others in each context. Whilst there is truth in this, the founders of NLP are very clear in saying that people tend to employ all representational systems all the time, whilst having, at least, a subconscious awareness for one system over another at differing contexts (Bandler and Grinder, 1979).

The sub-modality dimensions of NLP provide a visual, auditory and kinaesthetic framework for leaders to become more self-aware of the distinctions of their representations systems, and those of others, including their followers (Tosey and Mathison, 2010) How people use their senses internally, and the kinds of representations utilised is distinctive with each person, hence a key focus for NLP is making sense of how people interact with experience, with self, and with others (Pollitt, 2010).

2.9.1 NLP – how it works

Neuro-Linguistic Programming holds certain presuppositions that underpin it as a model of communication, a mind-body-emotion system of how we map and model information, run our own brain, and structure excellence that enables the replication of genius (Bandler & Grinder,1975, 1976, 1979).

The human experience of reality commences with an event or some action, speech, behaviour occurring in the world 'out there'. As we see, hear, feel, smell, or taste the experience, we represent it, (literally re-present) it on the screen of our minds as pictures, sounds, sensations, smells, etc (Bandler and Grinder, 1979). We take a snapshot of it in our minds, such that it becomes a movie that we play.

In this way, we develop an internal representation of it. It becomes our frame of reference through which we make sense of things. The is the filter through which we see and judge the world. As we continue to use the same frame, and similar frames repeatedly, it habituates, and becomes our frame of mind, or the way we see things (reality). It becomes our perspective and perceptual filter. Eventually, with further habituation and repetition, it becomes the framework that governs how we think, feel, and understand, use, and express our emotions. The framework of our personality (Hall, 2006).

In effect, this research suggests that thinking directly impacts behaviour (Gooty, 2010), and that the emotional 'state' of mind of leaders, determines follower behaviour – toward (Hatfield, Cacioppo & Rapson, 1994), or away from (Bower, 1981; Clark & Taraban, 1991; Fredrickson, 2001; Parath & Erez, 2007), becoming self-actualising human beings capable of leading sustained personal and organisational change (Hall, 2008). An NLP lens will provide crucial insight into the subjective mapping process of selected leaders to explore how they structure their experience, with the view to understanding how EI and NLP influence transformational leadership ability, which this research understands as a by-product of self-actualising individuals.

Research on aspects of NLP, particularly the representational systems theoretical framework, has raised some questions. Fromme and Daniell (1984) suggest caution in the therapeutic use of NLP, however, agree that people that are skilful with imagery may find NLP techniques useful particularly in exploring its role in communication. Similarly, Bradley and Biedermann (1985) argue that the theoretical, and linguistic analysis of clients' messages and interactions requires further empirical testing, however, suggest that NLP remains a viable model and guide for understanding language and related linguistic distortions.

The concerns expressed by Fromme and Daniell (1984) whilst anachronistic, signposts a number of historical criticisms levelled against NLP (Dowd & Pety, 1982, Ellickson, 1983, Gumm et al, 1982, Owen, 1977; and Shaw, 1977), and one that this study will contribute to by way of a systematic response to the research question. By so doing, an aim of this study is to contribute to providing academic input into scant NLP literature.

2.9.2 NLP and self-actualisation

The term self-actualisation (SA), or self-actualisation psychology (Hall, 2008), is not a grand abstraction or a defined, static, mystical state attained by a select few of a particular age. It is rather, a fluid, non-static, episode or spurt in which the powers of a person come

together in a particularly efficient and intensely enjoyable way, and in which the person is more expressive and spontaneous and fully functioning (Maslow, 1961, 1962, 1971)

In these episodes, the person is more truly themselves, perfectly actualising their potentials to the core of their Being. For this reason, it is argued that each person must do that for which he or she is fitted – because "what a person can be, they must be" (Maslow, 1961). The process of doing that for which one is fitted includes what are called "peak experiences" (Maslow, 1962).

Unlike the theoretical approaches of traditional EI and models (Goleman, 1998, Bar-On, 1997, Mayer & Salovey, 1997), these peak experiences are available to us now, on a moment-to-moment basis of experiencing fully, vividly, and selflessly with full concentration and absorption. This type of momentary experiencing without the self-consciousness of the adolescent, is experiencing when the person is wholly and fully human. This is a self-actualising moment, or a moment when the self is actualising itself (Maslow, 1971).

Interestingly, whereas leader emotion management (LEM) practices require the repeated selection of a mental script adjudicated as ethically justified by followers, the self-actualising experience is driven by a cause outside the self-actualisers own skin, something outside themselves. Further, unlike the mental scripts that are judged as appropriate by followers, self-actualiser actions are not judged as such, they are simply experienced beyond the traditional adjudication labels of 'good' or 'bad'. In addition, whereas all people experience self-actualising moments at different degrees of intensity, in self-actualising people particularly, these moments occur with more frequency, intensely and perfectively than the average person (Maslow, 1962).. This makes it amenable to further research.

Research is required, for example, to explore the 8 SA behaviours (Maslow, 1971) and their suggested correlations with the 4 TFL behavioural dimensions (Judge and Piccolo, 2004; Liao Chuang, 2007; Courtright & Colbert, 2011; Bass, Avolio, Jung & Berson, 2003; Schaubroeck, Lam & Cha, 2007), so as to contribute to the Maslowian thinking that SA is not merely about performing well but striving to be the best human being moment-to-moment as a continuous learning process (Bracket & Bar-on, 2010).

2.9.3 NLP and the self – a within-person variance leadership approach

NLP is a method designed and used to uncover the structures inherent in human behaviour (Bandler and Grinder, 1975). Aligned to the philosophical tenets of phenomenology, Bandler and Grinder, like Husserl (1907) before them, developed a systematic and experiential discourse focussed on distinguishing the "real world" from the "perceived" world, suggesting that our perception is limited and influenced by our neurology and our social and individual histories.

Similarly, in turning inward to examine the self, Husserl argued that the same social and individual constraints affect NLP's "surface" structure (Bandler and Grinder, 1975, 1976). Beyond this "I" lies a deeper hidden "I myself", similar to NLP's "deep" structure

(Bandler and Grinder, 1975, 1976). Borrowing from the phenomenology of Husserl, Hall, similar to Bandler and Grinder, argue that human beings can undergo a state of detachment, of standing back from the realm of reality, in order to experience it fully. This self-reflexive ability (Hall, 2002), or what is aptly called the ability "to shut out the noise of the world" (Maslow, 1971), constitutes the crux of knowing self, through standing outside of the self, to see self.

Like the within-in person leadership model, self-reflexivity, in part, is a strategy for managing the experience of emotions – and is a distinct constituent of the process of self-regulation (Lawrence et al, 2011). Arguably, self-reflexivity is a constituent part of the self-actualisation pyramid enabling people to move beyond lower needs to their higher ones (Hall, 2008) via an act of pre-potency or becoming that which we already are (Maslow, 1961). The self is one of the most challenging concepts to comprehend. It is not a thing or entity. It is a process of ever-becoming more than we are. As a narrative construction, it is always open to change and flux (Hall, 2002).

Arguably, the within-person model, which is a structure for the management of emotions (Jordan & Lindabaum, 2015) and the self-regulatory practice of emotional intelligence (Goleman, 2015) aligns with the mind-body-emotion system of the NLP model (Bandler & Grinder, 1975, 1976, 1979) and is therefore able to contribute to providing insight on the influences of TFL.

3 Research Design and Methodology:

The following approaches will be used to explore the research question:

- A qualitative thematic patterning approach will be used to execute the research, and enable the emergence of themes (Boyatzis, 1998, Roulston, 2001)
- Utilisation of multiple data sources, (including interviews, case studies and participant observations) to facilitate triangulation
- The research will be explored through the subjective experience of participants
- Interview questions based on the NLP model and designed on Visual, Auditory and Kinaesthetic (VAK) sub-modalities (Bandler and Grinder, 1975, 1976) for tracing the thread of participant conversation and to explore the structure of internal and subjective experiences.
- *A bracketing* approach will be used to facilitate suspension of judgement during data analysis (Moustakas, 1994)
- The themes and data sources from this research cannot be generalized given the small sample size

3.1 Data collation and analysis

- Leximancer (2018), a content analysis tool will be utilised to reduce potential for bias and human subjectivity whilst manually coding textual data (Baldauf & Kaplan, 2011).
- Four single-embedded case studies with 4 high performing EI leaders to describe context and processes, (Braun & Clarke, 2006) and literal and theoretical replication (Scholz & Tietje, 2002, Yin, 2003)
- 60-90 minute 1:1 semi-structured interviews with leaders using a recording devise (Manen, 1990). Data analysed on how leaders construct their realities through language (Drew, 2005).
- Participant observations of verbal and non-verbal behaviours during interview and case study to be analysed into themes and reviewed in terms of SA behaviours (Maslow, 1943, 1962, 1971; Hall, 2011).
- Personal feedback and observation sheet to capture researcher thoughts and feelings, and to provide context to enable interpretation and theming.

3.2 Sampling

Purposive sampling will be used to select 4 high performing emotionally intelligent Leaders (participants) from the researcher's network according to the below framework for selection:

- Participants must have a minimum of 10 years' professional experience working in the Corporate sector in Australia.
- They will be between the ages of 30 – 70.
- They will come from a range of professional disciplines including HR, Management, Business, Coaching & Personal Development, and Learning & Organisational Development.
- They will have an interest in EI, NLP and TFL practice.
- They will be open to NLP as a coaching method.
- Participants will be a mix of male and female

4 Conclusion

Potential implications of the research for leaders of organisations

From a theoretical perspective the research approach will:

- Explore the link between EI, NLP, and TFL abilities in terms of SA behaviors
- Signal the requirement for a further longitudinal research to enable greater generalisability
- Leverage current EI theoretical models with a corresponding practical approach

- Use NLP as an explorative framework and thereby bring it into academic literature

From a practical perspective it will:

- Provide a blue print for modelling excellent leadership practices so as to teach them to aspiring leaders
- Start discussions for a new type of emotion leadership based on self-improvement practices that actualise potential

The Role of Emotional Intelligence in Academic Leadership

Vidya. S. Athota *, Mark Hornshaw

Abstract

Studies on emotional competence have traditionally focused on the emotional competence of students and business leaders. There has been little analysis on how emotional competence influences university academics in teaching and career growth. Generally, academia appears to be driven by intelligence, scientific theories, policy, and related measures of success. Positions in the academic workforce are commonly awarded to those who have demonstrated high levels of scholarly attainment, relying on strong cognitive abilities combined with dedication and hard work within a field of knowledge. The influence of emotional competence in academia has remained unclear. The two primary aims of this theoretical paper are: 1. To examine how emotions contribute to academic performance. 2. To ascertain what kind of coping strategies academics use to manage emotions including their impact on complex outcomes in professional academic settings. Limitations and implications of the proposed research are included in the paper.

Keywords – Emotional competence; emotional management; cognitive skills; academic performance;

Paper type – Academic Research Paper / Practical Paper

1 Introduction

Generally, organizations downgrade the role of emotions in academic and business success (Mayer, Roberts, & Barsade, 2008). This aim of this research is to understand the role of emotional competence in academic success. Academia appears driven by scientific theories, academic credentials, intelligence, policy, and related measures of success (Mihaela, 2015). Positions in the academic workforce are commonly awarded to those who have demonstrated high levels of scholarly attainment, relying on strong cognitive abilities combined with dedication and hard work within a field of knowledge (Jaremka, et,. 2020). In the process, the emotional health of both academics and the students they serve is often neglected. Evidence suggests that emotion management skills are important as cognitive skills to career success (Mayer et al., 2008). Yet when it comes to performance evaluation and career advancement, the academic setting gives importance to things like research output, student teaching evaluations, and service to the

university. These measures, particularly the latter two, rely strongly on emotional intelligence rather than cognitive skills. Although emotional intelligence is required in order to build trust and rapport with students and colleagues, there is no systematic approach to or understanding of emotional competence within the academic workforce.

Furthermore, students benefit more from emotionally competent teachers. Mayer and Salovey (1990) defined emotional competence as "the ability to monitor one's own and others' feelings and emotions, to discriminate among them and to use this information to guide one's thinking and actions" (p.198). However, emotional management, as used by the authors is more in line with Mayer and Salovey's (1997) revised definition which states that "the ability to perceive accurately, appraise and express emotion; the ability to access and / or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth" (p.10). Petrides and Furnham (2000) discuss the idea that "EI research draws heavily on personality variables such as empathy, optimism and impulsivity, but often influences other, somewhat vaguer, constructs that seem to be potential correlates (e.g. motivation, self-awareness, happiness) rather than essential elements of EI. By contrast, the information-processing approach is much more focused and explicit as to the constituent parts of EI and its relationship to traditional intelligence" (p.314). Emotional management not only influences the academic arena but business organizations as well (McGough, 2004). Achievement in all domains, including facilitating learning experience for students is pivotal in order to justify an academic role (Preckel et al., 2020).

In this paper, we attempt to show that emotions contribute to academic performance. The specific objective of the paper is to present a theoretical explanation of how emotions contribute to academic performance. Moreover, we ascertain the kinds of coping strategies individuals use to manage emotions including their impact on complex outcomes in professional academic settings. Overall, the proposed paper will advance our understanding of the role of emotions in professional academic settings.

According to Mayer and Salovey's (1990) framework, emotional competence (intelligence) includes the following abilities; 1) Knowing/recognizing one's emotions; (2) managing emotions; (3) motivating oneself; (4) recognizing emotions of others; (5) handling relationships. In 1997, Mayer and Salovey further refined emotional intelligence into four mental abilities: perceiving/identifying emotions, integrating emotions into thought process, understanding emotions and managing emotions (Mayer & Salovey, 1997).

Petrides and Furnham (2000) discuss the idea that "EI research draws heavily on personality variables such as empathy, optimism and impulsivity, but often influences other, somewhat vaguer, constructs that seem to be potential correlates (e.g. motivation, self-awareness, happiness) rather than essential elements of EI. By contrast, the information-processing approach is much more focused and explicit as to the constituent parts of EI and its relationship to traditional intelligence" (p.314).

Research points out that there is a biological base to emotional competence, as Damasio (1994) defined emotion as a "combination of a mental evaluative process, simple or complex with dispositional responses to that process, mostly toward the body proper, resulting in an emotional body state, but also toward the brain itself (neurotransmitter nuclei in brain stem), resulting in additional mental changes" (p.139). Damasio's (1994) work provided further credibility to emotional competence.

Literature also establishes a strong association between Big Five personality traits and emotional competence (Athota & O'Connor, 2014; McCrae, 2000; Matthews et al,. 2006). Personality trait 'extraversion' has been found to have significant association with emotional competence (Matthews et al., 2006). The authors use emotional competence only due to the conceptual nature of the paper do not get it.

The framework of emotional intelligence has been positively associated with social network size (Austin et al., 2005), life satisfaction (Palmer, Donaldson & Stough, 2002), cognitive competencies such as verbal, spatial, and numerical aptitude factors (Bass, 2002), the prediction of job advancement criterion (Zeidner, Matthews & Roberts, 2004), better social and personal relationships; also, higher levels of life satisfaction and lower levels of depression (Austin, Soklofske & Egan 2005). Emotional intelligence has been found to have a positive correlation in dealing with moods and behaviors (Forgas, 2001), managing stress (Jain & Sinha, 2005) and even sports performance (Perlini & Halverson, 2006). Furthermore, low emotional intelligence in males has been positively associated with illegal drug and alcohol use, deviant behaviour and poor relations with friends (Brackett, Mayer & Warner, 2003). On the whole, the concept of emotional intelligence has shed new light on the importance of a healthy emotional life.

Overall, emotional competence has found to play a significant role in building personal and professional life. Much research has focused on how emotional competence is utilized among student and business communities. But to the authors' knowledge there is limited research on how emotional competence influences academic teaching and career advancement. We suggest that logically, good teaching requires emotional intelligence.

2 Good teaching

Emotional Intelligence is an essential attribute for educators in the university environment. The literature on best pedagogical practice emphasises the role of the educator in fostering a learning environment that inspires and engages students towards self-directed learning. This approach is illustrated by the Socratic phrase "kindling of a flame, not the filling of a vessel" (Robinson, 2011, p. 251). A student focus that influences conceptual change and that motivates and inspires students to become life-long learners (Biggs & Tang, 2007) are key themes in the literature. Student focussed teaching which conversation, debate and time for questions promotes self-directed learning (Trigwell, 2006). Therefore, emotional intelligence can play a key role in student focused teaching.

Passion and commitment in teaching the subject plays a pivotal role in positively influencing students' learning experience. According to Ramsay (2001), "the example of a teacher who is enthusiastic about his subject and passionate and truthful in his arguments is the most precious discovery a student can make. Being passionate oneself about independent thinking is the best way to develop independence in others" (p. 139). Therefore, the emotional component of teaching is significantly important in addition to the cognitive ability of an employee. Cognitive and emotional connectivity facilitates a pivotal learning experience in the classroom. Mezirow (1997) stresses that "educators must assume responsibility for setting objectives that explicitly include autonomous thinking and recognise that this requires experiences designed to foster critical reflectivity and experience in discourse". Such education, he says, is learner-centred, commonly involving "group deliberation and group problem solving".

Empathy is an integral part of emotional competency. Belanger and Longden (2009) found that students value teachers who display not only "enthusiasm for ideas and subject matter" but also "empathy towards them as persons". The literature emphasises mindfulness of the needs of students with diverse learning styles and levels of self-motivation (Ednilson & Hanna, 2009) coping with the pressures of today's university environment (Toohey, 2010) and the benefits of student-centred blended learning activities (Caulfield, 2011). These themes reveal a clear link to emotional intelligence as a preeminent trait of a good teacher in the academic environment. University teaching is about inspiring a large and diverse cohort of students, some of whom bring a high level of motivation, and others who turn up begrudgingly (Biggs and Tang, 2007). Emotional intelligence is essential in order to provide both empathy and inspiration in the classroom.

Based on the existing research we found two important research gaps in the literature.

2.1 Research Gap #1

The first research gap in this paper seeks to highlight is around the crossover between emotional intelligence research and the pedagogical literature. Research on emotional intelligence is primarily located within the fields of Management and HR, appealing to managers in private industry but rarely focusing directly on the academic workforce. Meanwhile, the research on good teaching practice implicitly highlights the need for emotional intelligence but does not provide enough research support that it in the language of emotional intelligence. The considerable overlap between the two fields seems accidental. Further research is required to explicitly draw these two fields together.

2.2 Lack of E.I. Training and Recognition

Research by Schimanski and Alperin (2018) found that university procedures for review, promotion and tenure focused excessively on "research at the expense of teaching and service" (p10). Research output is commonly judged according to oversimplified

rules-of-thumb like journal impact scores, leading to "barriers to career advancement" (p10) for educators taking non-traditional approaches (e.g. social media engagement) regardless of whether these novel approaches connect with students and the wider public. This leads to an institutional understanding of *impact,* and therefore career advancement, which is aloof; devoid of any need for emotional competence. Furthermore, the work of Brennan and Magness (2019) highlights the grave consequences of incentive structures built around the preservation of insider power and status, rather than the best service of the ostensible mission of the organization. Therefore, priority should be given in promoting emotional competence.

An extensive empirical study by Osinski and Hernandez (2013) found that *closeness to the student* was the preeminent trait of good teachers as reported by students themselves, once the restraints of the typical teacher evaluation survey were removed and a more open survey was used. The authors found a disconnect between the kinds of questions asked in formal surveys – and therefore judged as important by university administrators – and what students themselves deemed as the most important characteristics.

2.3 Research Gap #2

The second research gap this paper seeks to highlight is around the crossover between Emotional intelligence research and university procedures for review, promotion and tenure. Emotional Intelligence is the defining factor which distinguishes good teaching, yet it is absent or seriously lacking in university review and promotion metrics. Further research is required into how senior leaders of universities could use emotional intelligence for the purpose of identifying, recognising and promoting academic talent. Academia needs higher education practitioners with emotional intelligence and intrinsic motivation to promote learning mindset among students (Naude, Nel, van der Watt and Tadi, 2016). Generally, criteria for promotion revolves around, Research and Scholarship, Teaching and Curriculum Development, Academic Leadership and Service to the University. Academics need to demonstrate some level of performance in these areas in order to be considered for promotion. Yet the emotional component is significantly required for effective teaching, academic leadership, and service to university criteria. In this study we attempt to show that the role of emotional competence is central to good teaching and that academics may be rewarded for exercising emotional competence in teaching rather than just cognitive abilities.

Even though this paper focused on emotional competence of academics in teaching, it is vital to develop emotional competence beginning in the early years. Early social experiences play significant role in overall development of cognitive and emotional abilities, including the reduction in antisocial behaviour (Palmer, 2005). Therefore, developing emotional competence ought to be promoted for teachers in order to positive learning experience. Overall, the aim of this paper was to explore a research gap, therefore, empirical evidence is lacking in this conceptual paper. Robust qualitative and

quantitative studies are required to further establish the research proposal. A cross-cultural and longitudinal study can further strengthen the proposed research.

3 Conclusions

Overall, the paper explores the importance of emotional competence in promoting student learning opportunities. High cognitive ability and the publication of scientific papers are seen as important in promoting student learning, yet this paper has raised important questions about the role of emotional competence in teaching and promoting student learning opportunities. This paper has identified two gaps in current research: 1) That there is a lack of emotional competence training and research in academia and 2) Emotional competence has not be identified in higher education policy. The principle theoretical implication of this paper is clear: emotional intelligence in academic teaching practice requires further empirical research. Moreover, emotional competence should be given additional importance in promotions in the academic setting due to its influence on student learning.

Abstract

The main objective of this study is to create a systematic map of the existing state-of-the-art research on service provider incentive models and incentive functions in digital business ecosystems that promote collaborative value co-creation. The chosen research method is the systematic mapping study. The classification of publications revealed eight main categories of interest: 1) Incentives for collaboration 2) Incentives for cooperation 3) Design of incentive models 4) Trust management 5) Potential challenges with incentives 6) Incentives in non-cooperative networks 7) Incentives in value creation networks and 8) Blockchain or token-based incentives. The resulting systematic map was visualized using a sunburst chart combined with the research gap analysis. The identified gaps in the incentive related research were related to the lack of studies from the ecosystem point of view, lack of studies related to automating incentives processing and addressing the incentive related KPIs in ecosystems. To further strengthen the collaborative working and innovation between service providers, the following areas are suggested for further study: ecosystem level approach to incentives, service providers' preferences on desired incentive models and digital assistants for automating incentive functions for service providers.

Keywords – Incentives, Digitalization, Ecosystems, Value co-creation, Mapping study

Paper type – Academic Research Paper

1 Introduction

Business ecosystems compete with their diversity and scale. A business ecosystem is a diverse network of different types of organizations which together are able to produce

more value than any organization alone (Moore, 2006). High diversity means capabilities to evolve, adapt and innovate faster than the competition. High scale means capabilities to develop and expand the ecosystem further.

Business ecosystems are especially characterized by value co-creation activities actualized as collaboration between the ecosystem actors (Ranjan and Read, 2016). Previous research has shown that customers and other stakeholders' involvement in the value-creating process within the ecosystems has a positive effect on the final perceived value (Vuori et al., 2018, Prahalad and Ramaswamy, 2004). However, the perceptions between the different ecosystem actors may vary a lot due to their different viewpoints and variations in modus operandi, leading to a need to understand better the different incentives of the actors in business ecosystems.

Incentives are a mechanism to amplify desired outcomes in business ecosystems. Collaboration, sharing of information and co-creation of new solutions can be boosted by appropriately incentivizing these actions. Especially from the knowledge management point of view, incentives can support collaborative knowledge creation and more efficient knowledge transfer between different organisations (for example, Berger and Lettl, 2013).

The focus of this mapping study is to explore and recognise the different opportunities related to incentive models from the perspective of a service provider as an actor in a business ecosystem. More precisely, this study aims to identify the current state-of-the-art research on ecosystems related incentives published during the past 10 years. The study will consider both the technical and business-oriented research on incentive models.

In this paper, we use the Finnish national Aurora Artificial Intelligence programme (Kopponen et al., 2019) as a motivational example of a need to better understand ecosystem-level incentives.

The rest of the article is structured as follows: Chapter 2 presents a brief overview on the theory of incentives and contracts. Chapter 3 introduces the AuroraAI programme and defines a list of areas of interest for the study. Chapter 4 presents the research questions and the process of conducting the mapping study. In Chapter 5 the results of the mapping study are presented and visualized. The major findings are then discussed in Chapter 6 followed by the conclusions in Chapter 7.

2 Theoretical background

This section introduces the theoretical background of incentives. First, the contract theory is explored as basis for incentives. Then, theories of motivation are explored to better understand the needs linked with incentives. The chapter is concluded by an overview of the game theories and use of dynamic incentives.

2.1 Contract theory

The contract theory (Hart 1983, Holmström, 1994) and, in particular, the principal-agent theory forms the basis for the incentive theory (Laffont and Martimont, 2002). The principal and agents can agree on using incentives as a component of the contract to optimize the overall business value for both.

The incentive theory acknowledges the agents always pursue at least partly their own private interests. These private interests could be due conflicting objectives between the principal and agents, or due private information known only by the agents. The incentive theory calls these two issues as (1) moral hazard and (2) adverse selection.

For the context of this paper, the facilitating operator of the ecosystem can be considered as the principal and service providers as the agents. However, the principal-agent theory becomes challenged when extended to ecosystems because of its limited scope of addressing the complexity of ecosystem inherent relationships and collaboration.

2.2 Motivation theory

The different theories of motivation investigate and explain the behaviour of why people and organisations get motivated and what is the incentive they desire most.

The need-based motivation theories approach motivation through satisfying a person's or organisation's needs. A few examples of need based motivation theories are: (1) Maslow's hierarchy where the needs are related to physiological, safety, social, esteem and self-actualization (Maslow, 1943), (2) ERG theory where the needs are regrouped as existence (E), relatedness (R) and growth (G) (Alderfer, 1969), and (3) 2-factor theory where the needs are divided into hygiene factors and true motivators (Herzberg, 1968).

In the process-based motivation theories the approach is more focused on actions. A few examples of process-based motivation theories are: (1) Equity theory, which measures the ratio between a person's inputs (contributions) and outcomes compared to a referent. If the comparative ratios look equal the equity is perceived as fair. If not, then the situation is perceived as unfair and de-motivating (Adams, 1963), (2) Expectancy theory, where the level of motivation is determined by assessing how likely it is the effort leads to high performance in the reference group (expectancy), is the performance going to be rewarded (instrumentality) and how desired are the potential rewards (valence) (Victor Vroom in 1964, discussed in Lawler, et al., 1973), and (3) Reinforcement theory (Skinner, 1938) where interventions either aim to increase the desired behaviour (reinforcement) or to decrease the unwanted behaviour (punishment and extinction).

2.3 Game theory

From the ecosystem point of view, defining the incentive model becomes an optimization problem which can be modelled with game theories.

In non-cooperative games the Nash equilibrium refers to a state where each party is assumed to know the strategies of other players and still players cannot gain anything by changing only their own strategy (Kuhn et al., 1996).

The cooperative game theory (Harsanyi, 1963) allows players to form alliances and it focuses on the collective actions and collective payoffs. The latter theory is likely to be more usable in networks which promote collaboration and co-creation.

2.4 Need for dynamic incentives

The dynamic nature of collaborative networks produces small, fast, diverse and distributed contributions, which ideally should be captured by the incentive mechanism.

Distributed Ledger Technologies (DLT) based on blockchain are one potential solution for introducing mechanisms that can cope with the required dynamics (Wood, 2014). The natural characteristics of DLT systems seem to be well aligned with the needs of incentives:

- The incentive logic can be encoded directly into the blockchain (automation).
- The distribution of incentives is almost immediate (real-time payoffs).
- The unit of incentives can be very granular (small contributions).
- All incentive related transactions can be verified by anyone (high transparency).

3 Example: AuroraAI

The Finnish national Aurora Artificial Intelligence programme for 2020-2022 aims to develop a new distributed digital service operations model to support people's life events through a network of smart services and applications (Kopponen, et al., 2019).

In this smart network, a number of service providers are brought together to co-create seamless and versatile service offerings for different life events. Incentives are a potential mechanism to ensure the business case for each service provider will be healthy and with a sufficient scale.

For the purpose of this mapping study, the incentive related requirements were extracted and summarized in four themes as depicted in Figure 1. These high-level themes will be used as a guide later in the mapping process to assess the relevance of the identified articles.

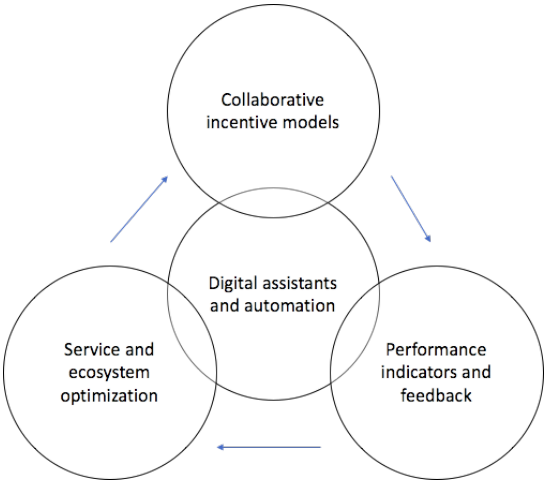

Figure 1. The incentive related topic areas based on AuroraAI ecosystem.

4 Research method

The chosen research method is the systematic mapping study according to (Petersen, 2015). The steps of the process are presented in Figure 2.

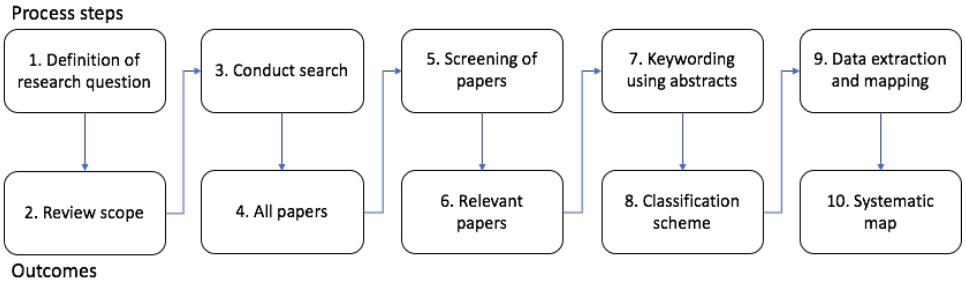

Figure 2. The overview of the systematic mapping process.

The goal of this mapping study is to identify the current state-of-the-art research on the service provider incentive models. Thus, the research questions are the following:

RQ1 *= What topics have been addressed in the current research on service provider incentive models?*

RQ2 *= Where and when were the studies published?*

RQ3 *= What are the current research gaps?*

First, a set of pilot searches were conducted using a modified PICO model (Santos, 2007) and selected topical anchor words to estimate the number of expected results. Based on the pilot searches, the final search string was decided as presented in Figure 3.

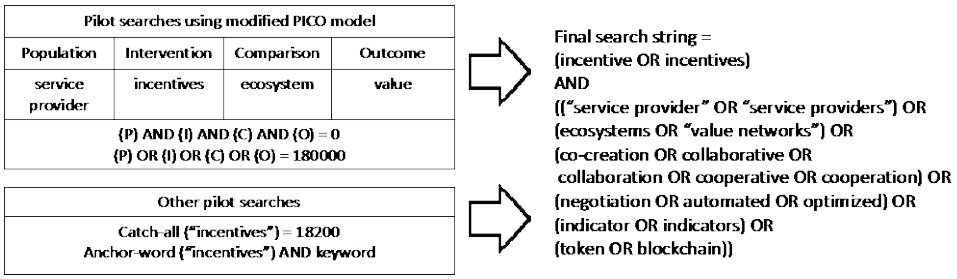

Figure 3. Formulation of the search string

The search, which was limited to titles, was conducted in multiple article databases: Google Scholar (890 articles), Elsevier ScienceDirect (78 articles) and IEEE Xplore (146 articles). The inclusion and exclusion criteria as presented in Table 1 was used in the screening phase with two reviewers for 932 articles combined. After screening, 61 remaining articles were dynamically classified into eight main categories.

Table 1. Inclusion and exclusion criteria.

Inclusion criteria	Exclusion criteria
- Topic is about service provider incentives or supporting functions - Topic is relevant in a value network or ecosystem - Topic is relevant for collaboration or cooperation	- Any other topics - Study has been published earlier than 2010 - Study is in other language than English

5 Results of the mapping

As outcome of the mapping process, 61 articles were included into the final map.

5.1 Topics of publications

The classification of articles revealed eight main categories which are described next with the references to the original publications.

Incentives for collaboration

Collaboration means working together for a common goal through shared objectives and vision, shared resources and shared responsibility (Jardine, 2010). The nature of collaboration is dynamic and roles of stakeholders may change during collaboration. Another concept which can be understood quite similarly is "co-creation".

The studies identified under the category of "incentives for collaboration" discuss how to define incentives for collaborative innovation when also small contributions are rewarded (Boss, et al., 2017), punishments in collaboration (Meng, Jang, 2010), definition of collaboration (Jardine, 2010), rewards sharing based on contributions (Bachrach, et al., 2012), risk-sharing in collaboration (Song, et al., 2017), incentives in knowledge sharing (Perkmann, et al., 2013) and aggregated performance (Zehir, et al., 2017).

Incentives for cooperation

Cooperation differs from collaboration in the sense it is more focused on reaching individual objectives with the help of other stakeholders. Cooperation typically means sharing resources or information based on agreed individual responsibilities.

The category of "incentives for cooperation" is the largest category and contains the highest number of sub-categories. The topics covered range from motives and trust to social preferences (Boone, et al., 2010 and Moisan, et al., 2017), choice of partners (Archetti, 2011), optimal distribution of incentives (Chen, Perc, 2014), cost and risk (Boukendour, Hughes, 2014) and resource-sharing (Vega, et al., 2013). Several papers utilize game theories.

Design of incentive models

The category "design of incentive models" discusses the different types of incentives (Hawa, 2010, Pajarito, et al., 2018, Manzato, 2010 and Mantilla, 2014). One common topic that is repeated in this category is the concept of dynamic incentives that change based on the state of collaboration (Vespa, 2015, Chen, et al., 2015, and Zhang, et al., 2015).

Trust management

A profound topic related to incentives is trust management. The level of trust between stakeholders affects the form of incentives which can be agreed for collaboration or cooperation. The identified studies in category "trust management" discuss defining a trust degree for selfish users (Wang, et al., 2016), addressing cold-start problem when trust is not yet there (Lafuente, Seigneur, 2015) and encouraging trust with incentives (Pippin, Christensen, 2012).

Potential challenges with incentives

In addition to potential trust management issues already mentioned, the category "potential challenges with incentives" extends to further challenges like the issue of community instability where participants join and leave (Song, et al., 2015) and incentives in uncertain collaborative environments (Bachrach, et al., 2013).

Incentives in non-cooperative networks

Incentives are naturally used also in competitive environments. As an example, knowledge sharing with non-cooperative incentives is discussed in (Kwiatkowski, 2010).

Incentives in value creation networks

The category "incentives in value creation networks" was one of the major interests in this mapping study. Two prime articles were identified in this category. The first discusses the potential challenges and research topics related to incentives in value creation networks (Hulkko-Nyman, et al., 2013). The second article presents an overview into a system concept of Service Value Networks (SVN) with highly specialized service providers contributing to an overall value proposition (Blau, et al., 2010).

Blockchain or token-based incentives

This category contains several examples of practical implementations or implementation proposals using bitcoin or token-based incentives. The articles in this category cover token design (Laskowski, et al., 2019), token use cases in vehicular networks (Bae, Cho, 2019, Wang, et al., 2019, and Park, et al. 2017) and peer-to-peer communication networks (ImaniMehr, et al., 2019, and Aslani, et al., 2018).

5.2 Frequency of publications

The publication years of the selected publications are distributed quite evenly over the time period under study (2010-2019) as in Figure 4. This further suggests the topic under study is scattered and covers aspects from multiple research domains. The average number of publications per year is 6,1 for the defined search and inclusion criteria.

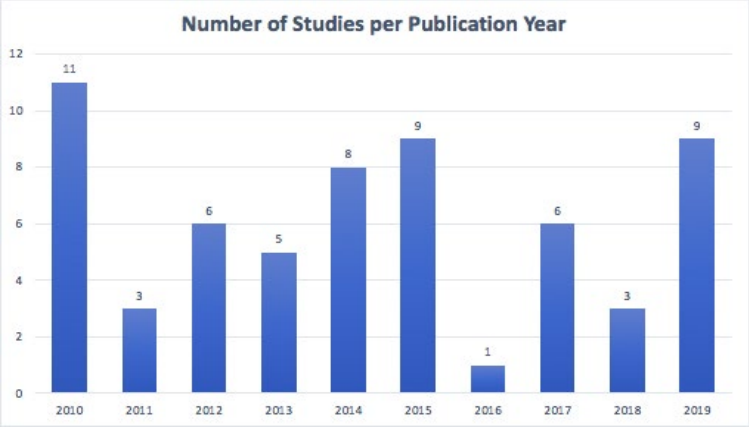

Figure 4. The number of studies per publication year.

5.3 Venues of publications

Most of the articles have been published in Journals (38%) and Conferences (33%). Still there are also single articles (16%) and a few thesis (7%) which are relevant for the topic. A few articles were published in a book or technical report (6%).

6 Discussion

The findings from the classification phase are evaluated next in comparison to the research questions set for this mapping study. The identified articles will be placed in a visual map together with the identified gaps. The research gaps are identified based on the theory part in Chapter 2 and the identified themes in Chapter 3.

6.1 What topics have been addressed in the current research on service provider incentive models (RQ1)?

Based on the results, the current research on incentive models is scattered into multiple research domains and there are few systematic approaches which combine the individual topics to an ecosystem level approach. The Figure 5 presents a summary of the currently addressed research topics and the identified gaps combined into one visualization.

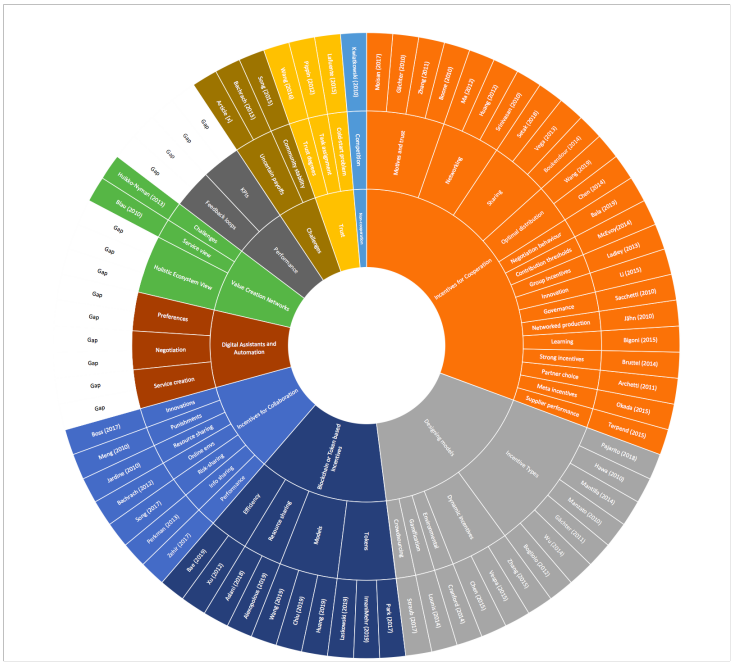

Figure 5. Illustration of the addressed topics and identified gaps.

6.2 Where and when were the studies published (RQ2)?

The identified existing research has been published quite evenly distributed over the time period under study (2010-2019) as described in Chapter 5.1. There is also a highly diverse number of publication channels. Clearly, there is no single channel with a sole focus on addressing the incentive functions in digital ecosystems.

6.3 What are the current research gaps based on the identified research activity (RQ3)?

The lack of systematic studies from ecosystem perspective is a research gap. Further, when comparing the findings with the topics of interest in Chapter 3, the lack of studies related to automating incentive processing, performance KPIs and feedback functions are also research gaps.

7 Conclusions

This mapping study has looked at the incentives-related research from multiple angles: From contracts theory to behaviour theory and from individual's view to ecosystem's view. Throughout the investigation, the need for a more systematic approach to describe the different aspects of incentives related functions has become clear.

On the other hand, there is a need to keep the incentive models understandable regardless of the complexities of ecosystem collaboration. This suggests a higher level of automation and simple tools are needed in incentive processing for service providers. To conclude this study, the following topics are suggested as focus areas for further research:

Ecosystem level approach to incentives. This research topic should study especially the trust management aspects of collaboration at the ecosystem level. Trust management is linked with the characteristics of the sharing economy: willingness to share risk, share information and share rewards among the actors of the ecosystem. Thus, it creates the base for defining the actual incentive models.

Further study on service providers' preferences. Incentive model is only one component of the business model canvas for the service provider. Further study is suggested on investigating what are the desired incentive models and functions from service provider's view. This research could be done as structured interviews with a number of digital service providers.

Further study on digital assistants and automating incentive functions for service providers. Based on the results of this mapping study, there is not much existing research on automating the incentive functions for the service provider. Further study is suggested on clarifying the need and requirements for digital assistants to help service providers understand the incentive models, measure the results and maximize their own business case.

Collecting feedback from pilot projects like AuroraAI helps to further align the research activities with the highest practical value. It is suggested to gather systematically the feedback from AuroraAI and other pilot programs.

Abstract

The Fourth Industrial Revolution (I4.0) is dramatically affecting firms' strategies, transforming their business models. In particular, a bunch of technologies like IoT (Internet of Things), cloud platforms, big data, and data analysis are offering firms the possibility to manage products functions, remotely and globally, kickstarting the design of innovative business models. The aim of this article is to investigate how incumbent manufacturing SMEs can manage the evolution of a new business model enabled by IoT in parallel with its extant business model, with particular attention to the main resources and capabilities required, as well as the main difficulties encountered.

Keywords – IoT, Business Model Innovation, Digitalization, SMEs.

Paper type – Academic Research Paper / Practical Paper

1 Introduction

The Fourth Industrial Revolution (Industry 4.0, I4.0) is dramatically affecting firms' behaviors and strategies, transforming products design, manufacture, operations and services (Rüßmann et al., 2015). This disruption is linked, in particular, to a series of technologies within the I4.0 framework that will dramatically change the way firms operate in their markets (O'Connell et al., 2015). Among I4.0 technologies, a set of outward-oriented, front-end set of technological streams – IoT (Internet of Things), cloud platforms, big data, and data analytics – are transforming business markets landscapes, offering firms the possibility to monitor, optimize and automatize product functions, remotely and globally (Porter and Heppelmann, 2014). These technologies are at the core of a radical transformation of manufacturing leading to a change of firms' business models (BMs) with the expansion of service innovation opportunities (Lusch and Nambisan, 2015).

The emergence of these disruptive technologies pushes incumbent firms to change and adapt their BM to stay competitive (Rachinger et al., 2019), thus transforming markets landscapes (Porter and Heppelmann, 2014) and posing big challenges to entire industries (Stock and Seliger, 2016). Indeed, "not all incumbents perform better after adding new business models to their existing one" (Kim and Min, 2015, p. 34). This suggests that despite some years have passed from the explicit call for research on how firms can organize these experimentations with BMs effectively (Andries et al, 2013), the lack of a better understanding of how this process unfolds overtime continues to be mentioned as a gap in the literature (e.g. Laudien and Daxböck, 2016; Müller et al., 2018; Parida et al., 2019).

Against this background, the purpose of this article is to investigate BM innovation (BMI) from the point of view of B2B manufacturing firms, whose traditional strategies are being disrupted by the ongoing I4.0 revolution (Laudien and Daxböck, 2016; Müller et al., 2018), especially as regards SMEs, for which these issues are even less investigated (e.g. Paiola and Gebauer, 2020). Therefore, more particularly, we aim to answer the following research questions: how can incumbent manufacturing SMEs manage the evolution of a new business model enabled by IoT in parallel with its extant business model? What are the main resources and capabilities required and what the main difficulties encountered?

The reminder of the article is structured as follows: in the next section, we set the theoretical bases for our study, then we illustrate the methodology we followed and the present the results of our analysis, before discussing them in light of existing studies and highlighting implications for theory and practice.

2 Theoretical background

IoT was firstly used to indicate the interconnection of physical objects through adding sensors for various purposes, including identification, sensing, communication and data collection (Ashton, 2009)." These features of IoT have affected manufacturing paradigms and the way of doing business, among which the possibility to offer these additional innovative services or features to the existing products is likely to influence value creation processes, which attracted researchers' attention on how firms can redesign their business models accordingly (e.g. Suppatvech et al., 2019; Paiola and Gebauer, 2020).

In this regards, authors have put forward different archetypes of IoT-based business models based on the role and importance of digital processes enabled by the IoT-related technology. Among the others (e.g. Laudien and Daxböck, 2016), for example Suppatvech et al. (2019), with a focus on the provision of servitized offerings through the use of IoT, propose four archetypes of IoT-enabled servitized business models based on their main value propositions: (i) add-on business model that uses IoT in enabling additional functions or adding personalised services to the existing physical products or service; (ii) sharing business model, where the customers pay for using or accessing a product for a limited amount of time; (iii) usage-based business model that uses IoT to measure the amount of product usage and allow customers to pay for or subscribe to the plan, based on their actual usage and needs (pay-per-use or subscription); and (iv) solution-oriented business model that utilises IoT in enabling the provision of integrated solutions to customers' needs, which in B2B practice relate to supporting customers' core operations and increases in efficiency, and expanding business capabilities.

It is clear how the opportunities offered by the IoT have made this stream of research merge with the BMI one that has increasingly focused on different strategies of BMI. More particularly, many (e.g. Khanagha et al., 2014; Savič et al., 2016; von Delft et al., 2019) distinguished between making incremental changes to individual components of the BM and disrupting the BM acting on multiple components. Others have distinguished among developing, transforming, enhancing, extending or redefining the BM (Laudien and Daxböck, 2016; Paiola and Gebauer, 2020), which recalls another relevant dispute, i.e. complementarity versus substitutability (Casadesus-Masanell and Tarzijan, 2012). Markides and Charitou (2004), introducing the concept of dual business, paved the way through research on how to manage multiple BMs.

Taking the dimension of time into consideration, come authors have taken a learning process perspective to study BMI, embracing the evolutionary view that sees BM development as an initial experiment followed by constant fine-tuning and learning (Savič et al., 2016). In this domain, despite the literature encourages firms to experiment with BMs stating that BMI cannot be completely anticipated and firms cycle through an iterative learning process by conducting experiments that allow them to test individual elements of a new BM (von Delft et al., 2019), it is still unclear how they can organize these experimentations effectively (Andries et al, 2013). After some years, the lack of a better understanding of how this process unfolds overtime (e.g. key phases, activities and

roles, customer involvement) continues to be mentioned as a gap in the literature (e.g. Laudien and Daxböck, 2016; Müller et al., 2018), even within the specific literature on digital servitization (Parida et al., 2019). Considered that the research in this domain has only marginally focused on SMEs in favour of large companies (Müller et al., 2018; Cosenz and Bivona, 2020), this study aims to investigate how incumbent manufacturing SMEs can manage the evolution of a new business model enabled by IoT in parallel with its extant business model, with particular attention to the main resources and capabilities required, as well as the main difficulties encountered.

3 Methodology

3.1 Research design and case selection

We designed an inductive research method founded on a qualitative exploratory and longitudinal research design based on a multiple case study (Bryman & Bell, 2011), which is recommended in exploratory research, as it provides detailed data and allow for the investigation of current managerial challenges (Yin, 2009). A purpose-oriented case selection was adopted (Eisenhardt, 1989): medium firms exploring the possible uses of IoT-based technologies to expand their service-oriented offerings and innovate their BM that could provide congruous access to information and knowledgeable informants were our target. Among many cases examined, we selected two exemplary cases located in two of the most industrialized areas having an acknowledged tradition and an excellent standing in the North of Italy, namely Lombardy and Emilia Romagna, and belonging to the same industry, i.e. packaging.

3.2 Data collection

We carried out multiple interviews, which were recorded and transcribed, with multiple respondents between 2016 and 2020, thus obtaining real time primary data, which was complemented by site observations, meetings and secondary data to enhance validity and reliability. We also gathered data from the preceding years to cover any relevant information and reconstruct the evolution of BMI since the beginning. In-depth longitudinal access is a desirable requisite of strong qualitative case study theorizing especially by means of the comparative case study method (Pettigrew, 1990).

3.3 Data analysis

We employed multiple tools and tactics for data analysis. Firstly, we performed the within-case analysis starting from the interview transcriptions and from other meetings and interactions minutes. More particularly, we prepared a comprehensive overview of each case's relevant features, using acknowledged techniques of data reduction and

display for structuring and thereby simplifying information (e.g. Miles and Huberman, 1984). This allowed identifying the relevant aspects pertaining to the changes of business model elements. Secondly, by analysing and ordering the significant events along the considered period, we outlined the phases of the new business model, building a stylized process. Thirdly, we proceeded with the cross-case analysis to identify similarities and differences across the two cases, always by means of tables.

4 Case analysis

4.1 Within-case analysis: Case Alpha

Company Alfa is located in Lombardy, it is a leader manufacturer of complete packaging systems for dried food. It is a medium-sized enterprise that employs 110 people with a total turnover of 30MEur, with a strong and long-standing reputation in quality, innovation and customer service.

Alfa recently signed an innovative performance-based contract with one large customer, leveraging a customized IOT-based remote condition monitoring solution. This product-service system allows Alfa to monitor customer's operations performance remotely and control machine settings and functioning to fulfil agreed-upon productivity and Overall Equipment Effectiveness (OEE), to which monthly fees are parameterized. The analysis and visualization of customer's processes data are fundamental to guarantee the agreed-upon Service Level Agreements, whose failure to achieve is at the supplier's responsibility and impact on actual revenues following bonus-malus mechanisms.

First attempts at the new solution date back to 2013-2014, but different improvements have been made over time. The next section describes this evolution.

4.1.1 Different phases in Alpha's BMI

At the end of 2013 a large player in the food industry is in need of replacing complete lines of packaging machines of one of its production plants in Italy. An invitation to tender for the supply of several production lines is transmitted to different suppliers both in Italy and internationally. The supply encompasses different connectable machines some of which coming from different suppliers (for asking the supplier to act as integrator). Moreover, the bid specifically calls for the provision of the machines within an overall contract in which the supplier would have committed to guarantee an agreed-upon level of performances (an OEE of 85%) along the machines' lifetime.

Alfa's CEO and R&D Manager meet the challenge and leverage all the internal competences they possess to satisfy the customer's needs. They commit for weeks in crafting an appealing and sustainable tender and in the end, as for January 2014, the bid is closed with their being selected as suppliers. Then the design and production of the production lines begin, and that requests several months to be accomplished, involving Alfa's BUs without any relevant organizational changes to the business-as-usual. In July

2014 the first production line is tested and begins production, which makes a new phase begin.

Most part of the innovative job requested to Alfa by the new service offering starts in 2014, when machines begin to be installed and tested. All the operational activities are hosted in the same product BU, no organizational modification is made. The team dedicated to the innovation development is however extended: alongside the CEO and the R&D manager, the first ramp-up period goes in parallel with the construction and assembling of the lines, that is managed by the technical division, and the production division as in business as usual. The team's work is aimed at the actual design of the solution (the service component of the product-service system) and is founded on the work of three internal people (taken from the technical office) and a newly hired computer engineer, dedicated to the design of software.

Although the team is quite small, it continues to have frequent and dense interactions with other internal organizational divisions and is regularly connected to a crew that is in charge of making the complex system work at the customers' premises. As new machines and lines are installed and added in the customer's factory, new members are gradually added to the on-site crew, totalizing 10 components (shifting accordingly to the customer's workhours) at the end of period 2. All these people belong to the same organizational BU inside Alfa.

A great deal of interaction characterizes the relation with the customer: both TMTs participate in main technical meetings, and the customer's contribution in the specification and refining of the design of the service is significant. "*There was a very good feeling among us, helped also by the very high professional level of the new managers in the client's organization*" says Alfa's CEO.

The first outcome of this phase is a functioning prototype of IoT-based solution capable of sustaining the contractual agreements: Alfa has to constantly monitor and be able to study process-related data in order to eliminate any operational dysfunction that may impede to reach the desired outcomes. This first version, called prototype 1.0, is a customized solution that leverages IoT technologies, and transmits data to a special control room in-house in order to be capable to monitor 24/7 every relevant efficiency-related input. This period sees also some relevant contributions from external actors and players, especially as regards the technologies that are more distant from Alfa's core knowledge, like for example data analysis and software design. A relevant role, especially in the first steps (but also in intermediate searches for solutions and benchmarks) is played by the CEO's epistemological network: he is in fact involved in cross-industry I4.0-related professional communities, in which precious experiences and prospective solutions circulate among participants.

Against this background, when in 2019 the same key customer asks to apply the solution to another of its production plants, Alfa approaches this subsequent request having accumulated almost 6 years of direct experience, and therefore possessing a much higher awareness of the project's challenges and their best solutions: it acknowledges the

possibility to leverage this unique experience in order to design services and solutions also for different customers and industries. In line with this, Alfa recognizes that architectural choices made years before are not appropriate for a replication of the solution neither for the same customer nor for other customers. Alfa chooses to develop the new solution using a cloud-based architecture and selects a world class cloud platform services provider. Version 1.0 is indeed adapted and finally migrates to the cloud, envisioning prototype 2.0. The internal team (with the help of few external contributions) works intensively for upgrading the graphic user interface (GUI) and the user experience (UX), and makes machines' data visual reporting more effective and usable, thus greatly improving the versatility of the solution, that now the customer can access from desktop controls and distributed personal devices via a dedicated app. Here the role of the cloud-related tools is fundamental in leveraging the full potential of IoT technologies for the innovation of the business model.

In the beginning of 2020, Alfa enters the current period of development with a significant experience and a bunch of customers that already have entered the first level of its 2.0 offer. Overall, 13 customers have installed the level 1 (for a total of 40 machines) and are paying fees or using for free within the warranty period (all the users of prototype 1.0 are invited to migrate to 2.0). Figure 1 highlights Alfa's BMI phases key points.

				Period 3: Replicate and commercialize	
		Period 2: building and refining the prototype			
	Period 1: inception				
Temporal horizon and main events	end 2013: Alfa wins the tender with a key customer	july 2014: the first line of 7 is activated, Alfa begins to learn	mid 2016: version 1.0 is stable (prototype 1)	mid 2019: version 2.0 (prototype 2) and 4layer value-proposition	New machines are upgraded, old applications (1.0) migrate to prototype 2

Figure 1 – The BMI process in Alfa

4.2 Within-case analysis: Case Beta

Beta is a medium-sized company that produces machines and solutions for the packaging of tissue products, with strong capabilities related to innovation and service development. It employs 120 people, has a turnover of 50MEur and is located in the industrial cluster named "Packaging Valley" in Emilia Romagna. Beta has developed a platform-based solution leveraging IoT and cloud solutions, and a complete connectivity outfit developed for the new machines (also available in retrofitting kits for some previous generations). The system is capable to report with an easy-to-use visualization interface the most relevant performance indicators related to the installed machines, available 24/7 in desktop, laptop and smartphone GUIs (increasing attention has been dedicated to UX). The system has a back-end engine able to automatically support users

to have ML-based hints and suggestions to correct any emerging efficiency problems and to introduce procedural changes able to improve efficiency and efficacy. The system is distributed for a free trial period during the warranty period (also helping to avoid free-riding behaviours during the warranty period): incremental revenues are based on the ability to convert free users into fee payers at the end of the warranty period (or earlier), basing on sales force activity.

4.2.1 Different phases in Beta's BMI

It is January 2016 when a Digital Transformation Manager (DTM) - formerly a Beta's sales manager - is appointed to explore the possibilities offered by the I4.0 scenario and in particular by the family of IOT-related technologies (IOT, Cloud, BD, data analysis), actively investing for the design of a possible new service solution, capable of sustaining machines' efficiency and able to differentiate Beta's offer in an increasingly overwhelmed competitive arena. The idea is to leverage technologies to design advanced services linked to the installed base lifecycle, thus generating incremental revenues through recurrent and stable fees within the same market.

The initiative is fully endorsed by the company's CEO, that gives the DTM a "blank proxy" on the strategic exploration activities related to the new technological applications, regarding which she reports directly to him. An intense 6-month period of exploration begins: the DTM exploits all the available external network contacts to explore the possibilities I4.0 could offer to her firm, participating in seminars and work groups, interacting with actual and potential customers, consultancy firms, research centres and universities.

At the end of this period, the DTM has clearer ideas and a better comprehension of the possible uses of the technology. However, the DTM acts alone and has the permission to demand resources to other internal offices (as the technical office, and the IT dept.), i.e. the specific budget is quite limited. The CEO helps for positive internal negotiation for resources and protects the projects from attacks and boycotting from other departments that may feel endangered by the possible future growth of the new business. Against this background, the DTM starts to pretotype the solution with the help of an external consultant, previously working in the industry and with a deep operational knowledge. "*We literally confined ourselves in a room for weeks… he made the customers' voice, and we developed the architecture of the new service functionalities*" says the DTM.

Therefore, the second period of Beta's innovation process begins with a clear intention to invest in the development of a prototype, but with a very gradual approach. For the second half of 2016, the DTM uses external partners and an internal employee co-opted within the technical office (with the CEO endorsement). This little group gives shape to the prototype 1.0, that is developed and distributed until end 2019, when the development of a second prototype begins. Approximately from 2017, the DTM starts scouting its account portfolio in search of a suitable customer to test the system and "go live". As Beta's DTM says: "*We are trying to invent new services that affect directly the customer's*

business; in a sense we are creating our future customers". Finally, a first pilot testing using a real use case is started, with the installation of the solution in two machines of one customer.

As long as the solution takes shape, additional resources are added to the project team through successive hiring. Notwithstanding, it remains a rather lean structure: with a first addition in fall 2017, then another after summer 2018 the team totalizes 4 people (plus one part-time internal and the DTM), mainly specific technical competences in the field of PLC programming and digital competences related to modern software languages and electronics. This progressive enlargement of the project team is fundamental to stabilise the functionalities of prototype 1.0 and manage the installations to gather feedbacks and analyse data useful for the service development.

With gradual increase of commitment and investments, this setting works smoothly for about two years. In that period, the number of installations rises, and - in the second half of 2019 - 45 machines of existing customers have installed prototype 1.0, of which approximately the 60% pays a fee (mainly those who expired the warranty period). The need to internalize that activity is at this point very clear: the DTM is conscious of its importance for the subsequent development of the solution. Therefore, she chooses to abandon the 1.0 software architecture to build on a more replicable and scalable one based on cloud technological modules. The team reproduces prototype 1.0 within the new cloud architecture and some precious features are added, especially in UX and visual reporting (both strategic aspects).

Between the end of 2019 and the beginning of 2020, prototype 2.0 is bundled with new released machines and offered in free subscription for the warranty period. In addition, a general campaign of migration is started to convert all 1.0 applications to 2.0. Currently, prototype 2.0 has 8 machines and 5 clients, and demonstrates to be reliable.

Prototype 2.0 marks the beginning of a new period of Beta's innovation process, which is fundamental for the replication and further commercialization. Following the request of one of the pilot customers, Beta recognized that the solution could be easily adapted also to other producers' complementary machines. This suggests also a possible application to different industries' operations, enlarging the scope of replication of the solution. A further person is hired in this period in order to streamline the technical back-end software-related activities of the solution. As far as challenges are concerned, the DTM acknowledges that keeping the new service team integrated with the original BU has been advantageous for the smooth development of the innovation, but also recognizes that for its further diffusion a specific investment in a dedicated sales force has to be made. Figure 2 highlights Beta's BMI phases key points.

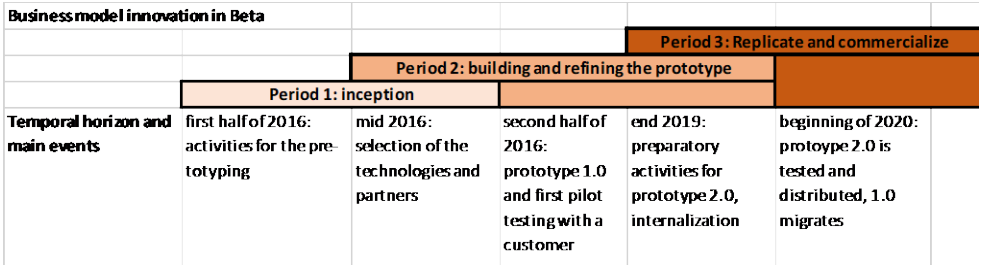

Figure 2 – The BMI process in Beta

4.3 Cross-case analysis

The two cases enable us to describe how exploration of IoT technologies can be approached by medium-sized manufacturing firms, going from envisioning the innovation to its broader commercialization. They also allow us to identify major common points and common challenges the two cases share (see table 2).

As far as organizational aspects are concerned, both cases embed and integrate the experimentation in the extant organization, and in particular in the product-related service side of the business unit. This choice is related to the connection between the activities to be implemented and the service-oriented activities already existent within the firm. In both cases the TMT is in favour or directly involved in the project, and this circumstance endures for all the investigated period.

Resources and competences dedicated to the new project grow during the period, following its capability to demonstrate its validity. The extent of financial resources allocated to the project comply to the conservative approach usually adopted by SMEs, due to limited resource slack. Both cases decide to internalize critical resources in order to hold the control of the development of the solution (this is critical for its replication and diffusion).

A similar approach is present also in the management of the value proposition, where the firms find it convenient to leverage technology in order to create a multi-layer offer of services with different degrees of completeness and different data intensity. Performance-based value propositions are particularly interesting and result to be directly comprehensible to sophisticated customers, that in both cases are international corporations with leadership positions in global markets (key customers).

As long as the revenue model is concerned, both cases adopt the subscription model with monthly fees (instead of the up-front one, traditional in manufacturing), and support the first commercialization phases through a free trial period (during the warranty), as an effective strategy to reduce market's uncertainty and lower cognitive mis-perceptions about the services' usefulness. This strategy is also important to convince the customer to grant data access to the supplier, being connected to warranty extensions. In both cases, data-related services affect supplier-customer relationships, since the ongoing information exchange influences the depth of knowledge exchange and mutual faith.

From a strategic point of view, it is also to be underlined that at the moment the new services are perfectly complementary to old businesses, generating additional streams of revenues (even if they ask for additional risk mitigation activities). This situation may change as the innovative business model catches on. Anyway, both firms recognize the hindering role of not having a sales force dedicated to the new advanced services.

A last comment regards a feature that distinguishes the cases and regards the inception: while in case Alfa the BMI starts as a consequence of a key customer specific request, Beta's management committed itself in the proactive search of viable uses of IoT technologies.

Table 2 – Business model innovation in the selected cases

Case	Origin	Organizational setting	Value proposition	Value creation	Value distribution	Value capture
Alfa	Reactive	No separated units are created, and the BMI is fully integrated in the product-related BU Alfa's CEO is fully involved in the BMI	Value-based service associated to the product, where subscription fees are weighted on performances	New-hired resources: 3 in house (10 on site coming from the extant filed service organization) External sources mainly for technology-related specific needs	Customer relationship is deepened; horizontalization and diversification of the offer	The revenue model is based on (additional) monthly fees
Beta	Proactive	No separated units are created, and the BMI is fully integrated in the product-related BU The CEO protects the newborn project from attacks and criticism	Improved availability control over machines via IoT, in subscription mode	New hired resources: 5 (software and digital) External networks (universities, technology suppliers, KIBS and consultants) help to explore and to build the prototype	Customer relationship is deepened; horizontalization and diversification of the offer	The revenue model is based on (additional) monthly fees

5 Discussion and conclusions

The purpose of this article was to investigate how incumbent manufacturing SMEs can manage the evolution of a new BM enabled by IoT in parallel with its extant business model, with particular attention to the main resources and capabilities required, as well as the main difficulties encountered.

Overall, based on a qualitative in-depth analysis of two cases, we show that SMEs analysed seem to experiment with BMI in parallel to the extant business model while still relying on its revenue streams (Laudien and Daxböck, 2016), which is consistent with the resource constraints of SMEs. Along the same line, the evolution of the new BM follows

some steps that recall the initial ones presented in the framework by Khanagha et al. (2014). His analysing a very large firm, compared to our SME context, could be the rationale behind the lack of the creation of an independent organization immediately after the piloting in our cases. Indeed, in SMEs, transition processes are slower and need careful action for the reasons explained above, which also includes the contextual ambidexterity in experimenting with the new BM while maintaining the extant business (Markides, 2013). This is reflected also in the fact that the experimentation is incremental in terms of resources dedicated to the new business, despite the change can lead to radical BMI. Actually, recalling the archetypes presented by Suppatvech et al. (2019), firms arrive to the most sophisticated one, i.e. solution-oriented business model. This seems to be the result of a learning process that makes the strategic intent and objectives increasingly clearer and the involvement of the management increasingly active.

Another interesting evidence emerged from cases is the relevance of customers in the experimentation phase, supporting, on the one hand, the fundamental role played by customers in the digitalization path (Rachinger, 2019) and, on the other hand, the relevance of an open approach to pursue BMI (Liao et al., 2019). Experimenting with the customer is beneficial for the firm since it allows piloting and fine-tuning the new solution, however it can create some difficulties for the replication and standardization of the service for different firms, because the solution is somehow crafted around the pilot customer. This point of the BMI evolution –i.e. between piloting and replication– seems to be particularly critical due not only to, among other issues, the effort required to abstract a general model from the implemented pilot one, but also to the need to internalize some competences that, with the new BM, become core for the firm.

This study has both academic and managerial implications. From an academic standpoint, our results provide support to the opportunities offered by IoT to innovate a firm BM and at the same time extend the contribution to the specificities of SMEs with respect to large firms in experimenting a new BM. This suggests the relevance of the dimension of firm size to shed more light on different BMI strategies and associated organisational solutions. Furthermore, we prove that open innovation with customers can allow the firm to be flexible in experimenting a new BM, which further supports the need to merge the open innovation and dynamic capability perspectives of BMI that have progressed independently (Liao et al., 2019).

From a practical viewpoint, managers can appreciate that also SMEs may take advantage of IoT to innovate their BM to offer new products and services more aligned with customers' needs and get some indication of possible paths. Moreover, managers can get some interesting advices regarding the challenges they are likely to encounter along the BMI experimentation, as well as the key resources and capabilities BMI may require.

We recognise this study has some limitations, mainly related to the fact that we analyse two cases and, thus, we do not claim to be exhaustive in presenting possible paths of BMI based on IoT solutions and associated requirements and challenges. Future studies could

enrich our understanding by analysing other cases to confirm or find out new paths for BMI experimentation.

Abstract

Digitalization has become known as one of the biggest drivers of developments in society and has put pressure on companies to innovate their business models with emphasis on the opportunities provided by application of new digital technologies. Accordingly, there has been a major growth in business models focusing on resource exchange, referred to as sharing economy. Currently, there is also a growing interest among researcher into the phenomenon of sharing economy with an exponential growth in published research. However, to date the literature addressing the sharing economy appears complex and unstructured. The purpose of this study is to take stock of extant literature with a particular focus on distinguishing between constituent elements of sharing economy business models across peer-to-peer (P2P), business-to-consumer (B2C) and business-to-business (B2B). This study was conducted using a bibliometric method to map prior research in the field of sharing economy. Utilizing a broad structured search in the Web of Science database we identify the most relevant articles and synthesis its insight to suggest a framework distinguishing between core properties of P2P, B2C and B2B sharing economy business models. In addition to provide a better overview of existing literature, the framework provides a foundation upon which further research can be built. The framework can also serve practitioners with a better understanding of the phenomenon of sharing economy and thereby a better basis for making strategic decisions in relation to their business model innovations.

Keywords – Bibliometric analysis, Business model innovation, Business-to-Business, Business-to-consumer, Sharing economy

Paper type – Academic Research Paper

1 Introduction

Digital transformation requires businesses to rethink and innovate their business models. Li, Brass, Hitt, Wang and Li (2018) claims that Internet and Big Data are currently making an impact in all industries, and therefore businesses need to reconsider their business models adapting to the environment. As new forms of businesses evolve, there is an emerging growth of practices of a sharing economy. A recent search on google scholar indicate an astonishing amount of published research articles for search phrases, such as: "digital business models"- 3 080, "digitalization" - 61 800, and "sharing economy"- 28 000 - only since 2016! Another illustration of the increasing interest in the sharing economy is the recent number of special issues addressing the phenomenon (Maurer, Mair & Oberg, 2020). In practice, within Europe's five most prominent sharing economy sectors, total value of transactions is expected to reach €335bn within 2025, from €28bn in 2015 (PwC UK, 2016, p. 3-4). This indicates increased attention to the phenomenon of a sharing economy, for research and practice alike.

Despite an overwhelmingly growing interest in the emerging phenomenon of sharing economy, it is referred to as an umbrella concept that is conceptualized with an inherent variety and unclear dynamics (e.g. Trenz, Frey & Veit, 2018; Wilhelms, Merfeld & Henkel, 2017). To date, there exists no unified definition (Schor, 2014) and the phenomenon remains debated (Martin, 2016). However, the idea of sharing instead of owning is not new (Belk, 2010; Botsman & Rogers, 2010; Schor, 2014). Extant research refers to the same phenomenon with terms ranging from; access economy, circular economy, collaborative consumption, collaborative economy, gig economy, to peer economy (Bellotti et al., 2015; Strømmen-Bakhtiar and Vinogradov, 2020). Despite the vast number of interchangeable terms, extant research seems to agree on some core properties of the phenomenon; relating to (1) peer platforms that coordinate (2) peer providers and (3) peer consumers. (e.g. Botsman & Rogers, 2010; Hamari, Sjöklint & Ukkonen, 2015; OECD, 2016; Schor, 2014). Schlagwein, Schoder and Spindeldreher (2019) suggest, after an analysis of 125 definitions, that commonly addressed core properties of 'sharing economy' relates to peer activities of coordinating sharing of goods or services through a digital technology platform without transfer of ownership. Consequently, existing research within the sharing economy is primary focusing on issues related to peer-to-peer (P2P) activities of obtaining, giving, or sharing access to goods and services, coordinated through community-based online services (Maurer et al., 2020), and have recently also attended to the P2P business models underpinning the sharing economy phenomenon (e.g. Apte & Davis, 2019; Assadi, 2020; Mosmann & Klutt, 2020).

However, established business model research (e.g. Baden-Fuller & Haefliger, 2013; Osterwalder & Pigneur, 2010; Teece, 2010; Zott, Amit & Massa, 2011) emphasize the distinction between business-to-consumer (B2C) and business-to-business (B2B) business models, but it remains uncharted to assess how these established business model distinctions relates to the P2P patterns described in the sharing economy literature. A business model "defines how the enterprise creates and delivers value to customers, and then converts payments received to profits" (Teece, 2010, p. 173). Mosmann and Klutt (2020) argue that the sharing can be of a commercial or non-commercial nature, and

therefore that the understanding of the phenomenon of sharing economy could be extended beyond P2P, B2C and B2B business models in particular. Therefore, the aim of this study is to assess extant research addressing sharing economy business models to synthesize a foundation upon which subsequent empirical research can be built. There is especially called for more research to unresolved issues in the case of B2B relations (Grondys, 2019), emphasis on the commercial aspects (OECD, 2016), and Agarwal and Steinmetz (2019) calls for further research on B2B and their engagement in sharing economy (Kathan, Matzler & Veider, 2016). Moreover, the lack of theorization of the business model variations underpinning the sharing economy in general, and in relation to distinctions between P2P, B2C and B2B in particular, warrant taking stock of extant research to establish a unified foundation for subsequent research (Maurer et al., 2020). The ambition of this study is therefore to address the following research question: *How can sharing economy business model variations and similarities be conceptualized beyond P2P and thus encompass traditional business model perspective of B2C and B2B?*

In order to address this research ambition, we started out examining extant published academic research by conducting a structured literature search, resulting in an initial sample of 1266 documents for the timeframe 1997-2020. By excluding irrelevant categories we had a final of 184 articles for our bibliometric analysis. To conduct the bibliometric analysis, we applied VOSviewer and identified 19 highly relevant interrelated sharing economy articles upon which we conducted a content analysis. This study identifies core articles addressing the constituent elements of sharing economy business model and illuminate variations and similarities across P2P, B2C and B2B business models as these are reported in extant research. Discussing these findings against the underlying theory, we suggest a framework distinguishing between P2P, B2C and B2B sharing economy business models. The proposed framework can serve as an important contributor and basis for discussion related to strategic decisions as it provides useful information for various structures and thereby value creation and value capturing activities, as well as guide future research.

2 Theory

The purpose of this chapter is to explain the concept of business models and how it relates to the sharing economy and thereby illustrate the gap in current theorization. Extant theory on business models will be presented before introducing current theory on the transition of sharing economy as well as business models variations.

2.1 Digital business models

Recently, “digitalization has been identified as one of the major trends changing society and business in general” (Parviainen, Tihinen, Kääriäinen & Teppola, 2017, p. 63; Veit et al., 2014). Since digitalization has influenced various business activities including companies’ business models, “digitalization has put pressure on companies to reflect on their current strategy and explore new business opportunities, by transforming their existing business models” (Rachinger, Rauter, Müller, Vorraber & Schirgi, 2019, p.

1143). This digital transformation is causing change in companies' business model, that be changes related to their products or services, the organizational structure, or automation of processes (Hess, Matt, Benlian & Wiesböck, 2016). Further, fundamental changes in the way businesses operate and generates value is referred to as a shift towards digital business models and the missing link between business strategy, processes, and information technology (Veit et al., 2014). Technology facilitates easy access to information and customer solutions at a lower cost, hence it is argued that businesses needs to be more customer-centric (Teece, 2010, p. 172). In terms of digital transformation, businesses need to re-evaluate their value propositions in terms of understanding business model design options as well as customer needs and technological trajectories (Teece, 2010, p. 173).

2.2 Sharing economy

The financial collapse in 2008 necessitated that people and firms found new and creative ways to create value and reduce costs (Habibi, Davidson & Laroche, 2017). Re-creating value by using existing resources, either for monetary or non-monetary benefits, contributed to more efficient use of resources (Botsman & Rogers, 2010). As a result, the term "sharing economy" were introduced and opened new ways to deal with capitalism and consumerism (Agarwal & Steinmetz, 2019). The increased attention regarding sharing economy is causing disruption in well-established and mature industries when consumers are provided with convenient and cost-efficient access to resources without the responsibility of ownership (Eckhardt & Bardhi, 2015; Schor, 2014, p. 4; Trabucchi, Muzellec & Ronteau, 2019).

Defining the sharing economy in a way that reflects common usage has proven to be difficult due to the wide range of perspectives (Schor, 2014, p. 3). One recent attempt on providing a unified definition by Plewnia and Guenther (2018, p. 576) define sharing economy as "activities or platforms which facilitate the sharing of material, products, product services, space, money, workforce, knowledge, or information based on for-profit or non-profit transactions in a variety of different market structures". However, Mosmann and Klutt (2020, p. 40) find that sharing economy are identified across P2P, B2C and B2B relational patterns. Hence, the literature indicates a shift towards a new set of business models that are emphasizing resource exchange rather than offering new ones (Laamanen, Pfeffer, Rong & Van de Ven, 2018, p. 213).

Access to new technology and its potential benefits has been an interesting topic within sharing economy as it allows for interaction between individuals, who not necessarily know each other, to get in touch for resource exchange (Schor, 2014, p. 12). Both products and services are described in the digital business strategy literature as they both can take advantage of the possibilities within digital resources (Bharadwaj, El Sawy, Pavlou & Venkatraman, 2013, p. 474). More user-friendly solutions as a result of digital improvements is facilitating more comfortable users, which in turn can open new business opportunities as a result of increased quality and quantity of generated data (Bharadwaj et al., 2013, p. 474; Laamanen et al., 2018, p. 213; Schor, 2014). Digital infrastructure that is

well embedded in the business strategy is seen as a strategic dynamic capability as it enables the company to scale up or down their infrastructure in line with the market (Bharadwaj et al., 2013, p. 475).

Sharing platforms, consisting of all involved parts, is referred to as communities where control and coordination is of high importance for being able to attract and retain participants (Mosmann & Klutt, 2020, p. 40-41). Their decisions regarding market orientation and market structure is fundamental when shaping the platforms' business model. In terms of market orientation, sharing economy platforms are either for-profit, striving to optimize generated revenue and asset maximization, or non-profit platform where the primary goal is to serve needs at a community rather than seeking growth or revenue maximization (Schor, 2014, p. 4-5). Companies' market structure reflects their market orientation, and the sharing economy literature distinguishes between P2P and B2C. Within P2P platforms, value capturing is generated through commissions where revenue-growth rise with the number of transactions, whereas for B2C platforms, value capturing occurs through maximizing revenue per transactions (Schor, 2014, p. 5). Sharing economy in terms of P2P has received a lot of attention. P2P is referred to as multisided platforms, consisting of intermediaries who brings together distinct groups of users where network effects is said to be a key differentiator when it comes to value creation (Bharadwaj et al., 2013, p. 475; Jabłoński, 2018). Communities as the source of value creation indicates a shift in value creation drivers (Stabell & Fjeldstad, 1998). Analysis conducted by Lang, Shang and Vragov (2015, p. 787) reveals that the co-creation mechanism within these communities can minimize the risk of revenue loss and will benefit the consumers as well as the producers.

Based on the underlying theory related to digital business models and sharing economy, we recognize a need for a better overview in the field of sharing economy. We note that much of the literature is based on the sharing economy as a whole, and does not differentiate between P2P, B2C and B2B. Agarwal and Steinmetz (2019, p. 12) suggests that P2P and B2C business models within the sharing economy can be variations of each other, but that B2B is rather excluded in existing literature. This missing link is also recognized by Grondys (2019) and Kathan et al. (2016) as they argue that existing literature to a large extent is focusing on private sharing and less focus on issues in B2B relations.

3 Methodology

In order to enlighten the understanding of the ambiguous umbrella-term 'sharing economy' and identify P2P, B2C and B2B business model variations we conducted a broad and structured search in prior published research. We subsequently conducted a bibliometric analysis on the database of retrieved articles in order to distil our search further. There is a significant increase in quantification of science, especially within use of bibliographic analysis used for evaluation and monitoring of scientific outputs has become widespread (Verbeek, Debackere, Luwel & Zimmermann, 2002). Fahimnia, Sarkis and Davarzani (2015) promotes some of the strengths associated with bibliometrics:

> *Network analysis through bibliometric tools can prove powerful for identifying established and emerging topical areas. It can also help identify the clusters of research and researchers showing how the various areas of thought may have emerged based on author and institutional characteristics. Identifying the more influential researchers within the clusters sets the stage for determining additional emergent study fields through capturing of more recent topics covered by these researchers. (p. 102)*

The aim of this study is to establish an understanding of business model variations as described in extant research on sharing economy, and thereby provide a foundation for future research and practice. Levy and Ellis (2006, p. 172-173) supports our choice of a literature review to (1) understand the existing body of knowledge, (2) provide us with a solid theoretical foundation, (3) substantiating the presence of the research problem, (4) justifying the proposed study as one that contributes something new, and (5) framing the valid research methodologies, approach, goals, and research question for the proposed study.

3.1 Search procedure and sample

The structured search, and subsequent refinement into a database of relevant research articles, progressed in several stages. Initially we experimented with several different search phrase combinations. By using following search string *Topic=((Business-model) AND Topic=(Digit* OR Sharing-econom*))*, without any limitations, we identified 1266 documents in an exhaustive search for the period 1997-2020, enabling us to understand the development of research focusing on the sharing economy. Then, we limited our search to only include English documents from articles, proceedings papers, reviews, editorial material, book chapters and book reviews. Excluding irrelevant categories and keep those with 50 or more contributions, we had reduced our database to 809 articles.

In the next stage, we selected all articles with ten or more citations within the timeframe 1997-2017, a total of 170 articles where we read all the abstracts. For all 397 articles within the timeframe 2018-2020 we did not emphasize the amount of citations as the articles might not have reached a certain amount of citations yet.

With the new sample of 567 articles published between 1997 and 2020, we now conducted a first order categorization of these articles by colour coding, based on the relevance for our research question, reducing the sample to 190 relevant articles. We subsequently omitted from our database the most recent articles of 2020 as this year had just started, and bibliometric analyses of that year would be skewed by the lack of a full year's publication. The 2020 articles were read and utilized in the positioning of our research question. Considering the final limitations and exclusions our final literature search sample was 184 articles which we downloaded from the WoS database.

3.2 Three phased analysis

The analysis of the 184 research articles included in our final search database also progressed in three distinct phases. First, we conducted a descriptive analysis of the

overall characteristics of the sample. Subsequently, conducted a bibliometric analysis, and finally we utilized the bibliometric analysis to further distil our sample and identify 19 core research articles included in a content analysis.

3.2.1 Descriptive analysis

Downloading our final search from the WoS database to Excel we had the basis for the descriptive analysis. We cleaned up all data in Excel so that the analytical tool Microsoft Power BI could read the data and create visualizations. Afterwards, all articles were represented with their title, author(s), journal, discipline category(s), and publication year. The descriptive analysis revealed the development within the field of sharing economy, journals that have emphasized the topic and discipline categories. The purpose of the timeframe is to map out the development of published articles within the last 22 years whereas the categorization overview has the purpose of identifying which categories the articles are allocated. We also constructed an overview of the top ten journals in terms of published articles.

3.2.2 Bibliometric analysis

We applied the software VOSviewer on the database of 184 articles downloaded from WoS enabling us to conduct bibliometric analysis. To answer our research question we conducted co-occurrence, co-citation, and bibliographic coupling analysis in VOSviewer to get a visual overview in terms of keyword relevance and citations (Van Eck & Waltman, 2009). This analysis is some of the most commonly studied types of relations (Ding, Rousseau & Wolfram, 2016, p. 285). By applying VOSviewer we were able to make an overall visualization of the articles as they were categorized into four different clusters narrowing our dataset down to a core of highly relevant interrelated sharing economy articles. By calculating network centrality for individual articles related to each of these clusters we were able to identify central articles for each cluster. When conducting the co-occurrence analysis we saw that both terms “business model” and “business models” was represented. In order to obtain a more trustworthy analysis we created a VOSviewer thesaurus file in addition to the file including all 184 articles to combine those two terms represented as “business model”. However, we did not combine terms like “digitization” and “digitalization” as these terms cover different aspects of the digital concept.

3.2.3 Content analysis

Finally, we utilized the findings from our bibliometric analysis to identify the most influential articles as we did a content analysis of the most relevant articles related to our research to spot conformity and differences within sharing economy business models. The categorization of the 567 articles and the exclusion of year 2020 resulted in a final of 184 articles representing the years 1997-2019. To get down to a core of highly relevant articles we did a two-fold process based on the 184 articles. This time we dug more into each article to ensure high thematic relevance. After skim reading all articles with high focus on results, implications for practice, and conclusion, we were able to discard

articles that did not contain information regarding business models or business model elements within the field of sharing economy. This process done we had identified 19 articles supported by the bibliographic coupling and the analysis of cluster belongingness, total link strength, and citations.

4 Findings

There has been a significant increase in the number of published articles in recent years, with the majority dealing within business and management, published in journals related to sustainability and technology.

4.1 Descriptive and bibliometric analysis

The exponential increase results in 75 percent of the articles included in our database were published between 2017 and 2019. That the 25 percent of articles included in the database published prior to 2017 are distributed evenly over a fairly flat and stable period between the years 1997 and 2011 followed by a gentle increase in 2012 before the development really gained momentum in 2017 (Figure 1).

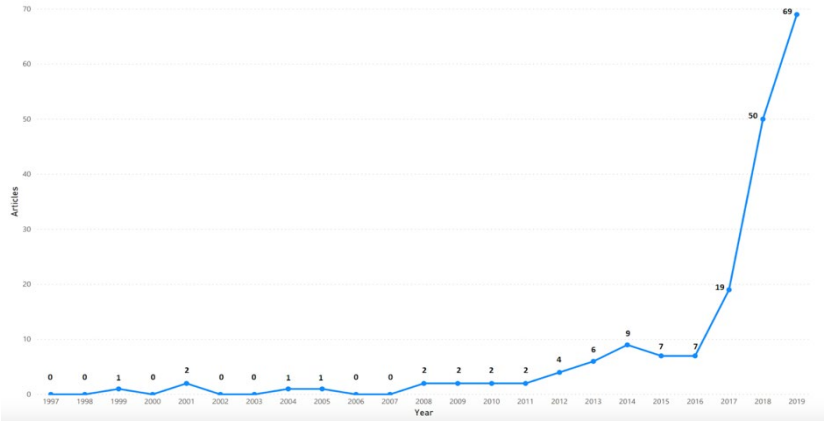

Figure 1: Development of publications per year for the period 1997-2019 (N=184)

The co-occurrence analysis (Figure 2) is generated in VOSviewer where several analyses were conducted to ensure high thematic relevance of keywords. Cluster two (red) has "sharing economy" as the most influential keyword but other close related terms that were identified in the theory chapter like "collaborate consumption", "access-based consumption", and "collaborate economy" is represented as well. The keyword "peer-to-peer" indicates a large amount of sharing economy articles related to P2P, whereas keywords for B2C and B2B is not present. Cluster one (green) contains keywords related to business models and strategy whereas cluster three (blue) consists of keywords related to digi* concepts like "digital transformation" and "industry 4.0". Cluster four (yellow)

contains three keywords representing the business model elements “value creation”, “value capture”, and “value proposition”.

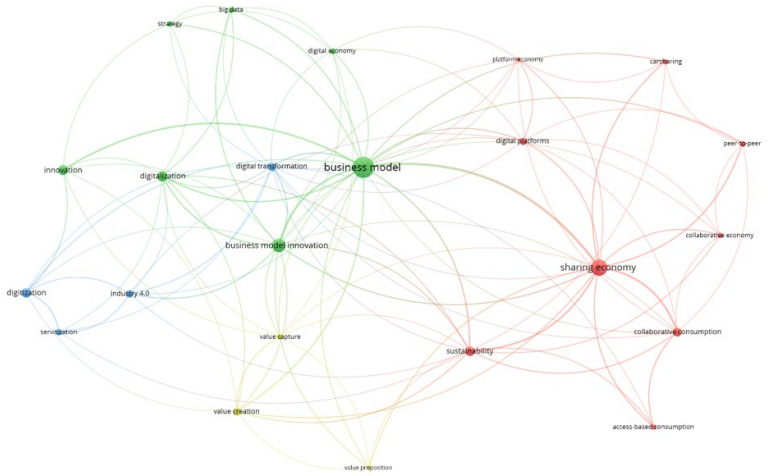

Figure 2: VOSviewer map with co-occurrence analysis

From the co-citation analysis (Figure 3), only Cohen and Kietzmann (2014) is included in our core articles as the other authors do not contribute to our research question. An explanation that we have only managed to identify one of our core articles in this analysis may be due to the fact that business models have been studied for a long time, but that sharing economy is relatively new, hence fewer citations. Another explanation related to the green cluster may be that much has been done in the field of sharing economy but limited when it comes to business models.

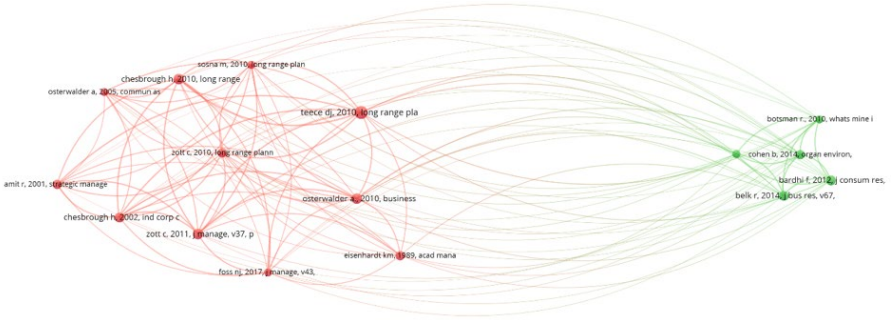

Figure 3: VOSviewer map with co-citation analysis

4.2 Content analysis

Within the sharing economy, P2P business models consists of a triadic structure where value creation takes place through decentralized transactions and co-creation where review systems are applied. Value capturing occurs through commissions, and where emphasis is placed on flexibility and safety for the consumer. B2C business models consists of a dyadic structure where value creation takes place in a centralized resource pool. Value capturing occurs through commissions, membership fees and public

subsidies, and where emphasis is placed on flexibility and safety for the consumer. B2B business models consists of a polyadic structure where co-creation is the basis for value creation. Value capturing occurs through membership fees and commissions, and where emphasis is placed on flexibility through coopetition.

5 Discussion

Based on analyses of findings and the ensuing discussion, there are some clear patterns. For the purpose of a better overview we have separated P2P, B2C and B2B, respectively, and each of the business model elements. There are several obvious similarities between these, but there are also some distinguishing characteristics that make them different in several ways. We have compiled these findings into a framework presented in table 1.

Table 1: Compilation of findings according to business model dimensions of P2P, B2C and B2B

	P2P	B2C	B2B
Value creation	• Triadic structure *(Ritter & Schanz, 2019)* • Decentralized transactions *(Acquier et al., 2019)* • Co-creation *(Apte & Davis, 2019)* • Review-system *(Täuscher & Laudien, 2018)*	• Dyadic structure *(Ritter & Schanz, 2019)* • Centralized resource pool *(Ritter & Schanz, 2019; Acquier et al., 2019; Vaskelainen & Münzel, 2018)*	• Co-creation (Laczko et al., 2019; Grondys, 2019)
Value capture	• Commissions (Acquier et al., 2019; Täuscher & Laudien, 2018; Guyader & Piscicelli, 2019)	• Commissions, membership fees, and public subsidies (Acquier et al., 2019; Täuscher & Laudien, 2018; Guyader & Piscicelli; Vaskelainen & Münzel, 2018)	• Membership fees, Commissions (Täuscher & Laudien, 2018)
Value propositions	• Flexibility (Apte & Davis, 2019), Safety	• Flexibility (Vaskelainen & Münzel, 2018), Safety	• Flexibility, "Coopetition" (Grondys, 2019)

Examples	*Airbnb, Uber*	*Zipcar, Wikipedia*	*WeWork, HeadBox*
Distinguishing characteristics	Consists of a triadic structure where value creation takes place through decentralized transactions and co-creation where review systems are applied. Value capturing occurs through commissions, and where emphasis is placed on flexibility and safety for the consumer.	Consists of a dyadic structure where value creation takes place in a centralized resource pool. Value capturing occurs through commissions, membership fees and public subsidies, and where emphasis is placed on flexibility and safety for the consumer.	Consists of a polyadic structure where co-creation is the basis for value creation. Value capturing occurs through membership fees and commissions, and where emphasis is placed on flexibility through coopetition.

Within the **value creation** dimension, two distinct structures have been identified for P2P and B2C, respectively. Triadic structure where interaction between two (or more) distinct type of users is facilitated by intermediaries is strongly associated with P2P platforms, while dyadic structure where interaction between owner and user occurs without the use of intermediaries is associated with B2C platforms. Within triadic structures, value creation takes place at a decentralized level, while within dyadic structures it occurs through a centralized resource pool. Ownership of resources is a part of the basis to separate the approaches; in P2P platforms, companies typically does not own any resources, while in B2C platforms, companies them self owns these resources. The literature does not relate B2B platforms to any specific type of structure, but as we argue that B2B platforms can take the form of triadic and dyadic structures, depending on the platform's purpose and thus ownership of the resources, we characterized this as a polyadic approach in this ecosystem. However, value co-creation within P2P and B2B platforms has been put forward as crucial activities and take the form of review systems in P2P.

There are several similarities within the **value capture** mechanism. Commissions is put forward as a source of value capture within both P2P, B2C and B2B. Within P2P platforms commissions is the only mentioned source for value capturing and is the primary revenue stream within B2C platforms. However, it is also recognized that membership fees and public subsidies are other sources for value capturing within B2C. In terms of B2B platforms, membership fees are the most preferred revenue stream but commissions are also frequently used.

In terms of **value propositions**, flexibility in relation to their consumers is put forward within P2P and B2C which can be achieved through operating different business models that leads to cost savings and efficiency. Within B2B platforms flexibility for both consumers and the company itself is achieved through the network of suppliers, referred to as the coopetition-model. Technological developments that facilitate better coordination and safety in terms of fraud and theft will in turn make more comfortable users and hence serve as an important value extender.

6 Conclusion

This study addressed sharing economy business model variations based on an exhaustive structured literature search and subsequent bibliometric analysis to identify 19 core articles to synthesize the current state in the sharing economy related to P2P, B2C and B2B business models. To answer the research question of this study we mapped similarities and differences in P2P, B2C and B2B sharing economy business models within the established business model dimensions; "value creation", "value capture" and "value propositions". The study contributes by distinguishing important characteristics between P2P, B2C and B2B at each of the business model dimensions. Our study reveal that business model structures provide variations when it comes to value capturing and that technological developments and value networks are at the bases of value propositions. Moreover, the study confirms that most studies relates to P2P sharing economy business models. Consequently, further research is called for to better inform sharing economy business model variation, in particular for B2B. In addition, there is a lack of empirical studies, especially addressing B2B sharing economy business models and contingencies of these experienced within different industries and business sectors.

Knowledge Management and the Role of Collective Intelligence & Organizational Design in Enhancing Productivity and Innovation among Employees

Sikandar Hayyat Malik, Sharoon Nirdosh *

Pakistan Security Printing Corporation

* *Corresponding author*

Abstract

Knowledge management can be defined as the process which is based on managing, utilizing, sharing and developing information and knowledge to enhance the functions of an organization. It assists organizations in enhancing their flexibility, profitability, and productivity leading to more innovative organizations (Hussinki et al., 2017). This paper will look at the role that knowledge management play to foster collective intelligence and under different organization designs to improve the productivity of human resource. Thus, the paper will present different theories, models as well as novel approaches related to the effective implementation of knowledge management in managing employees and helping them to achieve the organization's goals. Organizations and employees who collaborate to share knowledge usually tend to be more creative, innovative, and productive. In the present time, innovation is also becoming significantly important for organizations to counter the problems associated with economic meltdown which have been experienced by almost every company. It is pertinent to note that the right organizational design can determine the success or failure. By blending the concept of Knowledge Management with Organizational structure, Organizations can produce a workforce that is not only engaged but that is also innovative

The methodology of research of the paper is pre-dominantly theoretical and by studying and analyzing existing literature on the subject of Knowledge Management, Collective Intelligence and Organizational Structure. In the last decades, the basic functions and nature of organizational design have experienced dramatic changes. The nature of traditional organizational designs are more closely related to the mechanistic model and ideal bureaucracy which were proposed by Burns and Stalker, and Weber, respectively (Ahmad et al., 2017). The paper highlights the viability of the process of knowledge management among employees in the most common forms of organization designs.

From the analysis of this paper, it may concluded that the efficiency or performance of the human resource that is utilized by the organizations to accomplish their goals can only be enhanced if they create sufficient opportunities to promote and amalgamate collective intelligence and knowledge management, which in turn could help them to come up with innovative processes. The paper also suggests the organization design that better facilitate employees in sharing knowledge and experiences effectively.

Keywords - Knowledge Management, Collective Intelligence, Organizational Design, Organizational Structure

1 Introduction

Knowledge management can be defined as the process which is based on managing, utilizing, sharing and developing information and knowledge to enhance the functions of

an organization. It can also be described as a multidisciplinary approach that is used to accomplish the organization's goal by utilizing the available sources of knowledge in the best possible manner (Inkinen, 2016). The concept of knowledge management was developed as a response to deal with the increasing significance of knowledge for the companies. In any business, determination of success or failure largely depends on knowledge and for these reasons, it is also considered as an important source of wealth. It assists organizations in enhancing their flexibility, profitability, and productivity leading to more innovative organizations (Hussinki et al., 2017).

Moreover, it also represents an important competitive advantage for the business as well. This paper will look at the role that knowledge management play to foster collective intelligence and under different organization designs to improve the productivity of human resource. Thus, the paper will present different theories, models as well as novel approaches related to the effective implementation of knowledge management in managing employees and helping them to achieve the organization's goals.

2 Knowledge Management and Collective Intelligence

2.1 Overview

Collective intelligence can be described as a tool that helps to connect computers and people to develop intelligent systems to provide an added value to the core functions of the business (such as human resource management). Numerous studies have highlighted that there are various projects which have been conducted based on the cooperation of the employees who were connected to and performing their work on modern systems of IT. Even though individual applications commonly differ according to their functions or purposes, there are several common elements between them, such as the gene group (Woolley, Aggarwal, & Malone, 2015). An example of such a system can be taken from SaaS.

Within human resource management, SaaS (i.e., software as a service) can be defined as the delivery or provision of human resource software under the environment of cloud computing. For human resources, the delivery model of SaaS is usually included under the domain of those applications which can be classified as SaaS ERP (i.e., enterprise resource planning), since the functionality of human resource is generally considered as an important component of ERP software (Seethamraju, 2015).

SaaS is significantly helping the organizations and employees to better comprehend the needs of the customers, as well as the market that they need to target to attain financial success. Organizations that typically utilize SaaS are primarily interested to use it so that they can decrease their infrastructure costs (Yusuf, Silas, & Haruna, 2018). It also assists organizations to make user-friendly changes and easy upgrades within their processes or knowledge management systems. By using this tool, employees are better able to upload their ideas for enhancing the products and processes of the business and they often utilize the system to come up with the most effective solutions for the problems that they face in their day-to-day work (Wang et al., 2016).

In the article of Valmohammadi and Ahmadi (2015), it has been stated that fostering innovation among employees can provide significant opportunities to create collective intelligence and knowledge management within the environment of organizations. If collective intelligence and knowledge management are utilized by organizations as support to promote innovation among employees, the goals of the organizations would be met more efficiently and in less time.

2.2 Implications to foster Innovation

In recent years, it has been observed that innovative thinking among managers and entrepreneurs is becoming a major trend. To sustain profitability and ensure the survival of the business under a highly competitive environment of today, various non-technical and technical innovations are becoming increasingly important to revive the business model (Liebowitz, 2019). In the present time, innovation is also becoming significantly important for organizations to counter the problems associated with economic meltdown which have been experienced by almost every company. This, as a result, is stressing the importance to find better ways in enabling efficient management of innovation under the organizations. However, despite these issues, organizations can effectively accomplish their goals by utilizing the known methods associated with knowledge management, collective intelligence and most importantly the internal training and development of employees (North & Kumta, 2018).

Organizations and employees who collaborate to share knowledge usually tend to be more creative, innovative, and productive. They are also fast learners, which further assist them to enhance their collective intelligence and capabilities. This, as a result, enables them to share ideas and solve complex problems by giving novel or creative solutions. It is highly significant for organizations to generate social capital, transfer knowledge and innovate through inter-organization collaborations. The aim of those communities which are developed by collaborative learning networks is usually based on interacting and learning new knowledge from other users (Giampaoli, Ciambotti, & Bontis, 2017).

This newly learned knowledge is further shared under the network to other users. In several instances, users (or employees) might not have the same level of knowledge or expertise as their peers, but they are often interested to attain similar experiences of knowledge and practices. Platforms of the internet can be taken as a good example since it allows employees to comprehend new knowledge through promoting discussion in their teamwork, share ideas, lectures and provides them the opportunity to mentor each other. Thus, it can be stated that knowledge management, as well as collective intelligence input usually comes from the discussions, as well as conversations of employees/users. By using technologies related to WEB 2.0 or social media, this input can help to provide a type of intelligence that may represent new knowledge creation, presentations, and recommendations (Peters & Heraud, 2015). The below-provided figure summarizes the existing roles of collective intelligence and knowledge management in fostering innovation among the human resource of an organization to achieve high profitability and growth

2.3 Explicit and Tacit Knowledge

There are several forms and types of knowledge (i.e., procedural knowledge, specific skills, know-how, facts, etc.) that are often used by the organizations to assess the effectiveness of their employees (Bratianu & Bolisani, 2015). A general representation is that the hierarchy of knowledge often goes from data (i.e., figures and facts) to information (i.e., contextual data) to knowledge (i.e., meaningful information) and then finally to intelligence or wisdom (i.e., insightful knowledge). Under the realms of knowledge management, the knowledge that is possessed by the employees is often categorized into tacit and explicit knowledge. Explicit knowledge can be defined as numbers or words which can be shared and communicated easily in the form of codified processes, scientific formulae, hard data or universal principles. On the other hand, tacit knowledge is usually considered significantly difficult to formalize and is usually highly personal. Hunches, intuitions or subjective insights are usually included under this category of knowledge (Addis, 2016).

Thus, in most organizations, explicit knowledge is commonly found within the databases or documents. In contrast, tacit knowledge is usually present within the heads of employees. Many programs associated with knowledge management that have been provided to the employees have exaggerated the approaches of transforming tacit knowledge into explicit knowledge. However, such approaches were observed to be futile as no database can be created to imitate the vast experience of a knowledgeable employee and to comprehend (by using judgment) which information or data can be implemented under a certain/given situation (Nonaka & Toyama, 2015).

In most cases, the best approach is usually based on making some tacit knowledge into explicit knowledge by offering pointers to those experts who are responsible to implement such knowledge into a given context and assist those who might want to implement it. Therefore, under the management of knowledge, the challenge that human resource managers can face could be related to managing explicit knowledge by utilizing those techniques or methods which might be used under the information resource management discipline. These challenges can also be based on developing an environment for employees that helps them to share knowledge and come up with novel ideas (Park, Vertinsky, & Becerra, 2015). This approach is often regarded as similar to those approaches that are observed under the communities of practice.

3 Organizational Design and Knowledge Management

3.1 Organizational Design

Organizational design or structure can be described as an interrelationship and arrangement of positions and parts of an organization. It can also be defined as those established patterns associated under the relationships that exist between the important parts of any firm that outlines control, communication, as well as the patterns of authority. The structure of any organization differentiates its important parts and assist in

delineating the relationships that exist between them. Therefore, strong emphasis is usually put on control and communication (Albers, Wohlgezogen & Zajac, 2016).

In the last decades, the basic functions and nature of organizational design have experienced dramatic changes. The nature of traditional organizational designs are more closely related to the mechanistic model and ideal bureaucracy which were proposed by Burns and Stalker, and Weber, respectively (Ahmad et al., 2017). The characteristics associated with traditional structures usually include a high level of formalization, standardized activities, formal influence, centralized authority, vertical communication, a significant number of organizational levels, and rigid or strict tasks' definition. Various findings have provided a substantial amount of evidence that this model can be useful in stable or simple situations (Zheng, Yang, & McLean, 2010).

In contrast, organic models are usually considered as the logical opposite structures of traditional models. The characteristics of such models include less formality under rules, heterarchy, flat structure, low standardization, and flexible tasks' division. Several experts have suggested that organic models of organizational structure/design are usually created for knowledge-based companies who conduct their operations under dynamic milieu. Within the organic structure, knowledge and information flow among (or between) employees is more prompt, which further offers support within the exchange of experience and helps to promote unlimited creativity within employees. The below-provided sections highlight the merits and demerits associated with the process of knowledge management among employees in the most common forms of organization designs (Clement & Puranam, 2017).

3.2 Knowledge Management and Functional Structure

Within the organizational designs, functional structure is considered as the most basic design. This structure was created on the idea of grouping employees who perform the same activities or tasks under a single department of the firm. It tends to centralize decision making and coordinating procedures at the top level of the organization. Upon analyzing the processes associated with knowledge management under the functional structure, a good flow of information and knowledge would be discovered within the departments due to the similarity of activities and tasks (Jones, 2013).

As specialists under this organizational design (having the same discipline) are grouped and required to work in a single department, this also sometimes results in the promotion of knowledge creation. The same background, education and common interest field of employees also assist in organizing the training programs/courses more appropriately under the department (Foss, Lyngsie, & Zahra, 2013). The conditions under such a structure are considered positive for organizing the important databases of departments. For instance, the gathered data/information can be stored in a single centralized library, which can be administered by specialized employees and cataloged in a logical manner (Clement & Puranam, 2017).

However, the disadvantage of this structure is that the knowledge and information flow between the departments is usually poor. Employees are often observed

to be hostile towards each other and feel isolated due to the stringent functional divisions. There is also a significant lack of coordination between important functions of the business that, in turn, decreases the opportunities to come up with innovative ideas related to the creation of novel products or processes (Mills & Smith, 2011).

3.3 Knowledge Management and Divisional Structure

Divisional organizational structures are often observed under those firms who want to diversify their products, customers, and markets or who are endeavoring to achieve organizational growth. Under this design, every activity that is required to create a product or service is integrated (or grouped) to form an autonomous unit. Moreover, this structure usually decentralizes the decision-making processes by pushing responsibilities and authorities down to the lowest levels of the company. Knowledge management also differs significantly under this structure in comparison to the functional one. This is because typically the experience and flow of knowledge are observed to be efficient under the divisions that are set apart (Maier & Hadrich, 2011).

Nevertheless, the flows that are observed between specific strategic business units or divisions are found to be poor or limited. Processes associated with specializing and learning are not facilitated under this structure due to limited functional specialization. Handling of every activity under the business units is the responsibility of employees who are hired to work within them. These activities can range from finance, marketing, sales to production, logistics and supply chain management (Dalkir, 2013).

Hence, it can be stated that employees are usually provided with optimal conditions for developing and creating more general knowledge (rather than specialized knowledge). Within divisional structures, horizontal flows of knowledge and information are not typically found. Their practicality under this structure can be questioned. When divisions conduct their operations in differing fields (for example, entirely different markets or products) a single holistic process associated with the knowledge management under the systems of organizations is often not required (Becker, Kugeler, & Rosemann, 2013). In addition to this, several issues/problems related to the database's location (or knowledge base) can occur due to the large size of the firms and their diversified activities. Due to this demerit, managers can face significant variability in the problems associated with handling the knowledge management process under divisional structure depending on the size of their organization (Maier & Hadrich, 2011).

3.4 Knowledge Management and Matrix Structure

Matrix structure was created in response to the increased changeability and complexity under the environments of the organizations. It is described as the permanent and stable form of the organization which incorporates both vertical and horizontal relationships (i.e., both divisional and functional structures that are focused on vertical ones). Moreover, this structure also combines the important operational functions with markets, projects or products to highlight the simultaneous reporting relationships with two

different directors. The knowledge and flow of information under this structure is usually multidirectional (Hislop, Bosua, & Helms, 2018).

Furthermore, several experts have suggested that effective information sharing is one of the key strengths of the matrix structure. The creation of knowledge can also be more efficient in this structure if different specialists cooperate and support each other appropriately and engage in solving problems. This can also assist in updating processes and further promoting the creation of knowledge. Thus, it can be inferred that despite having some drawbacks that are exemplified in practice under this structure, overall, matrix design can be considered as a good structure to facilitate knowledge management (Becker et al., 2013).

3.5 Knowledge Management and Project Structure

Task forces and project structures that are considered as organic forms of organizational structure that are usually based on the work performed by temporary teams, commonly regarded as the most suitable and flexible designs for the processes associated with knowledge management (Fang, Lee, & Schilling, 2010). Experts or specialist employees who engage in projects by forming particular teams primarily emphasize on budgets, dates, and goals rather than sharing experiences or creating knowledge under project structure. Employees usually form groups to solve problems or complete a particular task and after adequately completing their objectives, the groups are disbanded with employees taking their experiences and knowledge with them (Mueller, 2012). (See figure below)

Employees, under traditional organizations, who have the same work background or discipline are often found to attend the same courses, meet with each other, report to the same leader/supervisor, share rooms, and work on different projects without disbanding or separating from their teams/work units. However, under pure project structure, employees are not given sufficient opportunities to share their experiences or develop novel organizational knowledge, which is also regarded as an important disadvantage of this organic design (Fang et al., 2010).

3.6 Hypertext Organizations

Hypertext organization utilizes the strengths of standardization and bureaucratic efficiency, as well as task force dynamism and flexibility. Such organizations combine the ‘project team layer’, ‘business system layer’ with a ‘knowledge-based layer’. This is considered as a value-added element of hypertext organizations. Daily operations or working activities are usually carried out under the business system layer. Moreover, the operations under this layer are commonly conducted along the lines of those models that can be considered as bureaucratic. In other words, this layer comprises all the activities associated with the delivery of products and services and it is also considered as the area where the majority of the tacit knowledge can be found in the company (Petersen & Wiil, 2011).

The organization's part which represents the business system layer directly deals with the market environment and customers of the business. Whereas, knowledge-creating activities that are performed by different project teams (such as the development of new products or strategies) are often found in the project team layer. The operations of this layer are conducted along the lines which are based on the model of a task force where employees are drawn from their normal work activities/responsibilities to participate under the work of project team where they are required to accomplish specific goals in a given time frame (Jo & Joo, 2011).

This layer can be considered as a place where conversion of knowledge takes place, pulling employees' tacit knowledge from the business system layer to engage it towards the development of new products, ideas, and concepts. After the completion of the project, employees return to their respective functional departments under the business system layer. Knowledgebase layer can be defined as a place where the generation of knowledge under the above two layers is stored and codified so that it can be made accessible for all the employees in the organization (Petersen & Wiil, 2011). The most efficient structure of the organization's knowledge base is usually created by considering its intent (i.e., the performance expectations, long-term goals, and vision). The important point to consider under the hypertext model is that it is mandatory for employees to possess sufficient capability associated with shifting themselves between these three different layers with relative ease, and the must have the ability to separate their business practice and mindset (Nwafor, Okezie, & Azubogu, 2018).

4 Conclusion

From the above analysis, it can be concluded that the efficiency or performance of the human resource that is utilized by the organizations to accomplish their goals can only be enhanced if they create sufficient opportunities to promote and amalgamate collective intelligence and knowledge management, which in turn could help them to come up with innovative products and processes. This also includes adapting to those organization's structures (i.e., matrix structure or hypertext organization) that better facilitates employees in sharing knowledge and experiences effectively.

Abstract

The aim of this paper is to investigate the role of entrepreneurial universities (EU) emerging perspectives that enrich regional knowledge spillover and enhance social innovation system. The existing knowledge spillover within the regions has influenced the creation of new knowledge and cross-disciplinary areas of research that empowers regional small firms and higher education institutes (HEIs) to face the economic, social, and industrial turbulence. This paper explores the impact of entrepreneurial universities effects on regional knowledge development, knowledge spillovers and social innovation based on understanding entrepreneurial universities strategic activities. Additionally, research on entrepreneurial universities emerging perspectives has received considerable attention due to its key enabling inspirations that enable higher education institutes (HEIs) and small firms (SMEs) to meet the development of business networks with ensuring the regional as well as social benefits. Where, it facilitates the regional innovation system and as a result, entrepreneurial university premeditated initiative that promotes regions tacit knowledge utilization, knowledge retention in small and medium-sized enterprises (SMEs), and knowledge dynamics. Finally, it is significant to highlight that while addressing the tension between

globalization and localization the idea of entrepreneurial universities initiatives and importance of social and regional innovation system has been viewed -with the perception of growing regional knowledge development process; and or taxonomy of knowledge economy for regional economic development.

Keywords - Entrepreneurial universities, Innovation ecosystems, Knowledge spillover, Social innovation, Regional growth.

Paper type – Academic Research Paper

1 Introduction

Nowadays the world is facing numerous multifaceted challenges exclusively in the areas of health, energy, environment, sustenance and social justice. The corona pandemics of our time is offering the most recent examples of how a global market and knowledge society are gaining experience in handling global crises. Therefore, in this turmoil condition, the significance of higher education institutions (HEIs) such as entrepreneurial universities emergences gradually recognizing that they can perform an important role by engaging themselves with the broader stakeholder community in order to overcome the outstanding challenges of the modern era. Thus, several researches' have identified that 'Entrepreneurial Universities (EU) 'plays a great role in promoting innovation driven regional growth that developed within the universities and government research and development institution. In addition, it has been observed that entrepreneurial universities act as a significant facilitator for regional economic and socioeconomic development, due to the spin-off of new, innovative initiatives that add value through knowledge creation and entrepreneurial discovery process (EDP) (Daniel et al., 2020; Saha et al.,2020a; Saha et al., 2020b).

In Contemporary, it is also necessary to mention that currently the changing perception for HEIs has put more emphasis on "entrepreneurial university" as well as "third mission" conception that fascinate one of the key activities of the HEIs, i.e. knowledge exchange with business, public organisations and society as a whole (OECD, 2019; OECD, 2017a; www.heinnovate.eu). The current discussion on knowledge spillover and regional innovation strategy represents one of the most common policies and practices to address the stresses between globalization and internationalization, i.e. (the processes by which HEIs as well as small firms can able to carries its activities worldwide and facilitate its internal operations to the international markets). However, many scholars (Budyldina, 2018; Pugh et al., 2018; Thomas, Pugh, 2020) highlight that the entrepreneurial university is first and foremost a regional actor. Accordingly, Sánchez-Barrioluengo & Benneworth's (2019), opinion it is increasingly common to claim that driving regional development represents a new 'third' mission for universities alongside the first (teaching) and second (research) mission.

Additionally, research on entrepreneurial universities emerging perspectives has received considerable attention due to its key enabling inspirations. Meanwhile,

entrepreneurial universities empowering the higher education institutes (HEIs) and small firms (SMEs) to meet the challenges of business networks with a positive impact of achievement of regional as well as social benefits. Where, it facilitates the regional innovation system and as a result entrepreneurial universities premeditated initiatives promote regions tacit knowledge utilization, knowledge retention in small and medium-sized enterprises (SMEs), and knowledge dynamics (Fuster et al., 2019; Baporikar.,2019). Consequently, the example of "World Class Universities for Societal Impact" conference shows the socioeconomic benefits, i.e. (the initiative as a novel means for broadening the societal impact by building a global brand, strategic collaboration and employment). Wherever, HEIs positive impact on societal development and technological disruption has a great influence in achieving an effective social innovation and sustainable development (Chan, 2018).

Regarding this vibrant topic several researchers have various thoughts. Though, there is a lack of definition or consensus about what an entrepreneurial university is (Pugh et al., 2018). According to Kirby et al. (2011) state that entrepreneurial university is a natural incubator that, by adopting a coordinated strategy across critical activities (e.g., teaching, research and entrepreneurship), tries to provide an adequate atmosphere in which the university community (e.g., academics, students and staff) can explore, evaluate and exploit ideas that could be transformed into social and economic entrepreneurial initiatives. Therefore, this paper from a conceptual perspective point of view, considers that regional innovation strategies and entrepreneurial universities key enabling features can enable regions to reinforce their regional knowledge spillover and raise social innovation–driven regional growth.

2 Theoretical background of entrepreneurial universities role on regional knowledge spill over and social innovation

The relevance of discussing entrepreneurial universities role on regional knowledge development process that accelerating the social innovation process, it is necessary to mention about the emerging perception of entrepreneurial universities strategic initiatives, which are nowadays have become a crucial issue. Since, it provides *an enthusiastic provision for academics, researchers, students and policy-makers in order to address and facilitate the development effect of an entrepreneurial universities strategic perspectives; entrepreneurial learning strategies, and collaboration with the multi-stakeholders' (practitioners' policymakers and research community) quadruple helix network* (Carayannis & Campbell, 2009); (Lindberg, et al., 2014).. Henceforth, directed research emphasizes the importance of entrepreneurial universities positive effects that consequently boost and enrich social as well as regional innovative skills, and creativity, diversity and inclusiveness at the university level (Caseiro & Santos, 2019); (Santos & Caserio, 2015).

On the other hand, from the policymakers' perspective point of view, all over the world entrepreneurial universities are considered as the central actors in regional innovation and development, as they can play direct and indirect roles in regional development. According to Pugh et al., (2018) entrepreneurial universities can play a direct role in

developing a regional strategy and working directly with government and policymakers. They are resolving regional social and economic problems, promoting innovations through projects, research or work as a knowledge spillover channel through dissemination of new knowledge and information. Consequently, Olo et al., (2020) also noted that their active role in regional development can be in commercialising their knowledge through spin offs, patents and licensing. In this way regions gain profit through job creation, spin offs, knowledge spillovers, attraction of new talents, and research that may be translated into products and services. Thus, HEIs can impact economic well being and foster innovations in the region.

Considering entrepreneurial universities significant role on regional knowledge spill over and social innovation, Audretsch et al. (2012) stress that the role of universities should be more than generating technology transfer (patents, spin-offs and start-ups), and rather, contribute and provide leadership for creating entrepreneurial thinking, actions, institutions and entrepreneurial capital. Simultaneously, concerning entrepreneurial universities initiatives for social innovation and social entrepreneurship development. Thomas, Pugh (2020) emphasized that the entrepreneurial university concept should go beyond its purely economic roles as a key deliverer of supports and services to local populations. Entrepreneurial university concept should incorporate socially-oriented ideas as social innovation and social entrepreneurship thinking. Furthermore, universities needs to develop and or create an environment of a positive force for social good in their regions“ According to his opinion, university‘s role in social problem solving are as follows: such as care for the elderly, digital inclusion, and education for art. Where, all these activities should be taken into consideration in the conceptualization of the entrepreneurial university’s impact on the regional community, too.

Similarly, considering the role of social entrepreneurs in the process of social innovation, it is necessary to mention that ‘social innovation’ actually deals with the contemporary social practices of social entrepreneurship (i.e. the development process, ability and opening the innovation process to the society). Wherever, multidisciplinary contributors like business people, accounting persons, economists and sociologists jointly put their effort with an aim to meet the social needs in a better way (such as by *providing better working conditions, better education facility, community development or healthcare services)* than the existing solutions, as well as to extend and strengthen the civil society (Biggeri et al., 2018). Similarly, Abbott et al. (2015), also highlighted that entrepreneurial universities contributes to social innovation processes by *providing knowledge which helps progression between the stages in helping move the process forward, either as piece of existing knowledge or something co-created with the affected community*; *making its resources available, whether providing direct financial support or providing access to university infrastructure and assets in the innovation process*; *supporting the social innovation process, either through advising social innovators how to access external knowledge resources, or persuading others to support participation in a social innovation.* Regarding this matter, Kim and Fuessel (2020) point out that HEIs needs not just only to support the progress of social innovation, but also to embed change making into their culture, operations, and educational offerings.Where, entrepreneurial

universities initiatives on social and regional innovation system have been viewed that focused on the taxonomy of knowledge economy.

2.1 Entrepreneurial universities in the context of European strategy for Smart, Sustainable and Inclusive Growth

In the "European strategy for Smart, Sustainable and Inclusive Growth" (COM (2010) 2020, 2010), for supporting the transformation of Europe into a "smart, sustainable and inclusive economy" providing enhanced productivity, high employment levels, and better social cohesion, the emphasis was placed on the following priorities:

- "Smart growth" (connected with creating an economy that is based on knowledge and innovation);
- "Sustainable growth" (linked to encouraging a greener and more competitive economy that supports sustainable development without degrading the environment);
- "Inclusive growth" (aimed at promoting an economy that supports both "territorial and social cohesion" creating more employment opportunity).

Significant changes in the economic and social context are associated with the phenomenon, which Thurik et al. (2013) call the shift from the "managed" economy in the direction of an "entrepreneurial" economy. The entrepreneurial economy is closely linked with innovation (Audretsch & Thurik, 2001; 2004; 2011), the central element of innovation being knowledge (Kruja, 2013). Today, innovation is not considered as being solely focused on technological innovations; it is increasingly focused on social innovation and the enhancement of knowledge on social innovation via research, use of various platforms, networks and tools that are supported in different policy areas including education as well (European Commission, 2014); (European Commission, Directorate-General for Research and Innovation, 2015). So, in the process of generating (disseminating) new knowledge and innovation, various business and non-profit organizations are involved, also higher education institutions being no exception (Kruja, 2013). Consequently, it is to be noted that modern universities play a key role in Regional Innovation Ecosystems and nowadays are becoming constructive places for innovation and "natural incubators", as they provide appropriate support structures for students and staff to initiate innovative projects, including intellectual, commercial and conjoint (Fernández-Nogueira et al., 2018 (Reichert, 2019).

According to OECD (2012), "A Guiding Framework for Entrepreneurial Universities" identifies seven specific areas of actions and initiatives, such as: leadership and governance, organizational capacity, people and incentives; entrepreneurship development in teaching and learning; pathways for entrepreneurs as well as university-business/external relationships for knowledge exchange in order to measure and transform institutions entrepreneurial role through multi-dimensional digital self-assessment and management tool (www.heinnovate.eu/en)

2.3 Entrepreneurial Universities in the context of Regional innovation systems and entrepreneurial Ecosystems

In order to determine entrepreneurial universities significant role in the context of regional innovation systems and entrepreneurial ecosystems, many researchers (Cooke, 2016; Brown, 2016; Reichert, 2019) commented on the way entrepreneurial universities improves the ability of enterprises, regions and countries to adjust to the new circumstances and enhance their capacity for knowledge-intensive production and innovation and stimulate local economies growth. Relating to this issue, Reichert (2019), indicated that the central contribution of a modern university is supporting regional innovation systems and entrepreneurial ecosystems (i.e. sustainable regional development), that accomplishing these following goals (Reichert, 2019). Such as:

- *Implementing interdisciplinary approach to promote digital and entrepreneurial skills and facilitate integrating technological development and human action;*
- *Incorporating project-based group learning system in order to establish a "university-business co-creation platform";*
- *Preparing students to address "disruptive" economic, social and technological challenges through entrepreneurial ecosystems at the regional and national levels;*
- Increasing digital skills of students as a response to face the challenges of digital transformation of the society in the regional development perspective;

Therefore, it is assumed that entrepreneurial universities play a significant role in promoting self-organised student activities such as innovation events for start-ups and investors, running a venture capital fund, etc.; this way students involve relevant stakeholders and get public support adopting the role of social innovators.

3 Research Methods

3.1 ***Definition of Entrepreneurial Universities used in this research***

This study mainly took the combination of both empirical evidence and inductive reasoning. Empirical argument depicts the methods of gathering information and data (knowledge). *Whereas, inductive reasoning depicts* some level of sustenance in the form of probabilistic reasoning and the groundwork of most scientific theories. *Definition of Entrepreneurial Universities used in this research to consider the responsiveness of regional knowledge development process that acts as some effective ways to foster the social innovation process which influence on regional entrepreneurship and provincial economic value. Where, the creative regions development process has a global charisma but in the context of Regional Innovation Strategy (RIS) its application has to be regional.* So, there is a vibrant role of entrepreneurial universities that enhance regional knowledge on regional organizations (ROs) for sustainable economic development program.

Therefore, to understand the study within the limited time frame, this paper considers *to carry out a systematic study about the entrepreneurial universities strategies that*

mainly focus on Higher Education Institutions (HEIs) policies and approaches. It measured in identifying the right path for entrepreneurial universities collaboration with knowledge-driven growth and societal engagement for promoting Social Entrepreneurship (SE) and Social Innovation (SI); determining entrepreneurial universities premeditated role and regional innovation strategies combined effort has a synergistic effect on regional economic development, is considered as one of the major policy and process of building regions, organizations and institutions more innovative and competitive. Thus, it is assumed that the added value of this knowledge development process will lead the regions to achieve their collective knowledge, and vice versa, through entrepreneurial universities strategic activities. Accordingly, focused research put emphasis the activities of entrepreneurial universities that linking different firms, people, and knowledge at a regional level. Where, education of HR and cooperation with HEIs appears as critical factors for the successful regional social innovation ecosystems, i.e. regional economic development.

4 Innovation-led Regional Knowledge Spill over Enhance Social Innovation system and Entrepreneurial setup

In the era of modernization, innovation-led regional knowledge spill over and entrepreneurial setup has been observed as the corner-stone of creating distinctive entrepreneurship and the knowledge-driven innovation center in the region associated with the regional innovation capacity development and social innovation system. Connecting to this issue, it is necessary to see whether entrepreneurial universities distinctive features and regional innovation strategies significant mechanisms along with the social innovation transformation development integrate together to accelerate and foster regional knowledge spill over and social innovation and social entrepreneurial network or not.

Concerning social innovation, several researchers have numerous opinions. Such as Szewczuk-Stępień, Jurczyk-Bunkowska, (2020), designated that social innovation is about cooperation with national and international public and private organizations to create changes in the surroundings. On the other hand, social entrepreneurship, commonly defined as an entrepreneurial activity with a social purpose, has been presented as an important economic phenomenon that has been observed on a global scale (D'Amario, Comini, 2020). According to Research shows that social entrepreneurship and social innovation are tools that meet social challenges and contribute to sustainable development (Pozzebon & Fontenelle, 2018).

Consequently, the synergetic encouraging influence of entrepreneurial universities and regional innovation strategies vibrant capabilities (know-how) put the emphasis on knowledge and innovation – driven regional growth, i.e. (sustainable value creation process within the region). In order to rationalize, Fig.1 illustrate whether the manifestation of entrepreneurial universities smart, inclusive and sustainable development goals, i.e. HEIs and small firms' performance can really effect the strategic positioning in a network that mediated through its enhanced innovativeness, i.e. (stimulus regional knowledge growth) or not; whether entrepreneurial universities regional and social

ecosystems initiatives (key drivers of regional innovation development & social economic development strategy) can really empower to influence the regional economic development through knowledge production, knowledge development, i.e. (innovation-driven knowledge spillovers) or not to cope up with the *societal challenges, social needs and systematic social change* that empower sustainable growth, social innovation and skills development. Whether, entrepreneurial universities support and focus the development of regional as well as social innovation strategies or not; whether the *entrepreneurial universities positive effect influence regional knowledge development process, knowledge spill overs and social innovation process* that are mainly based on the understanding of entrepreneurial universities strategic activities.

It can really incorporate its main novelties for enhancing regional economic development, i.e. (technological innovation and entrepreneurship) or not.

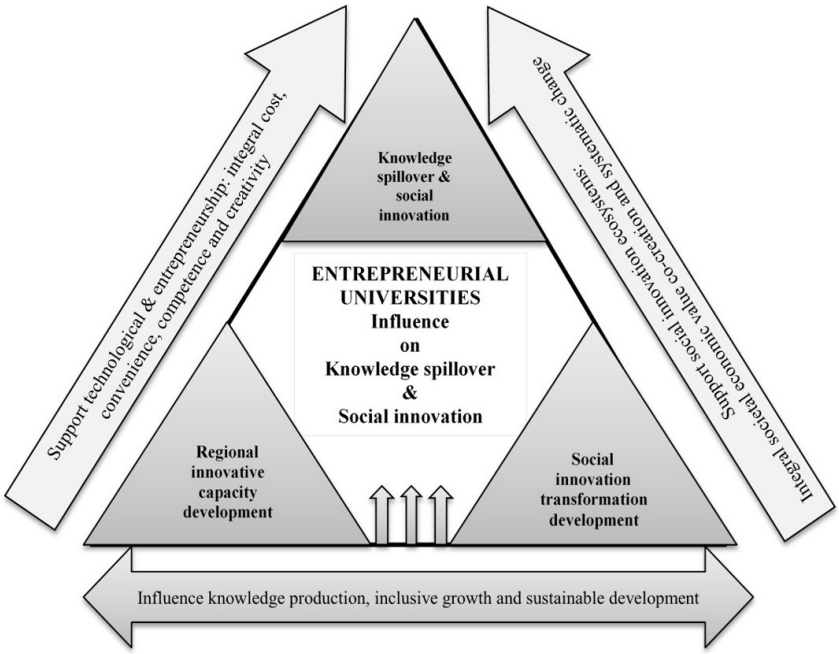

Figure 1: Thematic model of entrepreneurial universities role on influencing innovation-driven regional knowledge spillover and social innovation. (own interpretation).

In order to justify, the above mentioned Fig.1 and its illustration, the European Commission' Entrepreneurship 2020 Action Plan also states that "The role of higher education in entrepreneurship goes far beyond the delivery of knowledge to participate in ecosystems, partnerships and industry alliances. With high-tech and high-growth enterprises increasingly becoming a focus of entrepreneurship-related public policies, higher education institutions are an active component of the innovation policies of Member States and EU". Universities are viewed as proactive contributes to innovation, technological development and economic growth in a knowledge driven society (D'Amario, Comini, 2020) Similarly, Guerrero & Urbano (2010), stated that to address

entrepreneurial universities regional knowledge spillover and social innovation, it is necessary to mention that entrepreneurial society actually refers to places where knowledge-based entrepreneurship has emerged as a driving force for economic growth, employment creation and competitiveness.

Relating to the question of how regional knowledge spillover can accelerate their innovative capabilities through the distinctive features of entrepreneurial universities strategic approach and how entrepreneurial universities can foster inclusive growth as well as regional innovation systems and entrepreneurial ecosystems? This study leads to recognize the following three important research propositions or RPs that enable us to comprehend the rationalization of this research intents such as:

- RP1: Which states that entrepreneurial universities key enabling strategies and regional innovation ecosystems are the main driving forces, priorities and stimulation of a region to accelerate the regional knowledge production system and its implementation, i.e. (to enrich regional knowledge spillover);
- RP2: Which indicate that entrepreneurial universities intention is to provide a huge possible opportunity for implementing regional development strategies distinctive features in order to mobilise the existing resources, i.e. (human capital) through their knowledge, networks and dynamism that are available at local level, to create more value, i.e. (to enhance key enabling technologies for achieving competitive advantage);
- RP3: Which expresses that the added value of this regional knowledge development process (knowledge spillover) will lead the regional as well as social innovation transformation to achieve social entrepreneurship through the transfer of explicit distinct knowledge of the community awareness, and vice versa.

In short, it can be said that this study suggested that – the role of entrepreneurial universities on regional knowledge spillover could be very stimulating and sophisticated approach for the new EU member states territories their research institutions, universities, small and medium enterprises in order to create new business opportunity with worldwide competency. On the other hand, regional innovation ecosystems could be supportive for the universities and business to provide assistance in prospectuses to ensure that graduates have the right skills and transversal competences. Furthermore, it can be specified that the emerging conception of the entrepreneurial universities dynamic and inclusive approach is the process of entrepreneurial mindset development and social innovation process development. Where, entrepreneurial education means the activation of innovative processes and approaches that not only allow individuals to learn about entrepreneurship, but also to develop a social perception along with the entrepreneurial mindset for promoting inclusive and sustainable development.

5 Conclusions

To understand the practical, social and academic perspective of entrepreneurial universities role on regional knowledge spillover and social innovation, this paper discourse the significance of entrepreneurial universities key enabling activities that

connecting regional, inter-regional, national and global interactions at a regional level and contributing to knowledge based economy with the emergence social innovative process that foster social entrepreneurship. From the academic point of view, it may attract the young generation to go for higher studies on entrepreneurial and social innovation ecosystems and develop an entrepreneurial mind setup for social change. Whereas, from socioeconomic development point of view, it could enable universities to make an essential contribution to meet the societal challenges of promoting knowledge based economic development through universities' multidisciplinary teaching & research activities. Accordingly, the consequence of this study shows entrepreneurial universities inventiveness is influential instruments to foster and develop knowledge-development societies competitiveness, regional innovation and provincial growth due to their intrinsic competence.

Henceforth, it can be said that the entrepreneurial universities concept has been realized as the leading concept for formulating regions strategic goals and measures that are related to regional knowledge spillover through entrepreneurial universities formal factors, i.e. capitalization of knowledge, interdependence with the industry and government, independence with another institutional spheres, hybrid organizational forms and renovation. This thematic paper has focused on how entrepreneurial universities can generate the necessary conditions (social, cultural, institutional and territorial economic growth) in order to achieve the highest competitiveness and regional innovation levels possible. Though there are certain loopholes in entrepreneurial ecosystems to be protected, especially when referring to the strategic role of entrepreneurial universities. Finally, in view of the above discussion, it has been understood that an entrepreneurial university faces many challenges in the contemporary uncertain environment; they are very concerned about finding the ways to integrate traditional educational and research activities in the comprehensive institutional strategy, which has to be elaborated in the entrepreneurial agenda.

Abstract

Social innovation has been receiving growing attention from policy makers, international institutions, non-governmental organizations, researchers and the business sector around the world. Despite a growing belief that social innovation represents one of the key solutions to solving current societal problems, the field of social entrepreneurship research in higher education institutions provides disparate discussions of this phenomenon and there are only a few systematic reviews conducted, which severely impedes the advancement of social entrepreneurship practice and research in education context. Current literature describes the field of study regarding social innovation and entrepreneurship in higher education institutions (HEIs) as being not well-developed nor agreed upon. A macro-lens regarding the awareness of relevant actors about multiple dimensions of social innovation in universities, and connectivity with the reality of today, is needed. By building on existing frameworks on (social) innovation in higher education, created to increase competitiveness of universities worldwide, the present paper aims to discuss the dimensions in which higher education institutions can innovate and become social entrepreneurial. It seeks to present the perspectives against which relevant actor personnel should identify and analyse social innovation in HEIs. Also, this paper is an attempt to show that now more than ever there is a critical need to examine the societal impact of COVID-19 on higher level institutions actors. Further research should identify how higher education innovation assists societal challenges and investigate the most expected outcomes of social entrepreneurship in higher education. Also, it should explore the common ground where more actors can sustain the innovation.

Keywords – Social innovation, social entrepreneurial university, dimensions of social innovation, higher education institution, COVID-19.

Paper type – Academic Research Paper

1 Introduction

The higher education institutions are constantly changing and evolving to adapt to the needs of the current society (Clauss, Moussa and Kesting, 2018; Janiunaite and Gudaityte, 2007; Larran Jorge and Andrades Pena, 2017). The discussion about the social role of higher education institutions and the role they play in social entrepreneurship is highly relevant in the current social, economic and political context. In the past decades, the universities around the world have been required to become more involved in addressing the societal needs, and thus become more relevant for the communities which they serve. Universities have fought to maintain a balance between their traditional missions of education and research and their newer mission of direct contributors to economic and social development. Nowadays, the higher education institutions are seen more as drivers of social innovation and change as their main role is to help overcome social inertia and to advocate for a move away from the status quo and their inherent social problems (Janiunaite and Gudaityte, 2007). Thus, it is pertinent to ask the question as to how can higher education institutions become innovators and agents for social change? Also, what drives the model of social entrepreneurial university?

Although higher education presents the characteristics of a true potential social innovator through the skills and competencies developed for its graduates and the impact of its research, the scientific literature has failed to provide a detailed account of the dimensions of social entrepreneurship in higher education and the means through which these could be enriched. Thus, the paper aims to discuss the dimensions in which higher education institutions can innovate and become social entrepreneurial. Also, it seeks to understand the synergies and interconnections between these drivers of innovation in higher education context.

2 Characteristics of a social entrepreneurial university

Social entrepreneurship is becoming an extensively used term in various domains of activity, from health sector, to food industry and environment management (Weerawardena and Mort, 2012). It has so many ramifications that every analysis made in this field has an important role in clarifying social entrepreneurship's dimensions and the means through which these can be enriched. Social entrepreneurship nowadays seems to wear many forms, from corporate volunteering (Haski-Leventhal, Kach and Pournader, 2019), to social philanthropy (Leborgne-Bonassie, Coletti and Sansone, 2019), and social finance (Langley, 2020). In the current paper, we decided to approach the higher education area by directing our research towards the shape that social entrepreneurship takes in the higher education institutions (HEIs). This may lend itself in helping to alleviate the challenges that has evolved recently in society.

The context of higher education has changed dramatically due to the internationalization, the increasing competition between universities and through the development and growth of private universities. A university that is not entrepreneurial is more likely not to be competitive in the new market of higher education and won't

survive in the newly created environment based on extreme competition. Păunescu and Cantaragiu (2013) argue that higher education institutions are more likely to succeed on this market characterized by increasing competition if they build socially responsible practices and create an identity of a society-oriented university. To develop, universities should also have the ability to translate knowledge, creativity, and innovation into action and measurable outcomes as this is the essence of organizational intelligence (Riviezzo, Liñán and Napolitano, 2017). Also, they should care about all stakeholders' needs and they should be driven by a sense of moral commitment to serve their communities (Nejati et al., 2011).

With regards to the development of entrepreneurship in the HEIs, scholars ardently debate on whether universities should be construed as businesses with business-like purposes, mentalities and models, or as non-profit organizations with a tradition in serving the community in which they are present and the overall society (Schulze-Cleven and Olson, 2017). In the paper, we argue that it is fruitful to view universities (i.e., public universities in particular) as more similar to entrepreneurial non-profit organizations involved in commercialization activities and aiming to drive social change.

One of the models of entrepreneurial university, more frequently used in previous researches in diagnosing the entrepreneurial orientation of universities of various sizes and profiles from around the world, is Clark's (1998) model. The model refers to five principal pillars of an entrepreneurial university, which can be easily translated for the case of a university that intends to perform entrepreneurship with a social orientation. Thus, Drăgan (2018) discusses about five characteristics of the social entrepreneurial university, which build upon Burton Clark's (1998) model for the entrepreneurial university: (a) a strengthened social core and mission; (b) an expanded socially oriented periphery; (c) a socially stimulated academic heartland; (d) diversified funding for social initiatives; and (e) an integrated social entrepreneurial culture.

For the social entrepreneurial university, the signs of a *strengthened social core and mission* were taken to be the creation and implementation of university social responsibility plans (or the equivalent inclusion of a strong social responsibility dimension in the university's strategic plan) and sustainability plans. The socially *stimulated academic heartland* is considered to be the results of activities implemented with regards to the teaching and research of social entrepreneurship and closely related subjects such as social innovation, corporate social responsibility, social impact and community engagement. With reference to the *expanded socially oriented periphery*, for a socially oriented HEI it is crucial to extend relations with external stakeholders, to engage in volunteer actions and to encourage members of the universities to get involved in public engagement. The HEIs will need *funding for social initiatives*. Enterprising universities are competing for grants and contracts in order to expand their income sources (local governments, philanthropic foundations, royalty income from intellectual property, earned income from student fees and alumni fundraising) to go towards social initiatives. Furthermore, enterprising universities should develop a work culture that can easily adopt change. An integrated *social entrepreneurial culture* is considered to be the results of a social mission and a social vision, precisely statements which expressly

include the responsibility and desire of the university to serve its local community and society as a whole, to contribute to the economic and social wellbeing of those it serves and to mobilize its resources in order to identify means to solve the social and environmental concerns of its times.

3 Methodology

The paper aims to define and analyse the dimensions of social innovation in higher education, as well as their specific variables, which create the framework for a social entrepreneurial university. To explore the potential for social innovation in higher education institutions, the research relies on the HEInnovate framework (2018), a self-assessment tool created by the European Commission in partnership with OECD, which can be used by universities in order to initiate institutional development to increase the competitiveness of European universities and their relevance for economic and social development. The HEInnovate framework contains seven areas of focus: leadership and governance; organizational capacity: funding, people and incentives; entrepreneurial teaching and learning; preparing and supporting entrepreneurs; knowledge exchange and collaboration; the internationalized institution; and measuring impact.

Moreover, to further explore the dimensions of social innovation in higher education institutions, a multitude of criteria came out from studying the formal reports drafted by European University Association (EUA) – Institutional Evaluation Programme (IEP) of the universities from different countries, as well as from relevant international rankings of the universities worldwide. As such, the current research builds also upon the following dimensions of the EUA-IEP framework: norms and values, mission and goal, governance and activities, teaching and learning, service to society and research, internationalization, and quality culture. Furthermore, the analysis integrates the criteria used by QS Stars University Ratings to assess the social role of universities: community investment and development, charity work and disaster relief, regional human capital development, and environmental impact (Păunescu, 2017).

Building upon these frameworks, the paper discusses the dimensions against which relevant actors should identify and analyse social innovation in HEIs. It seeks to understand what the dimensions of a social entrepreneurial university are, and what are the synergies and interconnections between these drivers of innovation in higher education context. As Loogma et al. (2013) argue, any change in the educational system can be analysed using the theoretical lens of social innovation, especially if we are concerned with the depth of the changes.

4 Dimensions of social innovation in higher education institutions

Higher education has a tripartite mission: to provide education, ensure research and the third mission of the universities has been linked to their involvement in society and contribution to socio-economic development (Păunescu and Cantaragiu, 2013). Some researchers regard the third mission of the university as its ability to align its activity to

economic development of the community in which it is present (Etzkowitz, 2013), or having its faculty engaged in academic entrepreneurship (D'Este and Perkmann, 2011).

There are many social problems that the traditional public sector, or even private companies, cannot solve or fall beyond its scope. For this reason, universities can play a very important role in addressing these problems through entrepreneurial actions that could assist all possible actors who can lead the way to new horizons and new developments (Găucă, 2019).

There is an abundance of research into innovation in higher education, whether in curricular programmes (McClure, 2015), delivery mechanisms (Davis and Jacobsen, 2014), pedagogical approaches, support service mechanisms (Sultan and Wong, 2013) or effective management (Amaral, Fulton, and Larsen, 2003). The majority of these studies, however, tend to overlook the role of individual actors, nor the individual motivations of undertaking entrepreneurial actions or the dimensions of innovation that generate social changes (Hasanefendic et al., 2017). This relative disregard for individuals as innovators in higher education contexts and dimensions of social innovation might derive from the constraints posed by institutional factors (i.e. power structures, values, norms, taken-for-granted attitudes, behaviours and routines), which can delimit the level of success for innovation in higher education institutions (Campbell and O'Meara, 2014).

Innovation in higher education institutions takes part in all core and organizational processes and involves several groups of actors who are expected to take responsibility for initiating entrepreneurial actions. As the field of study regarding social entrepreneurship in HEIs is not well-developed nor agreed upon, a macro-lens regarding the awareness about multiple dimensions of social innovation in universities, and connectivity with the reality of today, is needed (Găucă, 2019). The present paper describes further the perspectives against which relevant actors should identify and analyse social innovation in HEIs.

Leadership and governance. Universities nowadays face high pressure from all stakeholders, being required to provide consistent socio-economic returns to justify the fund absorption rate by delivering highly skilled and entrepreneurial graduates. Nelles and Vorley (2011, p. 347) state that "university, administrators, board members, department heads, and the directors and staff within structures that support the third stream are important sources of initiative, all of which contribute to developing knowledge exchange strategies, processes, systems and a supportive … organizational culture." The higher education institutions are required to be innovative in structures (i.e., numbers of layers within organization, number of decision makers and support staff), systems (i.e., centralized or decentralized decision making process, digitalized education, technology-assisted learning and labs), leadership (i.e., KPIs defined, existence of an external advisory board, recurrency of the meetings with external advisory board, number of projects worked on together and number of decisions taken together, rankings pursued), strategies (i.e., flexibility of the strategy and its alignment with the current reality), and culture (i.e., appreciation for the cultural differences).

Teaching and learning. Higher education institutions contribute indirectly to the development of social innovations through teaching, as the process of learning enables

individuals to widen their skills and knowledge and become more prescient of the social problems encountered in today's societies and better equipped to act themselves as agents of change (Janiunaite and Gudaityte, 2007). The higher education institutions are expected to demonstrate innovation in their approach to teaching and learning by implementing a student-centred learning and by using multiple and alternatives learning methods, tools and materials, such as: case studies, business plan writing, problem-based learning, competitions, technology-assisted learning, etc. HEIs are also expected to support their faculty and staff members, by offering them opportunities for free or paid training and education, international exchange programs, participation at conferences. Similar opportunities should be also extended to students: opportunities for employment and career choices and development during and after the study, experiential learning, reflection and deep learning, part-time and life-long learning, interdisciplinary learning, emotional learning and curriculum.

Research. Through research, higher education institutions can develop innovative and sustainable solutions to social and environmental issues and thus contribute to increasing the responsiveness and impact of public policies, fostering social inclusiveness and allowing organizations to make better use of their resources in providing effective products and services. From the perspective of the research field, social innovation in higher education institutions should take into consideration challenges with local, national or global impact, that create economic well-being and competitiveness, research with societal relevance (i.e., addressing poverty, health issues etc.), and the quadruple helix (government, academia, industry, civil society).

Knowledge exchange. Social innovation in higher education institutions relies on trans-discipline and the ability to work across the boundaries that separate academic disciplines and ensure the transfer and exchange of knowledge. Taking into account the perspective of the knowledge exchange, social innovation in higher education institutions should lead to hubs for local development, from knowledge transfer to knowledge exchange, cooperation with private companies, cooperation with local groups with specific societal relevance (blind people, rroma society, persons with disabilities, poor groups, abandoned children etc.). Thus, the higher education institutions are required to have strong links with the socio-economic environment through incubators (i.e., partnership with business incubators, products developed in partnership, leased workforce for business incubators), technological parks, business portals and other external initiatives, and continuously create opportunities for innovation, which drive social change.

Partnerships and networking. The role of higher education institutions in creating social change is not only indirect, as these organizations can also play a more active part in the development of social innovations through research, triple helix partnerships, community engagement and many other forms of collaboration and partnerships (Krampetz and Smith, 2011; Brennan et al., 2014). HEIs are expected to actively encourage individuals to be innovative, by joining professional networks, alumni networks, business portals, etc. The quadruple helix, in which higher education institutions are placed within webs of interactions, supports the networking and

collaboration with all the other social agents such as governments, civil society, industry players and various communities (Park, 2014).

Funding. From the perspective of funding, social innovation in higher education institutions should facilitate access to private financing for their potential innovators to create innovative products and facilities and should ensure that there is a range of sustainable sources of funding. Also, this means that there are funds for entrepreneurial agenda of faculty, staff and students and there are scholarships funded by government, public sector, university or private companies.

Impact. Cabrera et al. (2018), after an analysis of the demands of the various stakeholders of the higher education system in regards to university social responsibility, concluded that the business sector is interested in receiving support for innovation, the public sector is interested in transforming universities in engines of economic and social development and that students are interested in receiving training imbued with social values and the opportunity to become involved in philanthropic activities. Taking into account the public policy perspective, social innovation in higher education institutions should lead to descentralization actions, leading roles of universities in the community agenda, systematic and structural changes, engines for higher education mobility and growth. Taking into account the business environment perspective, social innovation in higher education institutions should lead to knowledge providers, innovation partners, absorptive capacity of workforce, businesses that engage in education, talent providers. Taking into account the competition perspective, innovation in public higher education should lead to international rankings, highly regarded awards, globalization.

5 What roles can higher education play during and after the pandemic?

At the start of this journey very few people had heard about COVID-19 and least of all no one expected the tsunami of a pandemic that has occurred throughout the whole world. A research study from the European Union (Eurostat, 2020) has shown that the impact of the pandemic on jobs in some countries has been far greater than others. Ireland is one of those countries where the impact has been great. At present, there is over one million Irish workers depending on state funding for their livelihood. In Greece and Spain, according to the European Union report (Eurostat, 2020), the impact is at more than 13%. The exact data for Ireland it is at 12.7%. This is rated as the fifth highest in Europe. For other states such as Romania, Poland, Germany and Belgium, for example, the impact appears to be at 8%. There is a difference. According to some data it is the lower paid workers who are the most affected. So now more than ever they will need to be given the opportunities that third level can deliver. They need to be offered the opportunity to upskills and afforded the opportunity of social mobility that a higher education level can provide. From a gender perspective, it appears to be women who are more affected by this lockdown that has occurred in an effort to spread the virus. The EU report (Eurostat, 2020) has estimated of 45 million jobs in the EU alone affected by COVID-19 and another 22% of those employed are left bare to the risk.

Uncertainty abounds in Europe and the world in the wake of Covid-19. So, what will now happen to those who have to change their career perhaps or seek employment in

another area? The higher education sector has a definite role to play. Those most impacted are seriously disadvantaged. Remote learning is an opportunity now more than ever. However, this also depends on certain infrastructures been in place, such as access to the internet. That aside funding has to be made available to people who have been affected by COVID-19 to purchase the appropriate technology. It is also important that they are taught how to use this technology also. The economic impact on third level institutions due to COVID-19 will also be great. There will be no international students in some places that could cushion the bill. Nevertheless, those less fortunate have to be given the opportunity to upskill. Robots are in use to do the jobs of lowly paid workers in certain areas. They are the future. So, it is imperative from a moral and ethical point of view that higher education institutions reach out to those people and ensure that they are given an opportunity to work. As Rockfeller said the "Country does not owe you a living, but you owe the country to make a living in it" (cited in Martin, 1999). The economic impact of COVID-19 is going to last for some time. What is key to getting an economy moving is jobs. Jobs that will require a skilled workforce. This is where the higher education institutions come in to assist and prepare a workforce that is fit for purpose. Re-training programmes and education is key to getting economies moving following COVID-19.

Capacity will have to be built within HEIs to take on board the mature students that will need re-training. Governments will have to put funding into these organisations to ensure that educational programmes are provided to upskill people. Frameworks that will ensure participants have opportunities to build on credits will now be more important than ever. Technology expertise will have to be taught and a good infrastructure put in place. This will be costly but as Mandello (2003) says "Education is the most powerful weapon which you can use to change the world." The merits gained by investments in our HEIs will assist enormously in providing an ultimately a more sustainable society. The actions of higher education institutions in the aftermath of COVID-19 will set the course for economic sustainability for the future, if they provide the educational and training pathways for those most vulnerable in our society.

In this spirit, the International Association of Universities is reflecting on the impacts of COVID-19 on higher education around the world. A Global Survey on the impact of COVID-19 on HE has been conducted. It is planned with this report that solutions will be sought that can be replicated around the world. It has recognized the importance of having institutional portals and social networks to disseminate information regarding research, and to make available open access courses for those working in healthcare and other sectors.

6 Conclusions

The paper introduces a framework which explains the dimensions of social innovation in higher education institutions and describes the perspectives against which relevant actors should identify and analyse social innovation in HEIs. The key elements included in the framework are as follows: leadership and governance, teaching and learning, research, knowledge exchange, partnerships and networking, funding, and impact.

Also, taking into consideration these perspectives of social innovation in higher education, the paper discusses the roles that the higher education institutions can play now with the pandemic that has occurred throughout the whole world. The use of technology in supporting teaching and learning in higher education institutes has never been more important. The uptake of remote teaching and learning that has occurred due to COVID-19 has really highlighted how inequalities exist for some due to poor access to internet facilities and in some homes no access to a computer. This paper is an attempt to show that now more than ever there is a critical need to examine the societal impact of COVID-19 on students attending higher level institutions. Concerns defiantly have arisen at institutional level regarding students learning experiences during this pandemic. Knowledge construction and engagement of students is pivotal to their learning. COVID-19 has challenged everyone that is involved in higher level education to ensure that students are not short changed.

Future research should investigate, based on secondary data available at country level, how the synergies and interconnections between these drivers of innovation in higher education context address societal problems and impact the society. This could be achieved by conducting a systematic analysis and highlight how higher education assists social mobility and enhances the quality of life for people.

Abstract

The document explores the factors that influence the visit to The International Living Arts Festival (FIAVL, by its Spanish acronyms), through the study of sociodemographic variables of the visitors, the media through which they found out about the festival and the variables of recommendation and evaluation of the mentioned event.
In order to carry out this analysis, we use quantitative methods. Our sample includes 314 data, corresponding to people who attended open events (OFF), which are free events that took place as part of FIAVL 2018, using cluster analysis to segment them.
Our research contributes to the Theory of Planned Behavior (TPB) on the influence of factors in the choice of attendance at cultural events. Considering the analysis of the aforementioned variables, it is shown that there are internal and external factors that affect both the recommendation and the evaluation; these are mainly influenced by the means of communication by which the attendees found out about the event.
By identifying the sociodemographic profile of the attendees and the media with the greatest influence, the main contribution of this work is to provide clear evidence of the need to propose guidelines focused on specific groups of attendees; that guarantee the sustainability of cultural festivals in emerging countries, such as Ecuador.

Keywords – The International Living Arts Festival of Loja, sociodemographic profile, media, social networks.

Paper Type.- Academic Research Paper.

1 Introduction

One of the facts that gave rise to the FIAVL, dates back to the construction of the Benjamín Carrión National Theater in 2013, which led to the first perspective of performing arts in Loja province. By 2014, the first meeting of performing arts organizers and producers is held, in addition to the development of several workshops. Finally, in the "citizens outreach" tv and radio program number 388 hosted by the Ecuadorian government, dated August 30, 2014, it was declared that the International Living Arts Festival (FIAVL, by its Spanish acronyms) will be held in the city of Loja, taking as a model the Avignon festival, which has been developed for dozens of years in France (Ministry of Culture and Heritage, 2018). In emerging countries, these types of festivals are of utmost importance, since they vitalize the economy of the cities in which they take place (Pulido-Fernández, Cárdenas-García, & Carrillo-Hidalgo, 2016). In the case study of Loja, Ecuador, an increase in visitors of 52% is calculated during the development of the FIAVL in 2017 compared to visits in 2016 (UTPL, 2017). It is for this reason that this research has relevance in scientific development, especially because it is a subject that has not been adequately addressed from the different sectors involved. The results are expected to contribute to the government, business, academia and local society in general. The destination also receives the contribution, as a new opportunity for tourism development. Burneo (2016), mentions that the creation of a cultural product which transcends in the festival execution and contributes to the city that hosts the event, is pertinent because it creates new opportunities for local development.

Therefore, it is important to analyze the factors that come together in the tourists' visit to this type of festivals. The literature states that this can be done through the variables study related to the sociodemographic profile of the visitor, ways of traveling and social networks used to find out about the event (Collins & Potoglou, 2019).

An aspect that influences attendance to the festivals is the ways of traveling, since this variable allows the theories of travel behavior to be identified, as well as the internal and external variables that influence this factor; thereby determining the guidelines to guarantee the sustainability of the event (Collins & Potoglou, 2019).

Through the analysis of social networks, a different way of reaching the consumer of this type of event has been identified, taking into account the interaction that exists between the consumer and the festival brands which exist in the market. According to Hudson, Roth, Madden and Hudson (2015), in their work on the brand interaction of a festival through social networks; in which they identify that this interaction is related to the visitor's emotional attachment to the festival and, in turn, this attachment has a direct effect on the so-called "word-of-mouth marketing" which influences the loyalty building and the impact on the visit (Hudson, et al., 2015).

Although there are studies in emerging destinations on the variables that determine the attendance to cultural events or the consumers' preference, most have been approached

from the perspective of tourism expenditure (Pulido-Fernández, Cárdenas-García & Carrillo-Hidalgo, 2016). Other studies address the economic impact and the image of the destination; perceived not from the attendees direct point of view, but from the perspective of potential markets. However, the factors inherent to the recommendation, return visit and cultural event evaluation, have not been clarified yet in the existing literature (Arnegger & Herz, 2016). Even Maeng, Jang and Li (2016), state that it is necessary to further investigate the motivations for attending Festivals, since only the motivations for tourism have been analyzed so far.

The contribution of this work aims to fill the gap on cultural events research in emerging countries, where the profiles of consumers attending this type of event have not been adequately characterized, in order to identify the expectations of every group and seek to meet their requirements.

In light of the preceding considerations, this work aims to answer the following research question: What are the guidelines for the FIAVL sustainability, according to the sociodemographic variables of the attendees and the use of social networks?

To answer the question stated, the aim is to work in a conceptual framework based on the Theory of Planned Behavior (TPB) (Schifter & Ajzen, 1985). This theory has been used in research carried out by Collins and Potoglou (2019), on the influence of internal and external factors that lead travelers to choose to visit cultural festivals; similarly Han, Meng and Kim (2017), address the same theory in research on emerging bicycle tourism and behavioral theory; also Kim and Han (2010), about the paying intention of travelers in conventional hotels and the modification of the Theory of Planned Behavior.

2 Conceptual background

2.1 Sociodemographic determinants for a cultural event sustainability.

The organization and planning of the visitors' travel is essential to guarantee the success and sustainability of the festivals (Collins & Potoglou (2019). It is stated that there are several factors by which visitors decide to attend an event and / or festival. According to research by Collins and Potoglou (2019), the results are focused on several internal and external factors. Internal factors include the use of a car, trips with young children, the possibility of making independent trips on different routes and times, travel costs and physical health and mobility problems. Regarding external factors, they indicate the location of the city, type of overnight accommodations, the location of the event and the quality of public transport services. These are factors that the Theory of Planned Behavior (TPB) identifies, over which the decision maker would have limited control. By identifying them, it is possible to anticipate how attendees perceived or foresaw the effects on their trip and festival experience. It also highlights how these factors are interconnected in terms of influencing the visitors' final choice.

Visitors who attend cultural events correspond to different profiles; for example, at events related to film festivals, the spectators are quite young with a high level of education and an average age of 26.3 years old (Báez & Devesa 2014). Similarly,

Robbins et al. (2007) determine that age is a main factor that influences the intention of visiting a cultural event or festival. On the other hand, Nicolau (2008) associates the possibility of visiting an event with the level of income. For Collins and Potoglou (2019), socioeconomic characteristics such as age, income, family life cycle and the presence of children influence the intention to travel to an event.

Through the sociodemographic profile results, it is possible to identify the visitors' characteristics who arrive at a certain tourist destination and of those who attend a cultural festival. These data shall make it possible to establish segments of the groups, in order to focus and promote cultural events in different media based on specific groups.

2.2 Media that influence visits to cultural events.

In large social contexts such as schools, universities, workplaces, neighborhoods and online digital communities; people join smaller groups in which they experience a higher level of communication, security, belonging, interdependence, social norms and psychological well-being in comparison to the rest of the social context (Stadtfeld, Takács & Vörös, 2020).

Therefore, the media are important tools to transmit information to the general public. Currently, there are traditional means of communication such as: press, television and radio, which are used by a certain segment of users to find out about products or services that exist in the market or to learn about news or events that occur worldwide.

During the last few years, the emergence of information and communication technology has caused a fundamental change in the world tourism system; for example, the way to look for travel-related information, to receive travel advice and to communicate mobility guidelines, which has deeply changed the practice of the tourist activity (Gössling, 2017).

These technological innovations have brought a new form of communication, generating a greater use of media such as social networks; they have become an important recognized channel for tourist information (Han, McCabe, Wang & Chong, 2018).

Currently, social networks are an element of personal, professional and business interaction to share content and increase visibility to other users.

Researchers are interested in these tools because of the scope that this emerging phenomenon has generated, due to the valuable information that can be produced, through the interrelationship of cultures; this means the exchange of experiences and shared interests. For this reason, experts have considered social networks as a means by which users' practices, relationships and culture can be understood (Boyd & Ellison, 2007).

Social networks in cultural festivals also play an emerging and important role, since they must generate recommendation systems, in which the offer and marketing strategies are personalized according to the preferences of the identified users in order to achieve the best results in terms of the number of the applications users and, consequently, the results of promoting events through social networks (Milovanović, Bogdanović, Labus, Barać, & Despotović-Zrakić, 2019).

Considering the importance of digital tools, it is possible to investigate the analysis of the media that influence visits to cultural events, with variables related to the sociodemographic profile of visitors and their direct relationship.

3 Research Methodology

3.1 Sample

In order to answer the question posed in this research, the sample of people attending the OFF events of the International Living Arts Festival in 2018, was determined. It is a probability sampling design; therefore, it consists of simple random sampling. As a result, the formula for sampling infinite populations was used to determine the exact number of people to be surveyed, since there is no exact data on the number of attendees. For this work, 386 surveys were applied between November 16 and 26, 2018. Nevertheless, at the time of analyzing the data, 72 surveys were excluded because the data were not consistent for the analysis and the application of the model, leaving a total of 314 valid responses for the analysis.

The surveys were applied during eleven days in which this event took place in the city of Loja. According to Burneo (2016), this city is traditionally known as the epicenter of some artistic and identity manifestations in Ecuador. These characteristics have served as motivation for the city to host the festival that has been held since 2016.

The survey instrument was applied on-site by the Tourism Career students from Universidad Técnica Particular de Loja (UTPL), to people who were attending open events, called in official programming as "OFF events" because they are free for the attendees. These events took place at different schedules. The survey was prepared by the teachers' team from the Departmental Section of the Hotel and Tourism Faculty of the UTPL; the development of this instrument arise from previous research on the profile of the tourist and is adapted to this type of event under technical validation of the Ministry of Tourism of Ecuador (MINTUR, by its Spanish acronyms) and the contribution of the organizers in every edition of the festival. The set objectives to apply the survey were: to evaluate the OFF events, to determine the sociodemographic profile and to know through which media the attendee found out about the event.

3.2 Measures

The instrument was made up of some sections, in which 47 questions were grouped. The sections that correspond to this study were:

- Section A: FIAVL data
- Section D: Evaluation of Loja as a tourist destination

Section A includes the variable that corresponds to the means of communication through which the attendee learned about the festival. This variable was made up of six indicators: social networks (1), television (2), radio (3), written press (4), digital press (5) and others (6); in the last indicator, some responses were given such as: friends, festival

webpage and municipality. In line with similar works in emerging contexts (Dávila, Andreeva & Varvakis, 2019), we chose the Likert scale of 1-5 as evaluation options for the questions implemented in our questionnaire. Other variables considered in this section are: the evaluation of the events, in which the attendee has participated, is built with a Likert scale from 1 to 5, where 1 represents "not at all satisfied" and 5 "very satisfied". The recommendation of the FIAVL to other people is also measured, it is done on the same scale as the previous variable. As well as, the variable of whether the attendee would participate in other editions of the FIAVL, which is also evaluated on the same Likert scale from 1 to 5, where 1 represents “I would not participate again" and 5 “I would definitely participate again". Section D considers the remaining variables which determine the sociodemographic profile of the respondents; as gender which includes two elements: masculine (1) and feminine (2); age is an open-ended question that is determined by the respondent; in the same way, the level of Education includes some options: none (0), primary (1), secondary (2), tertiary (3) and postgraduate (4). Finally, the income level of the respondents was also considered, placing ranges of 500 dollars, drawing from the premise of the unified basic monthly salary in Ecuador for the year 2018 ($ 386.00), the indicators were: less than $ 500 (1), from $ 501 to $ 1000 (2), from $ 1001 to $ 1500 (3), from $ 1501 to $ 2000 (4), from $ 2001 to $ 2500 (5), from $ 2501 to $ 3000 (6) and from $ 3001 onwards (7).

From the analysis of these data, three dependent variables (core) were determined, which allow evaluating the development of the festival in general way, in this sense we have: evaluation of the events which were attended, whether the attendees would recommend the FIAVL to other people and whether they would participate in future editions. While the control variables are associated with: age, gender, educational level, income level and the media.

3.3 Method of analysis

There are two main approaches to segmenting a market, that is, a priori and a posteriori. Segmentation "a priori" or "common sense" involves grouping people according to profile (Mazanec, 2000). For example, the country of origin is often used to segment visitors of a tourist destination, as it offers advantages to destination management organizations to develop personalized marketing strategies (Dolnicar, 2008; Zeugner-Roth & Zabkar, 2015). Segmentation "a posteriori" or "data-based" consists of statistical techniques that include analysis of clusters, correspondence analysis and analysis to identify and outline customer segments (Dolnicar, 2004).

Cluster analysis was used to identify possible groups of those attending the FIAVL OFF events, this is a procedure used to determine the best group segmentation according to motivations and behavioral characteristics (Kim, Duncan, & Jain, 2016). According to Formica and Muzaffer (1998), this technique has been used in previous investigations by exploring existing markets to events that combine cultural exhibitions, a process that has been developed through cluster analysis to identify groups of respondents based on motivational behaviors.

First, we applied Hierarchical clustering to determine the appropriate number of groupings. Next, we used Centroid clustering of the Hierarchical procedure as initial grouping seeds to perform the k-means procedure. In order to explore the differences between the identified groups, we used the usual one-way ANOVA and a post-hoc criterion (Tamhane's T2, at $p < 0.05$), since the sizes of our groups were unequal (Moder, 2010).

For the grouping, the following variables were used: gender, educational level, income, age, social networks, TV, radio, written press, digital press, others (friends, festival webpage, Municipality), and then we compared the evaluation behavior, recommendation and assistance to future editions of the festival in each group.

4 Results

To identify the groups of participants in the FIAVL 2018 event, the two-step cluster analysis was applied, which is recommended in the work of Ketchen and Shook (1996), as well as in the work of Hait et al. (2006). In a first phase, Hierarchical cluster analysis is applied and in this way it is possible to identify the most appropriate number of groups. In this phase, the Ward and complete linkage cluster solutions were applied and compared, as suggested in the work by Ketchen and Shook (1996). For the present case study, the grouping into 4 clusters was taken into account, since it is the most appropriate procedure for the presentation and analysis of the results. Then the Centroid clustering of the Hierarchical procedure, which was above explained, was used as initial grouping seeds and thus, to develop the grouping procedure known as k-means.

Table 1: Groupings of FIAVL-OFF attendees, according to the analyzed variables.

Variables del cluster	**Average of clusters**			
	1	2	3	4
Gender Average	1.42	1.54	1.52	1.48
Education Level Average	3.08	3.08	2.87	2.91
Income Average	2.33	3.23	1.92	2.67
Age Average	3.88	4.54	3.04	3.96
Social Networks Average	0.33	0.23	0.90	0.02
TV Average	0.08	0.23	0.00	0.20
Radio Average	0.17	1.00	0.00	0.00
Written Press Average	0.17	0.23	0.01	0.14
Digital Press Average	1.00	0.00	0.00	0.00
Other (friends) Average	0.00	0.00	0.00	0.20
Festival webpage Average	0.00	0.00	0.00	0.03
Municipality Average	0.00	0.00	0.00	0.01

Dependent variable				
Event evaluation Average	4.42	4.38	4.60	4.33
Recommendation Average	4.58	4.92	4.85	4.73
Cluster size (N)	12	13	193	96

The clusters were consistent using the two techniques, mentioned in the methodology; this indicates a robust solution. A statistical analysis based on the grouping variables is presented below. Table 1 presents the grouping of attendees at FIAVL 2019, based on the variables that have been selected for this research.

Relationship between the analyzed clusters and the satisfaction of FIAVL - OFF attendees.

Once it is verified that the groups of attendees are statistically different, this study will verify whether the satisfaction in the mentioned clusters is statistically different. When analyzing the evaluation that the participants made to the event within each cluster, the Test F (3,310) = 3.47, p = 0.01 shows that the groups are not statistically similar. Table 2 shows the results of the post-hoc analysis where can be confirmed that cluster 3 presents the highest event evaluation average for the 2018 FIAVL edition, which is statistically and significantly higher than cluster 4 (p = 0.00) and almost significantly higher than cluster 2 (p = 0.08), finally it is evident that there is no significance with cluster 1 (p = 0.18).

Table 2: Comparison of satisfaction averages among the analyzed clusters.

		Differences between clusters (i-j) (p values in parentheses) Cluster (j)		
Cluster (i)	Average	1	2	3
1	4.41	-		
2	4.38	0.032 (0.447)	-	
3	4.6	-0.184 (0.185)	-0.216 (0.081)	-
4	4.33	0.083 (0.348)	0.051 (0.377)	0.267 (0.002)

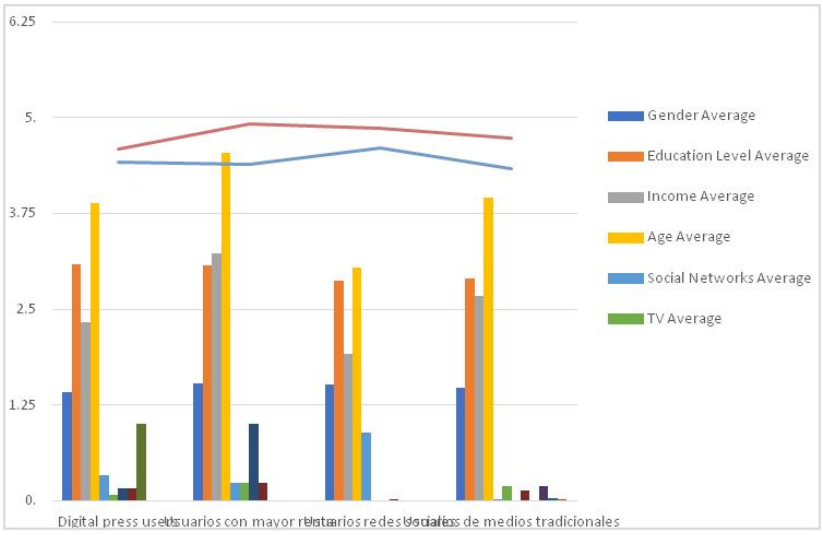
When analyzing whether the participants in each cluster would recommend the FIAVL to other people, the Test F (3,310) = 1.40, p = 0.24, also indicates that the groups are not statistically similar. Table 3 presents the results of the post-hoc analysis where it is possible to state that cluster 2 has the highest evaluation average and is statistically and significantly higher than cluster 4 (p = 0.03), and it is also almost significantly higher than cluster 3 (p = 0.07), to conclude it is observed that there is no significance with cluster 1 (p = 0.13).

Table 3: Comparison of recommendation averages among the analyzed clusters.

		Differences between clusters (i-j) (p values in parentheses) Cluster (j)		
Cluster (i)	Average	1	2	3
1	4.58	-		
2	4.92	-0.339 (0.091)	-	
3	4.85	-0.271 (0.133)	0.068 (0.226)	-
4	4.72	-0.145 (0.277)	0.193 (0.038)	0.125 (0.075)

Interpretation of the identified clusters.

Figure 1 allows observing the differences between the clusters, in such a way that the discussion of the results obtained in the present study is facilitated. In order to achieve this objective, a label is given to each identified group according to the most outstanding results.



Graph 1: Attributes of the clusters.

Group 1. This group includes 12 people, being the smallest group in relation to the rest of the analyzed groups. Regarding gender, there is equality in the analyzed data, obtaining an average of 1.42. In the case of educational level, it has an average similar to cluster 2 (3.08). The income level variable has an average of 2.33, the highest income is $ 1,500.

According to age, this cluster shows that the average is 39 years old, similar to the average age of cluster 4, so that the total average is 3.88. The most used means of communication in this group belongs to the digital press with an average of 1.00, considered the most outstanding of this group in relation to other groups analyzed. For this reason, this group has been called “digital press users”, it should be considered that this is the group with the lowest number of data, which is reflected in the results for the festival's recommendation. An additional factor is associated with the expectation generated by the digital press, which is not related to the lived experience; for this reason, this is one of the groups that would least recommend the festival.

Group 2. This group has 13 people, it is made up of 7 men and 6 women, with an average of 1.54, similar to group 3 that we will analyze later. The income level differs between the two genders, the male gender has the highest level of income up to $ 3,000, obtaining this indicator the highest average of all the groups analyzed (3.23), for this reason they have been called "higher income users”. The average of the educational level variable is similar to cluster 1 (3.08). The age variable has an average of 4.54, which implies that the average age is approximately 45 years. The means of communication most used by this group to find out about the FIAVL was radio (1.00), presenting an equal average, although with less significance in the media such as: social networks, television and the written press (0.23). Muñiz, Rodríguez and Suárez (2017), mention that the factors of the sociodemographic profile, such as the education level and those related to income, are determining variables; both in the probability of participation and in the frequency of participation in this type of event. Likewise Georgiev, Noulas and Macolo (2014), present some hypotheses about the factors that motivate participation in this type of event and conclude that social aspects play an important role when determining the probability of a user participating or not in an event.

Group 3. This group is made up of 193 people, it is the largest among all analyzed groups. The data shows a greater representativeness, but not outstanding, of the female gender with 101 people and a total average of 1.52. In relation to clusters 1 and 2, this group shows a lower educational level, the secondary level being the predominant one, obtaining a total average of 2.87. The income level variable indicates that this group has the lowest income level (less than $ 500) of all the analyzed clusters, with an average of 2.87. The age variable reflects that this is the youngest group with an average of 3.04, which corresponds to 30 years old. The use of social networks predominates in this group with an average of 0.90, due to this result, this group has been called "social network users”. This group along with cluster 2 are the ones that would recommend the visit to the festival, which means that for both groups the lived experience does meet the expectations.

Group 4. This group is made up of 96 people. As in the previous groups, there is no significant difference between male (50) and female (46), obtaining an average of 1.48. The educational level variable shows similarity to the average of cluster 3 obtaining a result of 2.91. The income level corresponds to the second position of all the groups, being surpassed only by cluster 2 with an average of 2.67. The age of this group has an average of 3.96, which indicates that the average age among the members is 40 years old.

The group is called “traditional media users”, due to the use of means of communication such as: television, written press and friends, which are more frequent for this cluster. This is the second most robust group which does not recommend the festival, the existence of possible external factors could condition the visit to the event.

6 Conclusion

The purpose of this research work was to identify the guidelines that lead to achieve the sustainability of the FIAVL, through the recognition of the attendees' sociodemographic profile and the most used means of communication to find out about the event.

The results obtained in this investigation corresponding to the satisfaction variable, showed that the identified groups are not statistically similar; in this case, cluster 3 presented the highest average with respect to the event evaluation, which shows to be significantly higher than cluster 4. For the remaining clusters 1 and 2, the results show that there is no significant difference because the rates are similar between these groups.

For the second outcome variable analyzed, which corresponds to the propensity to recommend the FIAVL to other people, we find that cluster 2 has the highest and most significant evaluation average in relation to cluster 4, the others do not have a significant difference because the average is similar.

Regarding the analysis of the sociodemographic profile, it is stated that gender does not seem to be a determinant factor of the visitor's profile, since its configuration is comparable in all the analyzed clusters and hence, the number of men and women is similar in the results. In cluster 3, age is lower than what is shown in the other analyzed clusters, the same result was obtained in relation to income level and educational level.

This research is relevant because it allowed us to characterize the sociodemographic profile of the visitors who attend cultural events in emerging countries, such as Ecuador; through the analysis of the FIAVL 2018. Likewise, it allowed identifying the use of the media with greater frequency, through which the attendees found out about this event, highlighting the main results based on the groups analyzed; thus we have that in Cluster 3 users prefer the use of social networks, Cluster 4 maintains the use of traditional media, Cluster 1 prefers the use of digital press and Cluster 2 uses radio as their preferred means of communication. The results of this research have practical relevance, since the findings allow establishing guidelines for the sustainability of a cultural event in Latin America. The identification of the profiles of those attending the FIAVL event, the need to improve the offer to attendees and the proposal of guidelines, constitute a significant contribution to the public management of the sector and to the organizers of the event.

As any type of research, this study has some limitations; caution is needed in generalizing the results, since this study involves the analysis of a single edition of the event, in a single event area (OFF events) and in a single city. Consequently, it is recommended to extend this type of research to other festivals that take place in Latin America, in all areas of programming, considering several editions and the analysis of the quality-price ratio.

This work contributes with the Theory of Planned Behavior (TPB), which allows analyzing, in this case, the relationship of the media in the influence of visiting the FIAVL. Through this analysis, it is possible to propose the appropriate guidelines for the sustainability of this type of event.

Abstract

The purpose of this paper is to identify the key factors that influence the intention of use of non-banking correspondents (NBC) in Ecuador.
The present study used a sample of 4961 people economically active in Loja province. The data was collected using scales previously validated in international context. The hypotheses were tested using structural equation modelling (SEM).
By improving our knowledge about the intention of using new technologies in the financial sector, and by exploring the aspects that affect the intention and attitude towards the use of NBC in emerging economies, this research contributes to the Theory of Reasoned Action and Theory of Planned Behavior.
By identifying the most important determinants for NBC adoption in emerging economies, this study brought valuable information to managers of banks for the efficient allocation of resources for the deployment of new NBCs.

Keywords: Technology acceptance model; Customer Knowledge; Ecuador;

1 Introduction

The use of new technologies in the financial system, in addition to increasing levels of financial deepening, makes it possible to reduce the costs of financial institutions. But as mentioned by Zhang, Weng, & Zhu, (2018) and Shih & Fang, (2004), even though operating financial costs are reduced, it must be analyzed how the insertion of new forms of banking.

These new forms of banking offer customers greater comfort and a higher level of access, which is easier and quicker. Despite these benefits, the levels of use remain low, motivated by cultural factors as mentioned by Zhang et al., (2018); Warkentin, Charles-Pauvers and Chau, (2015); Yuen, Yeow and Lim, (2015) and Zhao, Shen and Collier, (2014). In the same line, Riyadh et al., (2020) point out that clients in the financial system are used to the conventional banking system and they use to demand traditional transactions.

Because the use of NBC depends on the consumer's acceptance, this research is based on the Theory of Reasoned Action, proposed by Fishbein and Ajzen (1975). The theory proposes that behavioural intentions are set as the pre-behaviour factor, i.e. they are about the likelihood of performing a behaviour. In this theory are inserted beliefs generated by the behavioural aspect, as well as by the normative. Normative beliefs have an impact on people behaviour, so the information or belief affects behaviour intentions (Fishbein & Ajzen, 1975).

This theory has easily developed in some researches that include endogenous and exogenous variables which affect behaviour. Several studies around the world have focused on analysing the intention and the subsequent behaviour of individuals concerning their income and their use of financial products and services (Yen Nguyen & Cassidy 2018, Ali, Raza, & Puah 2016, Farhat, Wajeeha, Mohd, & Mokhtar 2019; Oladapo, Omar, Muda, & Abdurraheem 2019).

This research is the first empirical attempt to test the customers´ behavioural intentions to use NBC in an emerging economy, such as Ecuador. By doing so, we contribute to a better understanding of the intention of the use of NBC in emerging countries. This study introduces a new construct to measure the effectiveness of the perceiving quality in the intention of use of them. In line with recent studies (Zhang & Mao, 2020; Oladapo et al., 2019; Charag et al., 2019), we applied the Theory of Reasoned Action.

When conducting a study on the perception of non-bank correspondents, the literature provides two approaches, firstly, in expanding the use of the TAM methodology and, secondly, in providing the perception of location factors, comfort, adequacy of the places where the non-bank correspondents are located. Previous studies have analyzed different technologies such as ATMs Shih & Fang, (2004) electronic banking Pham & Phi Anh, (2018), but a search of literature performed by the present authors shows that there is a lack of studies that analyse how customers perceive NBC in emerging countries. It is important to fill this gap because NBC allows people to carry out traditional transactions, but unlike the current system, they are located close to the clients' place of residence and with greater ease of accessing these services.

2 Conceptual background

2.1 Financial innovation and consumers´ behaviour.

Information and communication technologies (ICT) are heavily related to innovation. The banking industry is one of the most dynamic sectors in the economy, and it is considered an intensive activity based on ICT (Keramati, Azadeh, Mehran-Gohar, & Afshari-Mofrad, 2012). Understanding the main determinants of technological banking adoption is crucial for banks to improve the way of doing business. Internet banking has emerged as one of the most profitable e-commerce applications (Lee, 2009), and banks take this as an opportunity to get more clients and promote their financial products.

There are three widely-known theoretical models used to explain the relationship between users beliefs attitudes and intentions; Theory of Reasoned Action (Fishbein & Ajzen, 1975), Theory of Planned Behaviour (Ajzen, 1991) and Technology Acceptance Model –TAM (Davis, 1989). These theories have been used by recent studies: (Martins, Oliveira, & Popovic, 2013); (Nasri & Charfeddine, 2012); (Giovanis, Spyridon, & Polychronopoulos, 2012); (Al-Ajam & Nor, 2015); (Kaakeh, Hassan, & Van Hemmen Almazor, 2019); (Seenat Maryam, Saqib Mehmood, & Abdul Khaliq, 2019).

Sakala and Phiri (2019) used the TAM to identify the factors that affect the adoption and use of mobile banking services in Zambia, resulting in a significant positive relationship between perceived ease of use, perceived utility, user, external variables, user intention with the use of mobile banking services. In the other hand, the study also found that the variables related to user attitude and user intention have no significant relationship. In their study, Jamshidi & Hussin (2018) found that adoption of Islamic Credit Card would be more likely to occur among banks consumers when it is compatible with their value system and norms. As a result, they also found that there is a positive and significant relationship between the relative advantage and attitude toward the use of Islamic Credit Card by banks customers. In the same line, Siray (2014) revealed that the variables like attitude, subjective norm, perceived behavioural control, perceived risk was significant in affecting users´ behavioural intention to use e-banking.

By focusing on determinants related to NBC adoption, the results of the present study are going to complement the insights provided by the aforementioned literature.

2.2 Financial inclusion in Ecuador

In Ecuador, insufficient access to products and services provided by the national private banking system is tied to the lack of attention to those most vulnerable groups, generally located in the most remote or marginal areas. According to Central Bank of Ecuador, in December of 2019, 61 of each 100 Ecuadorian had access to financial products and services. It means about 6.8 million adults who are included in the financial system. About 3,7 million of them are men and 3,1 million are women. Between 2017 and 2018, the number of current and saving accounts decreased by -2.56% and 16.10% respectively (Central Bank of Ecuador, 2020).

To improve customer' access to their financial products and services is a challenge that the banking industry must face off. The connectivity is another problem that affects financial inclusion. According to the National Institute of Statistics and Censuses, about 37.2% of the Ecuadorian population had internet access, but there is a gap between rural and urban population, so, in the rural areas the average of internet access was about 16.1% in contrast with urban areas with 46.6% (National Institute of Statistics and Censuses, 2020).

The national financial system has primary and complementary services for the financial sector. NBC stands out. In Ecuador, the banking industry has evolved over the years to get more clients and improve banking deepening. One of the most recent access channels is NBC, which are private firms located in commercial places where people can use them to make some banking transactions without having to go to the bank. Thus, NBC is recognized as channels that promote financial inclusion. In Ecuador, NBC is the banking channel that ranks second growth, after ATMs. According to the Superintendent of Banking (2020), in April 2015 Ecuador has 23,858 NBC and in April 2020 the amount was 28,321, with an increase of 18.7% in this period. There are five private institutions which offer this service along with the 24 Provinces. The Province of Loja has 3% of the total of NBC in April 2020, an important fact is that Loja has NBC in all its 16 towns. The Loja city concentrated about 65% of the total. Although, the NBC grow on average less than ATMs. In April 2020, there were 4554 ATMs versus 28,321 NBC. To deploy an NBC is cheaper than to deploy an ATM. Operating an NBC cost about 3,000 dollars instead of an ATMs which cost runs from 20,000 dollars to 30,000 dollars depending on if it is a simple ATMs or a multiple services ATM (Superintendency, 2020).

Considering the use of NBC depends on the consumer's acceptance, this research is based on the Theory of Reasoned Action, proposed by Fishbein and Ajzen (1975). The theory proposes that behavioural intentions are set as the pre-behaviour factor, i.e. they are about the likelihood of performing a behaviour. In this theory are inserted beliefs generated by the behavioural aspect, as well as by the normative. Normative beliefs have an impact on people´s behaviour, so the information or belief affects behaviour intentions (Fishbein & Ajzen, 1975).

3 Research Methodology

3.1 Sample

Data collection was carried out in Ecuador in the Province of Loja, in which according to data issued by INEC 2014 is the Espindola town, considered one of the poorest cantons in Ecuador determined by unsatisfied basic needs, was 4961 surveys were conducted for the economically active population, the criterion of using a non-bank correspondent was a non-mandatory option.

The sample is made up of 52% of men and 48% of women, it is more representative in people in ages ranging from 18 to 48 years, while people over 49 years represent

approximately 24%. The secondary education level is the one with the highest percentage with more than 44%.

In the sample, 86% is a client of a financial institution, of which banks have the highest percentage with around 58%, unlike the cooperative sector which is 27%. Additionally, it is important to mention that 72% have used an NBC, while 28% have not used it.

Table 1. Sample description.

Question	Category	Percent
Gender	Male	52,37%
	Female	47,63%
Age	18 - 28 years	26,31%
	29 - 38 years	25,14%
	39 - 48 years	22,60%
	49 - 58 years	15,88%
	59 - 60 years	6,39%
	68 years or more	3,61%
Level of instruction	Primary	18,81%
	Secondary	44,00%
	Technological	10,70%
	Undergraduate	22,92%
	Graduate	2,74%
	None	0,73%
Are you a client of a financial institution?	Yes	85,79%
	No	14,21%
What kind of financial intermediary customer are you?	Bank	57,59%
	Cooperative	26,93%
	Savings bank	0,85%
Have you used the attention channel known as NBC?	Yes	71,90%
	No	28,10%

A survey was established by the University Technical Particular of Loja, which contained two sections, in the first section are general data related to age, gender, education and questions related to the use of the financial system were established and especially of non-bank correspondents.

In the second section are the questions that make up each of the constructs such as attitude toward using the NBC, intention to use NBC, perceived usefulness of mobile payment services, perceived ease of use of NBC, perceived security of NBC, perceived compatibility of NBC, subjective norms, perceived quality of NBC. Except for the perceived of NBC construct, the instruments are based on studies such as Jamshidi & Kazemi, (2019); Breward, Hassanein, & Head, (2017); Gardner & Amoroso, (2004) and Shih & Fang, (2004).

The instrument to measure Perceived of NBC was created by the authors and validated by academic specialists before its application, each of the items that make up the survey

was measured using a 5-point Likert scale, which varies between (1) totally disagree, (2) disagree, (3) neither agree nor disagree, (4) agree and (5) strongly agree.

Method

The structural equation model (SEM) is used to check the hypotheses, as mentioned by Ringle, Wende and Will, (2005) allows describing models that evaluate the validity of the theories applying empirical data. SEM helps to assess relationships between multiple independent and dependent variables. According to Henseler, Ringle and Sinkovics, (2009), SEM allows the evaluation of complex models with several variables, being adequate to determine an optimal estimate. The present study uses software ADANCO for supporting our SEM analysis.

In order, to obtain results, the reliability and validity of the model were analyzed, and then an evaluation of the structural model was carried out to test the hypotheses, as suggested by Anderson and Gerbing (1988).

Measurement model

The measurement model evaluated the reliability of the construct, indicator, convergence validity and discriminant validity, considering the results obtained in the AVE, reliability, Cronbach's alpha, loadings and t-values. Table 2 shows good reliability as all the variables have values above 0.7 for Cronbach´s alpha, Rho (pc) and the Rho A tests. Following suggestions of Churchill (1979), the loadings above 0.6 allow us to confirm that the indicators are reliable. AVE values greater than 0.5 for all variables show adequate convergent validity, following the criteria of Fornell and Larcker (1981). Furthermore, the discriminant validity was confirmed by checking that the square root of the AVE of each variable is greater than the correlation between this variable and the other ones.

With this analysis, we can indicate that the model presents reliability in the indicators and constructs, in addition to presenting adequate values to check the convergent and discriminant validity, that is, that the constructs are statistically different and the structural model can be applied.

Table 2 Measurement results of indicators that make up the constructs

Construct	Indicator		Loadings	Media	Alfa Cronbach's	Composite reliability	Rho A	AVE
Attitude toward using the NBC								
	AU01	Using NBC is a good idea	0.922	4.34	0.9423	0.9585	0.9424	0.8525
	AU02	Using NBC is wise	0.915	4.11				
	AU03	Using NBC is beneficial	0.936	4.30				
	AU04	Using NBCis interesting	0.921	4.22				
Intention to use NBC								
	IU01	I plan to use NBC in the future	0.867	4.26	0.9025	0.9320	0.9054	0.7742
	IU02	If I had the opportunity, I used NBC in the future	0.894	4.29				
	IU03	I intend to use NBC	0.913	4.12				
	IU04	I use NBC as much as possible	0.844	3.95				
Perceived usefulness of mobile payment services								

	PU01	NBC is a useful form to realize financial transactions.	0.868	4.34	0.8708	0.9126	0.8789	0.7244

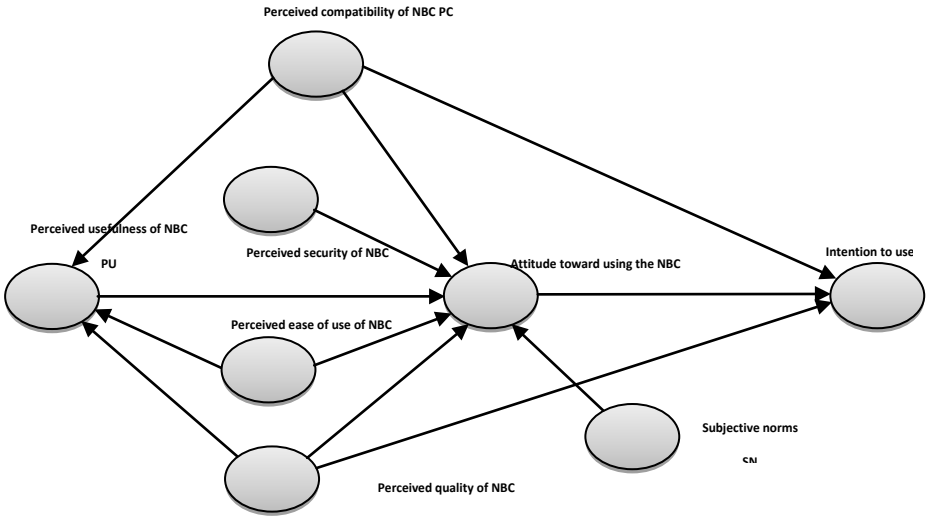

Figure 1 Structural model

Structural model

The structural model presented in figure 1, was assessed after running the bootstrapping procedure. The SRMR value below 0.08 (see table 4), indicate an adequate fit of the model, in line with the criteria proposed by Henseler et al. (2016). R^2 values in table 5 show that the model explains 54% of the variance of Intention to use NBC, 58% of Attitude towards use NBC and 61% of Perceived usefulness of mobile payment services.

Table 4. R^2 and SRMR

Construct	(R^2)	Adjusted R^2
AU	0,5802	0,5794
IU	0,5474	0,5470
PU	0,6186	0,6182
SRMR	0,0779	

As shown in table 5, are hypotheses were accepted. Fist, hypotheses 7.1, 7.2 and 7.3 shows that the perceived quality of NBC is an antecedent of the perceived usefulness of NBC (0.000, p <0:05), the Attitude Towards using the NBC (0.0016, p <0:05) and the Intention to use NBC (0.000, p <0:05).

Beyond the perceived quality of NBC, the intention to use NBC is predicted by Attitude towards using the NBC (H1) and the perceived compatibility of NBC (H5.2). The attitude of using the NBC is predicted by Perceived usefulness of NBC (H2), the perceived ease to use of NBC (H3.1), the perceived compatibility of NBC (H5.1), the subjective norms (H6) and the perceived quality of NBC (H7.1). Third, the Perceived usefulness of NBC is predicted by the perceived ease to use of NBC (H3.2), the perceived compatibility of NBC (H5.3) and the perceived quality of NBC (H7.3). Our results are in line with Schierz, Schilke, & Wirtz, (2010), who have found a positive relationship between the perceived usefulness of NBC, the attitude towards using the NBC and the Intention to use NBC.

The importance of the perceived ease of use of NBC for leveraging the perceived usefulness of NBC and the attitude toward using the NBC is in line with the study of

Riyadh et al., (2020). The study of Shih & Fang, (2004) showed that there is a positive relationship between the perceived security and the attitude towards the intention to use NBCs, as shown in our hypothesis H4.

6 Conclusions

The present study aimed to analyze the determinants of the use of NBC in an emerging country like Ecuador. First, our results showed that the perceived usefulness of NBC influences positively the attitude towards using NBC, and this variable influences the intention to use NBC. Second, we identified the antecedents of the aforementioned variables, and within these antecedents, the results helped to discover the role of the perceived quality of NBC as a key determinant for leveraging the intention to use NBC.

Our results complement previous studies (Zhang & Mao, 2020; Baptista & Oliveira, 2016; Schierz, Schilke, & Wirtz, 2010) that aim to explain to intention to use ATMs in developed countries. By exploring a new variable such as the perceived quality of NBC, and by improving our understanding of the determinants of the intention to use NBC, a new banking channel, in an emerging economy, this study contributes to the Theory of Reasoned Action as well as the Theory of planned behaviour. In this sense, this is the first study that applies these theories to determine the intention of use in NBC in the Latin American context.

There is a high potential for the use of NBC in emerging economies, and the present study provides insightful evidence for supporting decisions of managers and policymakers, oriented to the development of NBC in those contexts.

Like all studies, this research has some limitations, so it is not possible to generalize the results obtained. We recommend that future studies include data from other Ecuadorian provinces or other emerging economies.

Abstract

This study seeks to explore the phenomenon of immigrant entrepreneurship in Italy, with the main objective to explain the factors that influence the decision of immigrants to become entrepreneurs in the host country, especially during the pandemic situation. A Structure Literature Review (SLR) in the Italian context is presented followed by a quantitative empirical research, aimed to deepen the understanding of both, the factors and the process. A system of integration indicators was constructed, analyzed and compared to immigrant entrepreneurship phenomenon through a multivariate logarithmic regression model (log-log) estimated by the Ordinary Least Squares (OLS) technique, referred to the secondary data collected on ISTAT official website and Italian Chambers of Commerce. Findings pointed out a weak relationship between the set of immigrant enterprises and institutions, due to the limited resources devoted to integration and social inclusion of immigrants. Therefore, we argue that a well-structured, clear and specific regulatory framework on the integration of immigrants and, in particular, on immigrant entrepreneurship, can positively contributes to create a solid socio-economic environment, both for immigrants and for native-run businesses. Drawing from the state of the art of the immigrant entrepreneurship phenomenon, was pointed out the limited contribution of management and accounting studies in deepening this topic. Considering the development of this phenomenon in the new era of globalization and the growing of recent flows of immigration in all continents, particularly in Europe, we claim for the need to fulfil this gap through further studies. In this regard, this empirical research provide useful insights in pointing out some research path to cultivate in the future.

Keywords – Immigrant Entrepreneurship, Social Exclusion/Inclusion, Structured Literature review (SLR), Italy, Quantitative approach

Paper type – Accademic research paper

1 Introduction

The participation of immigrants in local labour market is one of the most discussed issues in literature, paying particular attention to immigrant workers as job seekers, and only in the last decades focusing on immigrant entrepreneurship as a particular phenomenon. The events occurred during the recent weeks, related to a progressive social tension due to the global pandemia and the increase in the gap between rich and poor people, have elicited some reflections related to both social inclusion and entrepreneurship, presented in the following section (section 2), while section 3 describes the methodology used, the definition of the research questions, and the application of the Structured Literature Review (SLR). Section 4 describes the empirical research methodology and performance. A system of integration indicators was constructed, analyzed and compared to immigrant entrepreneurship phenomenon through a multivariate logarithmic regression model (log-log) estimated by the Ordinary Least Squares (OLS) technique. It referred to the secondary data collected at ISTAT official website and Italian Chambers of Commerce. The National Council of Economics and Work (CNEL) list of indicators was used to construct indices on immigrant integration. Section 5 discuss the findings of the research and policy opportunities of immigrant entrepreneurship in the Italian context, presents several limits and unanswered problems as well as opportunities for future research direction.

2 Some drivers to reach a new paradigm of integral and inclusive entrepreneurship

The logic under which this problem is analysed concerns the accounting perspective and some drivers emerge from what we are experiencing, namely: the ways adopted to manage the companies and involve people and the environment and the new research perspectives that are necessary to help companies do their best. About the way to manage companies the first concerns a more in-depth concept of ethics within the company, the second is about the need for a globalization of solidarity. The explosion of episodes of racism, the loss of jobs and therefore the presence of progressive tensions claim for a challenge for the entrepreneur who, in addition to managing the business in the best way, must also react to face and manage emergency situations.

But this ... why? We are imbued with an economic theory that aims at profit as an end in itself and this has been demonstrated by the need of the Coronavirus to close all production activities to safeguard health (!) and consequently the social and environmental aspects have potentially gained benefits .

Regarding to the first driver, ethics discourse in the company arises in a domineering way. According to Rusconi (2019), the company is a system of stakeholders, who often are in conflict with each other. In the absence of an ethical basis, there is a risk of being exploited for the company and/or for personal interests, especially in the context of a large company. The ethical basis is fundamental for the relational mediation necessary to make the right decision considering the specific circumstances (Rusconi, 2018, Baldarelli, 2005).

Another important author moves in search of variables that can guide the entrepreneur. In fact, some "drifts" stand out which we had perhaps not noticed before the Pandemia. These include the pervading of "work" as the "whole" of our existence that leaves no room for other circuits such as: family, friendships and hobbies (Bruni 2018: 13).

The entrepreneur often underestimates that the current state of the art market is mainly based on a new and destructive destruction, that is to make "spoils" of the "lives" of workers as a "sacrifice" devoted to the idol of money and capitalism. Over time we have lost authenticity with the (wrong) belief that everything can be "bought" (Bruni, 2018: 25). It is dangerous to move from a logic of work for everything, to that of consumption for all (Bruni, 2018: 29) endorsed perhaps by a minimum income. To avoid this path, some guidelines are outlined. According to Bruni (2018), it is necessary to re-discover the work, also by those who have the responsibility to govern the companies that leave their "aseptic" rooms and mix with the workers and employees in the various departments to appreciate the work done by the employees and collaborator at all levels. Managers should approach workers by understanding their needs and recognizing them as people who work all the year to contribute to the company and therefore should be treated as such.

The second variable is that in this context, examples of companies that try to reason differently (Baldarelli, 2011) seem to emerge as it is needed to activate “the globalisation of solidarity” (Cillerai, 2002: 370). But what is the meaning of this? The meaning is that since in the countries where immigrant entrepreneurship are present, they need to develop a model of growth and relations and to adapts themselves to the circumstances and the competitive as well as environmental situations of the specific area where they operate. In this way coming up with a model, differing for certain aspects from country to country and capable of adapting itself to the local specific context. Indeed, every company has the intention of adapting itself well into the place where it is sited, but the rooting with respect to environment typologies: competitive, social, cultural, political, seems more complete to us and especially seems truly in favour of sustainable development of the place where they are means that the development of “ethical” potential in these companies, opens itself up to acquiring a whole series of “bearings” that respect their place of origin. Moreover, these “bearings”, from their place of origin without badly upsetting the base that already exists, get a stimulus, from time to time, different to taring the vector of objectives and ways for governing the economic factors and the environmental and social sustainability, in order to become real engines for economic development in that area where they operate as well as in the surrounding ones (Baldarelli, 2011).

About the new perspectives of research that are required to help companies do the best there is the rise of protests by some intellectuals, such as Cooper (2005) in which potential and persistent inequalities should be noted. "I think that it is important for academics to break down the myths of our contemporary age, promote a recognition of and find potential solutions to gross inequalities, and ensure that our students leave university with the ability to be sceptical and to give a voice to the disadvantaged” (Cooper, 2005: 597) as some immigration situations could also be. So even the

entrepreneur will have to deal with the search for a new relationship, not only based on power and interest, but on friendship and mutual trust.

After this analysis in the next paragraph we will consider methodology of research.

3 Methodology

The study starts with a SLR pursuing Massaro et.al. (2016) guideline, and is followed by a quantitative empirical research focused to the Italian context.

The early step of the SLR, was to identify that to date there has been not other SLR on Immigrant and/or Ethnic Entrepreneurship, specifically for the Italian context, published in academic journals indexed in Scopus. Then the research was expanded on other SLR with a specific focus on Immigrant and/or Ethnic Entrepreneurship in the international arena. From this second research three significant papers were individuated (Dheer, 2018; Yalaz, and Zappata-Barrero, 2018; Aliaga-Isla, and Rialp, 2013), pointing out the necessity of more studies on immigrant entrepreneurship, especially in Italy. We adopted the Scopus database. Three keywords - immigrant entrepreneurship, ethnic entrepreneurship and immigrant entrepreneurs – were used. The selected articles were analysed according to a Literature Review Protocol, based on objectives, theoretical frameworks and methodologies. There were analyzed with the help of the computer-assisted qualitative data analysis software NVIVO 12.

The second research step was based on the empirical quantitative analysis. A system of integration indicators was constructed, analyzed and compared to immigrant entrepreneurship phenomenon through a multivariate logarithmic regression model (log-log) estimated by the Ordinary Least Squares (OLS) technique. Secondary data (Vartanian, 2010) were taken from ISTAT official website and Italian Chambers of Commerce. Three main dimensions are taken in consideration in order to measure the immigrant integration in the Italian context: territorial attractiveness, social dimension and economic dimension (Golini, et.al., 2001; Cellini, and Fideli, 2002; CNEL, 2013). The outcome of interest was the measure of the relationship of the host country integration factors and their influence in the entrepreneurial activity of Extra EU immigrants in Italy. For homogeneity reasons, data refer to the year 2017. They are elaborated with STATA software.

3.1 Research questions

As mentioned above, this study seeks to explore the immigrant entrepreneurship phenomenon in the Italian context and identify the reasons that push immigrants to become entrepreneurs in the host country. In order to reach the objective, the following research problems and questions arise:

- RQ1: Depict a state of the art of immigrant entrepreneurship in Italy.
- RQ2: Are immigrants decisions to become entrepreneurs related to the degree of social and economic integration in the host country?

By answering these questions, we aim to contribute in finding gaps for future lines of research and creating critical conscious of how this field of knowledge has evolved.

3.2 Selecting relevant publications

In order to explore the development of the immigrant entrepreneurship in the Italian contexts, to highlight gaps and address future research, a SRL was conducted. For this research step we selected the Scopus data base due to its emphasis on providing relevant multidisciplinary research connected through linked content citation metrics from multiple sources. There were three key-words, and the research arena was limited to Italy:

- Ethnic Entrepreneurship Italy - 12 results
- Immigrant entrepreneurship Italy - 30 results
- Immigrant Entrepreneurs Italy - 48 results

Despite the attention is on immigrant entrepreneurship, the term ethnic was taken in consideration too, as previous literature in the field has done. However, when used in this context, it is purely considered as the operational definitions used by the author and the particular study being discussed at that time.

For the selection of articles, paper titles, key words and abstracts have been reviewed to ensure that they discuss one or more of the three key arguments of the research topics. Editorials, commentaries, interviews, conference proceedings, book reviews and very short articles (4 pages or fewer) were excluded (Lockett, 2006), as well as articles not available in the electronic form (Jones, Coviello, and Tang, 2011). We decided to maintain books and books chapters founded in the electronic form, as they make a notable contribution in constructing the literature of immigrant entrepreneurship in Italy. There was no exclusion of articles based on language only articles in English language are found. After the first research with the above mentioned parameters, 90 potential articles for the review were identified. Duplicates, resulting from the crossed research within the keywords (25 articles) and 1 article with no author were discarded. Specifically, we tried to be consistent with academic trends; this does not mean, in any case, that other publications do not contribute or are less relevant for academic arenas. 64 abstracts were reviewed, 13 were discarded because treats argument not closely related to the topic, or which not concern the Italian context. For 50 articles or book chapters we tried to download the pdf file, through the proxy of the University of Urbino library. 18 full text articles were not available in free download, therefore only abstracts were reviewed and included in the final analyse. In sum, 32 articles downloaded in full text and eighteen abstracts were included in the final analyse.

This search had no time-constrain. However, it is only in the last fifteen years that we have a growing interest from researchers, policy makers and professionals on immigrant entrepreneurship studies in the Italian context. The retrieved articles cover a period of time from 1998 to 2019, peaking in 2014 (7 publications) and 2018 (8 publications) (Figure 1), in line with the growing interest on this field in the global arena, especially in Europe.

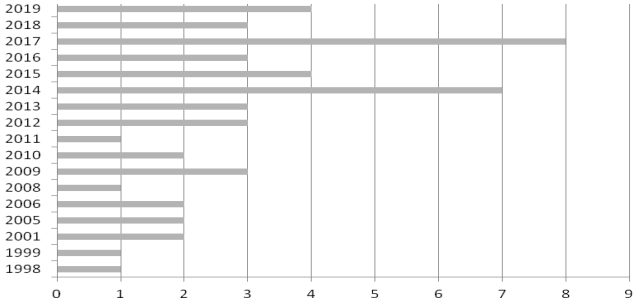

Fig. 1. Trends of publication through years (focused country – Italy)

3.3 Defining the Literature review Protocol

In order to read, classify and analyse the content of the selected publications, a literature review protocol was developed. Table 1 schematically represents the final version, or a coding frame, of the formal reading protocol. Based on this protocol, a coding list is created and used for coding articles with NVivo 12 software.

Table 1. Literature Review Protocol

Article Impact	**Belonging scientific discipline**	**Article Content**	**Future research**
Author(s); Title; Journal; Year/Nr/Impact Data – base found Citations	Macro domain (e.g. SSD); Discipline	Research objective; Theoretical framework; Research results; Audience	Identify Gaps; Develop future paths and address questions

3.3.1 Article Impact

Articles have been selected drawing from internationally recognised academic journals cited in Scopus, covering different disciplines, considering valid for the study only scientific journal articles and a limited number of book chapters. In order to measure the article impact, the number of citations was considered. Table 4 at the end of this section, shows the list of authors, article title, year of publication, journals and number of citations. However, the latter is not exhaustive for the fact that, as Dumay et.al (2014) outline:

> *"one problem with determining the impact from citations alone is that older articles can accumulate more citations than others" (Dumay, et., al., 2014: 270).*

As we can notice, this is not always true, because articles published in the early years (1998; 1999; 2000), have less citations than some others. Three articles have the major number of citations, namely: Baycan-Levent, and Nijkamp, 2009 (60 citations); Mingione, 2009 (28 citations); Dei Ottati, 2014 (36 citations); Brzozowski et.al, 2014 (31 citations). On the other side, books and book chapters have the lowest citation number or no citation at all, independently from the year of publication. The language of

downloaded articles or abstracts is English, so it cannot be said that there is a linguistic problem for citations.

3.3.2 Thematic grouping by scientific domain (ERC)

Articles were divided into core categories by their scientific domain. The scientific domain was defined by article research focus, journal research domain and author research field (Table 2).

After analyzing all articles by the above mentioned criteria, two main scientific domains were defined as follows:

- SSD – Social Sciences & Demography (31 articles)
- EMA – Economics, Econometrics, Management and Accounting (16 articles)
- Multidisciplinary – both SSD and EMA (3 articles)

Classification of the selected publications according to their scientific domain is fundamental for one of the objectives of the present research, which aims to identify the state of art of the immigrant entrepreneurship research in Italy, and the role that the management field, and in particular, the accounting field, have on the topic. The research confirmed what previous studies pointed out (Dheer, 2018; Yalaz, and Zap-pata-Barrero, 2018; Aliaga-Isla and Rialp, 2013). The immigrant entrepreneurship topic mainly concerns the social sciences and in particular the field of sociology, and it is only in the last 8 years that the management field is dealing with the subject. In particular, Aliaga-Isla, and Rialp, (2013), among others, pointed out that:

> *"The review also revealed a heavy reliance on sociological theories which, on one hand, have enriched the understanding of the topic but, on the other, in a certain way is troubling, considering the multidisciplinary character of immigrant entrepreneurship. As we suggested before in the objectives, the incorporation of theories and perspectives from management field would be interesting to study the performance of immigrant businesses" (Aliaga-Isla, and Rialp, 2013:837).*

4 From integration to entrepreneurship: Sample overview

As stated above, one of the main objectives of this paper was to study the relationship between immigrant integration level and immigrant entrepreneurship, in order to explore factors relating to the host country that impact on the decision and the opportunities of immigrant entrepreneurship. As literature suggests, three main dimensions are taken in consideration in order to measure the immigrant integration in the Italian context: territorial attractiveness, social dimension and economic dimension (Golini, et.al., 2001; Cellini, and Fideli, 2002; CNEL, 2013). A system of integration indicators calculated on integrated data was constructed based on the indices suggested from the last CNEL report, (CNEL, 2013). Table 3 presents a summary of the dimensions, indexes and their measurement as well as the official sources from which the secondary data were collected.

Table 3. A system of immigrant integration indicators

DIMENSIONS	**INDICATORS (polarity)**	**SOURCES**
TERRITORIAL ACTRACTIVINESS DIMENSION (X1)	**Incidence of the foreign residents (+)**	
	the ratio of foreign residents on the total population in a given territory	ISTAT
	Indicator of migratory receptivity (+/-)	
	internal balance of foreign citizens (change of residence of foreign citizens from one province to another within the territory of the state)	ISTAT

	Foreigners Resident Density (+)	
	the number of foreign residents per square km (density) compared with the Italian residents per square km	ISTAT
	Stability Indicator (+)	
	The ratio of foreign minors residents among the total foreign population residents (population under 18 years old)	ISTAT
SOCIAL DIMENSION (X2)	**Indicator of accessibility to the real estate market (-)**	
	incidence (the ratio) of the average of the annual rental price for a 50 square meter house in the periphery of the metropolitan area	ISTAT
	on the average of the annual per capita salary of non-UE employees	
	Mixed marriage rate (+)	
	number of marriages with Italian citizens on the total of foreign marriages celebrated in Italy	ISTAT
	Stable residence indicator (+)	
	Number of EU residence permits compared to total residence permits for non-EU citizens	ISTAT
	The Italian language knowledge ratio (+)	
	It is detected by the number of EU residence permits	ISTAT MINT
	Non professional high school education indicator in % (+)	
	the ratio of non professional high school students on the total number of foreigners enrolled in high schools	ISTAT
	Fertility rate (-)	
	the average number of children per foreign adult woman, possibly compared with the same rate relative to natives - the closer the foreign fertility rate is to the general one, the more integration is considered- the more the difference of fertility rate among foreigners and Italians, less integration is considered.	ISTAT
	Naturalization indicator of foreign citizens	
	Number of foreign citizens who have acquired the Italian citizenship in 2017	ISTAT MINT
ECONOMIC DIMENSION (X3)	**Employment ratio indicator**	ISTAT ASIA
	The ratio of full-time not UE employees	
	on the total Extra UE employees (full time + Part Time) in%. The closer it is to a hundred, the more full-time employees are.	
	Employees income ratio	
	difference between gross remuneration per hour between not UE residents employees and Italian ones	ISTAT
	Work stability	
	the ratio of permanent employment contracts on total not-UE worker contracts	ISTAT

Legend	MINT = Ministry of Internal Affairs; LAV = Ministry of Work; ANAG = Demographic Registry Office ; MIUR=Ministry of Education, University and Research; ISTAT= Institute of National Statistics;	

The data set was referred to four levels: Italy as a whole country, geographic areas (northwest, northeast, centre, south and islands), regions and provinces. The outcome of interest was the measure of the relationship of the host country integration factors and their influence in the entrepreneurial activity of Extra EU immigrants in Italy. For this purpose, in addition to the above mentioned data, to the data set were added the number of immigrant enterprises, also for the four territorial levels. Data refer to the year 2017.

4.1 The Results

This section presents the results of the quantitative research used in this thesis. The multivariate regression model was estimated as follows:

over twenty Italian regions, indexed by i=1,2,…,20;

The outcome of interest was the measure of the growth of entrepreneurial activity of Extra EU immigrants in Italy, and its relationship with the integration factors based on three dimensions at territorial level. From the above dataset, the ratio of immigrant enterprises to the total ones was constructed and a logarithmic transformation to approximate its growth was used. In sum, a growth model was used to study the phenomenon over 20 regions.

4.2 The Model

The selection process of the regional model started with a saturated model, i.e., a model with a large dimensionality of independent variables. Then, the diagnostic tests and checks of the model, have facilitate possible exclusions of the insignificant variables, without affecting the functional form tests. The circle of estimation and diagnosis tests is repeated several times on different model specifications, narrowing down the number of explanatory variables and keeping the desired parsimonious principle, until the final model satisfies the assumptions and passes the selection tests. Further, the selection considers the economic implications of the model, i.e., the results should not be contradictory.

The regional model has the following specification:

$$\ln\left(\frac{Y^f}{Y^T}\right)_i = \alpha + \beta_1 \ln\left(\frac{N^f}{N^T}\right)_i + \gamma_1 \ln(fe^f - fe^I)_i + \gamma_2 \ln\left(\frac{M^{\text{mix}}}{M^T}\right)_i + \gamma_3 \ln\left(\frac{RP^u}{RP^T}\right)_i + \gamma_4 \ln\left(\frac{E^{HS}}{E^T}\right)_i + + \delta_1 \ln(w^I - w^f)_i + \delta_2 \ln\left(\frac{L_{nEU}^{full}}{L_{nEU}^T}\right)_i + \delta_3 \ln\left(\frac{C^p}{C^T}\right)_i + \epsilon_i$$

Where:

- $\ln\left(\frac{Y^f}{Y^I}\right)_i$ is the growth of the share of immigrant enterprises in region *i*;
- $\ln\left(\frac{N^f}{N^I}\right)_i$ is the growth of the share of foreigners in region *i*;
- $\ln(fe^f - fe^I)_i$ is the growth of the fertility gap among foreigners and Italians in region *i*;
- $\ln\left(\frac{M^{\text{mix}}}{M^T}\right)_i$ is the growth of the share of mixed marriages between Italians and foreigners in region *i*;
- $\ln\left(\frac{RP^u}{RP^T}\right)_i$ is the growth of the share of permanent residence permits in region *i*;
- $\ln\left(\frac{E^{HS}}{E^T}\right)_i$ is growth of the share of high-school enrollments in region *i*;
- $\ln(w^I - w^f)_i$ represents the growth in the wage gap between the hourly pay rate of Italians and foreigners in region *i*;
- $\ln\left(\frac{L^{full}_{nEU}}{L^T_{nEU}}\right)_i$ is the growth in the share of full-time non-EU employees in region *i*;
- $\ln\left(\frac{C^p}{C^T}\right)_i$ is the growth in the share of permanent contracts among foreigners in region *i*.

The estimated parameters represent the elasticity between the dependent variable and the independent ones, in a given moment. Before interpreting the results and their implications, it is important to discuss the diagnoses of the model.

First, missing data is often an issue in econometric models, and the set of regions and provinces selected in this work are no exception. Several indicators, including the share of foreigners, the share of non-EU full time employed and the share of mixed-marriages are missing for Trentino Alto Adige (and both provinces of this region). A common method of handling missing data is by imputation. Allison (2001) argues that in the case of multivariate analysis, if there are missing data on several predictors, it can be better to drop those cases (rather than do imputation). Little and Rubin (1987) suggest that if the cases for which the researcher faces missing data constitute less than 5% of the sample, then the researcher can drop them. At the regional level model, we report missing data only for Trentino Alto Adige, and since the 5% rule of thumb holds, then dropping this region from the observations set would still yield consistent estimates of the OLS model.

Imputation is not a common practice when using cross-sectional data as the ones used in this study. Hence, the regional model includes 19 out of 20 regions.

Starting the diagnostic checks with the functional form specification test, the results of the Ramsey Reset test (Table 4) indicate that at the 5% level, we fail to reject the null hypothesis of no-omitted variables, meaning that the functional form of the model is correctly specified. The F-statistic is 4.04 and Prob > F=0.06.

Table 4. Ramsey Reset test for functional form

```
. estat ovtest

Ramsey RESET test using powers of the fitted values of lR
       Ho:  model has no omitted variables
                   F(3, 7) =      4.04
                 Prob > F =      0.0584
```

The check for multicollinearity is performed through VIF (Table 5) and the index equals 6.66, which means that multicollinearity is not a severe problem in the model, i.e. it is not inflating variances of estimated coefficients. However, VIF indicates a high correlation between the share of foreigners and the share of mixed marriages. This means that a higher share of foreigners is associated with a higher likelihood of a possible marriage between a foreigner and an Italian citizen, which is something that could be expected.

Table 5. Variance Influence Factor (VIF)

```
. vif
    Variable |       VIF       1/VIF
-------------+----------------------
       lmarr |     13.59    0.073599
          fo |     12.55    0.079682
  fertility |      5.57    0.179578
         lnw |      5.38    0.186016
       lprof |      5.12    0.195423
         lRP |      5.06    0.197613
        lemp |      4.28    0.233531
        lper |      1.76    0.568497
-------------+----------------------
    Mean VIF |      6.66
```

Next, we formally test for the assumption of the constant variance. The Breusch-Pagan test suggests that at the 5$ level, we fail to reject the null hypothesis under constant variance (Table 6). The test statistic has a Chi-square distribution (as LM follows a Chi-square distribution) and has a value of 3.33 and Prob>chi-square = 0.068.

Table 6. Breusch-Pagan test for heteroscedasticity

```
. estat hettest

Breusch-Pagan / Cook-Weisberg test for heteroskedasticity
        Ho: Constant variance
        Variables: fitted values of lR

        chi2(1)      =     3.33
        Prob > chi2  =   0.0679
```

Despite the homoscedastic environment, Hansen (2018) argues that in contemporary econometric research the use of robust standard errors is recommended. The relatively low number of observations is an additional reason towards the use of robust standard errors. Hence, failure to reject the null hypothesis at 5% level, but not at 10%, is one more

reason towards the use of robust standard errors, so we use robust standard errors to make statistical inference.

The Shapiro-Wilk W test of normality was carried out (Table 7) in our model the W statistic is 0.905 with a p-value of 0.06. Hence, at the 5% we fail to reject the null hypothesis of residual normality.

Table 7. Shapiro-Wilk W test for normality of the residuals

```
. swilk R

                    Shapiro-Wilk W test for normal data

    Variable |        Obs        W           V          z       Prob>z
-------------+-------------------------------------------------------
           R |         19    0.90466      2.177      1.562      0.05911
```

Lastly, the histogram of residuals is roughly bell-shaped, indicating that residuals are probably normally distributed (Figure 2). The non-parametric estimation of the kernel density, is close to the normal distribution. Asymptotically the densities would overlap.

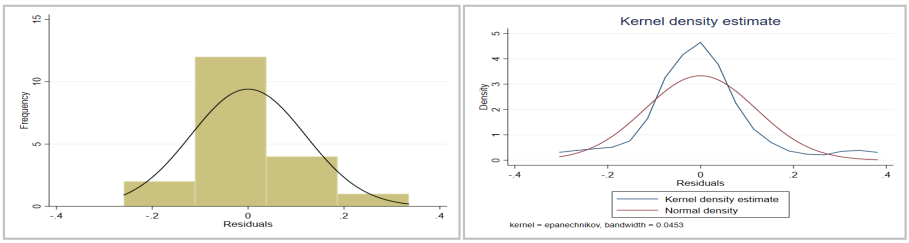

Fig. 2. Histogram and Kernel Density estimate of the residuals

Table 8 displays the results of the estimated regional model.

Robust standard errors in parenthesis Source: Author's elaboration

The most striking result is the high R-squared. It indicates that the variation or the growth in the predictors explains around 90% of the variation in the dependent variable. While one could suspect that the predictors include some form of the outcome variable, in this model, we claim that although it is uncommon to have high R-squares in models using cross-sectional data, it is common to get a high R-square growth models using cross-sectional data. To support this argument, in the seminal work of Mankiw, Romer and Weil (1992), the benchmark Solow Growth model R-squared is around 0.6. When the model accounts for further factors, not necessarily predicted by the theoretical model, the R-squared increases, which is one of the main characteristics of the R-square measure of goodness of fit.

The relative growth of immigrant entrepreneurship in a particular country is likely to vary with the necessary conditions required to start a business activity, and the dynamics of the input markets. In our growth model, we have controlled for Labor-Market conditions, Social Integration and Territory Attractiveness.

Regarding the Labor market conditions, the growth of non-EU full time employers was considered. It was pointed out that an upward trend in the relative growth of non-EU full-time employees - keeping constant the other independent variables of the regression - would increase the relative growth of immigrant enterprises. This prediction is supported relatively well by the estimated model: an increase by 1% in the share of non-EU full time workers, increases the share of immigrant entrepreneurs by 15 percent, considering all the other predictors as constant. This result does not take in consideration the unemployment rate, which is not influenced. An explanation would be that in case of full time employment of family members, immigrant entrepreneurship would increase, as the entrepreneurs will be more inclined to take the risk, following greater guarantees in affording the daily life expenses offered by the employment of family members.

Further, we considered the wage differences between foreigners and Italians, in order to measure the wage discrimination between them. Micro evidence suggests that in some cases people cannot bare the discrimination and therefore might turn to self-employment (Piore and Doeringer, 1971; Bonacich, 1973; Zhou, 2004). In our model, the pay-gap elasticity is 0.6.

Social integration is another key determinant of the entrepreneurial activity of immigrants in the regional level. What most affect this result is the ratio of permanent resident permits in relation to total permits. A growth by 1% of this ratio, affects a growth of 1.5% of immigrant entrepreneurship. The higher this indicator is in a specific region, the more confident immigrants are to start commercial activities.

Fertility is another driving factor of the growth of foreign enterprises. Specifically, an increase of 1% of the fertility difference among foreigners and Italians, increases the share of foreign firms by 0.75%. Hence, the more fertile, relative to Italians, foreigners are, the higher is their business activity share. The more the difference of fertility rate among foreigners and Italians, and among foreigners and the Italian national fertility rate, less integration is considered.

Regarding mixed marriages, we would expect a positive and significant effect as mixed marriages would incentivize the foreign partner to start up a business as having an Italian partner would facilitate the entrepreneurial process. However, due to the elevated multicollinearity of this independent variable with the other, its results are not so reliable.

With regard to the territory attractiveness indicators, we found a significant elasticity between the growth of immigrant enterprises and the share of incidence of foreign residents. This result is logical, as immigrant enterprises grows when the foreign population grows. This scenario presents two possible solutions: (a) immigrant entrepreneurship would grow as a result of a growing demand for ethnic goods and services by other immigrants (Waldinger, et. al., 1990); (b) immigrant entrepreneurship would grow as a result of racial exclusion and discrimination that erects structural barriers to prevent immigrants from competing with the natives on equal basis in the mainstream economy. Consequently immigrants have two alternatives; to take jobs that natives do not desire anymore or to carve out market niches for themselves, meeting the potential demands for specific goods and services unmet by the mainstream economy (Bonacich, 1973; Clark and Drinkwater, 2000; Zhou, 2004).

5 Conclusions

This study contributes to immigrant entrepreneurship literature by deepening the knowledge of the factors that push immigrants towards entrepreneurship and offers useful cognitive insights to improve immigration integration policies, and policies aimed to support the development of immigrant enterprises and reduce barriers to productivity and growth.

The results have shown that the host country integration factors (Territory Attractiveness, Social Integration and Labour-Market conditions) are closely related with the immigrant entrepreneurship growth. Accordingly, attention has been paid to the mixed embeddedness approach, addressing both economic and socio-cultural factors.

The economic factors include the labour market condition, market accessibility, capital accessibility, competition and the impact of immigrant enterprises in their reference markets. The socio-cultural factors include integration factors as accessibility to real estate market, fertility rate indicator, permanent residence permit and acquisition of citizenship.

Findings pointed out a weak relationship between the set of immigrant enterprises and institutions, due to the limited resources devoted to integration and social inclusion of immigrants. Therefore, we argue that a well-structured, clear and specific regulatory framework on the integration of immigrants and, in particular, on immigrant entrepreneurship, in terms of facilitations in granting loans, incentives for start-ups, can positively contributes to create a solid socio-economic environment, both for immigrants and for native-run businesses.

Drawing from the state of the art of the immigrant entrepreneurship phenomenon, we underlined the limited contribution of management and accounting studies in deepening this topic. Considering the development of this phenomenon in the new era of globalization and the growing of recent flows of immigration in all continents, particularly in Europe, we claim for the need to fulfil this gap through further studies. In this regard, this empirical research provides useful insights in pointing out some research path to cultivate in the future.

However, we are aware that this study is affected by limitations. The quantitative research is affected by the limited amount of available data from the official sources on the phenomenon. The data on immigrant entrepreneurship may present some minor inconsistencies due to the fact that in the data-base held from the Italian Chambers of Commerce, immigrant enterprises are classified based only on the country of birth of the enterprise founders and/or the administrators. The risk is that there may be Italian citizens who, for different reasons, were born abroad, as well as immigrants of the second or third generations who were born in Italy. We argue that more accurate official data on immigration and immigrant entrepreneurship in general, and their integration in particular, would contribute to a better analysis of the phenomenon.

Despite the limits, this study contributes to fill the gap in the local literature, as pointed out by Arrighetti et, al. (2014: 772) who have recommended the inclusion of social and institutional factors in the study of immigrant entrepreneurship in general and multicultural hybridism in particular.

Abstract

One of the main challenges was acceptance the use of information and communication technologies (ICT), in education and learning in the health field. And doing this multidisciplinary project, at different field like health, engineering, Marketing and International business.
Today, with the evolution of the digital era and the inclusion of artificial intelligent (AI) it's and advantage to use them.
Some authors like (Ross, 1989, Schank, 1982) said, that use case-based reasoning (CBR), it is the retention of experience and development of a learning theory and reminder based on retention
At this situation in the University of Guadalajara came out the project in our University the use of ICT and IA in education and apply it mainly in the health field for their multidisciplinary development, taking some knowledge management models (Kerschberg, Sandoval). With the support of data analysis and supercomputing center (CADS) and LEO ATROX computer

equipment of the University of Guadalajara, that provides a special technology place and support with courses
Taking multidisciplinary, interdisciplinary and transdisciplinary comparisons (Choi & Pak 2006)

Keywords - TIC. IA, ,CBR, multidisciplinary and learning

Paper type – Academic Research Paper

1 Introduction

This multidisciplinary, interdisciplinary and transdisciplinary project, that participate different careers, at first point health area (Neurology), followed by Engineer, International business and Marketing.

This with the objective to connect knowledge and applying at the same aim, which is integration of ICT and AI. In order to support knowledge and development in a health prototype, it is coeducation in learning and case study reasoning.

CADS provides: data and images processing, scientific application configuration, development and code optimization, knowledge management models (Kershberg y Sandoval).

Software parallelization is performed, big data volume solutions (big data), scientific visualization, consulting services for the development of research training. With LEO ATROX innovation and adoption is available

They are learning with some digital education models to integrate different areas and boost them at health area and then continue with more areas.

We are going to use reasons to cases, which we can use them to solved previous problems as we mentioned above by some authors.

"AI is going to transform deeply the education", said Audrey Azoulay, UNESCO general director, "teaching methods, learning process, knowledge access, teachers learning will be revolutionized"

Young and Norgard (2006) said that student realized support is the mainly factor to success in activities by ICT.

ICT, AI, CBR together are going to obtain a big advance in learning and get a good result to apply at health area.

With this support that are given in different areas, learning will lead to the new digital age

2 Problem, Hypotheses and Rationale of the Study

The problem is to accept ICT and AI at health area, because they use CBR and integrate it into multidisciplinary area.

H1. A bigger ICT knowledge, better result to AI application

H2. A bigger CBR, better ICT application.

H3, A bigger ICT, CBR and AI knowledge, better multidisciplinary application result.

3 Literature Review

Information and communication technologies (ICT)

Robles (2020) said, years ago, workers have been demanders whoa have teamwork, leadership, flexibility, continuous training and to improve their skills in ICT

It is one of the mainly factors to incorporate ICT in the University, classroom, we are taking in count the labor market, which demands knowledge in all areas and this will improve learning

Robles (2020) said some learning advantage with ICT

1.- Interaction without barrier
2.- Information diversity
3.- Self paced learning
4.- skill development
5.- Strengthening initiative
6.- Immediate correction

Artificial Intelligence (AI)

Figure 1.1 present some definitions of artificial intelligence; those definitions are from eight different textbooks. The ones at the top are about mental processes and reasoning, meanwhile the ones in the bottom are about behavior. The definition in the left measure success in terms of fidelity in the ways of humans to act, meanwhile in the right are about ideal intelligent concept, that we are going to call rationality. A system is rationality if it does the right thing, based on its knowledge

Systems that think like humans	**Systems that think rationally**
The exciting new effort to make computers think… machines with minds, in the broadest literal sense (Haugeland, 1985) The automation of] activities that we link with human thought processes, activities such as decision making, problem solving, learning...(Bellman, 1978)	« The study of mental faculties through the use of computational models ». (Char- niak y McDermott, 1985) «The study of calculations that make it possible to perceive, reason and act». (Winston, 1992)
Systems that act like humans	**Systems that act rationally**
"The art of developing machines with the capacity to perform functions that when performed by people require intelligence."(Kurzweil, 1990) «The study of how to get computers to perform tasks that, for the moment, humans do better.». (Rich y Knight, 1991)	« Computational Intelligence is the study of the design of intelligent agents ». (Poole *et al.*, 1998) « AI ... is related to smart behaviors in artifacts». (Nilsson, 1998)

Figura 1.1 Some definitions of artificial intelligence, organized into four categories
Russell, J., Norving, P (2004)

Case based on reasoning (CBR)

Case based on reasoning beginning thanks to the work of Roger Schank and their students at the University of Yale, in the early 80´s. Schank dinamic memoria model was a reference for the CBR early sistems. Another case based on reasoning school came out at the 80`s.

At 90´s, the interest in the case based on reasoning grown in the international community, all this beacuse on 1995 was a international conference about case based on reasoning, just like europe, germany, british, italians, and others workshop case based on reasoning. Case based on reasoning technolgy produced numerous success stories

Multidisciplinary

"Relative to involving various disciplines like Univiersities, industry, and goverment" (Alberta Inventor and Inventions, 2006), " brings knowledge of different disciplines but remains on the borders of those fields" (Natural Sciences and Engineering Research Council of Canada - NSERC, 2004), " a combination of various disciplines in research of a objective, it is no necessary work in a integrate or coordinate way" (International Rice Research Institute, 2005).

"Multidisciplinary projects are those which researchers from different fields contribute with methods and ideas of their respective disciplines, to analyze investigation questions" (Rosenfield, 1992), " multidisciplinary research, varierity of disciplines colaborate on a research program without concepts, epsitemologie, methodologies integration. The grade of integration between discilines are restringe for the investigation results" (Flinterman, Teclemariam- Mesbah & Broerse, 2001).

Interdisciplinar

Sciences and Engineering Research Council of Canada - NSERC, 2004), "La habilidad de analizar, sintetizar y armonizar los lazos entre disciplinas en un todo coordinado y coherente" (Canadian Institutes of Health Research, 2005). "Un equipo interdisciplinar aspira a un nivel más profundo de colaboración (que un equipo multidisciplinario), en el cual quienes constituyen diferentes acervos combinan su conocimiento mutuamente para completar distintos niveles de intereses planeados" (Bernard-Bonnin, Stachenko, Bonin, Charette & Rousseau, 1995), "La investigación interdisciplinaria es una colaboración de varias disciplinas, pero en este caso, conceptos, metodologías, o epistemologías son intercambiadas e integradas explícitamente, resultando en un enriquecimiento mutuo" (Flinterman, Teclemariam-Mesbah & Broerse, 2001).

Transdisciplinary

"An aproximity of new data and new interactions between disciplines, give us a new view of reality and naturality. Transdisciplinary does not strive to dominate more disciplines, its objective is to open all adisciplines that share and observe beyond them" (First World Congress of Transdisciplinarity, 1994) "a more specific way of interdiscipliny which the limits between disciplines are transcended and knowledge, and different prespectives from other cientific disciplines, just like non cientific sources are integrated" (University of Southampton, 2005).

Tabla 1. Comparation between Multidisciplinary, interdisciplinary and transdisciplinary

Multidisciplinary	***Interdisciplinary***	***Transdisciplinary***
	Working between several disciplines	Working across and beyond several disciplines
Involves more than two disciplines	Involves two disciplines	Involves scientists from relevant disciplines, as well as stakeholders,

		nonscientists, and non-academic participants
Members from different disciplines working independently on different aspects of a Project, working in parallel or sequentially	Members from disciplines working together on the same Project, working jointly	Members from different disciplines working together using a shared conceptual framework
Individual goals in different professions	Shared goals	Shared goals and shared skills
Participants have separate but-inter-related roles	Participants have common roles	Participants have role release and role expansion
Participants maintain own disciplinary roles	Participants surrender some aspects of their own disciplinary roles, but still maintains a discipline-specific base	Participants develop a shared conceptual framework, drawing together discipline specific bases
Does not challenge disciplinary boundaries	Blurring of disciplinary boundaries	Transcend the disciplinary boundaries
Summation and juxtaposition of disciplines	Integration an synthesis of disciplines	Integration, amalgamation, assimilation, incorporation, unification and harmony of disciplines, views and approaches
Additive, Integrative, Collaborative	Interactive, Integrative, Collaborative	Holistic, Trascendentantal, Integrative, Collaborative

Choi & Pak (2006)

Why Pursue Multiple Disciplinarity

To resolve a real world problem

Life is multiple disciplinary: disciplines are the result of artificial fragmentation of knowledge. Real worl problemw are realy confined to the artificial boundaries of academic disciplines (Krahn, 2006). Multiple disciplinar y research evolves to meet the demands of many societal, environmental, industrial, scientific and engineering problems that cannot be adequately addressed by single disciplines alone. (NSERC, 2006).

The requirement for mul tiple disciplinarity is emerging at a time when pace and complexity of science and technology is accelerating, such as in the fields of bioinformatics, hydrogen fuel cells, and broadband infrastructure (Mandel 2006).

With this disciplines, differents areas are going to evolve, just like health, engineer, and administrative cience to evolving for the same purpose.

MANAGMENTE KNWOLEDGE MODEL

It takes as reference two models

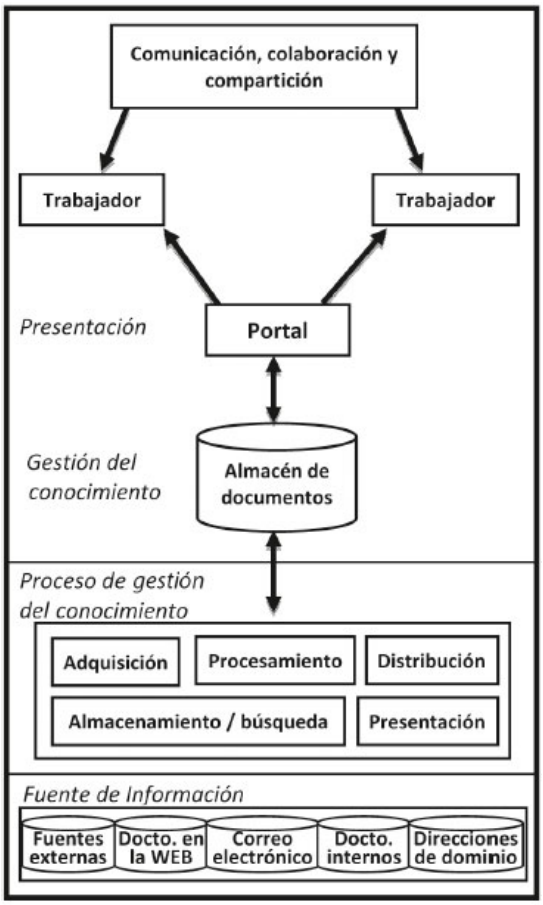

Fig. 1 Technological integration model by Kerschberg.

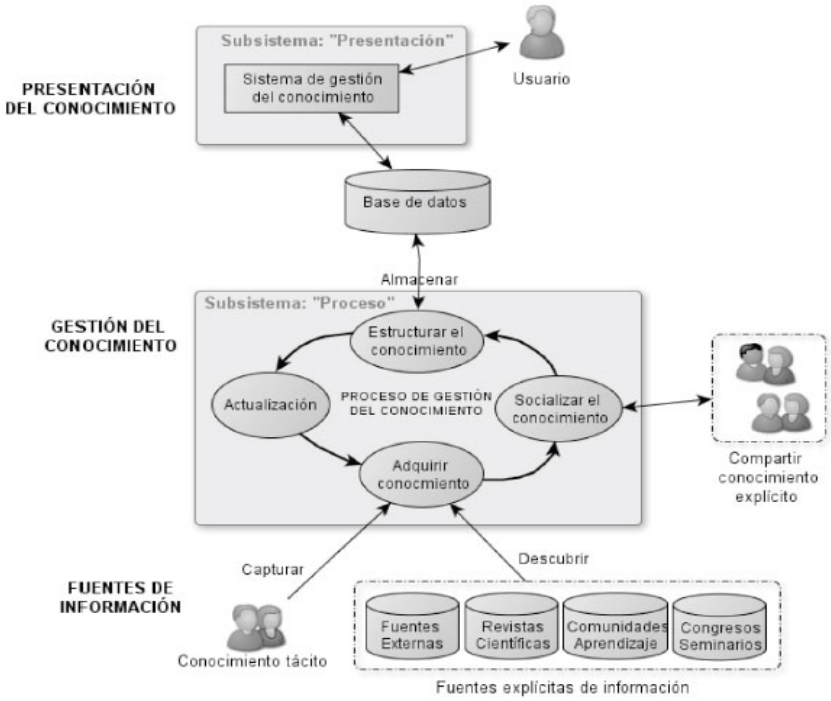
This model give us the knowledge generation, using ICT, it will help to take some parts of this model with the ontegration of AI and CBR.

For the multidisciplinary learning development and the application of each one.

The next knowledge model that we are using as reference, its by Capas de Sandoval (2013).



Elaborado: Sandoval 2013

Fig. 2 Sistem managment knwoledge model

This model is when you already obtain data or the cases obteined by health and we made the codification process, with the help of engineers, at the same time bussines and marketing sholud do a CANVAS model for the presentation.

4 Analysis of Results

This systems use case based on reasoning (CBR), like a solution problem method, to help to resolve new situations. CBR support their predictions, an example (cases) which are stored in the learning phase. A distance or similar function determinate cases that are the most similar to the new problem and give the solutions of the recovered cases are adapted to obtain a solution (Delgado 2005).

From January 2020 to March 2020, it has been analyse 45 cases of patients at Hospitals, this research is in charge of students of health science (neurology)

Patients with different characteristic, some of them with similar symptoms, we take tomography images and then we look at them.

We made a record of each one, with a basic database, we use the program excel, because this research also count with some questions to the patient.

Then this information, we give it to the engineer, and the engineer leads the record with the algorithm, then this information is in conjunction with CADS which helps us

with data and image processing, scientific application configurations, code development and optimization.

5 Conclusions

It is not possible to give a conclussion due to the pandemic, we are still working in the cases so they can be studied together with the MIT and University of Guadalajara and their health, engineer, marketing and international bussines areas.

6 Proposal for future research

Continue working with CBR and the introducction of ICT, AI, at the multidisciplinary learning and develop the planned prototype . At 2021 this research is going to obtain their first prototipe and continue with the diferent health, engineer, marketing and international bussines areas.

New Technologies for Managing Knowledge in Education: a Framework for Knowledge Management

Sikandar Hayyat Malik*, Sharoon Nirdosh

Pakistan Security Printing Corporation

* *Corresponding author*

Abstract

The importance of knowledge as a strategic resource is well realized in the corporate world. The educational markets are becoming global as universities adopt international curriculum, invite students from diverse backgrounds to enrol in their programs, and design the educational experience in a way that maximizes international exposure. This paper reviews the need for adopting knowledge management practices in the education sector, and elaborates on the knowledge creation process before suggesting a framework for implementation, and technological trends adopted by educational institutions worldwide. There is a variety of technologies and tools available today to capture, organize, and provide access to knowledge. Seamless resource access for instance, is possible with technology as students refer to online journals and publications on a smart device, then pick up on where they left off on another device. Technology brands like Apple iCloud, Google Drive and Amazon Kindle have enabled cloud services on their devices, which produce a seamless filing system. Augmented Reality (AR) is a fairly recent learning technology used to train students in a learning environment for medicine and manufacturing-focused skill sets. Students partake in simulations of real-life scenarios and receive sufficient training while also being prepared for mishaps and disasters.
In terms of technological evolution, knowledge management systems are moving from basic search and retrieval systems to sophisticated artificial intelligence-based technology that can be customized for individual user needs and preferences.

Keywords ─ Technologies, Education, Knowledge Management

1 Introduction

The importance of knowledge as a strategic resource is well realized in the corporate world. Knowledge Management gives them a sustainable competitive edge (Drucker 1993), and helps achieve long-term organizational goals as it is used to spur innovation, improve customer experience, achieve operational excellence and ultimately increase revenue.

According to Brown and Duguid (1996), profound changes in competition have made educational institutions strategize like businesses. The educational markets are becoming global as universities adopt international curriculum, invite students from diverse backgrounds to enroll in their programs, and design the educational experience in a way that maximizes international exposure. To attract talented students from all parts of the world, these universities offer some courses and certifications exclusively online.

Universities are developing such high-quality programs in response to the rapid change in technology, and demands of stakeholders.

This paper reviews the need for adopting knowledge management practices in the education sector, and elaborates on the knowledge creation process before suggesting a framework for implementation, and technological trends adopted by educational institutions worldwide.

2 The Need for Knowledge Management Technology in Education

In an electronic, global learning paradigm, knowledge management is a key element of the educational process. Just as employees are considered knowledge providers in an organization ((Tubigi & Alshawi, 2015), teachers, professors, instructors and trainers have a critical position in the knowledge management profession. How they create, build, translate, store, and transfer their knowledge to an ever-increasing population in need of education – from kindergarteners to C-level executives – is changing. Learning in a brick-and-mortar institution of education, while not entirely obsolete, is being challenged. Distance education programs, degrees via the web, corporate universities, virtual universities and other non-traditional means are some of the new methods of gaining education or training (Dutta, 2004). The need for education or training won't go away, but how students acquire it is changing.

The combined knowledge assets of our institutions of learning throughout the world consist of the largest repository of knowledge anywhere, and it is essential that we effectively manage and share this information with those willing to use it, no matter who they are and where they are located (Galbreath, 2000).

Unfortunately, much of this knowledge remains confined in the minds of professors and teachers (dispersed candidly only in the faculty rooms), stored in libraries and laboratories, and with the students who pass through local halls and classrooms. Granted, books and journals, lectures and conferences, and various presentations communicate knowledge and learning, but if I am a student working on a course assignment in "Foundations of Human Behavior" and want to find out the views of faculty and former students, let alone the behavioral scientists from around the world, how can I quickly and efficiently – regardless of where I am located or the time of day – find this information from a single source – from a single user interface? To make information accessible and useful, knowledge management technology is needed for educational discourse today.

3 Knowledge Management: A Definition

The following definitions guide our thinking in what knowledge management means in the corporate world:

[Knowledge management is] “the collection of organizational beliefs and practices, underpinned by ubiquitous supporting technologies, that facilitate the capture, manipulation, and global dissemination of information, which forms the core knowledge critical to that organization’s ability to compete in the Knowledge Age.” (Meta Group, 1998)

- [Knowledge Management is] “the best practices and processes of an organization. It is everybody’s bag of tricks, facts, procedures, and contacts.” (Forrester Research, 1998)
- “Knowledge management is defined as the acquisition, storage, retrieval, implementation, generation and review of an organization's knowledge assets in a controlled manner.” (Pathirage et al., 2008).
- “Knowledge Management is a discipline that promotes an integrated approach to the creation, capture, organization, access and use of an enterprise’s information assets. These assets include structured databases, textual information such as policy and procedure documents, and, most importantly, the tacit knwoeldge and expertise resident in the head of the individual employees.” (Gartner Group, 1999)

Applying these fundamentals to the education sector, we can create our own definition of knowledge management as follows:

- Knowledge Management combines the processes and application of technological tools to digitize, store, and make universally accessible, via electronic networks, the ongoing creation and transference of knowledge and wisdom throughout the educational experience.

4 Knowledge Management: The Technology

According to Galbreath (2000), in order to fully leverage the benefits of a knowledge management program, it is conducive to define an overall approach and process.

- **Create:** The activities that result in new knowledge.
- **Capture:** The activities required to capture and represent all types of knowledge in explicit form, thereby collecting knowledge from multiple sources and making it available to diverse users.
- **Organize:** The activities that classify and categorize knowledge for storage and retrieval purposes. This includes maintenance of knowledge data as well as the indices, maps and the processes that manage it.
- **Access:** The activities through which knowledge is disseminated to or requested by individual users.
- **Use:** The application of knowledge to educational activities, corporate decisions, and other opportunities.

In our institutions of education, not only is new knowledge being continuously created, but also, we have a body of existing knowledge that rivals the collection of any knowledge producer in the world. The challenge isn't in creating the knowledge, it is in capturing, digitizing, organizing, and making available this knowledge in electronic format to any and all who would choose to access and use it.

Knowledge that is created, captured, and organized for access and use can be categorized into two types: digital and non-digital data. Non-digital data would include such information as class lecture notes (prepared in handwriting by both instructor and student), research notes, paper documents, course handouts and materials, books, magazines, journals, and specific media such as analog video and audio tapes. Digital data on the other hand, would include information such as HTML (Web) pages, PowerPoint presentations, word-processing documents, reports generated through data visualization applications such as Power BI (.PBIX file), digital audio files (e.g., .wav files), CD-ROMS, research databases, message boards, digital video, and any information source in digital format.

One might view knowledge management in educational institutes as basically a closed-system approach to leverage both digital and non-digital data sources, to drive an institution's objectives. But as Galbreath (2000) rightly argues, one of the powerful advantages of using knowledge management systems in education is to leverage not only the knowledge capital of educational institutions from around the world, but also of the business community. As Metcalfe's law states, the value of a networked medium increases as the square of the number of users. Knowledge Management was designed as a networked medium, and its use in education should be designed, applied, and used accordingly.

There is a variety of technologies and tools available today to capture, organize, and provide access to knowledge. Seamless resource access for instance, is possible with technology as students refer to online journals and publications on a smart device, then pick up on where they left off on another device. Technology brands like Apple iCloud, Google Drive and Amazon Kindle have enabled cloud services on their devices, which produce a seamless filing system. Augmented Reality (AR) is a fairly recent learning technology used to train students in a learning environment for medicine and manufacturing-focused skill sets. Students partake in simulations of real-life scenarios and receive sufficient training while also being prepared for mishaps and disasters. Moreover, 5G technology which is a new mobile spectrum meant to replace 4G/LTE, is set to revolutionize education with increased bandwidth and connectivity. It is substantially faster than the home Wi-Fi and relieves campus Wi-Fi from the burden of data centers, laptops and numerous student cell phones. An important technology in education is adaptive online assessments which allow universities to evaluate students beyond theoretical knowledge. Online assessments are a vital component of knowledge management and collaboration tools used by institutions to improve practical knowledge of the students, making them industry oriented and practical.

5 Knowledge Management Systems

Technology provides a mechanism to store, index, and organize electronic documents for access over networks by groups and individuals. In terms of technological evolution, knowledge management systems are moving from basic search and retrieval systems to sophisticated artificial intelligence-based technology that can be customized for individual user needs and preferences. Knowledge management systems aim to efficiently utilize existing knowledge and implicit resources, to reproduce fresh knowledge and to achieve sustainable competitive advantage on the basis of these knowledge-based assets (Alavi & Leidner, 2001).

The effective application of knowledge management systems can give a business competitive edge over its competitors (Theriou et al., 2011; Johnny & Bolloju, 2005). Firms need to acquire and retain intellectual resources to pro-actively engage with the upcoming market trends and utilize them effectively (GarcíaLillo et al., 2018). With such interest in knowledge management as a weapon for competitive advantage in the corporate world, we can expect to see continued rapid advances in the technology and specialized versions for exclusive use in education, as this sector of the economy fully begins to exploit its position as the quintessential knowledge producer.

A high-level picture of a typical knowledge management system in an educational setting is as follows:

1. **Repositories:** These are the sources of digital and non-digital data, and comprise mainly of (but not limited to) class presentations, databases, libraries, CD-ROMS, and the internet.
2. **Process/Metrics:** Data from repositories is pushed into the knowledge management system through workflows defined by the institution.
3. **Transport:** Internet, WWW, Intranet, Extranet, LAN, and WAN facilitate the intake of data from various sources and transfer to intended user.
4. **Intelligence:** Agents, Filters, Broadcast, Search/Retrieval, Information Mining are some of the ways data can be customized for each intended user, in a way that is useful.
5. **Manage:** Data in a knowledge management system may be organized in a catalog or directory.
6. **Distribution:** Knowledge generated from the institution's sources may be published according to standards.
7. **Interface:** Knowledge may be delivered to users via browser and mailbox (email).
8. **Users:** These are the intended recipients of knowledge who may have requested for information.

A useful benefit of knowledge management systems that is often overlooked in educational settings is the ease of communication created through its implementation. Teachers can communicate administrative issues with the higher management, and may also receive evaluations and feedback from students anonymously. Over time, the knowledge management system becomes a database of best practices and strategies, that

can be transferred to new teachers to maintain consistency. Such a system strengthens the knowledge-sharing culture and builds harmony within the organization

6 Knowledge Management: Leveraging a New Technology in Education

The demand for education and training is ever-increasing. Given the dynamics of a highly competitive global economy, the need for lifelong learning, and a continued population expansion, countries as well as corporations have prioritized the provision of innovative means of education to ensure that every citizen or employee has access to a quality educational experience. Knowledge Management, while still a relatively nascent technology, is gaining traction as a medium to support and at times, even improve education at all levels.

Some recommendations on leveraging knowledge management in education is as follows:

- **Ownership:** At institutional level, there must be clear ownership of a knowledge management program. The owner is responsible for general oversight, without which the knowledge management program will be out of control, and out of sight.
- **Goals and Objectives:** The owner(s) of a knowledge management program must define why they want to implement the program and what they want it to accomplish. Goals and objectives should be clear and coherent, so as to provide new and innovative means of assessing and delivering education.
- **Organization and Process:** Once the goals and objectives are defined, owners must propose the ways to achieve them. Defining the organizational roles and responsibilities and the day-to-day processes of knowledge management facilitation is essential.
- **Cultural Considerations:** For lecture notes and class presentations to be available to remote learners, faculty and local students should be willing to share their resources with users of the knowledge management system. Their consent and willingness to contribute to the knowledge repository is critical to the success of such a program. Without knowledge producers, the users are limited in their access and use of knowledge and wisdom.
- **Standards:** Defining document standards, design standards, and permission levels of access, to name a few, are important to ensure coherency and consistency in "packaging" knowledge for use.
- **Technology Specifications:** Knowledge management cannot be accomplished without the use of software and communications technology. Defining a clear vision around the type of technology needed and the type of functionality required is critical in evaluating and selecting the right technology for the goals and objectives of a knowledge management program.

- **Technology Implementation:** To ensure that the selected technology is achieving desired results, it is imperative that the technology is implemented at optimum potential and capacity.
- **Maintenance and Support:** The technology implemented for knowledge management will require ongoing upgrade and maintenance, so that stakeholders can continue to benefit from it.

The following framework is a useful guideline for knowledge management creation:

- Knowledge creation begins at the individual level.
- Knowledge created by individuals is shared and exchanged at departmental level.
- Knowledge is exchanged between communities of interest. Communities of interest are departments that share common academic interests or disciplines, such as sales and marketing, or accounting and finance.
- Knowledge generated amongst departments is shared at institutional level. This is done through knowledge management networks placed across the entire institution.
- Knowledge created within an institution is shared with other institutions and corporates. This facilitates researchers with in-depth insight of the work done in similar departments of other institutions.

Knowledge in an organization is often built up and generated by small, informal, self-organizing network of practitioners (Senge 1990). Ultimately, knowledge is created to be shared and leveraged across a variety of constituents. The true value of knowledge management systems in education will be found beyond the walls of a single institution (Lave & Wenger 1991).

7 Conclusion

Knowledge management is becoming an integral component in the development and delivery of education. More than a process technology, knowledge management is a strategy and even a culture. From a financial view point, Weisberg (2010) theorized that explicit knowledge or data is not expensive because it can be conveniently transferred via IT. On the other hand, the tacit or implicit knowledge that is innate in the minds of the teachers and students, which is based on one's own insights, interpretations, experiences, is very hard to be extracted. The sharing of knowledge-based assets provides benefit to both sharer and receiver as it will expand their current knowledge base (Chiu & Veras, 2018).

Leveraging this technology in educational settings, while ensuring that it is productive, will not be easy. The fundamental components of building knowledge management programs are complex, time consuming and complex. The risk-reward ratio and return on investment considerations will need to be carefully evaluated against goals and objectives.

In the end, are the voluminous amounts of intellectual capital contained in any institution of education really something that can be digitized and made available to

anyone who would desire to access and use it? Should this knowledge be made available for free? What are the copyright issues? As institutions of education grapple with knowledge management issues, many questions will need to be raised and answered to determine the viability and optimum use of this new technology.

Abstract

The paper aims to gather information about if and how organizations address supply chain risk management. To do so the paper provides findings of a pilot study involving Estonian and Swedish organizations and their approaches to supply chain risk management. More precisely, findings regarding how these organizations manage supply chain risks and what tools and methods are used to manage these risks are presented. This research continues with the main study involving both a larger sample and additional countries.

Keywords – Supply chain, Supply chain risks, Supply chain risk management, Risk management, Risks.

Paper type – Academic Research Paper

1 Introduction

Today's supply chains are exposed to a great number of risks, old ones, and completely new ones, such as COVID-19. Risks are inherent in complex systems created by humans, which could unintentionally emerge, as also unexpected consequences can arise based on couplings in the complex systems (Perrow, 1984). Supply chains can also be affected by risks consisting of malicious disasters and natural disasters. Moreover, the risks can arise from the external environment that can potentially cause more or less collapse of the global financial system and wars. These risks are triggered by a manifold of developments, such as the increasing digitalization and connectivity of supply chains but also political instability and aggressive actions of the big players in the market such as Amazon which give customers the appearance that goods are available anytime, anywhere; in fact, only a mouse click away. This combined makes supply chain operations increasingly fragile. To manage critical risks, any organization is advised to have a systematic and holistic approach to risk management (Smallman, 1996) so that it is in a better position to handle present and forthcoming risks. Recent research shows that organizations are also increasingly addressing so-called knowledge risks (Durst et al., 2019) in their risk management.

Organizations, in general, are advised to have a contingency plan at hand to be prepared for the possible occurrence of serious risks. This can reduce some risks by carefully selecting their customers and suppliers in the supply chain (Olson & Dash Wu, 2010), while with other risks, such as cyber risks emphasizing training and preparation can help to reduce those incidents that go back to human error, representing one of the main causes of cyber incidents (Allianz Risk Barometer, 2020).

Against this background, the authors of this paper see a clear need for obtaining an in-depth understanding of how organizations handle supply chain risks taking into account the rapid developments that have taken place in this particular environment.

Thus, the paper aims to gather information about if and how organizations address supply chain risk management. To do so the paper provides findings of a pilot study involving Estonian and Swedish organizations and their approaches to supply chain risk management. More precisely, findings regarding how these organizations manage supply chain risks and what tools and methods are used to manage these risks are presented.

2 Theoretical background

2.1 A brief introduction to the theory of risks

Risk often involves both physical aspects, such as ecological threats, physical infrastructure, land use considerations, etc., and social dimensions, including people's judgment about risk and likelihood (Macgill and Siu, 2005; Taylor-Gooby and Zinn, 2006).

Risk assessments were originally related to numerical evaluation and rank of the probability, and the potential impact, of a risk event, occurring using statistical data based on the studies of past occurrences or 'known' scientific knowledge. The social sciences rejected the notion that probabilities and consequences of adverse events are thought to be quantifiable, as they claim that risk is subjective and culturally dependent (The Royal Society, 1992).

Accordingly, social scientists have emphasized the variations in risk perceptions among technical experts, the general public, ethnic groups, and social demographics and individual and group preferences (Slovic and Weber, 2002). Experts have, for instance, a tendency to assign lower estimates to risks that fall within their area of expertise and responsibility, compared to the general public (Sjöberg 2002). Sjöberg assumes that this can be explained by the level of responsibility felt by experts about risk, as well as the level of knowledge. Experts tend, moreover, to be overconfident in the exactness of their estimates (Pidgeon et al., 1992). Activities are perceived as being riskier if the people or agencies managing them are perceived as untrustworthy. Also, information from trusted sources is given more weight than that from untrusted sources. Taylor-Goodby and Zinn (2006) point out that if the 'non-expert' perception of the strength of uncertainty, or threat caused by a risk differs from that of the objective scientific or 'expert' community, this is neither irrational nor uninformed.

People's sense of risk is related to numerous external factors. Three factors were found to be particularly important in influencing people's acceptance of risk according to Slovic, Fischhoff, and Lichtenstein (1979). These factors are known as uncommon risks or dread risks, unknown risks, and the number of people potentially affected. People tend to overestimate risks that score highly in terms of these properties and underestimate those they are more familiar with. A 'dread risk' is related to the controllability of risk or hazard; potentially catastrophic consequences, being irreversible, being involuntary and risks being inequitably distributed, etc. 'Unknown risks' have been linked to the characteristics of not being known at all, not known to science, new and delayed. Similarly, the acceptance of technological risks is based on multiple qualitative dimensions.

2.2 Risk and supply chain

According to Wieland and Wallenburg (2012), the management of supply chain risks (SCRM) is about reducing vulnerability from risks. Supply chain risks involve a variety of risks, as cash-flow risks, risks of a shortage of staff, and other resources, as well as other business disruption risks arising from within and without the supply chain. Thus, companies need to reduce costs and vulnerability and to ensure business profitability and continuity in their SCRM. The SCRM process has been suggested to represent four main stages, as risk identification, risk assessment, risk treatment, and risk monitoring (Fan & Stevenson, 2018).

The first stage in the SCRM process involves the identification of relevant risks, to recognize future uncertainties (Kern et al., 2012). Businesses need to make a judgment

about the relevance of each risk. This is an activity where potential supply chain threats and vulnerabilities need to be identified. The probability and the impact on the vulnerability need to be considered and could be dependent on other actors and/or partnerships in the supply chain (Li et al., 2015). Different methods and tools can support in identifying the risks.

Risk assessment is the second level in the SCRM process. Available data according to what constitutes a risk need to be subjectively judged of each analyst, formal or informal, and quantitative or qualitative, as well as in upstream and downstream relationships. Scenarios can also be used as a complement in the risk assessment (Cohen & Kunreuther, 2007). Supply chain risks also need to be prioritized, to consider the most significant risks and those risks that have a high degree of impact, as it is impossible to deal with all possible risks. Potential causes or sources of risks also need to be assessed in the supply chain (Wever et al., 2012).

In the risk treatment level, risk treatment plans can be designed to decrease or remove the probability and impact. Different generic risk treatment types can be used, as risk acceptance, risk avoidance, risk transfer, risk sharing, and risk mitigation. The risk acceptance is related to the willingness of a company to engage in risky behaviors and acceptance of risks, without ignoring the risk (Park et al., 2016). Risk avoidance is about eliminating activities that could trigger risks as if a supplier is unreliable the company could terminate the relationship (Hajmohammad & Vachon, 2016). To push the responsibility to another party in the supply chain is called risk (Diabat et al., 2012). In risk-sharing, another party is involved in sharing risks. Risk mitigation involves reducing risk to an acceptable level. This considers both the reduction of the probability of a risk event and the probability of its consequences, but this is dependent on the risk type and the company's budget (Norrman & Jansson, 2004). Therefore, companies should carefully evaluate the options for acceptance, avoidance, sharing, and transfer of risks, before selecting a mitigation strategy. Risk monitoring is the fifth level in the SCRM process, and it would be a continuous activity to be conducted to evaluate how risks are developing and if the treatment strategies or plans need to be changed. It is also about continuously collecting new information.

3 Method

3.1 Data

The data for our pilot study were collected between February and March 2020. The collection method was in the form of an online questionnaire, using the free online survey tool e-surv. To develop the questionnaire, we took advantage of previous research. In addition to the supply chain risks related questions, demographic data were collected, such as the year of organization foundation, type of organization as well as the number of employees.

To access possible participants, convenience sampling was used, which means two of the authors informed about the survey using their contacts to send out personal invitations

to the survey. The pilot study consists of responses from ten organizations located in Estonia and Sweden. The findings are presented in the following section.

4 Presentation of findings

4.1 General information about the participating companies in the pilot study

60% of the ten participating organizations reported that their organizations do risk management, while 40% replied in the negative.

In the following section, specific findings related to SCRM are provided.

4.2 Specific information about supply chain risk management

In order to gather information about the organizations' maturity level with regard to SCRM, the participating organizations were asked to assess a number of items. The findings are presented in Figure 1.

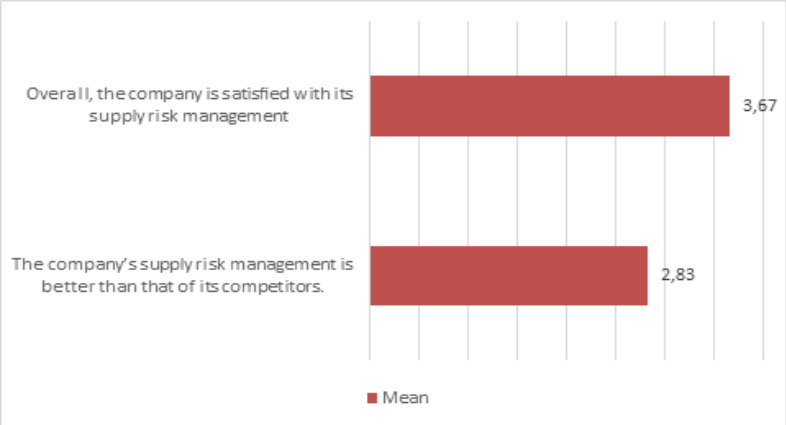
Range 1 (no, not at all) – 5 (yes, completely)

Figure 1. Supply risk management process maturity

From what can be seen in Figure 1, one can conclude that the maturity level of the companies shows potential for development in all mentioned areas. Either the companies have not put a special focus on SCRM to date or they have only recently begun to do so.

There were also two questions that addressed the issue of supply risk management performance. The findings are displayed in Figure 2.

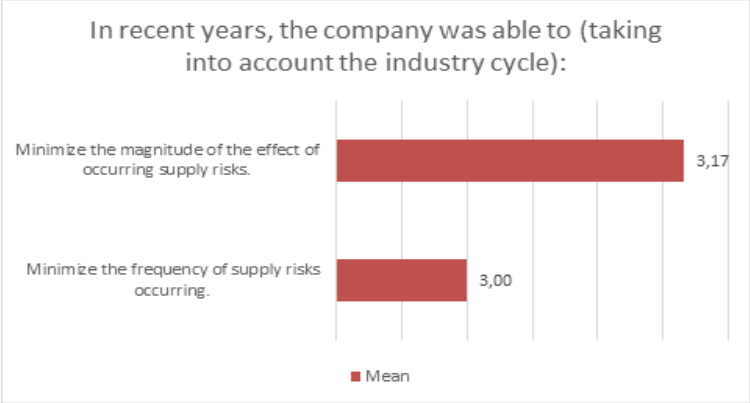
The companies seem to be satisfied with the performance of their supply risk management on an average level. The findings also suggest that the firms' SRM performance is comparable with those of other organizations.



Range 1 (no, not at all) – 5 (yes, completely)

Figure 2. Supply risk management performance

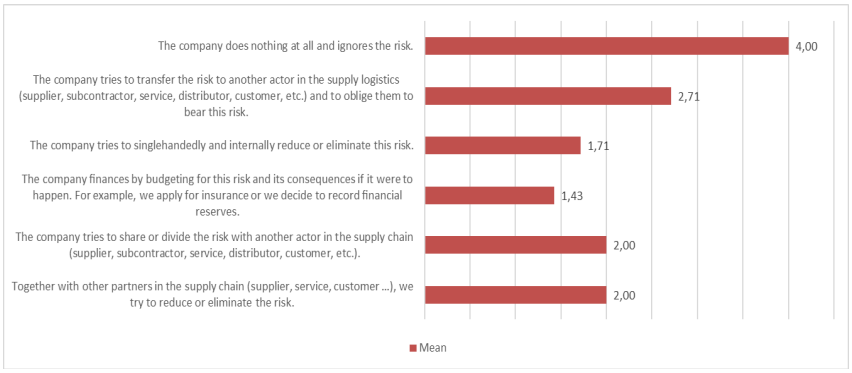
We were also interested in gathering information about whether the companies involved have improved their supply risk management over time. The findings are presented in Figure 3. In line with the previous findings, the activities conducted are on an average level.



Range 1 (no, not at all) – 5 (yes, completely)

Figure 3. Supply risk management over time

Next, we were interested in gathering information about what the organizations are doing when they are confronted with a crisis. To address this aspect, the organizations were asked to assess a number of different items. The findings are presented in Figure 4.

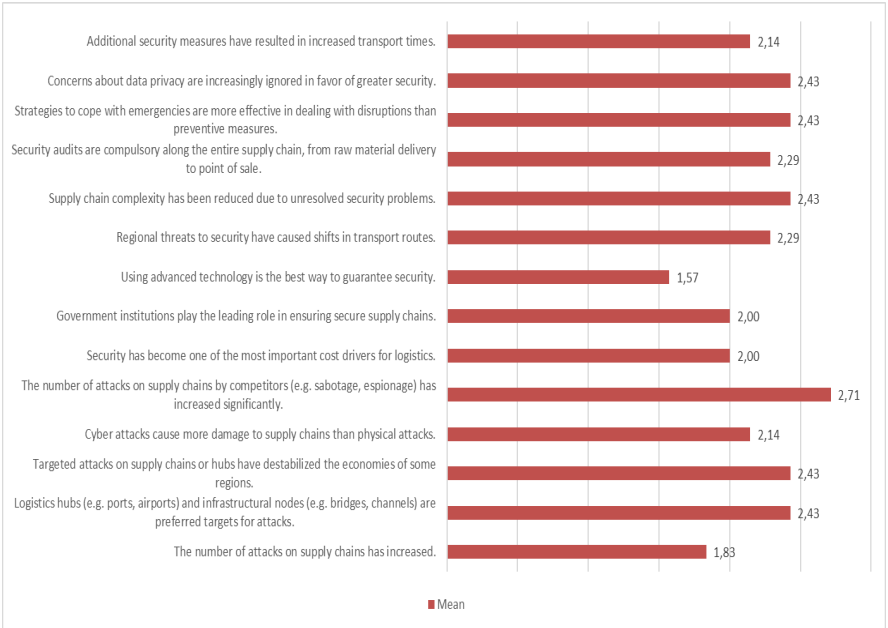


Range 1 (Strongly agree) – 5 (Strongly disagree)

Figure 4. Responses to risks exposures

The findings suggest that companies involved take proactive steps when being exposed to risks, thereby they seem to prefer internal solutions to supply chain risk management or risk management in general.

Additionally, the companies were asked to assess a number of additional items related to risks related to supply chains as experienced in their business operations and the environment they are working. The findings are outlined in Figure 5.



Range 1 (Strongly agree) – 5 (Strongly disagree)

Figure 5. Supply chain risk management and business environment

The participating organizations seem to have learned that the usage of advanced technologies can help them to better address security. One can also see that the organizations see an increase in attacks on supply chains. The overall findings indicate

that the business environment the organizations are operating in has become riskier and the aspect of security has increased in significance.

5 Conclusions

We have all learned that the world has become riskier and we are all facing new unknown risks. Taking the focus on risks related to supply chains. This paper presents some findings of a pilot study that gathered information about the management of supply chain risks in organizations from Estonia and Sweden. The findings indicate that organizations manage their supply chain risks to a certain degree, that is, on an average level. This finding is not surprising considering that only 60% of the participants stated that their respective organization do risk management. Moreover, the findings confirm that working in the sector has become more riskier which has primarily to do with security issues that in turn influence the companies' operations.

The pilot study which is part of a bigger research project involving a number of different countries has provided the necessary information for the authors to take the next steps. The overall research project aims at developing an in-depth understanding of supply chain risk management as well as how organizations, smaller organizations in particular, perceive current developments in the industry, their possible implications and what they are doing to tackle them. Developing this understanding is very important, especially against the background of the rampant pandemic which presents the topic of risk management with a new, hitherto unknown challenge.

Abstract

Responding to recent calls in literature, this article aims at investigating the effect of information and communication technologies (ICT) on job crafting, a proactive behaviour defined as work personalization or individual job redesign. More specifically, through a qualitative pilot study, we examine the attitudes toward technology – namely the individual's collection of beliefs which determines whether or not to engage in certain related behaviours – leading to these "do it yourself", unstructured, and self-targeted practices at work. This inductive qualitative research with 28 interviews suggests the mediating role of two variables in the smartphone usage and general social media usage. Implications for theory and practice, suggesting optimal behaviours and functioning within organizations arising from positive and proactive attitudes and traits of individuals, are discussed.

Keywords – Job crafting, Attitudes toward technology, Smartphone usage, Social media usage.

Paper type – Academic Research Paper

1 Introduction

The organizational culture and behavioural dynamics of the past 20 years have had to deal with a "do it yourself" (DIY), unstructured, and proactive approach toward work called job crafting (Wrzesniewski and Dutton, 2001). This can be defined as "work personalization" or "individual job redesign": these are changes made independently by workers to make their job more stimulating and motivating (Tims and Bakker, 2010), but also to improve work engagement and meaningfulness (Tims, Bakker, and Derks, 2013).

Job crafting captures "the physical and cognitive changes individuals make in the task or relational boundaries of their work" (Wrzesniewski and Dutton, 2001, p. 179). It consists of three proactive individual behaviours enabling employees to modify their jobs to fit more their natural skills, preferences, and inclinations at work. For example, a personal trainer behaves in task crafting when choosing a different environment from the usual gym to train customers (Grant, 2007), an accountant behaves in relational crafting when preferring to participate in social initiatives rather than focusing on the traditional job (Buonocore, de Gennaro, Russo, and Salvatore, 2020), and the cleaning staff of a hospital behaves in cognitive crafting when attributing to the own work a wider and more significant meaning in relation to the contribution made to the healing process of patients (Ghitulescu, 2007).

The literature on the topic has grown a lot together with the new organizational dynamics that have taken hold at work, but at the same time some points remain unsolved. First, the analysis of the antecedents of job crafting is still overlooked (Niessen, Weseler, and Kostova, 2016), even if job crafting literature examined personality, work, and demographic determinants such as proactive personality (Bakker, Tims, and Derks, 2012), general self-efficacy (Rudolph, Katz, Lavigne, and Zacher, 2017), and job performance (Gordon, Demerouti, Le Blanc, and Bipp, 2015). Moreover, despite it has long been predicted that information and communication technologies (ICT) are fundamentally changing the way we work and live (e.g., Beno, 2019), just few authors have dealt with issues related to ICT – such as the use of technology or other information systems to maintain increased flexibility (Sturges, 2012) – so scholars did not define any specific technology-related crafting forms and the contributions on the subject are scarce (Lazazzara, Tims, and de Gennaro, 2020). Furthermore, a shortcoming of current research concerns the overemphasis on the task and relational dimensions of job crafting and the little scholarly attention towards the cognitive one, as testified by the fact that most of the scales to measure job crafting do not even include items to measure the cognitive dimension (Weseler and Niessen, 2016). Finally, in our knowledge also studies in the public sector are scarce, except for a few examples (e.g., Bakker, 2015; Tuan, 2019), although they are prescribed jobs with well-defined tasks, expectations, and positions in which the behavioural practices of job crafting could creep in (Berg, Wrzesniewski, and Dutton, 2010).

To fill these gaps, this study aims at investigating job crafting in a "technological" perspective, that is to identify – within a central public administration of a region of southern Italy – how the positive attitudes toward technology affects these proactive

behaviours. Through a qualitative pilot study with 28 interviews, this study tries to shed light on the neglected relationship between ICT and job crafting, also contributing to literature by advancing research on antecedents and "digital" causes that can lead to changes in one's job and by considering all the three facets of job crafting. The mediating variables of this relationship, which emerged from the pilot study, suggest that the positive attitudes towards technology leads to job crafting behaviours through the use of smartphones and social media.

2 Theoretical framework and hypothesis

The job crafting expression was proposed in 2001 by two psychologists in an attempt to describe a possible magic: that of transforming the work you have into the work you love. It is about actions undertaken from a bottom-up approach that generates greater work engagement and higher performance (Tims *et al.*, 2013).

Job crafting is an activity that employees spontaneously undertake to meet their needs and preferences in the workplace (Kira, van Eijnatten, and Balkin, 2010). It's a behaviour that requires an adaptation to the challenges and to the constraints imposed by an employer (Berg *et al.*, 2010) and it represents a strategic advantage for individuals and for the organization as a whole, although these changes are not always in line with the organizational goals and needs (Van den Heuvel, Demerouti, Bakker, and Schaufeli, 2010). These are changes which can have a structural (physical or procedural), social, or cognitive form (Wrzesniewski and Dutton, 2001) and which are self-targeted and volitional (Tims, Bakker, and Derks, 2012).

Wrzesniewski and Dutton (2001) argued that individuals are motivated to engage in job crafting behaviours because they are guided by three types of needs: the control over work, the social relations individuals experience in the workplace, and the attractive image. Based on these needs, many scholars distinguish "personal/individual" and "contextual" antecedents of job crafting (Wang, Demerouti, and Bakker, 2016), i.e., respectively, the self-efficacy (Tims and Bakker, 2010) and the work context (Vera and Crossan, 2004). The personal/individual determinants affect person's behaviours, such as the Big Five personality traits and the proactive personality (e.g., Parker, Bindl, and Strauss, 2010); nevertheless, personal/individual factors influencing job crafting behaviour cannot do without contextual factors – such as leadership (Leana, Appelbaum, and Shevchuk, 2009) – referring to the environments condition where work activities take place.

Drawing on job crafting theory and responding to recent calls in literature (e.g., Lazazzara *et al.*, 2020; Lee and Lee, 2018) this study aims at identifying an antecedent of job crafting in technology, since behaviours could be oriented towards the technological aspect of work (Parker, Morgeson, and Johns, 2017). The advent of technology has changed the landscape so that almost all activities can be carried out via a portable device or with a laptop; for example, thanks to Wi-Fi, people can have access to the Internet, e-mails, and many different types of applications anywhere and at any time of the day, and this undoubtedly influences the way people carry out their work (Rosen, Whaling, Carrier, Cheever, and Rokkum, 2013). More specifically, the goal of this study is to

investigate the attitudes towards technology, and in this way to understand what are the digital tools and ways through which individuals behave like job crafters.

Attitude represents an individual disposition toward performing a certain behaviour (Davis, Bagozzi, and Warshaw, 1989) and it is influenced by the perception of utility and ease of use (Pynoo and van Braak, 2014). It is a concept of three-dimensional nature, involving cognitive, affective, and behavioural components (Breckler 1984). Among the studies on the topic, an attitude toward a concept, such as technology (Ankiewicz, 2018), is the individual's collection of beliefs which determines whether or not to engage in certain behaviours (Ankiewicz, van Rensburg, and Myburgh, 2001). Attitudes toward technology may include enthusiasm and at the same time boredom interest in the subject (Ardies, De Maeyer, Gijbels, and van Keulen, 2015) and this dual perception of the phenomenon translates into numerous contributions on the topic in the literature of the last years. Nevertheless, in our knowledge, so far it has not been studied in depth in relation to proactive behaviours.

3 Method

The proposed study represents the first of the two phases in which it was conceived. It is a qualitative pilot study useful for formulating hypotheses and subsequently measuring them with a quantitative methodology to be referred to the entire organizational population to give greater rigor to the results. The use of a pilot study is fundamental for a good study design as it can provide interesting and unexpected insights from a study object (Kim, 2011).

3.1 Data and procedures

In this pilot study, we adopted an inductive qualitative approach (Höglund, Holmgren Caicedo, Mårtensson, and Svärdsten, 2018), by employing a qualitative research method based on different sources in order to reduce the impact of potential biases (Bowen, 2009). In line with this, empirical data are based on formal documents, such as appointments decrees and job descriptions, which gave us an overall overview of the organizational and work situation of the public administration object of the study, and workshops and focus groups organized to develop our initial insights with a sample of volunteer workers involving 3 to 5 participants.

Data were collected through semi-structured interviews conducted with workers of a central public administration in southern Italy dealing with healthcare. Healthcare organizations in recent years embraced the digital paradigm and they are characterized by a high degree of complexity because of the heterogeneity of healthcare professionals' mindsets, networks, and decision-making processes (Karamitri, Talias, and Bellali, 2017). Since there is a growing awareness that recognizes the need for healthcare professionals to take a proactive role in shaping their future jobs to improve healthcare systems (Gordon *et al.*, 2015), this sample may be particularly interesting to investigate these behavioural dynamics.

As part of a work process reorganization study, it has been possible to recruit 28 participants including managers, employees, and interns. The average age of participants was 48.4 years (*SD*=8.74) and gender was almost equally distributed (13 women and 15 men). All interviews were audio-recorded and then transcribed for the qualitative analysis.

3.2 Coding and analyzing

We followed the Gioia Method (Gioia, Corley, and Hamilton, 2013), which is a systematic approach useful for bringing "qualitative rigor" of inductive/abductive research. The study's approach depended on a generic research question, i.e. "we wished to explore attitudes, beliefs, and behaviours about ICT and the use of technology at work". The interviews were administered without a structure of questions, but rather as if they were informal conversations within which it was possible to range over all the topics that concerned attitudes and working behaviours of public workers.

In analyzing the interviews, we adopted Gioia method (Gioia *et al.*, 2013), and this analysis process involved three phases. In the first stage, the focus was on finding recurring themes in interviews based on respondents' answers. Two researchers independently coded all the transcribed interviews and subsequently compared personal codes by engaging in a discussion when disagreements emerged. Then, we discerned patterns in the data with the aim of bringing out concepts and relationships and then of formulating them in theoretically-relevant terms, giving particular attention to nascent concepts that seemed to have no adequate references in the literature. Once we identified all the relevant first-order recurring themes and codes and the second-order concepts and relationships, we assembled them into a data structure that can be presented as a visual representation (Figure 1).

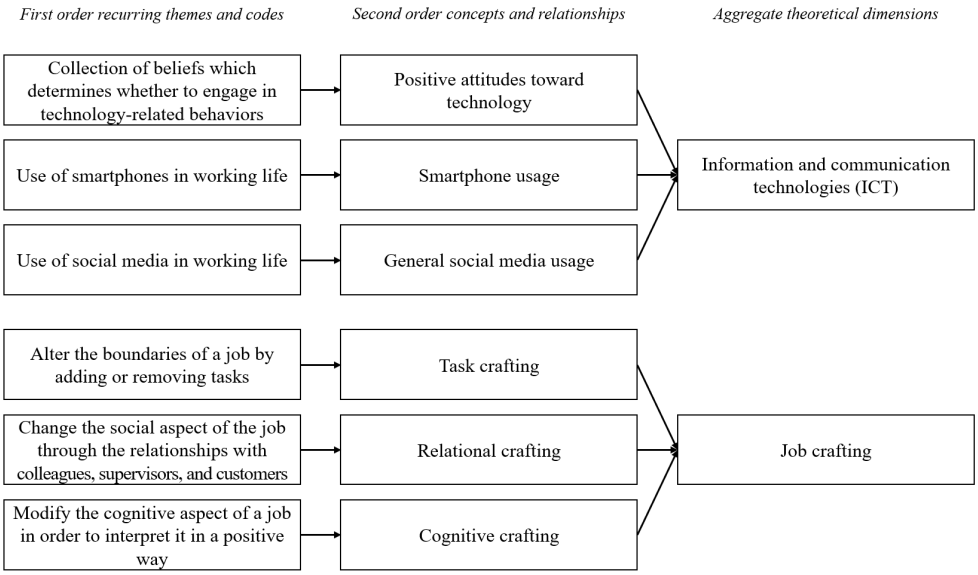

Figure 1. Data structure

4 Results

As above mentioned, none of the public workers interviewed was familiar with the concept of job crafting; however, the majority of them revealed to regularly engage in a series of proactive behaviours that were aimed at modifying some aspects of their job which fit with the task, relational, and cognitive techniques described by Wrzesniewski and Dutton in their seminal contribution (2001).

With reference to the attitudes towards technology, the interviewees showed different (and also diametrically opposed) opinions, without any particular correlation emerging on the basis of demographic variables:

> *I believe that technology is fundamental for our lives and for our work; to date it is unthinkable to live without! (Respondent #3, example of positive attitudes toward technology)*
>
> *The human mind is not replaceable by machines, indeed we should reclaim its centrality. (Respondent #8, example of negative attitudes toward technology)*

On the one hand, some interviewed workers claim to have positive attitudes toward ICT since they use these tools to improve their work; this positive approach refers both to the performance of work activities ("*e-mails, for example, make communication effective and eliminate barriers and distances typical of our bureaucracies*", Respondent #17), and to the place where these are implemented ("*I can practice smart working on certain days of the month and for me it is a very pleasant way of working*", Respondent #24). On the other hand, others prefer the "traditional" work that does not include technology, showing negative attitudes toward it. Although the latter do not present particularly relevant results from the point of view of job crafting, interestingly those who show a positive attitude towards technology are also those who modify their work proactively.

In line with the job crafting literature, findings indicate that workers were motivated to craft their job by the desire to increase the resources and relations at their disposal, to introduce new challenges to work activities that were considered as too "boring", and to seek improving the external prestige of their work that was particularly denigrated in recent years. Indeed, workers claimed to change the characteristics of their work thanks to technological tools according to approaches that are reminiscent of job crafting and it is interesting to note that almost every respondent talks about two main tools, namely social media and smartphones, in crafting his/her job:

> *Thanks to technology I am able to carry out activities other than traditional ones (...), for example I have set up a data archive that had never been put in order (...). Technology is also useful as it allows me to avoid many superfluous activities and sometimes with my smartphone I monitor the progress of tasks. (Respondent #27, example of task crafting)*
>
> *I think technology is fundamental (...), for example I can use the smartphone at any time of my day to interface with colleagues and experts and thus I can improve my work performance (...). I also use Facebook to follow groups of colleagues, take a cue, and answer questions. (Respondent #10, example of relational crafting)*

Citizens must be aware of the work we do (...). I often share my experiences and activities on social networks in order to make everyone participate in my work and feel myself even more appreciated. (Respondent #21, example of cognitive crafting)

The positive attitudes toward technology, therefore, could prove to be an antecedent of job crafting as the actors who show this cognitive and behavioural predisposition proactively modify the characteristics of their work to make it more stimulating and motivating. Moreover, since they are reported in almost all the interviews, smartphones, as a technological tool, and social media, as a virtual "place", appear relevant in this possible linear relationship and could represent mediating variables capable of explaining the previous relationship and ensure a greater understanding of the phenomenon. On the contrary, respondents who showed a negative attitude toward technology or who did not express themselves in this regard were found to be less proactive and not actively committed to changing the characteristics of their activities, relationships, and cognitive perception.

5 Discussion

The aim of the present study was to examine the relationship between the attitudes toward technology and job crafting. Using a qualitative method approach and laying the foundation for a quantitative validation, our results suggest the presence of a linear relationship, perhaps mediated by smartphone usage and general social media usage.

Our work offers several contributions to theory and research. First, we address the call from Zhang and Parker (2019) and Niessen and colleagues (2016) to provide new insight on both the antecedents of job crafting beyond individual dispositions and on cognitive crafting, a dimension that has been little examined in the job crafting literature. A study of all the components of job crafting helps investigate the behavioural dynamics that lead to a shift in work meaning, work identity, and emotions (Grant and Campbell, 2007). Moreover, in line with prior studies that have shown job crafting to be a contextually embedded phenomenon (Zhang and Parker, 2019), we have demonstrated that individuals' attitudes represent significant drivers of the entire job crafting process. More specifically, we demonstrated that workers who have a positive attitude towards technology are the same workers who reinvent themselves to modify their job and make it more pleasant. This insight can open up new avenues in research on antecedents of job crafting, as it is possible that the personal characteristics of individuals play a critical role in the changing process that has not yet been fully investigated.

Second, by integrating ICT into job crafting literature, we have demonstrated that the new organization of work and the new working practices evolve hand in hand with workers' trends and behaviours. Lazazzara and colleagues (2020) had already identified this literature gap, but no study had gone so far in investigating these dynamics. Interestingly, smartphones and social media have been shown to be critical tools and virtual places for practicing job crafting and some studies had already foreseen this future trend. An example is characterized by locational crafting, which has been defined as the possibility for an individual to carry out one's work tasks in different locations (Sturges, 2012; Van Wingerden, Derks, Bakker, and Dorenbosch, 2013).

Furthermore, the study of job crafting in a prescribed work context such as that of the healthcare public sector is also an interesting contribution for literature. Identifying a "stable" work as a sample, from the point of view of its characteristics and duration over time, is undoubtedly a rigorous way of doing research because it allows not to suffer distortions due to improper contextual factors.

5.1 Practical implications

Practically, this study suggests that a positive attitude toward technology makes workers more motivated and satisfied, so managers should increase their performance and well-being by facilitating job crafting behaviours and helping them developing digital skills, knowledge, and competencies needed to expand their tasks. Managers in fact play a critical role in motivating individuals to undertake proactive behaviours by supporting initiatives and experimentation or assisting them in pursuing their unanswered callings (Berg *et al.*, 2010). It could be also useful providing opportunities to participate in job crafting interventions and sharing "what works" could be the kick-off toward improving healthcare (Gordon *et al.*, 2015).

Furthermore, it has been shown that social support and organizational culture, also through appropriate and innovative solutions with employees (Van Wingerden *et al.*, 2013), are decisive for the implementation of job crafting, so leaving more autonomy to workers could generate positive consequences for the organization from the individual (Lyons, 2008) and collective (Mattarelli and Tagliaventi, 2015) points of view.

Finally, given the possibility of distraction and distorted uses of technology (e.g., Brooks, 2015), managers should pay close attention to these behavioural practices to ensure that they are in line with business objectives. When an individual perceives supportive personal factors (e.g., increased self-confidence), approach crafting is associated with positive experiences, such as meaningfulness, esteem-enhanced occupational identity, and job satisfaction (Meged, 2017); on the contrary, constraining personal/contextual factors along the job crafting process means that even job crafting may result in negative experiences (e.g., Van Wingerden *et al.*, 2013) or that people do avoidance crafting (Lazazzara *et al.*, 2020), i.e. limiting positive behaviours and refraining.

5.2 Limitations and future research

This study has several limitations. First of all, it is a qualitative pilot study which draws inspiration and formulation of the hypotheses from an exploratory and semistructured investigation, so that the results may appear to be partial and not theory-founded. Although there is a strong methodological rigor, it is indeed important to proceed with a quantitative investigation by developing the hypotheses and further deepening the concepts emerged in this first phase. Moreover, this study focuses on one of the aspects of technology, which refers to workers' attitudes, but does not deepen all its facets, such as issues related to the digitization of work. Furthermore, future research may measure the consequences of job crafting in terms of technology and digitalization, also by not

excluding any of the three components of job crafting to avoid partial studies. Finally, since the literature to date has mainly focused on the positive outcomes, not considering the dysfunctional consequences – such as the frustration resulting from not being able to meet proactive goals generates negative experiences (Meged, 2017) or the shift towards an interest in crafting in other domains (Sturges, 2012) – of job crafting (Lazazzara *et al.*, 2020), studies on the subject should not overlook these aspects, especially when it comes to technology.

6 Conclusions

To the best of our knowledge, this study is the first to respond to recent calls in literature by investigating the effect of ICT on job crafting via the attitudes of public workers toward technology. Through an inductive qualitative research with 28 interviews, it has been suggested the role of smartphone usage and general social media usage in this relationship. A subsequent quantitative analysis will try to give greater rigor to the present study, thus enriching the literature on the antecedents of job crafting in an ICT's perspective.

Platform-Dependent Entrepreneurship: Entrepreneurial Roles on Digital Platforms

Sergey Yablonsky

Department of Information Technologies in Management
The Graduate School of Management, Saint-Petersburg State University
Russia, 199004, Saint-Petersburg, Volkhovsky per., 3

Abstract

This paper investigates entrepreneurial roles on digital platforms and platform ecosystems. We draw on research on dozens of industry platforms and products to offer a framework for building a successful platform-dependent entrepreneurship built around a multi-dimensional platform ecosystem based on platform stack and on the digital value creation framework. The outcomes of the research could be used for planning, oversight, and control over ecosystem management and the use of digital platform entrepreneurship ecosystem's knowledge-related resources for research purposes.

Keywords – platform-dependent entrepreneurship, digital platform entrepreneurship ecosystem, business model

Paper type – Academic Research Paper

1 Introduction

Digital entrepreneurship is a phenomenon which arose through technological innovations and digitization (Elia et al., 2020). In general, any entrepreneurial activity that transfers an asset, service or major part of the business into digital can be characterized as digital entrepreneurship (Kraus et al., 2018). According to Hull et al. (2007) and Kraus et al. (2018), products, marketing activities and workplace are major differentiation criteria between digital and non-digital entrepreneurs. In recent decades, digital entrepreneurs with their new ways of doing business had a huge effect on the global economy. "Born digital" companies Google, Facebook, Amazon and Apple absolutely changed the business world. The operating models and capabilities of this generation of "born digital" platform organizations founded after 1995 are based on exploiting digital technologies and technological platforms as a core competency. They are:

- not just startups — Amazon and eBay are 25 years old,
- not just small — Google has about 100,000 employees,
- not just pure digital businesses — Tesla Motors makes cars,

- not just American — Alibaba Group is Chinese, Yandex and Mail.ru Group are Russian.

It should be further noted that two emerging trends have jointly changed the nature of entrepreneurship and especially digital entrepreneurship across industries and sectors: open innovation and platform transformation (Kraus et al., 2018). Platform transformation refers to the increasing importance of digital platforms as a venue for value creation and capture (Jacobides et al., 2018; Yablonsky, 2018ab). Together, open innovation and platforms have created numerous opportunities for entrepreneurs and their firms - from serving as ecosystems for platform firm innovation to participating as complementors on existing platform(s) for startups and SME (Jacobides et al., 2018; Yablonsky, 2019, 2020). Digital platforms and open innovation environments have provided numerous promising chances for entrepreneurs, in industries ranging from consumer software, entertainment, and home appliances to auto, health, and energy. To engage in those opportunities, however, entrepreneurs will need to achieve a deeper understanding of the factors that facilitate and constrain them.

2 Research design and methodology approach

While digital entrepreneurial opportunities and conditions have established themselves in rich and varied ways, understanding of these new forms of entrepreneurship has dropped behind. Objective of the paper is to bring a sharper focus on the following research questions:

- What digital activities (new business and social innovation processes) can be activated or enabled by a digital platform entrepreneurship ecosystem (or DPEE)?
- How digital platform organizations designed and implemented to favor the development of the DPEE?
- Who are digital actors of DPEE? What categories of individuals, groups and institutions may favor the development of successful DPEE? How the crowd can be actively and effectively involved into a DPEE?

Digital platforms often require contributions from various actors with diverse perspectives and goals (Jacobides, Cennamo, & Gawer, 2018; Nambisan et al., 2019). Though, governing a diverse set of actors to pursue activities and outcomes that are suitable to all can be especially challenging. Through the structuring of decision-making authority and control rights of entrepreneur's opportunities and roles, effective platform entrepreneurial governance can help align incentives, coordinate actions, mitigate conflicts, and foster a common identity and thus can be critical to platform performance (Mair, Reischauer, 2017).

3 Defining platforms and ecosystems

We should distinguish a technology platform from a business platform, which includes technology platform as a main block.

Definition 1. (Gawer, 2009)

A *technology platform* is defined as building blocks that act as a foundation upon which an array of firms (a business ecosystem) develop complementary products, technologies or services, proposing such requirements for a platform:

It should perform a critical function of the overall system or should solve a crucial technological issue of an industry,

It should be easy to connect to, ‘‘build upon’’ and provide space for new and unplanned usage.

Defenition 2. (Parker and Van Alstyne 2015)

A *network technological platform* or *network platform* is usually based on digital network(s) building blocks. Network platforms differ from product platforms because of stronger network effects, switching costs and multihoming costs.

Definition 3. (Eisenmann et al., 2011)

A business platform is a nexus of rules and infrastructure that facilitates interactions among network users.

Definition 4. (Parker and Van Alstyne, 2015)

A *business platform* is a published standard, together with a governance model, that facilitates third-party participation.

Platforms have unique characteristics, with one of the central features being the presence of network effects or externalities (Parker, Van Alstyne, Choudary, 2016)). The value of platform affiliation for a user depends on the number of other users. Most of today’s platforms are principally digital. They capture, transmit and monetize data, including personal data, over the Internet and other networks (Evans and Gawer, 2016). They may not be purely digital, but most successful digital platforms currently take advantage of the digital innovations and power of pervasive Internet connectivity in the hand of billions of users. A platform provides common standards, interfaces and tools to power core technologies in order to increase the productivity and profitability of a company, a set of companies, or users (Teece, 2017). Platform technologies are essential for coordinating suppliers and buyers to deliver consumer value.

Digital platform strategy becomes extremely complex as firms consider dynamic interactions of a multilayered business ecosystem (Teece, 2012). The concept of platform innovation can be widely defined as architecting new platform strategies and business models (or BM), making and promoting new platform products and services, developing new platform processes to facilitate platform activities, to interact with platform actors and to design new platform structures for industry institutions (Yablonsky, 2018ab, 2019).

Unlike a traditional business, with a clear inside and outside, a platform provides business with a foundation where resources can come together in different combinations - to create value. Some resources may be inside, permanently owned by the company; some may be shared; and some can come from an outside ecosystem. The value comes largely from dynamic connection of those resources and the actors, and the network effects between them. The generativity of digital platforms produces exponentially growing of platform ecosystems, thereby creating research objects that are several orders of magnitude larger than any traditional IS system (De Reuver, Sørensen, Basole, 2018).

Platform providers such as Google, Facebook, Amazon, Alibaba and eBay are transforming the Internet into de facto closed domains, implying that all relevant interactions take place outside the view of researchers (Eaton et al., 2015).

There is a rising interest in business platforms in the scholarly literature (McIntyre and Srinivasan, 2017). Digital technological platforms are altering phenomena over the entire information systems (IS) domain (De Reuver, Sørensen, Basole, 2018). Architectures of platform artefacts are changing as the modularity of digital platforms is replacing traditional monolithic approaches (Tiwana, Konsynski, Bush, 2010). As digital platforms are competing on multiple levels of the technical architecture, specifying the appropriate unit of analysis is becoming increasingly difficult (Yablonsky, 2018ab). To architect a digital platform-based business, organizations must lead their business to take a business driven, outside-in approach (Yablonsky, 2018ab,2019,2020).

Starting from Moore (1996) and Kauffman (1993), the ecosystem concept has been actively discussed in management studies.

Valkokari (2015) distinguished three different economic ecosystem types:

- *Business ecosystems* as well as *service or industrial ecosystems*, where the economic outcomes and business relationships between actors are highlighted.
- *Innovation ecosystems* and *regional clusters* focus on mechanism and policies fostering the creation of innovative startups around so-called regional hubs or clusters.
- *Knowledge ecosystems* have their main outcome in creation of new knowledge through joint research work, collaboration, or the development of knowledge base.

Definition 5. (Teece, 2012)

A business platform ecosystem contains a number of firms and other institutions that work together to create and sustain new markets and new products. An ecosystem may be anchored by a platform. The co-evolution of the ecosystem is typically reliant on the technological leadership of one or two firms that provide a platform around, which other system members that provide inputs and complementary goods align their investments and strategies with.

A business ecosystem contains a number of firms and other institutions that work together to create and sustain new markets and new products. Business ecosystems continue to advance, becoming the basis of innovative business models. In a digital business ecosystem main digital economic agents (humans, business and smart things/smart machines) can play any combination of roles, such as entrepreneur, customer, partner, supplier, employee or competitor.

A platform-based business ecosystem consists of

- Platform,
- Target Group of Customers,
- Target Ecosystem partners,
- Complementary products and services,

- Rival platform ecosystems, and competitive environment in which they exist, upstream and downstream parts of a platform value chain (Tiwana, 2014).

The co-evolution of the business ecosystem is typically reliant on the technological leadership of one or two firms that provide a platform around, which other system members that provide inputs and complementary goods align their investments and strategies with. Usually platform organizations exist in a "business ecosystem" — the network of other organizations that interacts to create shared value (Tiwana, 2014). Teece (2017) mentions that today the concept of "industry" as a group of firms performing similar activities and competing or cooperating with each other is less and less aligned with the way firms think about themselves. In the digital economy firms see their role less in industries and more in business ecosystems.

Platform by enterprise typology indicates (Evans, Gawer, 2016)

- *asset heavy enterprises* with heavy physical assets and *light platform business ecosystem* (example: Samsung with Tizen platform),
- *asset mixed enterprises* with heavy physical assets and platform business ecosystem (example: Apple with App store platform), and
- *asset light enterprises* with light physical assets and *heavy platform business ecosystem* (example: Uber with Uber app platform).

The main outcome of a *knowledge ecosystem* is a new knowledge, and it could be shaped by pointing out the network nodes where the knowledge is created and retained (Valkokari, 2015). Open source communities are a well-known example of this ecosystem type based on knowledge exchange (Koening, 2012) and therefore recent research highlights how colocation can also mean virtual proximity, like emotional closeness, between the actors.

The *innovation platform and ecosystem* approach emphasize fostering the creation of growth, interaction, and innovative startups around so-called knowledge hubs (Engel & del Palacio, 2011). Within the innovation ecosystem, the financial network that supports the actors (both companies and research institutes and other technology developers) has recently been identified as one of the key platform investment type (Evans, Gawer, 2016). Several concepts about value co-creation within open innovation, such as "collaborative", "democratized", "open", "networked" or "co-innovation" have been introduced (Yablonsky, 2020). The technology-intensive business organizations, from specialized startups to diversified multinational enterprises, increasingly participate within innovation ecosystems in different roles such as adopters and patrons of open platforms, and stewards and promoters of innovation communities (Muegge, 2011).

An open innovation process (Chesbrough and Rosenbloom, 2002; Chesbrough and Bogers, 2014) comprises several activities that involve resources within and beyond organizational boundaries, mostly human participants (Chesbrough et. all, 2018). The characteristics of the activities and resources within this process depend on the specific purpose of an open innovation platform (Abbate et al., 2015). Open innovation is a multi-dimensional phenomenon that should be described from different perspectives – cultural,

organizational, and technological spheres – have transformed significantly under the development of innovative network technologies.

As shown by Parker, Van Alstyne, Choudary (2016), platforms all have an ecosystem with the same basic structure, comprising four types of actors/player/roles:

1. *Owners* of platforms or platform *sponsors* control their intellectual property and governance. The owner sets the direction, controls the underlying platform technology and provides the overall organizing structure for the platform via rules, governance, and ecosystem support. It can assist the ecosystem work by helping participants see how they are better off by being part of the system rather than outside of it. This role can be performed by one or many firms.
2. *Platform providers* operate as a platforms' interface with users. Platform provider is the point of contact for common components, rules and architecture for the users of the platform. This role can be done by one or many firms.
3. *Users (supply side)* or *the producers* create their offerings. These are content and application developers. Producers provide specific items that attract users to the platform – music, games, information, services etc.
4. *Users (demand side)* or *the target consumers* of the platform solutions and services use producers' offerings. They can be individuals, businesses, organizations.

There is different logic of action in the different platform or/and ecosystem types (Clarysse et al., 2014; Valkokari, 2015) and the same actor can be involved and play different roles in each ecosystem. From the viewpoint of each individual actor, the interaction area between the platform and/or ecosystem types and their relationships are different. Thus, highly mobile actors, platform owners, or keystone companies are examples of actors boosting the interaction between the ecosystem types. On the other hand, a platform – an organization of things such as technologies or complementary assets (Muegge, 2013) – also may be the interconnecting factor between the ecosystems (Valkokari, 2015). Because of these interconnectivity actors and platforms, ecosystems do interact with each other and therefore are evolving and emerging next to each other.

A platform ecosystem usually goes through periods of competitive strength and weakness as external circumstances change, and these dynamics also need to be managed by the platform owner. Teece (2017) described a platform ecosystem lifecycle as consisting of four phases: Birth, Expansion, Leadership, and Self-Renewal. This model provides a useful framework for thinking about how platforms and dynamic capabilities interact.

There are several broad categories of platform/ecosystem value chain types:

- *Linear value chain ecosystem* orchestrates and optimizes the organization's value chain. It is a favorite type when multiple partners are involved in a complex value chain.
- *Platform-led ecosystem* mediates the ecosystem using a platform.
- *Decentralized ecosystem* is the business ecosystem itself, which defines and mediates the transactions among partners. Cryptocurrencies, such as Bitcoin, are well-known case of decentralized ecosystem.

These ecosystem types have resulted in different types of entrepreneurial roles and opportunities. In the value chain, the business ecosystem opens the reach and range of value. Today the platform ecosystems provide access to a wider range of partners with complementary capabilities, and the ability to create and coordinate these highly complex, demand-driven supply networks.

Each of mentioned ecosystem types has created its own business model opportunities. These opportunities require a change in perspective, away from a traditional, input/output process to a dynamic ecosystem perspective.

Most companies still focus on how value appropriation mechanisms work in linear value processes. To benefit from platform ecosystems, entrepreneurs not only need to develop an understanding of their own value creation and appropriation strategies, but rather how this strategy works in a platform ecosystem and influences the actions of other actors (Schmeiss et al., 2019; Yablonsky, 2020). For this, they need to understand their own role and the roles and contributions of other actors in this system. In enabling maximum openness to create joint innovation while guaranteeing value capturing for all actors Schmeiss et al. (2019) recommend three governance mechanisms embedded into the technical architecture of the platform, addressing the dimensions of access, control, and incentives.

Existing research on platform governance tends to take the perspective of platform owners and focuses on identifying governance mechanisms that can help platform owners realize their objectives (e.g., Reischauer & Mair, 2018). When we consider the perspective of platform owners, we may ignore the prosperity and business needs of other platform participants. As digital platforms become increasingly integrated into economic transactions and social activities, it is essential to examine platform governance not just from the perspective of platform owners but also from the perspectives of other stakeholders, for this study - entrepreneurs. It contributes to research in the strategic management domain by presenting a set of multi-dimensional frameworks that identify how digital platform business ecosystems improve entrepreneurial management within platform organizations. Strategy in this context must guide entrepreneurial roles in platform business models portfolios and related business ecosystems trajectories.

4 Entrepreneurial roles on platforms

From the most general point of view entrepreneurs' roles include roles of *platform leaders, complementors, and users* (Yablonsky, 2019a). These categories of entrepreneurs' digital actors for individuals, groups and institutions may favor the development of successful DPEE.

The sharp rise in the number of businesses offering platforms that connect users for communication or commerce creates platform-dependent entrepreneurship. Entrepreneurs as platform leaders are particularly drawn to these platforms because they create significant value and have modest operating costs, and network effects protect their position once established users rarely leave a vibrant platform (Edelman, 2015). But these businesses also raise significant start-up challenges. Every platform starts out empty. Platforms need to immediately attract not only many users but multiple types of users.

The following key stakeholders are the main entrepreneurs' actor roles along the platform value chain (Yablonsky, 2019ab):

- *User Enterprises* in all sectors, who want to improve/transform their services and products using innovative technology, data products and services;
- *Data Generators and Providers,* who create, collect, aggregate, transform and model raw data from various public and non-public sources and offer them to customers.
- *Technology Providers,* who provide tools and platforms that offer BD management and analytics tools to extract knowledge from ecosystem data, curate and visualise it;
- *Service Providers,* who develop applications on top of the tools and platforms to provide services to User Enterprises.
- *Entrepreneurs*, who build innovative businesses and services based on the demand and supply side;
- *Researchers and academics*, who provide access to state-of-the-art research in innovative technologies;
- *Policy makers*, responsible for establishing policy framework conditions that foster the adoption of innovative technology in various sectors.

It should be mentioned that entrepreneur's platform actors can play simultaneously roles of User Enterprises' owners, Data Generators and Providers, Technology Providers, Service Providers, and Policy makers.

The crowd can be actively and effectively involved into a DPEE by crowdsourcing types of digital platform organizations designed and implemented to favor the development of the DPEE. To meet the needs of potential target consumers, the platform entrepreneurs can adopt four major types of innovation ecosystem governance models (Kaganer et al, 2013; Yablonsky, 2019ab):

- *Facilitator*: connects suppliers and buyers directly through a bidding process; *case examples:* Freelancer, Elance, oDesk,
- *Arbitrator*: engages multiple suppliers through competitions; *case examples:* crowdSPRING, 99designs, MediaPiston, InnoCentive, Witmart,
- *Aggregator*: aggregates hundreds or thousands of microtasks performed by multiple suppliers; *case examples:* Mechanical Turk, MobileWorks, CrowdFlower, CloudFactory,
- *Governor*: provides project governance and certifies supplier quality; *case examples:* TopCoder, Trada, uTest.

The expansion of crowdfunding raises two related entrepreneurial questions: what type of platform suits each entrepreneur's project and how should existing platforms expand? The answer lies in analyzing the field of crowdfunding as a solution to four specific problems: gatekeeping, coordination, inexperience, and patronage (Younkin, Kashkooli, 2016; Yablonsky, 2016). Industry types of platforms also differentiate entrepreneurs' roles. For retail platforms like Amazon the most common roles are complementors and

users: User Enterprises' owners, Data Generators and Providers, Technology Providers, Service Providers.

While studying digital platforms is already challenging because of their distributed nature (Constantinides, Henfridsson, Parker, 2018), developments in the platform entrepreneurship pose even larger research challenges for scholars. The variance in company's digital business performance is a function of differences in the platform resources and capabilities of competing companies. A digital platform is a business-driven framework that allows a community of partners, providers and customers to share and enhance digital processes and capabilities or to extend them for mutual benefit (Burton and Basiliere, 2016). There has been a growing interest in utilizing more than one methodology and method possibly from different spheres of thought within the same intrusion of digital economy and digital platforms.

5 Conclusion

Given the growing dominance of digital platforms and the shared responsibilities of platform governance, studies along these lines can greatly improve our understanding of the characteristics, antecedents, and consequences of effective platform governance and may have important implications for the future development of the platform-driven entrepreneurship.

This paper investigates entrepreneurial roles on digital platforms and platform ecosystems. In the full version of this article to be published in the journal we draw on research on dozens of industry platforms and products to offer a framework for building a successful platform-dependent entrepreneurship built around a multi-dimensional platform ecosystem based on platform stack (Yablonsky, 2018a, 2020) and on the digital value creation framework. The proposed framework is related on our understanding of the emergent DPEE literature, and on the digital value creation cases. The outcomes of the research could be used for planning, oversight, and control over ecosystem management and the use of digital platform entrepreneurship ecosystem's knowledge-related resources for research purposes.

Abstract

The digital economy has strongly impacted the complexity of the worldwide economy. The rapid advancement of digitization and the impact of digitalization have led to different dynamics of competition and new venture creation. The external environment moves so fast that companies can no longer rely only on their own forces to react and create an offer that is attractive. They need the support of an external, open, digital ecosystem to maintain a sustainable competitive advantage: open source becomes the best option to survive. Big data and the digital ecosystem make it possible for companies of all sizes to work and compete internationally and create scalable products. In this paper we observe the digital transformation through the lens of the "economics of complexity" proposing a new theoretical paradigm to study the phenomenon. Additionally, we analyze the relationship between digitalization and international entrepreneurship focusing on cognitive computing, artificial intelligence and data mining. We then introduce the Italian Cognitive Computing Community and suggests the need to re-shape traditional education contents and dynamics to develop new professional skills and keep firms competitive.

Keywords – Economics of complexity, Digital transformation, Cognitive computing, Digital ecosystems, International entrepreneurship.

Paper type – Academic Research Paper

1 Introduction

Diffusion of digital technologies (big data, artificial intelligence, internet of things, cloud computing and so on), far from being merely an IT evolution, is greatly impacting firm activities, business models, boundaries, cultures and value chains. Such effects are increasingly assuming an international dimension. This explains why the research field of digital transformation is emerging.

On the one hand, the new landscape strengthens the microenvironment of companies whose understanding of markets and input is improving day by day thanks to data. On the other, it increases the complexity of the external environment as it becomes faster every moment. This increased ability to read and interpret data has an impact on the external environment which, inevitably, becomes more complex. Large corporations and new start-ups must constantly adapt their business models as rapidly as possible to react to this change, which big data and artificial intelligence are imposing upon the market.

In this paper we observe the phenomenon of digital transformation through the lens of the "*economics of complexity*" (Section 2).

We start with analyzing the phenomenon, identifying its defining characteristics (section 3). Then we focus on three of the main – partially overlapping – elements of digital transformation impacting firm activities and the economy as a whole: cognitive computing, artificial intelligence and data mining (Section 4). Indeed, in the new era of digital transformation, companies' competitiveness depends no longer on whether they are digital but on whether they learn from their own data. We then introduce the Italian Cognitive Computing Community, aiming to promote the use of cognitive computing technologies and develop new professional skills in line with the digital transformation of the economy (Section 5), and digital ecosystems as the new prevailing organizational mode in the context of current digitalized scenario (Section 6). Finally, we conduct a literature review covering works and research perspectives dealing at the same time with the issues of digitazion/digitalization and internationalization (Section 7). This is followed by some concluding remarks.

2 The economics of complexity

The theoretical approach of this paper is to insert the phenomenon of digital transformation within the "economics of complexity"[1]. The latter term derives from observation of configurations that are based, on the one hand, on complexity of a phenomenological nature (such as that resulting, in the analysis in question, from digital systems and their applications) and, on the other, on an epistemological complexity, which envisions greater sophistication of epistemological views that are used to interpret

[1] *This approach is based substantially on Luhmann's theory on complex systems (found chiefly in Luhmann, 1984), integrated with some other theories on self-referential systems (von Foerster, 1960; Maturana, Varela, 1980; 1984), reflections on the epistemology of complexity (e.g. Morin, 1977; 1984), some concepts from organization studies, such as that of the enacted environment by Weick (1969), and several insights into method in the social sciences (Weber, 1922). For a broader reference to the economics of complexity see Mazzoni, 2007, p. 37 ff.; p. 317 ff.; Mazzoni, 2019.*

such phenomena. Hence digitalization may be observed from various perspectives and with different cultural backgrounds.

The various attempts to incorporate the situations under observation within a scientific-type vision leads to a multiplication of the decodification possibilities, with the consequence of adding to complexity of a phenomenological nature a no less significant epistemological complexity. The latter grows due to the progressive legitimizing of several perspectives which are often difficult to integrate, or rather, in some cases, inconsistent or even contradictory. There is no unifying perspective, no general law able to understand multiform phenomena. Pluralist epistemological views are given credit, in which the objectivity of the subject observed is lost, and the observer enters the phenomenon of knowledge with his/her subjectivity, with his/her values and cognitive maps. It is hard to decide whether the change influences the methodological renewal or whether the opposite is true.

Complexity lies at the basis of contemporary economics because the system in question (firm, network, district, team) is defined by a differential complexity compared with the environment that surrounds it (the environment is always more complex than the system, and the system is self-defined through this diversity). In its attempt to deal with external complexity, the system organizes itself into a structure. On the one hand, this involves an attempt to simplify the external inputs and relationships (as occurs using digitalization systems). On the other, it steers the system towards greater internal complexity (procedures, programs, equipment, and skills for effective digitalization). Moreover, the attempt made by the system to tackle the complexity of the environment produces a system configuration (e.g. through the functioning of digital ecosystems) which generates greater complexity also in the external environment where all the other enterprise systems are to be found (just think of competition phenomena induced by digitalization processes from a single network).

3 Digital Transformation

The term ‘digital economy’ refers to ‘the broader economy as it undergoes the process of becoming increasingly digital’, while ‘digitalisation involves the conversion of things (sound, shapes, information, etc.) into digital data, which can be infinitely (re)processed and stored at negligible marginal cost’ (Gestrin and Staudt, 2018). Digitization is the technical process, whereas digitalization is a socio-technological process of applying digitization techniques to broader social and institutional contexts that render digital technologies infrastructure (Sussan and Acs, 2017).

The diffusion of digital technologies, far from being merely an IT evolution, represents a phenomenon which impacts deeply firm activities, business models, boundaries, cultures and value chains. Thus, what is being called ‘digital transformation’ is affecting both, firms on a micro-level, and industries, markets and more generally the firm's task environment on a macro-level[2].

2 In the economics of complexity, the traditional categories of interpretation – firms as microeconomic entities and contexts as macro scenarios – no longer produce satisfactory analyses.

The digital transformation can be defined as 'the seamless, end-to-end connectivity of all areas of the economy, and as the way in which the various players adapt to the new conditions that prevail in the digital economy' (Roland Berger Strategy Consultants, 2015). It has four main levers (Figure 1).

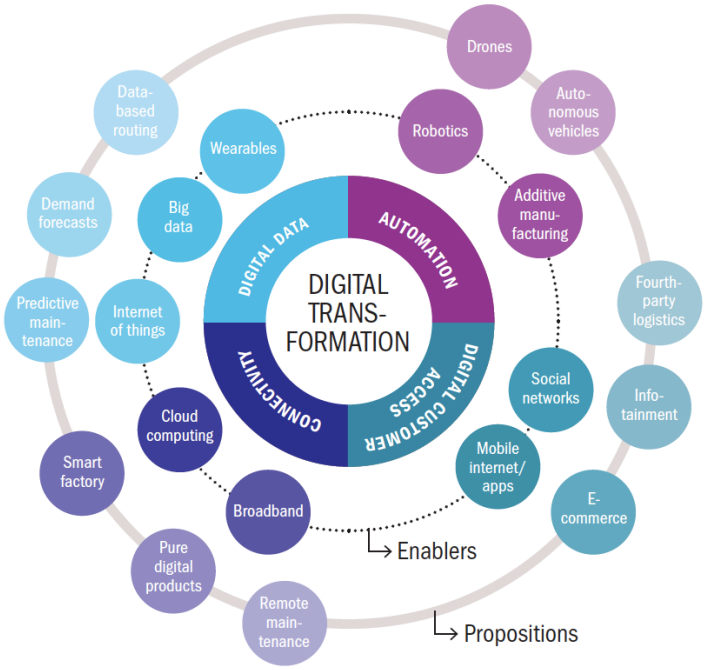

Figure 1: The four levers of digital transformation (Roland Berger Strategy Consultants, 2015) .

DIGITAL DATA. Capturing, processing and analyzing digital data, which allows better predictions and decisions to be made.

AUTOMATION. Combining traditional technologies with artificial intelligence, which is increasingly giving rise to systems that work autonomously and organize themselves, thus reducing errors and operating costs and increasing speed.

CONNECTIVITY. Interconnecting the entire value chain synchronizes supply chains and shortens production lead times and innovation cycles.

DIGITAL CUSTOMER ACCESS. The internet gives direct access to customers, thus globally enlarging their choice options.

This is leading to a new era, in which two phenomena in particular should be subject to scrutiny. First, systems able to self-learn, also *from their own data* (see the section below) and self-organize are being generated (von Foerster, 1960). Secondly, the value chain is being dismantled and redefined in circular and interactive diagrams (see for example the impact of digital transformation on the value chain of the automotive industry in Figure 2).

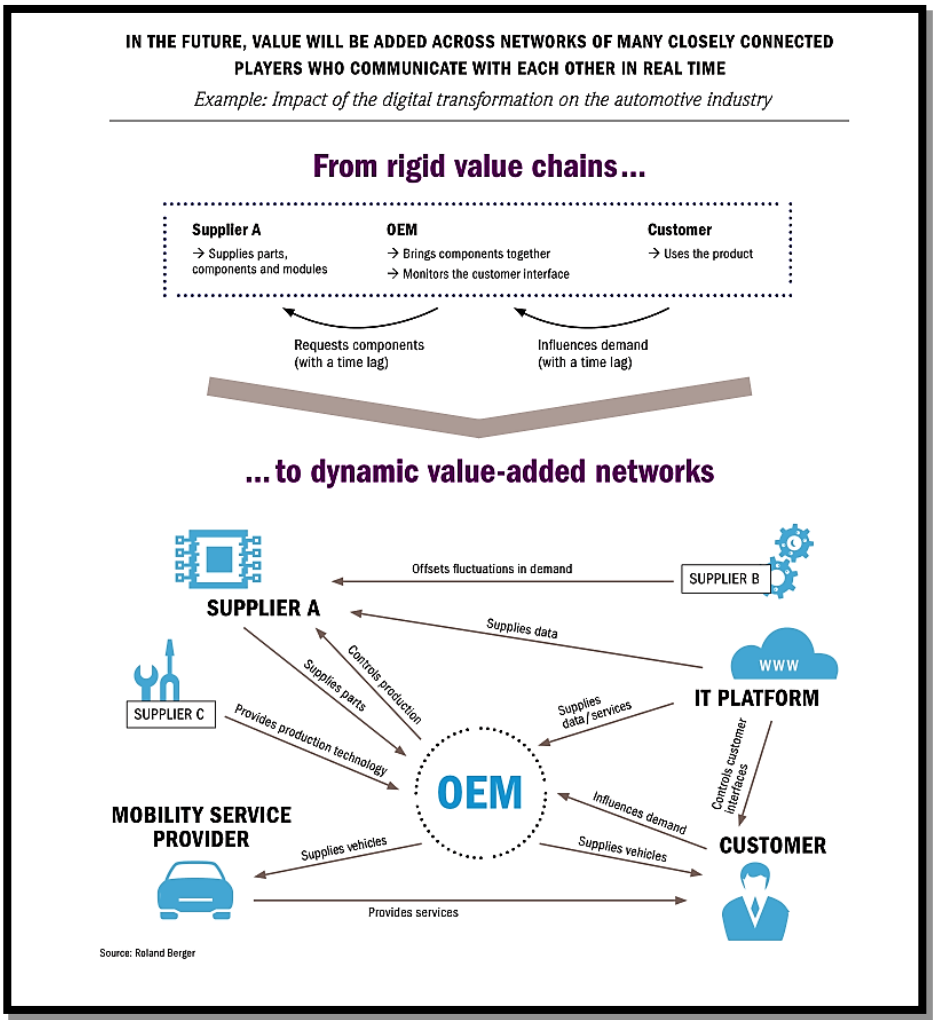

Figure 2: Impact of the digital transformation on the automotive industry (Roland Berger Strategy Consultants, 2015)

4 Cognitive computing, artificial intelligence and data mining

In the new era of digital transformation companies are no longer competitive because they are digital but because they learn from their own data. The new digital technologies aim to support the collection, analysis and processing of big data and thus sustain the decision-making process (Russo Spena and Mele, 2018). The advent and diffusion of cognitive computing (CC) and artificial intelligence (AI) is one of the main drivers of digital innovation. CC and AI enhance human-machine interaction, supporting collaboration.

Cognitive technologies are an evolution in computing that mimics some aspects of human thinking on a larger scale, while adding the ability to handle large amounts of

information and evaluate it without bias (thus surpassing the main limitations of human cognition) (Chen et al., 2016).

Cognitive computing arose as a model based on human beings' reason, whose application is transversal across several domains ranging from meteorology to economics, from the automotive industry to healthcare, from the block chain to retail, from smart cities to cuisine.

We are moving from the era of information to that of knowledge technology: cognitive computing introduces new methods to extract value from data and support decisions (Chen et al., 2016; Russo Spena and Mele, 2018). The definition of cognitive computing is a topic of debate in the computing community. It is often associated with artificial intelligence (AI), a field of technology that covers broad aspects of human intelligence (Chen et al., 2016). Indeed, cognitive computing uses machine learning algorithms to reproduce human thinking, and is thus employed in several AI applications, where AI designates a broad suite of technologies that can resemble human capabilities, particularly those involving cognition (reasoning and problem solving but also perception and the ability to manipulate objects) (Chen et al., 2016; Russo Spena and Mele, 2018).

The explosion of comprehensive data warehouses, which integrate operational data with the customer, supplier, and market data, has led to the release of an incredible amount of information. Therefore, competition requires timely, sophisticated and integrated analysis of such data, in order to identify useful information and react. Data mining tools and services are providing the necessary support to close the gap between more powerful data warehousing systems and the user's ability to effectively analyze and act (Kleissner, 1998).

Data mining offers automated discovery of previously unknown patterns as well as automated prediction of trends and behaviors. Its technologies are complimentary to existing decision support tools and provide the business analyst and marketing professional with a new way of analyzing business (Kleissner, 1998).

5 Perspectives and projects of the Italian Cognitive Computing Community (ICCC)

We are a sociotechnical, interconnected and mobile society, which produces fast, varied and numerous data. Indeed speed, variety and volume are the defining characteristics of big data. How can individuals and companies handle this data in order to extract value? Cognitive computing (CC) can support us in this challenge. Why CC? Because it is shaped on a human brain, it is based on the way human beings think but, at the same time, CC amplifies the power and the achievable results of our mind mechanism.

But how does the human way of thinking and elaborating information work? It is based on four phases: observe, use, evaluate, decide. We observe what is around us, we collect objective evidence, and we use our knowledge to interpret what we see. Then we formulate hypotheses and evaluate them to finally decide. As human beings we are neither too precise nor too fast, and this is where CC can help us and amplify our skills.

To promote the use of cognitive computing technologies and develop new professional skills in line with this digital transformation of the economy, the Italian Cognitive Computing Community (ICCC) was established on May 18, 2018 at the University of Naples Federico II (http://it-cogcom.com). The ICCC aims to promote the use of cognitive computing technologies and accelerate research in this field, thus becoming a point of reference in Italy. The community would like to accomplish, amongst other things, some more immediate goals: 1) to establish an ecosystem in which to share knowledge and growth; 2) to promote links between university research and industry; 3) to sustain research in the field. The actors in this community will be companies, professional organizations, professors, researchers and students who will need to be ready for the future jobs they face.

This revolutionary change leads to the need for the emergence of new skills, which will be based on the man-machine interaction. The process model will probably be that in which cognitive systems will have the ability to extract knowledge automatically from application domains and will be able to build useful knowledge for the professions of the future themselves (Coccoli et al., 2016). In short, the user will interact with cognitive systems directly and therefore will have to be trained to interact with systems with which "we speak" but will have to be able to understand much more complex architectures than those at present (Coccoli et al., 2017). The knowledge generation will be more efficient and rapid, and the transfer into the social world will be the fundamental key for business and the new professions. One of the goals of ICCC is to make this transition to the near future possible.

6 Digital ecosystems

As the organization of knowledge and relationships has become increasingly digital, thus consistently changing the cognitive environment in which companies work and individuals live, new ways of generating and employing knowledge have become feasible, while – as a consequence – previous organizational modes have become obsolete (Castellani et al., 2017).

Looking at interfirm relationships, digital transformation means a shift from more traditional value networks to digital ecosystems.

As the rapid advancement of digitization and the impact of digitalization increase, in order to stay competitive and execute strategies effectively, firms must rely on networks, consisting of multitudes of people and organizations to create innovation and commercialize products (Vasilchenko and Morrish, 2011). This need has led to the emergence of the digital entrepreneurial ecosystem (DEE) defined by Sussan and Acs (2017) as “the matching of digital customers (users and agents) on platforms in digital space through the creative use of digital ecosystem governance and business ecosystem management to create matchmaker value and social utility by reducing transactions cost”. At the same time, digital ecosystems (DEs) “transcend the traditional, rigorously defined, collaborative environments from centralised, distributed or hybrid models into an open, flexible, domain cluster, demand-driven, interactive environment. A digital ecosystem is a

newly networked architecture and collaborative environment that addresses the weakness of client-server, peer-to-peer, grid, and web services" (Boley and Chang, 2007).

The concept of digital ecosystems has been subject to many perspectives and interpretations. Yet despite the divergences, all agree on two foundation pillars of DE – digital technologies and people. Essential in DE is the idea that such an ecosystem is user-driven, bottom-up, and open source oriented (Dini et al., 2011), emphasizing the pivotal role that users play in the ecosystem. Companies need to be flexible, rapidly change their strategies, adapt their business model and react to market inputs. DE and more specifically DEE can support them in this attempt.

However, to come into existence and be effective, digital ecosystems today require the development of necessary "relational intelligence". Relational intelligence is the ability to share an innovative idea and make it practicable. It is the ability to connect those who possess resources (knowledge assets, financial resources, professional skills, products, relationships, etc.) with those who can usefully employ them for their requirements, which requires not only to imagine but also to design, convince, contract, organize the supply chain and reliably fulfill the obligations undertaken (Rullani, 2015). Relational intelligence is a connective resource that, in today's global and digital economy, is increasingly valuable, as the connections among the actors of the supply chain are no longer predetermined nor numerically contained; relationships must be constructed at a distance, choosing among a multiplicity of possible, varied solutions (Rullani, 2015). As the scenario becomes complex and the choice difficult for both suppliers and buyers, agents need to invest to create a substrate of relational intelligence, useful for interacting with the outside world, either directly or through intermediaries specialized in the supply of the relational intelligence supporting choices (Rullani, 2015).

This explains why the new digital competitive landscape has seen the rise of a new company type. Ever since the launch of Uber, Snapchat, AirBnB, Google, Amazon and Facebook, a new variety of company has emerged that uses digital technology, entrepreneurship and innovation to overturn industries on a global scale. These companies are called matchmakers (Evans and Schmalensee, 2016). Matchmakers connect members of one group with another. The core competencies of these companies are their ability to match one group of customers with another by reducing the transactions cost of the match. This trend is also reflected in the decline in the cost of computing, the rise of open-source software and the move to the 'cloud' (Sussan and Acs, 2015).

7 Digital transformation and internationalization

There are many mentions of the importance of 'the digital'[3] in supporting the globalization of production (Foster and Graham, 2017). Castellani et al. (2017) observe there exists an intrinsic synergy between digitization and globalization.

[3] *Foster and Graham (2017, p. 70) use the notion of 'the digital' to define 'the constellation of digital ICTs, connectivity, infrastructure, data and new digital resources that are increasingly crucial in all aspects of the economy'*

Internet-based digital technologies represent one of globalization's drivers, transforming work patterns and divisions of labor and, therefore, influencing the processes of value creation and power exercise. They contribute to shape modern global production networks (GPNs), which represent a key framework to explain linkages, power and structure in globalized production (Foster and Graham, 2017). Nonetheless, Foster and Graham (2017, p. 69) observe that 'while the literature often acknowledges that the digital plays an important role in tying together increasingly geographically dispersed production networks, it rarely explores the digital as anything more than an infrastructural component. There is a disparity between the relative absence of research and the fact that digital data flows and services are increasingly central to the efficient management and monitoring of global dispersed networks. Thus, they propose to better integrate 'the digital' into the GPN framework, as characterized by three main 'conceptual categories': embeddedness, value, and power. As shown in Table 1, they start from the state-of-the-art literature (second and third columns) to propose how the digital might be better integrated into GPN analysis (fourth column)[4].

Table 1: The three conceptual categories on relations in GPNs (elaboration from Foster and Graham, 2017)

Conceptul category	**Coverage in existing GPN literature**		**Conceptual category**
	Use in GPN literature	**Incorporating the digital**	
Embeddedness	Move beyond 'overterritorialized' focus to explore network embeddedness	Embeddedness	***Network diversity*** Problematizing network embeddedness – diversity of digital networks ***Digital (infra)structure*** The digital as an infrastructure in shaping network embeddedness
Value	Value distribution and the network mechanisms which support changes in distribution	Value	***Digitally-driven shifts in governance and value*** Critical approach to new value distribution enabled by digital – exclusionary, spillover effects, who are the winners and losers?
Power	Power mainly seen in terms of agency, but actor-network theory (ANT) offers ways of exploring complex networks in flux	Power	***ANT – Non-human actants*** Considering a central role of the digital in the constitution of actor-networks ***ANT – Translation processes*** Focus on translation processes to better explore power and circulation

[4] *'Embeddedness' refers to the durable relations and norms that guide economic activity. 'Value' identifies how the value is created, enhanced, and distributed in networks of firms. 'Power' refers to the shifting nature of control in networks, and the multiple scales at which they act (Foster and Graham, 2017).*

Thus, digital technologies have profound effects on the decentralization of channel structures and the development of interorganizational networks: they enable new channel partners to be found in foreign markets as well as new digital-only business models that easily cross-national boundaries (Watson et al., 2018).

In a cognitive perspective, it has been observed that digital transformation means new ways of producing and using knowledge assets, which in turn changes the function and importance of geographic proximity (Castellani et al., 2017).

By virtue of digital transformation an 'empowerment effect' is generated. SMEs can gain access to digital networks and interact with distant counterparts, differing from the usual ones based on proximity (Castellani et al., 2017). This is important given that, in today's fast-paced business cycles, early internationalization becomes imperative (Sapienza et al., 2006), especially for smaller born global firms, as windows of opportunities do not stay open for long (Vasilchenko and Morrish, 2011). In this perspective global value chains (GVCs) appear a means by which export-oriented production is operationalized in a globalized world (Foster et al., 2018). However, prior research yields contradictory results, as firms might benefit from connectivity through increased efficiencies and improved access to markets. Or vice versa, they might be further marginalized through increasing control of lead firms (Foster et al., 2018).

Interestingly, digital technologies have given rise to new businesses and international business models that allow firms to extend their presence globally without significant amounts of foreign direct investment (FDI) (Gestrin and Staudt, 2018).

The ability of firms to access international markets with smaller "asset footprints", thanks largely to the digital economy, has also been associated with the emergence of so-called micro-multinationals and born global firms that quickly attain global reach with minimal cross-border investment (Gestrin and Staudt, 2018).

From an international investment perspective, the main implication is that "the trade-off between exporting and market-seeking FDI as market entry modes for delivering products to host countries may be shifting toward exporting" (Eden, 2016, p. 6). While reasons for market-seeking and efficiency-seeking FDI are partially undermined by digitalization, other types of FDI are becoming more important, such as knowledge-seeking and financial and tax-driven FDI (UNCTAD, 2017).

While FDI continues to play an important role as a means of expanding internationally for firms in more traditional "bricks and mortar" industries (outside the digital economy), there has been a modest contribution of digital firms to overall cross-border investment flows: Digital firms only generated USD 153 billion of cross-border M&As in 2017 (13% of total cross-border M&As) and the 100 largest digital economy MNEs only accounted for USD 20 billion in cross-border M&As in 2017, about 1% of total cross-border M&A (Gestrin and Staudt, 2018).

However, recent trends suggest that the role of digital firms in international investment flows is growing as they are rapidly increasing their cross-border physical presence: Global cross-border M&As by digital firms since 2010 have recorded an average annual growth rate of 30% (against general 9% of global cross-border M&As) and the 100 largest digital firms grew their cross-border acquisitions on average by 90% annually over

the same period, a large share of this international investment going into digital infrastructure (Gestrin and Staudt, 2018). Also, knowledge-seeking FDI (e.g., cross-border acquisitions of software developers) has been an important driver of growth in cross-border digital investment. A key factor behind the recent rapid growth in M&As directed at acquiring digital assets is the sharp increase in cross-border acquisition of digital corporate assets by firms outside the digital economy: While until 2014 non-digital and digital firms were roughly equal in terms of their acquisition of digital assets, since 2015 the former have significantly increased their digital acquisitions (from acquiring USD 78 billion in digital assets in 2013 to acquiring USD 458 billion in 2016) (Gestrin and Staudt, 2018).

As previously observed, the effective use of digital technologies can facilitate valuable learning about foreign markets and potential international customers, including cultural, political, and economic contexts, impacting on international market entries (Watson et al., 2018).

On this point it is worth noting that there is ample scope for the practical application of artificial intelligence: Effectively implemented, AI systems are likely to outperform statistical-based tools for complex, qualitative, or difficult-to-program problems and decision making (Martínez-López and Casillas, 2013; Watson et al., 2018).

As shown by Fish (2006), AI can support international market selection (IMS). The study uses empirical data to demonstrate that an AI approach can assist the market screening phase of IMS, providing information that is not readily available by standard statistical techniques. The purpose of the screening process is to allow the firm to quickly focus efforts on the most promising foreign markets by identifying a group of markets that merit further research.

Fish (2006) applies artificial intelligence (AI) computing in the form of Kohonan Self-Organizing Maps (SOMs). Self-Organizing Maps organize data in a manner that is inspired by how the human brain organizes received external inputs. 'The salient benefit of the SOMs is their ability to take classes of vectors that are similar in high-dimensional space and display them in two-dimensional space, where humans more easily visualize them. In this regard they are a type of DSS model that is distinct and different from standard clustering techniques. The DSS is an easily interpretable map that displays markets which are very similar to each other in the same cells. Markets that are somewhat similar are grouped in neighboring cells and, markets that are very different are found in cells that are a great distance away on the map'. Moreover, it has been observed that SOMs can assist small firms in making decisions about optimal overseas market locations (Fish and Ruby, 2009).

Accordingly, Gnizy (2018) proposes big data (BD) as a key driver of strategic orientations, empirically finding that BD usage enhances international performance through strategic orientations.

8 Conclusions

The field of digital transformation is still new and emerging. At the beginning, scholars started to describe a phenomenon not fitting with pre-existing paradigms. Now that the

phenomenon has a more complete description, attention is shifting onto describing its existence and behavior, initially borrowing paradigms developed elsewhere, and then developing new frameworks (Sharon and Burney, 2008). Thus, investigation of the digital transformation is moving from the concrete description of the digitalization-digitization phenomenon to the attempt to develop theories to explain digital transformation and its consequences (Sharon and Burney, 2008).

In this vein, from a theoretical point of view this paper contributed to this emerging field by proposing the *economics of complexity* as a paradigm to observe and study the issue of digital transformation. On the one hand, tools and services of the digital transformation support either big corporations or small companies in dealing with the complexity of the external environment. Data mining, AI, and CC are all ways to simplify external and internal inputs, in order to reveal potential ways to react, which are otherwise impossible to identify due to the quantity of information and the speed of market changes. On the other hand, in such a complex scenario where the categorization of firms as microeconomic entities and contexts as macro scenarios no longer exists, digital ecosystems allow companies to participate, innovate and compete globally in a new and unexpected way.

Digitalization involves an attempt to simplify external inputs and relationships. However, it also steers the system toward greater *internal* complexity (procedures, programs, equipment, and skills for an effective process of digitalization). Moreover, the attempt made by the system to tackle the complexity of the environment produces a system configuration (e.g. through the functioning of digital ecosystems) that generates greater complexity also in the external environment where all the other enterprise systems are to be found.

In the new digital transformation era, venture management means rethinking existing business models and being ready to work in a global digital ecosystem, accepting and implementing new mechanisms of knowledge creation, sharing and management, and creating and using new skills. Moreover, the open source model on which the global digital ecosystem is based makes it necessary to further analyze and develop mechanisms of value appropriation within a new knowledge management paradigm.

As seen in Section 7 above, digital technologies intrinsically foster internationalization. Although some studies already deal with this issue, there is still a need to analyze the international dynamics of global digital ecosystems from a managerial point of view. Even though the adoption of digital technologies has been one of the most significant international business developments of the past 25 years, fewer than 3% of peer-reviewed research articles in the international marketing (IM) domain (comprising thousands of publications that study various aspects of the exchange between international buyers and sellers) examines digital topics (Watson et al., 2018). Looking at big data (BD), Gnizy (2018) argue that research on the use of BD and its effects in international firms is in its embryonic stage.

From a managerial and policy making point of view this suggests the need to re-shape traditional education contents and dynamics. A fairly common idea is that while some of the new skills will come from different domains (cognitive psychology, developmental

methodologies, education, social behavior, economics), many other professions will have to be re-grounded in skills such as communication, teamwork, problem-solving, creativity and resilience, leading to new professions such as cognitive system developers, cognitive system integrators, cognitive evaluators, cognitive trainers, etc., all needed along with data scientists and data integrators.

The following kinds of professional skills could be useful in this respect:

(i) Multi-disciplinary:

An integrated skill set that covers math, machine learning, artificial intelligence, statistics, databases, and optimization, along with an in-depth understanding of engineer-specific troubleshooting.

(ii) Multi-domain

Learning aware of the existence of contexts other than those in which it was generated, e.g. socio-economic, in sectors such as medicine, energy, the environment, finance, transport, etc.

(iii) Multi-empathic

Professionals will have to interact with

- Human beings: as data / generators of knowledge / consumers
- Cognitive systems: they will be instructed (not programmed)
- Human beings in augmented reality (assisted by devices and gadgets)
- Robotized systems
- Hybrid - a set of previous points

(iv) Multi-interaction and multi-communication between people and things.

As to who will have to produce all these new professional skills, there is no doubt that universities should take such tasks on board. Yet at the current rate of change we are constantly behind schedule, in deficit. Hence the question is how to anticipate change and turn the deficit into surplus. Cooperation between academia and industry will probably help to achieve the goal. The role of the academy will be different but always central: the university of the future will shift from the role of "*knowledge generato*r" to the role of "***generator of knowledge generators***", a "meta-model" vision in which all together, universities, organizations and companies, learn from each other by becoming "smarter" and more "cognitive". Knowledge must be generated more intelligently, and the new professions will become increasingly cognitive with new technicians to be trained and new skills.

Abstract

The purpose of this paper is to grant insights into airport customers' perceptions regarding the use and appropriateness of digital features. It is worth to examine whether sharing these findings with experts in the context of knowledge management activities reveal strategies and processes to be adjusted on corporate level. The question is whether defined strategies always respond to actual customer expectations and if sharing digital intelligence on a collaborative level could prevent airports from choosing inadequate concepts and process optimisation models.

A qualitative approach has been applied to assess airport specific digitalisation features including airport staff s' expertise compared to the perception of airport passengers and their demands. In order to contrast realistic customer experience with internal views primary data has been collected in the form of airport manager interviews and passenger questionnaires.

Artificial Intelligence, Big Data, Machine Learning as well as Internet of Things being constantly developing and dynamic topics require organisations to exchange knowledge and data with customers. The main outcome revealed airport managers' assumptions differ from passengers' needs and interests.

Key findings of the paper revealed that top priorities perceived by passengers are not represented by entertainment and shopping facilities whereas airport professionals tend to focus a lot on these features. Process optimisation and simplification of check in and boarding activities play a much more important role to airport customers. This also implies that strategy definition processes can be performed more efficiently when considering and communicating consumer-oriented needs. Since the paper deals with strategic management and service operations these widely discussed and on-going topics are worth to be improved and optimised using knowledge management instruments within the organisations and its collaboration with customers.

Keywords – Knowledge Management, Digitalisation, Airport Industry, Customer Experience, Knowledge exchange in collaborations

Paper type – Academic Research Paper

1 Introduction

The fact that globalization favours the increase in passenger numbers to be transferred through airports in an efficient and time-saving way forces airport managers to rethink long-term strategies. Airports face the challenge of rising passenger transfers for a number of years and need to define and develop new strategies and concepts to be able to cope with changing demands and "to stay afloat" (Andreassen et al., 2015, p. 25). Another aspect is the intense technological progress and the requirement to keep pace with digitalisation demands of different target groups (Abdelaziz et al. 2010; Aloulou, 2019). In times of inevitable digital transformation and enhanced technology demands airports are forced to involve digital solutions to handle the mass of customers through more efficient processes (Bolton et al., 2018).

Digitalisation eases data collection and allows the use of remote control and automation features (Davidsson et al., 2016; Kauffman and Weber, 2018). A company such as Fraport AG in Frankfurt is an example of how passenger flows are managed successfully and what an organisation needs to take into account to satisfying its customers on the one hand and to comply with latest trends of the industry on the other hand.

Hence, it can be assumed that the analysis of passenger's perceptions and needs may reveal aberrations and discrepancies when comparing these to assumptions airport professionals and experts tend to have. The motivation was to gain knowledge about potential trends and misconceptions to enhance the performance of the case study company Fraport AG through process optimisation solutions and a better understanding and response to passenger needs.

The purpose of this study was to evaluate current and future challenges of airport specific management tasks regarding cost-effective transfer processes and efficient customer handling to recommend implementation approaches for Fraport AG by taking emerging digitalisation requirements into account. The underlying research question was as follows:

How to ensure a smooth customer experience at an airport through knowledge management while coping with process enhancements through digitalisation? - A framework of influencing factors and potential measures for information exchange.

To find answers to this question the following research objectives have been defined:

- To analyse current and future challenges of airports in managing successfully the increasing digitalisation demands in the air transportation sector

- To examine passengers' expectations regarding digitalisation requirements that enable information exchange at airports based on a knowledge management approach
- To reveal outcomes from customer satisfaction analyses to be implemented and considered in process optimisation through knowledge management
- To recommend customer related knowledge sharing means to be considered for the future implementation at airports

2 Critical Literature Review

2.1 Key challenges of the airport industry

Airports are associated with congestion issues, time intensive queueing and stressful security checks. In times of rising passenger numbers an airport needs to identify ways of structuring their processes in a more efficient way.

Firstly, the question will be how to ensure safety in an increasingly crowded environment with rising use of data and technology? Secondly, according to the Garcia (2018) digitalisation produces transparency and has the potential to dissolve boundaries. Often the airports processes mainly focus on peak time, times in which the highest volume of passengers and customers in general are transferred through the building and terminals as well as processed for boarding at the gates. Rothe (2018) and Zografos et al. (2017) stress that the rethinking towards a more sustainable capacity planning instead of peak-hour facility planning is essential.

One example is Frankfurt Airport whose terminal capacity of 64 million passenger per annum will be exceeded by 2021 (EOACQ, 2015).

2.2 Digitalisation at airports

According to Larsen (2013, p.3) "the primary aviation data sets include flight tracking data, airport operations data, weather conditions, airline information, market information, passenger information, aircraft data and air safety reports".

Digitalisation is assumed to referring to a major remodelling of societal aspects and relationships through the application of digital technology. Digital transformation of a company is a "multi- faceted phenomenon that originates from the synchronous adoption of the bundle of digital technologies" (Lanzolla et al., 2018, p. 379). The following technologies can be considered at airports:

- Artificial Intelligence are software algorithms to find solutions to complex problems
- Big Data from sources such as sensors, digitizers, scanners, numerical modelling, mobile phones and the Internet
- Block Chain are information blocks to exchange content among applications and data bases in real-time processes

- Automation of processes that are mostly performed automatically and controlled by an autonomous device such as Robotics (electromechanical or bio-mechanical device) and
- Combination of these technologies described as Internet of Things solutions.

These digitalisation elements offer a great potential but mean significant investments, a potential loss of work places due to automation solutions as well as the adjustment regarding data protection responsibilities (Parviainen et al., 2017).

In addition, the digitalisation can bring new business opportunities, change the roles and remove intermediates in the supply chain and leads to competitive advantage (Robinson et al., 2015; Gillen and Lall, 2004).

Process optimisation by applying digital solutions such as increased automation or self-service mechanisms for passengers in order to attract more end-users is in focus (Biehl, 2017). Responding to latest trends but at the same time being available for generations that might not be as familiar with digital features and devices is a key challenge (Woods and Davis, 2017). One example are information kiosks where passengers can get in contact with either an automated bot [1]or via real-time chats with an individual that provides support (Hwang and Seo, 2016). Singh et al. (2019) indicate this as 'supervised and unsupervised learning'.

Davidsson et al. (2016) refer to possibilities of collecting and categorizing data, tracking patterns, behavior and preferences with which airports have access to numerous sources of customer information .Machine-generated data is produced in much larger quantities than non- traditional data. It is moreover available in real-time and can be accessed through networks (Wilkesmann and Wilkesmann, 2017). Airports are therefore required to know how to manage this customer information in a compliant way (Gopalakrishnan et al., 2013).

2.3. Digitalisation as main driver for enhanced efficiency

Xiangmin and Li (2017) argue that accurately installed and used software can enhance the prediction in departure capacity and allow analysing passenger flows more accurately. Adler and Gellman (2012, p. 24) call it "computer-centric air traffic management" that require capacity restructuring but develop business model adjustment to be competitive.

There is a growing demand for customer centric service delivery and orientation for airports in order to meet the expectations of older generations and the desire of younger generations to experience a digital, easy and entertaining journey (Arif, Gupta and Williams, 2013).

The aspect of drones are usually associated with risks and dangers as well as being disruptive objects for all airport operations that have to be handled with anti-drone equipment accordingly (Penton Media, 2019) but drones are becoming relevant for

[1] *Chat bot = a computer program designed to simulate conversation with human users*

operational efficiency and security matters in particular (Norman, 2018). According to Labeodan et al., (2016) sensors help detect capacity shortages, improve occupancy-based lightning and also allocate resources in a better way.

Besides Flight Information Display System (FIDS) and its expansion to passengers' devices one can observe a rise in implemented self-service machines such as self-bag-drop solutions, check-in, boarding pass printer machines, electronic passport control checkpoints. According to the Passenger Terminal World Magazine (2018) such resources could then be positioned where elderly people require assistance from a human being.

2.4. Digitalisation as an enabler of knowledge sharing with customers

Digitalisation makes it easier than ever to access, modify and analyse data in order to use it in innovation or business process modelling procedures by applying knowledge management (KM). According to de Felice et al. (2019) the basis for innovation and therefore competitiveness is knowledge and its sharing with both internal and external parties. Social interaction becomes the centre of knowledge management in order to enhance customer satisfaction and process efficiency. By using the benefits of interaction with external relations such as partnerships and alliances, the success of firms – in particular during digital transformations – can be fostered. Another significant point of using a knowledge management approach is stated by Nezakati et al. (2015) who argues that travelling has become an information-intensive environment that enables organisations to understand and discover consumers' demands. Bolisani and Scarso (2019) refer to it as knowledge transfer or knowledge creation in order to incorporate outcomes of customer satisfaction activities into strategy definition. Through easily accessible apps and digital platforms, passengers create, share and exchange information and individual patterns. Those can be implemented to process optimisation procedures by the respective organization.

In the context of airport and airport lounge design Conforte (2017) confirms the significant impact customer satisfaction can have, when shared information regarding expectations, needs and interest are analysed and implemented by using empathy for the passenger. Gao et al. (2019) further argues that not only for customer satisfaction but also for overall organizational goals KM is highly important and is best achieved by activating the personnel's individual knowledge and knowledge sharing with stakeholders. Hence, using information and spread them through knowledge sharing may turn knowledge into "profitable industrial commodities" (Gao et al., 2019, p. 10). Since more automated process implementations together with the analysis of customer needs can lead to profitable business modelling the knowledge on this can be shared and further developed by e.g. online trainings (Kovynyov and Mikut, 2018).

In a very diverse and growing environment such as the travel industry and aviation related industries, Paschek et al. (2017) stress the importance of creating innovative opportunities and new skills through knowledge sharing in order to ensure one's

persistence on the market. Nonetheless, all used information and knowledge must be managed accordingly and in a professional and beneficial way as Stone et al. (2017) stresses.

3 Methodology and Methods

3.1 Case study research

The methodology is based on a qualitative approach when a specific case in-depth should be studied. The inductive exploratory approach was applied as an overall problem is transferred to a specific area.

Case study research explores a contemporary phenomenon in depth and within a real-world context (Yin, 2018). Since the research seeks answers to the research questions 'how' Fraport AG should handle future digital passenger requirement a single case study research with two primary data collections was used.

Yin (2018) posits that multiple case studies are popular to either compare deviating results for expected causes or suggest similar results within the cases. Grant et al. (2013) argue that especially the additional "user value of IT innovations" (p. 1507) can hardly be measured with traditional approaches..

3.2 Primary Data collection and analysis

For this study passenger surveys at three German airports (Frankfurt, Hamburg and Munich) took place to reveal insights of passengers' expectations that were not limited to the location and facilities of the case organisation Fraport AG.

According to Gall et al. (1996) 150 completed surveys represent reliable and credible research. Between February and early April 2019 anonymous surveys with a target group of business travellers and holiday travellers have been carried out at three airports as well as online via the survey platforms 'SurveyCircle.com' and 'EasyFeedback.com'. A number of 225 people received the survey from which 193 completed questionnaires could be achieved. The questionnaire consisted of 14 open and scaled questions covering the topics of digital habits of airport customers and digital features.

In addition ten semi-structured interviews were carried out within Fraport AG to analyse what directly involved aviation professionals think are the demands of passengers.

All of the selected interviewees are practitioners of the airport industry and employed at the case company Fraport AG (e.g. Head of Corporate Development, Head of IT Project Management, Head of Cleaning Services). The semi-structured interviews using mainly open questions were conducted on-site at Fraport AG in Frankfurt between the 11th March 2019 and 1st April 2019.

To present the results a qualitative content analysis with a matching of patterns as suggested by Yin (2018) was performed. Thereby, a frequency analysis was chosen in order to find out what nouns or codes were used by how many participants.

4. Findings

4.1 Efficient process optimisation

The top three missing elements at airports according to passengers are charging possibilities, a reliable and fast Wi-Fi connection and rest areas designed for working and relaxing while using digital features.

Asking for the satisfaction of elements at airports revealed that 54% of passengers miss a fast and failure-free internet connection. A significant portion of dissatisfaction (42%) is caused by insufficient charging options (see figure 1). In the context of the increase in the use of digital solutions this is a clear deficit.

For a better readability, passengers' responses 'very satisfied, 'rather satisfied' and 'satisfied' have been combined to 'Satisfied' in the graphic. The same applies to the dissatisfaction data 'very unsatisfied', 'rather unsatisfied' and 'unsatisfied'.

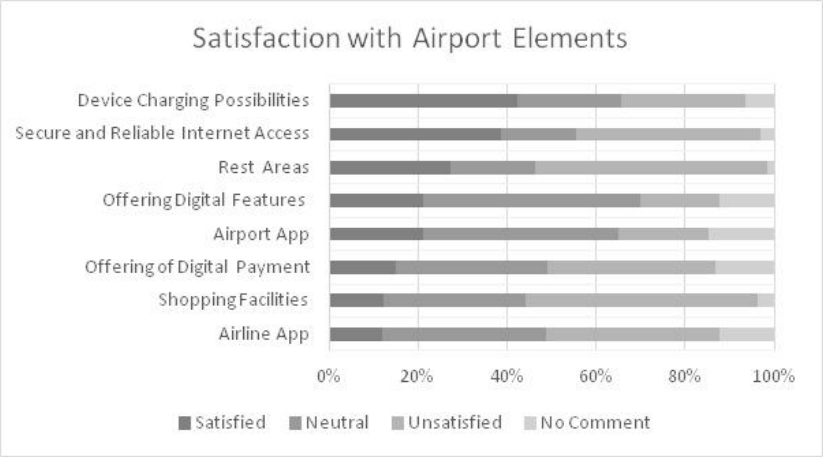

Figure 1: Passengers' satisfaction with airport elements

It became obvious that 67 % of the passengers of all generations rather agree to equip processes with more digital solutions such as electronic passport control or self-check-in to reduce waiting times and to increase efficiency. In regard to digital maturity, no clear attitude became obvious (see figure 2). For a better readability, the graded responses of the questionnaire were summarized to agreement and disagreement.

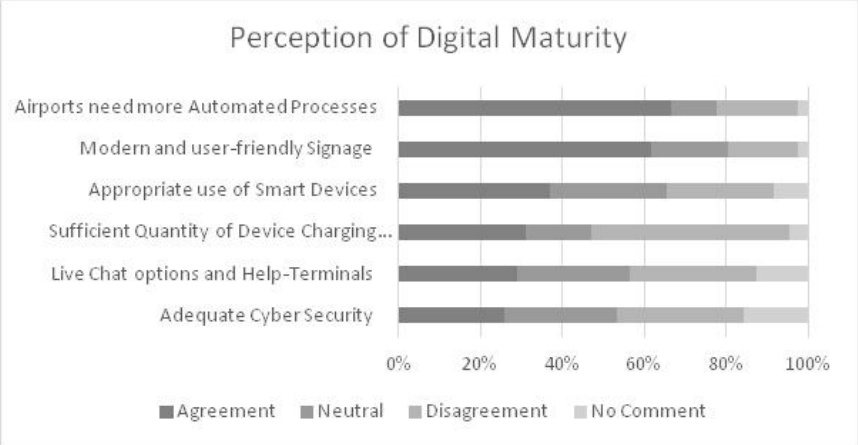

Figure 2: Passenger perception of the airports' digital maturity

While 60% of the Airport professionals agree that a fast internet connection is important only 40% realize that enough device charging possibilities are highly important for passengers. Nonetheless, the above mentioned lack of digital maturity were confirmed by the interviewed airport practitioners who agreed that additional digital solutions are required to handle current and especially future passenger transfer situations (Westerman et al., 2014).

Another interesting result is a deviating assumption of airport employees who think that passengers are significantly interested in digital entertainment solutions while the majority of 75% declared them as 'not important'. In addition, four out of ten airport professionals consider management strategies to be insufficient and need to be adjusted towards more technological advances to share data among stakeholders more extensively so that not only parts of information are passed on.

4.2 Managing increasing digitalisation demands

Passengers and airport professionals concluded that the increasing use of automated digital features at the airport will optimise passenger processing activities. More than 76% of passengers use the airport internet system which requires to be improved in regards to reliability and speed. About 42% use google maps extensively at the airport. This indicates to offer better navigation options at airports in order to make passengers use airport services rather than google maps. There are several features in the Fraport App but it lacks of self-explanatory design.

A significant amount of respondents (49%) stated that they don't use the airport app because the Wi-Fi connection is unsatisfactory. Moreover, one third (33%) of passengers does not even know about airport apps and digital services. Missing elements of airport apps demonstrated that passengers miss clarity and a user-friendly handling of help desks, emergency notification and live-chats with customer service. This leads to the number of

31% participants that would rather use the airline app than downloading the app of the airport.

In general, airport customers notice the challenge to manage rising passenger numbers. A central aspect is the reduction of waiting time and the offering of well-organized and functioning services that allows the passenger to use the time efficiently by accepting digital process optimisation.

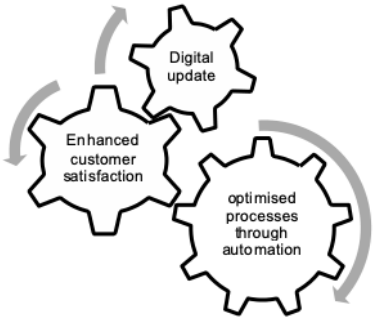

Figure 3: Interrelation of digitalisation and customer satisfaction

4.3 Potentials to avoid performance deficits

With the basis of 88% of passengers considering the airport Wi-Fi as 'important' the basis for implementing more digital services is given. Passengers indicated the interest in more assistance through apps. Whether it is the airport map that helps navigating through the area or a restaurant menu that helps spending waiting times with already choosing the restaurant for lunch, passengers request real-time data to be applied in order to ease and improve the stay at the airport. The likelihood for passengers appreciating additional digital services is high and needs investment. The phrase 'customer assistance', 'real-time help' or 'contact point' where mentioned several times with a frequency of 136 times checking this box in the survey or asking for this in comments.

Airports currently do not offer sufficient high quality working environments and tailored app features because airport practitioners deviate from perceptions of airport customers. Therefore, analysing passengers' needs remains important and digital offers as well as terminal equipment and architecture can be enhanced.

5 Discussion

5.1 Efficient process optimisation at airports

Customer service has to be organized in a highly efficient way to keep the travel time short and to ensure capacity for subsequent passenger flows. The findings show that

potential improvements exist internally when it comes to processing data and tasks to provide airport customers with all information. It shows that efficiency matters significantly but leaves room for the interpretation that more process optimisation and initiatives to familiarise with the new digital environment are required (Riedl et al., 2017 and Ramseook-Munhurrun, 2016).

However, especially holiday travellers try to escape from extensive technological use and digitalisation in their daily lives. Therefore, their interest in using digital services is limited to flight delay information and gate allocation. Business travellers more often appreciate a wide range of digital service and connectivity reliability. The growing popularity of the airport as the starting point for journeys increases the demand for latest technology implementation likewise (Dorndorf et al., 2007). Technological change and various stakeholders' needs demand the incorporation of digital features.

Another constraint of applying latest technological achievements is the fact that modern airport operations being equipped with digital features are unlikely to work effectively with outdated processes or mechanisms. Consequently, significant investment is required in order to process and use collected data from the passenger processes accordingly.

Nevertheless, digitalisation lack of financial resources needed for the implementation of a new digital business model. “The relative pessimism linked to budgets and business cases stems from the nature of digital projects as they deal with disruptive innovations and new business models for which there is limited or no past performance data and management heuristics” (Kotarba, 2017, p. 135). It therefore makes more sense for airport management to analyse and know customer needs in depth before adjusting processes in the context of value co-creation through customers (Majra et al., 2016).

Self-service check-in machines offer benefits such as optimised use of limited space within the airport, time savings for passengers and a decreased need for ground handling staff (Kovynyov and Mikut, 2018). Thus, airport management boards have to estimate and forecast customer needs and passenger requirements in an appropriate way. If data and internal processes or interaction are not effective false outlooks lead to deficits that should be improved (Pinon, 2012).

5.2 Managing increasing digitalisation demands

Fraport employees already support the common approach to put the customer in the centre of all activities to keep customer service excellence at a high level. A challenge is to know exactly the needs of all different passenger categories (business travellers, holiday travellers, different generations). The first issue is the offer when it comes to internet access and a secure and attractive connectivity. Additionally, services such as booking administration, online queries at customer service, online feedback possibilities are unlikely to be used if the internet access and availability is insufficient. The organisation of transfers and transportation of passengers via their smartphone

might reduce the number of passengers at information and service points (Kalakou et al., 2015).

A contrasting scenario is shown by passengers who are not interested in digital services. For those people personal contact points such as customer service, information kiosks and check-in counters will remain a relevant part of their travel (Hwang and Seo, 2016).

There are different opinions regarding the importance of the correlation between existing and well-functioning digital equipment and the future upgrade of airports. It is to question if airport management focus on relevant elements. The finding that 30% of airport customers do not even know airport apps leads to the recommendation that Fraport could promote their app in a better way. Also, digital solutions need to be extended to connect to passengers before they even reach the airport.

The majority of passengers expect an airport to be equipped with latest digital features that allow an easy connection of passengers, the airport, airlines and destinations (Mezghani and Aloulou, 2019). Any airport management approach should thus seek for ways to respond and fulfil this expectation to ensure an above average satisfaction and hence superior reputation (Manor, 2019). To conclude, investing time and money in the digital transformation of airports may be challenging but is a way to respond to customer needs

5.3 Potentials to avoid performance deficits

If airports introduce digital features such as automation for process support it is a matter of financial assets, political bias and societal demands. One example for efficiency improvement at airport premises derived from the interviews are extensive checks by facility management on buildings being replaced by drones. A lot more body scan machines could help to clear a higher number of passengers in less time.

Referring back to the airport app, airports are currently attempting to counter the fierce competition by entering into cooperation agreements with their retail business partners. By establishing joint ventures in the development of the airport app, they aim to ease the joint use of the airport app by customers at several airports. Examples are the airports in Singapore, Dubai or Paris. In the future it is required to apply commercial airport models. The case company Fraport AG is already working on exclusive commercial offers (e.g. extended Porter Service) in order to respond to such societal demands. Nonetheless, International Air Transport Association's (IATA) already works on an alternative solution that does on facilitating the efficient and smart use of existing capacity, space and buildings: Project NEXTT means 'New Experience in Travel and Technologies'. It covers off-airport activities, advanced processing of passengers and goods as well as the implementation of interactive decision-making models. Customers and their feedback and needs are required to be collected and managed in order to improving processes towards a more digital and hence more efficient way of working (Garcia, 2018).

6 Conclusions

With the knowledge derived from conducting interviews and surveys it can be concluded that deviating perceptions exist when it comes to digital entertainment and the adjustment of shopping facilities. This is a hint to a lack in knowledge management and information sharing activities since passengers do have the right channels to articulate their needs.

A special focus has to be laid on expecting passengers to increasingly take over responsibility for certain activities with their electronic devices. This require a self-explanatory and easy to use connectivity and data processing.

A shift of personnel away from tasks that can be performed by smart devices (machine learning, robotics, automation) and towards process support where technology takes over is much more likely to lead to savings and competitive advantage.

Further, analysing the different generations or age groups could reveal which generation is mostly present at the airport. The focus on specific needs and expectation could be rearranged to better respond to most important and urgent requirements. Linked to knowledge management this can be a real value-add in today's organisations.

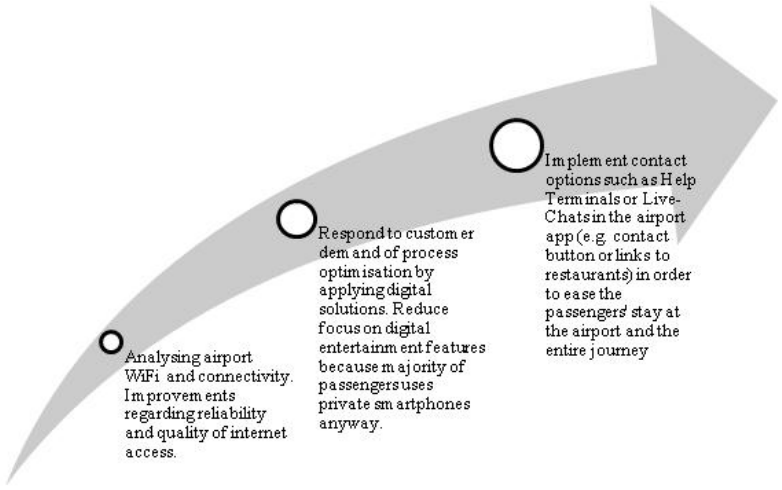

Figure 4: Potential action plan for airports

Since this study is limited to one case company it would be interesting to expand this research to compare the performance of airports on an international level, especially the more developed digital maturity of Far East airports for example. An investigation of passengers' experiences regarding the differences of airports such as Dubai or Qatar compared to German or European airports could reveal different results.

Abstract

In this paper, we share our experience in applying Design Science Research (DSR) for knowledge management and knowledge transfer in the context of source water protection (SWP) in the province of Quebec, Canada. This research is motivated by the challenges, faced by various stakeholders, of implementing Quebec's new provincial regulation for SWP, adopted in 2014. In fact, SWP implementation is complex due to multiple stakeholders, multiple jurisdiction levels, complex tacit and implicit knowledge and external factors (social, environmental, political contexts). Our goal as university researchers is to contribute to improving the general understanding of Quebec's water governance and to facilitating the knowledge transfer in environmental decision-making processes. In order to attain our goal, we focused on designing a knowledge-based decision support system (DSS) prototype using Case-Based Reasoning (CBR). The methodology included a

survey and interviews with over 200 respondents in order to identify knowledge sources, gather and structure knowledge and capture the requirements for a DSS.

Keywords – Design Science Research, Source Water Protection, Knowledge Management, Decision Support System, Case-Based Reasoning

Paper type – Academic Research Paper

1 Introduction

As *"an educational institution designed for instruction, examination, or both, of students in many branches of advanced learning"* (Oxford University, 2020), universities have always been a place to learn where knowledge is created and shared. From a knowledge management (KM) perspective, universities are seen as knowledge creators through three main functions: the education of students, the development and sharing of research, and their participation in social and economic development. This has led to the concept of entrepreneurial universities (Hermans & Castiaux, 2007) that emerged in a context where universities have new responsibilities to society, such as economic and social development, health service improvement, innovative technologies, etc. (Guerrero et al., 2006). Furthermore, the decrease in public research funds has forced universities to search for new sources of income by becoming involved in public-private consortiums or by developing research & development partnerships with public and private organizations. These organizations are often direct users of universities' research outcomes, including standardized questionnaires for social sciences, algorithms in computer science, new technologies in natural sciences and engineering, clinical procedures for health sciences, etc.

Unger et al. (2017) present various classifications of entrepreneurial universities including research-preneurial, techni-preneurial, inno-preneurial and commerce-preuneurial. Each of these has its own specificities that describe the interactions between the university and society. In this paper, we present an applied research project that fits within the boundaries of a techni-preneurial university. As a matter of fact, the research is conducted within a research center that focuses on applied multidimensional research, is mainly financed by public funds and is based on a strong partnership between stakeholders, be they researchers, public, associative or private organizations. Our project's focus is on a real decision-making issue through which the university can have a real impact on society, namely source water protection (SWP).

Since water is an essential resource for both ecosystems and human activities, the UN has adopted, in 2015, the Sustainable Development Goal (SDG) No. 6 for "Clean Water and Sanitation". Along with 16 other SDG aiming to promote a global framework for sustainable development, SDG nº6 sets ambitious targets for water pollution prevention (target 6.3), integrated water management and local stakeholder participation (targets 6.5 and 6.b) (UNESCO—IIWQ, 2016). However, in practice, the implementation of this SDG poses a major decision-making challenge since it is bound to involve several

stakeholders, decision-making levels and mobilize multidisciplinary knowledge. The complexity of this issue led our research team to formulate the following research question in the context of Quebec Province, Canada:

As academics who depend on public funds intended to help society, how can we help break down silos and bridge gaps within and between organizations (public, private) and contribute to knowledge transfer and exchange among stakeholders involved in source water protection?

The research presented in this paper was conducted within the Design Science Research (DSR) paradigm, a research approach for problem solving that has been widely used in information system (IS) research (Baskerville et al., 2009; Carlsson, 2007; Goos et al., 2010; Johannesson & Perjons, 2014; Peffers et al., 2007; Pirkkalainen, 2015). It focuses on the design and development of artifacts (algorithms, human/computer interfaces, design methodologies [including process models] and languages) with the explicit intention of helping people fulfill their needs (A. Hevner & Chatterjee, 2010). We illustrate our experience with DSR in the context of the collaborative environment of our research center which aim is not only to build bridges between researchers and stakeholders, but also, between the organizations.

This paper is structured as follows: in section 2, we present the background of our research and describe our research design, along with a situation portrait of the knowledge available around water management in Quebec. In section 3, we explain the methodological choices behind the development of a case-based reasoning (CBR) prototype as our knowledge-based decision support system for source water protection. In section 4, we discuss our experience of collaborations between research and practice as well as the influence of academics on decision-making processes as knowledge creators, knowledge organizers, and knowledge sharing facilitators.

2 Background

In Canada, while spatial planning is under the exclusive jurisdiction of provinces and territories (OECD, 2017), jurisdiction over water is shared between the federal, the provincial/territories and municipal governments (Canada Water Act [R.S.C. 1985, c. C-11]). To address the potential threats to water quality from anthropogenic activities, the federal and provincial governments created a multi-scale committee: The Federal-Provincial-Territorial Committee on Drinking Water of the Canadian Council of Ministers of the Environment (CCME). This committee has adopted, in 2002, a multidimensional approach to ensure safe, secure and reliable drinking water from the source to the citizen's tap (Federal-Provincial-Territorial Committee on Drinking Water [Canada] et al., 2004). One of the components of this approach is source water protection (SWP) that seeks to (1) reduce public health risks, (2) reduce drinking water treatment costs, (3) maintain or improve water quality, (4) protect aquatic ecosystems and adapt to the effects of climate change (Federal-Provincial-Territorial Committee on Drinking Water [Canada] et al., 2004; Quebec's Metropolitan Community [CMQ], 2016). To

achieve these goals, it is essential to acquire knowledge about the state of the resource (water quality monitoring), the associated territory (delineation of watersheds and aquifers) and the various natural or anthropogenic activities that could alter water quality (inventories of land uses and contaminants, vulnerability evaluation, risk analyses, etc.).

Furthermore, in order to integrate SWP into spatial planning and water regulatory frameworks, and thereby allowing stakeholders to act within the territory, the Government of Quebec adopted in 2014 the *Regulation on water withdrawal and protection* (Environmental Quality Act [EQA, chapter Q-2, r. 35.2]). However, implementing SWP entails some decision-making challenges du to water governance issues. Water governance, which refers to the "decision-making processes by which water is managed" (De Loe & Kreutzwiser, 2007 in McGregor, 2012), is a complex environmental decision-making process characterized by multidimensional factors including economic, political, ecological, cultural, and social factors (Ekroos et al., 2017; Kiker et al., 2005). Also, the decision-making process is multi-level, involving the national, regional and local levels (Elsawah et al., 2015) with multiple stakeholders having different values, powers, agendas and objectives (Martínez-Sastre et al., 2017), as well as possibly competing interests (Ascough et al., 2008). A real example of such a complex decision-making issue directly related to SWP is a case where a watershed organization projects to plan a protected area on a municipal agricultural land along a river to protect its water quality. The watershed organization must deal with the city, that prefers to sell the land to a real estate developer in order to raise recurring municipal taxes. In doing so, the city will also have to deal with non-profit organizations and regional authorities that support the watershed organization's project, organizations that promote agricultural activities because it is an arable land, as well as local resident groups that may be opposed to a real estate project. All these stakeholders create, share and use a diversity of knowledge (know-how, technical expertise, as well as their local knowledge) in order to support their interests. In this type of situation, water management issues require a wide range of interdisciplinary knowledge (such as politics, economics, biology, chemistry, etc.) (Medema et al., 2015, 2017; Orr et al., 2016; Tengö et al., 2014). However, stakeholders do not necessarily share their individual knowledge (Elsawah et al., 2015), or use it to its full potential (Kirchhoff et al., 2013) due to a possible lack of mechanisms for better access to or understanding of the knowledge created (Jager et al., 2016). This context could explain why organizational responses to environmental issues remain uncoordinated and difficult to achieve (Baechler, 2012; Nielsen et al., 2013).

In order to help address some of these challenges, our aim in this project is to promote the integration of source water protection by facilitating the knowledge transfer in environmental decision-making processes. In the next subsections, we describe the research design, provide methodological context and give an overview of the knowledge created for source water protection in the province of Quebec (Canada).

2.1 Research Design

As a means for knowledge transfer, we chose to design an information system (IS). IS can play a significant role in sustainable development by effectively providing knowledge to solve environmental problems (Brocke and Siedel in Peffers et al., 2012). From a methodological point of view, our research is conducted according to the DSR principles, which provide a rigorous cycle for developing an artifact (a usable research outcome) and promote research as a response to real-world issues (A. R. Hevner et al., 2004). This requires involving the stakeholders in the problem definition and the design of the functionality of the artifact (Johannesson & Perjons, 2014). DSR is centered around two main components: a research entry point and the various activities conducted to develop an artifact.

A DSR process may be initiated from four possible research entry points: Problem-centered initiation, objective-centered solution, design and development-centered initiation, and client/context initiation (Peffers et al., 2007). Our project has a problem-centered initiation research entry point, as it was defined within the context of the new Quebec regulation for SWP and the stakeholders' need to have access to water-related knowledge in order to implement this regulation.

We follow Peffers et al.'s (2007) design science research methodology (DRSM). This methodology is based on 6 activities (table 1) translated into an iterative process (figure 1) based on A. R. Hevner et al.'s (2004) work on DSR mental models.

Table 1—Activities of DSR

Activities	Description (based on Peffers et al., 2007)
1. Problem identification and motivation	Define the specific research problem to justify the value of a solution and to develop the artifact that can help provide a solution to the problem.
2. Define the objectives for a solution	Identify a solution from the definition of the problem, the knowledge of the problem and the feasibility of a solution to the problem. The choice of the type of the solution is to be defined in this activity.
3. Design and development	Develop the artifact by determining its functions and architecture, and then designing it.
4. Demonstration	Demonstrate the relevance of the solution proposed as an answer to the problem for which the artifact was developed. This can be carried out in a variety of ways such as experimentation, simulation, etc. Knowledge of how to use the artifact to solve the problem is necessary. This implies that users who test the artifact need to be trained.
5. Evaluation	Observe and measure the relevance of the solution proposed by the artifact. This can be done by comparing whether the solution meets the objectives identified in Activity 2, conducting a satisfaction survey, or objectively measuring the impact (if quantifiable) of the use of the artifact. If the objectives are not met, researchers may decide to repeat Step 3 to improve the artifact or leave it for future projects.
6. Communication	Communicate the overall DSRM process to the partners, stakeholders, users and the research community.

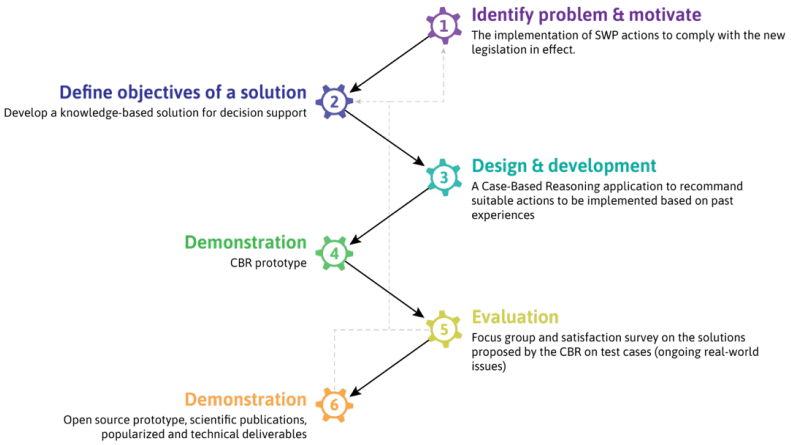

Figure 1 — Our DSRM adapted from Peffers et al. (2007)

2.2 Water Management in Quebec: A Portrait

The first step of our methodology was to draw a picture of the current situation in Quebec (intelligence gathering). We needed to gather knowledge to improve our understanding of Quebec's water management framework by identifying the decision-making challenges around water management and the implementation of SWP. To do so, we used an exploratory and descriptive approach based on the research survey methodology (Nardi, 2018) where we gathered data using an online survey. The complete methodology of this survey is described in Cerutti et al. (2020). Three dimensions were portrayed within this survey: 1) The profile of the stakeholders currently involved in water management; 2) the current knowledge created and shared in order to implement SWP; and 3) the decision-making processes followed by the stakeholders to implement SWP. In the final section of the survey, we also asked respondents to describe the decision-making problems they have faced in the past or are currently facing. Because our research center has strong ties to practice, we were able to count on a wide collaborative network to maximize the response rate of our survey by including important stakeholders in Quebec's water management such as: the Ministry of Environment and Fight Against Climate Change (MELCC); the Ministry of Municipal Affairs and Housing (MAMH); the Quebec Water Research Center (Centr'eau); The Quebec Groundwater Research Network (RQES); the NSERC Industrial Research Chair in Drinking Water (CREPUL) and Quebec's Watershed Organizations Association (ROBVQ). The survey was accessible from November 2018 to March 2019 and resulted in 208 completed questionnaires. The large majority of the respondents (n=154) belong to a governmental agency (ministries or regional bureau) or a local government (regions, cities). The remaining stakeholders (n=54) belong to parapublic (independent governmental agencies) or non-governmental organizations such as private companies or non-profit organizations (trade unions, watershed organization and environmental associations). The results of the survey

revealed a complex water governance framework where responsibilities are multi-scale and can be either shared or exclusive. The survey brought to light the presence of a set of public, private or parapublic stakeholders (including universities and research centers) that surround decision-making (Figure 2).

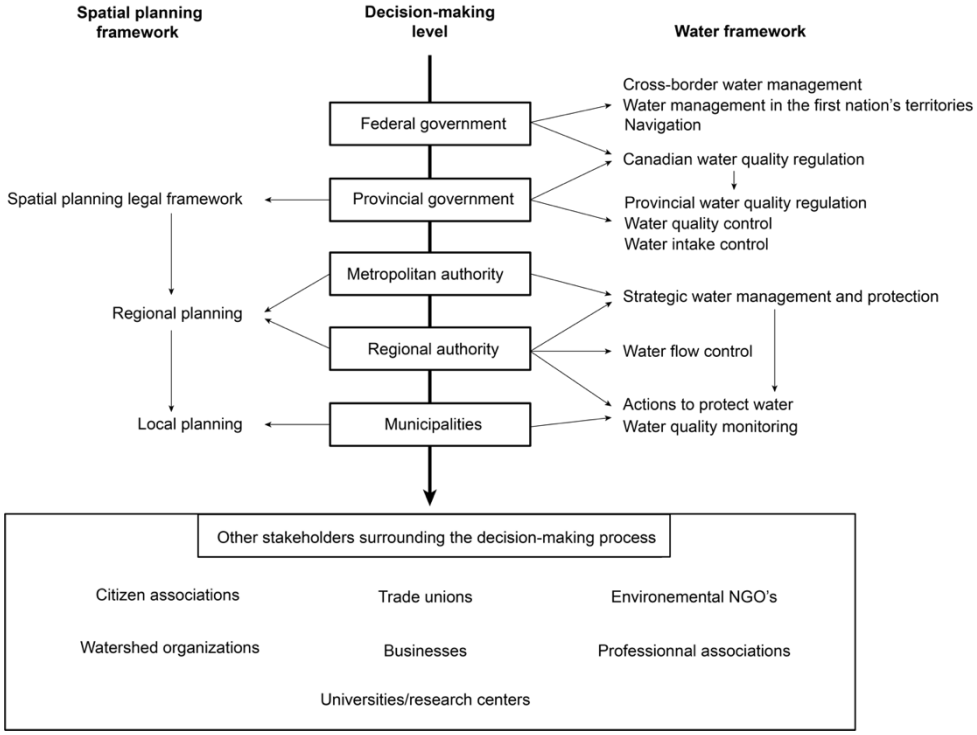

Figure 2—Overview of Quebec's water management in a decision-making context

The results of the survey also provided an overview of the knowledge available for decision-making when it comes to protecting source water. Based on more than 4000 answers from open-ended questions, we were able to structure the interorganizational knowledge by topics and subtopics using qualitative data analysis. By doing so, we contributed to the improvement of the general understanding of the available interorganizational knowledge that can be used for decision-making. We found that this complex water management framework comes with a great diversity and redundancy of knowledge (both in their forms [dataset, guides and reports, know-how] and their scale [local, regional and national knowledge of the territory]) (Table 2).

Table 2—What knowledge do we have and who produces it?

KNOWLEDGE TOPIC	SUBTOPIC	STAKEHOLDERS INVOLVED IN KNOWLEDGE PRODUCTION BY SCALE							
		Local	Regional		National				
		Municipalities	Regional authorities	Watershed Org.	Federal gov.	Provincial gov.	Private companies	Environmental asso.	Professional asso.
WATER RESOURCE	Territorial availability of water	X	X	X		X		X	
	Groundwater	X	X	X	X	X	X		X
	Surface water	X	X			X	X		
	Rainwater	X	X	X		X		X	
	Waterflow		X						
ANTHROPOGENIC	Municipal wastewater	X	X	X		X			
	Individual wastewater	X	X	X		X		X	
	Forestry impacts	X						X	
	Agricultural impacts	X	X	X		X		X	X
	Land-uses description	X	X	X	X	X	X		
	Water catchment	X	X			X	X		
	Water consumption	X	X	X		X			
ENVIRONMENTAL	Invasive species	X		X				X	
	Climate change					X			
	Wetlands	X	X	X					
	Erosion and sedimentation	X	X	X			X	X	X
	Flood-risk area	X	X	X					

Our results did not include knowledge production by universities since, surprisingly, no university researcher responded to the survey. This may be related to a limitation of our survey, as we focused the survey on the implementation of SWP and researchers may not have felt concerned by implementation issues. However, further analysis of the documentation available (reports, case studies, presentations, etc.) showed that universities are involved with all the topics and subtopics identified in the survey. Furthermore, open-ended questions allowed us to gather some clues about knowledge transfer issues that were faced by the stakeholders when it comes to the research versus practice dynamics. These are related mainly to the costs for accessing scientific

knowledge: “Scientific studies … sometimes with costs” and “Events … such as symposium with high registration fees” (Respondent 25); “Scientific papers only available under subscription for. e.g. publishing editors” (R.97). In addition, issues of language[1] in scientific knowledge (published in English) or support in understanding knowledge (overly technical language) were also raised by some respondents: “The translation of scientific studies.” (R.97); “Statistical studies … difficult to interpret” (R.25); “Accessibility and uniformity of reference data” (R.34); “Popularization of research/data to enable its ‘good’ use” (R.56); “Use of the results of the groundwater study” (R.140); “Meaning of scientific results of water analysis” (R.193).

3 A Case-Based Reasoning Application to Share Knowledge for SWP

The second step in our DSR methodology, which follows knowledge gathering and structuring for SWP decision-making, is to build a tool that can facilitate the SWP implementation by improving knowledge transfer between the stakeholders. To achieve this objective, we need a tool capable of managing multi-scale and multi-stakeholder knowledge transfer. For this reason, we focus on decision support systems (DSS), computerized information systems developed to improve the decision-making process (Gourbesville et al., 2016) by facilitating the organization of knowledge (Alyoubi, 2015). More specifically, we will use an environmental decision support system (EDSS) approach. This concept was defined by Rizzoli & Young (1997) as “DSS developed for use in environmental domains that integrate models, or databases, or other decision aids, and package them in a way that decision makers can use”. The main advantage we see in using an EDSS approach is to achieve a greater collaboration between research and practice. Indeed, the design of the EDSS invites researchers to involve end users and sets some objectives to be attained such as the ability to support policy and management decision-making, to cope with uncertainty, with a special attention to underlying software capabilities such as transferability, scalability and ease of maintenance (McIntosh et al., 2011).

Several types of DSS are reported in the literature that focus, to varying degrees, on five types of elements: communications, data, documents, knowledge and models (Alyoubi, 2015; Gourbesville et al., 2016; Power et al., 2015). Our project is centered around knowledge and uses knowledge-based DSS (KB-DSS). Liu et al. (2015) describe four approaches to a KB-DSS: Rule-Based Reasoning (RBR), Case-Based Reasoning (CBR), Network-Based Reasoning (NetBR) and Narrative-Based Reasoning (NBR). The main difference in these approaches is the way knowledge is gathered, structured, stored and used by the system. RBR uses decision rules to identify causal relationships in various decision environments. CBR uses subsets of similar or most reusable experiences previously encountered to solve a problem. NetBR uses probabilistic inference engines such as Bayesian networks or artificial neural networks. All three of them deal mainly with structured or semi-structured knowledge. In particular, NBR uses specific linguistic

[1] *The Quebec population is mainly French speaking, and its official language is French*

algorithms to identify hidden knowledge in unstructured narratives (stories, report, records, etc.).

In order to choose the most appropriate approach for the design of a KB-DSS prototype, we focused on its end use: decision support for implementing SWP. To this end, we collected data on the decision-making problems encountered by stakeholders in our survey (presented in section 2.2). The open-ended answers showed a great diversity of problems such as pollution from various types of contaminants (hydrocarbons, nitrates, iron, manganese, sediments, microorganisms, invasive species, etc.) or source water scarcity (illegal dams, climate-related droughts, or conflicting human uses [residential vs. agricultural vs. industrial]). Most of the problems identified are complex and ill structured and some may have repercussions that last for decades (e.g. a contamination from a crop field). Furthermore, they are context-dependent (because of the geographical specificities of each problem), involve or have involved different stakeholders over time, and are strongly influenced by the political factor, can make knowledge expensive (for example between governmental departments that have to pay a high price to exchange data and knowledge) and, above all, making knowledge confidential.

In light of our survey (and subsequent interviews conducted with some of the stakeholders), we chose to use past decision-making experiences as knowledge transfer opportunities to solve current problems, as they provide accessible (publicly available) knowledge and concrete examples of problem solving. This led us to exclude NetBR because we could not gather enough data. We also excluded RBR because no explicit rules could be identified, and we excluded NBR because the end users of our prototype come from different organizations and do not have the same language (expert vs non-experts). Consequently, we focused on CBR to design our prototype. CBR consists of a problem-solution (case) combination in which similarity of the current problem to past (solved) cases is computed based on a problem's attributes, i.e., their characteristics (Richter & Weber, 2013). This approach, considered to be very close to human reasoning (Richter & Weber, 2013) encourages learning from past experiences (Lamontagne & Lapalme, 2002). A CBR process consists of four phases: retrieve, reuse, revise and retain (Aamodt & Plaza, 1994). This process allows CBR systems to acquire knowledge (from user-introduced experiences) and reuse it by identifying all the main components of the problem-solving process (what were the objectives and resources available, who was involved, what knowledge was used, etc.). To illustrate how we plan to apply CBR, we use the following real-world decision-making issue identified in the survey. A municipality D is faced with water contamination by hydrocarbons in the intake of its drinking water plant (raw water). Based on the description of the problem (contamination by a chemical pollutant: hydrocarbons), and its context (such as the size of the city, the source water type, etc.) the CBR system can use its case base to identify that municipalities A, B and C faced a similar water problem in the past: the *presence of contaminants* (*hydrocarbons*) in the *intake of their drinking water plant*. Also, we learn that as a solution, municipality A decided to use an additional water treatment process

(biological activated carbon). Municipality B decided to issue a drinking water advisory (to not consume drinking water) and Municipality C used both solutions.

In order to gather the knowledge needed to construct our case base for the CBR KB-DSS, we used both answers obtained from the survey's respondents (in the survey and in subsequent interviews) and a web inventory of water-related actions elaborated by the Quebec Watershed Organization Association. The first model of our prototype contains attributes for computing similarities between current and past problem based on problem situations (such as water bodies description, territorial description [anthropogenic activities, distances, etc.] and decision-making context [stakeholders involved, knowledge available, etc.]). Since we gathered both quantitative and qualitative dimensions, we will be using a multi-criteria similarity measure. It should be noted that this CBR prototype is being designed, and will be validated, with the participation of an end-user group composed of stakeholders from governmental/parapublic and NGO experts, as described in section 2.2. Finally, tests will be carried out to evaluate and validate the relevance of the recommendations of the CBR approach for SWP actions.

4 Discussion and Conclusion

Through this research project where our aim is to design a case-based reasoning prototype as a knowledge-based decision support system, we see an opportunity for research to bridge practical knowledge gaps between organizations by sharing lessons learned and overcoming knowledge sharing issues (such as redundancy, confidentiality, cost or language).

This project highlights the multiple role of the university as a knowledge creator, knowledge organizer, and facilitator for knowledge sharing. First, universities are involved in knowledge creation to solve environmental problems. Second, universities can observe and explore dynamics between organizations and improve the understanding of decision-making processes. Third, universities have evolved in an entrepreneurial model that encourages researchers to be involved in guiding and improving decision-making processes by using techniques (such as designing KB-DSS, Multicriteria decision analysis processes, etc.) in private companies or public administrations. This research therefore illustrates how universities can bring together decision-making levels and various stakeholders by breaking existing silos between organizations in public, parapublic and private environments. In such a context, the university has the needed legitimacy to provide solutions to societal problems by remaining neutral and promoting dialogue between organizations in order to achieve a common goal: the protection of water.

Notwithstanding the many good intentions motivating collaboration between research and practice, many hurdles still exist. For example, it is increasingly difficult to transfer knowledge between science and practice due to the prerequisites of scientific publication that render research results inaccessible to practice. Some of the reasons cited by the respondents to our survey include the costs of scientific publications or an overly

scientific and methodological vocabulary. Second, as researchers developing this tool, we face the difficulty of transferring our tool to the main end users (public and parapublic stakeholders), due to several reasons related to the costs, the lack of material, administrative requirements (confidentiality or intellectual property for example) or the risk of implementing a tool that has not yet proven its mid/long-term effectiveness. Also, the issue of maintenance and training is a tricky one in public/parapublic contexts as they may not have the technical resources to maintain such a tool. It therefore might be easier to transfer research results to the private sector instead of the public sector, even though most of the research is publicly funded. The irony is that the public sector might ending up having to pay twice for the same product: once for the research and once again to acquire the research results from the private sector. This, in our opinion, is one of the main challenges facing the success of knowledge transfer from university to the public sector. How to ensure the usability and long-term viability of the knowledge products disseminated by university?

Logical Connections between Stakeholders' Expectations and the Development of New Education Programs

Maria Franca Norese

Department of Management and Production Engineering
Politecnico di Torino
Corso Duca degli Abruzzi, 24 – 10129 Turin

Abstract

A two-way dialogue between universities and public and private organisations, in the context of stable relationships and collaboration, enhances their processes and orients research and education programs.
Different mechanisms can be used to create and exchange knowledge but in practice some of them are not always feasible. For this reason, some specific approaches were implemented at the Politecnico di Torino.
The paper presents the main practices of knowledge exchange and share between this university and the territory stakeholders that were involved in the education process in the past. Now the COVID-19 emergency forces all of us to re-think procedures and processes on the basis of a solid past experience, a networking approach to the problem and the aid of the digital transformation tools.

Keywords – Knowledge creation, Cognitive mapping, University-industry collaboration, Higher education, Management engineering

Paper type - Practical Paper

1 Introduction

Stable relationships, a two-way dialogue and collaboration are required between universities and public and private organisations, to create and exchange knowledge that enhances their processes and orients research and education programs.

This two-way dialogue can include different mechanisms: collaboration in applied research, programs of technology transfer, participation of enterprises as partners in a university incubator and mentors in its services for the start-ups, or as actors of career days and meetings with students.

Enterprises and public administrations host the students, who get an internship during the courses, and select them, after their degree, master degree or PhD, testing their competencies in relation with their requirements for specific (and often new) job positions.

Some enterprises become members of the advisory committees the universities create to involve the socio-economic actors of the territory. Others are involved in specific PhD programs and projects.

Good practices of collaboration are essential to create and exchange knowledge but they are not always feasible. The advisory committees always and explicitly propose their expectations, in terms of new education profiles, which sometimes are linked to interesting but not realistic visions of the university life. The advisory committee members often have a limited knowledge of the bureaucratic and economic constraints that control the university innovation processes and this fact can limit the organisation of an effective collaboration.

For this reason, a new approach was implemented some years ago, when new engineer profiles were created at the Politecnico di Torino. A set of simple tools was used to propose virtual or practical collaborations. When the digitalization processes were step by step activated, communication became always easier.

The first section of the paper presents the main processes of knowledge exchange and share, between this university and the stakeholders that are involved in the education process in the territory. Some processes started in the past and developed, and some of them have to be changed and improved in the present phase of the COVID-19 emergency. The second section describes an analytical procedure that started to be used some years ago to acquire knowledge from the stakeholder expectations, and its use to improve education and the relationships between the actors of the generated network. Some remarks on how the digitalization process, which has changed the university administrative procedures, can stimulate new dynamics of knowledge acquisition and sharing are proposed in the conclusions.

2 Processes and tools of knowledge exchange

Collaborations between university and industry, but also non-profit organisations, government and, in general, the territory, are studied, above all in terms of effectiveness of these interactions, needs and desires in the different contexts and impact on the academic research productivity (see for instance Agrawal, 2001; Charles, 2003; Perkmann et al, 2013; Garcia et al, 2020). Joint research centres of the university and industry, European research projects that always include university and other organisations, research spin-offs and university spin-out companies are some examples of the growing interaction and knowledge exchange between university and territory.

Another kind of university-territory collaboration is oriented to create a shared knowledge on the competences that an educational system should develop and a work context needs, to improve the processes and generate innovation (see Aasheim and Li, 2009; Schneider-Störmann et al, 2020). Sometimes, a clear picture of the work practice is not present in the academy, while the students perceive their future work in technological contexts that are not often available in practice.

When the management engineer profile appeared in Italy, it was so new that most of the enterprises did not understand the nature and potentiality of this technical profile.

The students, getting an internship or working on true problems to write their theses, became the main channel to present the innovativeness of the new profile to enterprises or public administrations. Students and new graduates sometimes became the stimulus and stakeholders of innovation processes.

A set of simple tools was used, in the last ten years, to create a continuous and structured link between the Politecnico and its territory and to exchange knowledge about innovative technologies and specific work environments that are mainly oriented to innovation. Two questionnaires, one for the students and another for the host organizations, had always to be filled, but they can only be useful to detect the very few critical situations. An e-mail, sent every year to thank all the old and new organizations that have hosted our students, turned out to be more useful. A frequent result was a call from the new host organisations to confirm an actual interest in a stable relationship, but also to inquire whether the management engineering students acquire some specific competences and/or can use them in contexts where in general the engineers are not present (while there is a predominance of jurists, economists or psychologists).

The same e-mail was used to announce and describe another occasion of knowledge exchange, a meeting at the Politecnico to allow the students (and teachers) to connect with the host organizations. Internship opportunities and thesis projects became the occasion to better know each other. The number of the participants increased every year, from a two days meeting we passed to a three days, while in 2019 a multiplicity of different meetings was organized, in relation to each different engineering branch.

More than 2500 students of the Politecnico get an internship every year and more than 500 tutors, in the host organizations, are contacted every year from the College of Management engineering. When the number of students getting an internship became sufficient to list more than 300 education projects in the College of Management engineering, a new analytical approach was implemented, in order to obtain and organize knowledge from this process and to use these elements as inputs for the development of new courses or the inclusion of these stimuli in the previous education programs. This analytical approach is described in the next section, together with some results.

On-campus company presentations became very frequent, not specifically for recruiting (the Career days are more oriented to it) but to involve teachers and students in innovative projects, or in change management processes, by means of a formal collaboration with the Politecnico.

The digitalization processes allowed the direct access of the enterprises to the web portal www.polito.it. The career services of the Politecnico di Torino put students and graduates in contact with the labour market through the creation of direct relations between the university and companies. Thanks to tailor made strategies and the consultancy of Carrier service staff, companies can choose and modulate various recruiting and employer branding tools. Contact and selection of the profiles that best suit the recruitment needs are facilitated by an online access of the companies to a list of

potential preselected candidates, while a direct contact is possible in recruiting events. Targeted communication plans with partner companies are built using tools, such as direct mailing, university web site, electronic monitors, social networks. Targeted actions are implemented inside the Campus to help any specific company to communicate its employer branding strategy and attract the requested profiles. The Career service team, which meets new employers every day, can guide them in understanding the university context and the procedural complexity of the different activities. The team guides the companies in exchanging the knowledge, of the course catalogue of the university and the career paths in the enterprises, to identify services and activities the students and graduates can carry out.

In addition to the digital media, a direct communication between any host organization and the team in charge of the internships for a specific College is facilitated by a good relationship between the teams of the different Colleges of the Politecnico. An effective network was created and any request of an engineer profile that is not so consistent with the branch of a College or a specific contact with experts is immediately re-directed at the team of the correct College. The network involves some central services (above all the Career service and the ICT service) and the Rector's Delegate for Alumni and Career orientation, together with the most active teams (Automotive, Aerospace, Electronic, ICT, Mechanical and Management Engineering). The main external to the university actor is the Public administration, above all the Regional Government, together with all the private and public host organisations.

The role of this network is even more important now, when every day university and Regional Government have to negotiate the action space. The COVID-19 emergency changed our work and the communication processes. Urgent decisions transformed the life of the Politecnico at the end of February 2020: remote work and online lessons and laboratories. Some events were postponed and others cancelled. Any direct contact between the Politecnico and its territory became impossible.

Now the situation starts to change, the next 10th of June the students can activate new internships and work in presence and not only remotely. New events are presented on the site https://careerservice.polito.it/, and include virtual presentations, visual storytelling experiences and courses on the firm's platforms, but also the first recruiting days of some enterprises at the Politecnico.

Clearly, the conditions of any work environment have to be changed and this may be an important occasion for our students. The network is studying a new and coordinate way of contacting the enterprises and proposing a direct connection where the enterprises indicate their needs and the students, with the aid of their academic tutors, design specific answers to their requirements. In this new situation, the network coordinates the work and creates relationships between students and tutors of the different Engineering Colleges. This project can be an important answer to the urgent needs of some enterprises and, meanwhile, an occasion to analyse how new education programs can include the new expertise.

3 How to acquire knowledge from the communication between the Management Engineering College and territory

Each student getting an internship works in relation to a formalized Education project. An internship has, as a first aim, the possibility of knowing real production processes and seeing which are the main dynamics of the true organisations. The students of Management engineering start working in relation to the declared Education project but often pass from an activity to another, because of (and thanks to) their non-specialized competences.

Therefore, the team in charge of the internships for the Management Engineering College explains to the students that an Education project is sometimes the indication of a specific need of a host organization and not a plan for a project, and that often an enterprise postpones the decision on a specific task because of the versatile nature of their profiles. Meanwhile, this high number of formalized Education projects allows a deep analysis, to identify which competences the host organisations aim to find in our students, to verify if there is correspondence between our education objectives and the profiles the host organisations need, and to obtain information on specific requirements and organize and use these elements of knowledge in the internal education processes.

An analytical approach was implemented for the first time when the number of formalized Education projects of a specific academic year (2014-15) was 300, all in relation to the students of the bachelor course in Management engineering. They were analysed manually by means of a cognitive mapping approach (see for instance Eden, 2004). The texts were analysed and their number was reduced to 185, by means of the elimination of texts that only included long lists of tasks without any description of a project, or an indication of an enterprise department or a specific activity without any definition of an education project. The texts were synthesized by means of the elimination of useless elements, such as the descriptions of the host organisations, and coded. A first tentative code was defined in relation to a distinction of the Education projects into two main clusters, in relation to our two paths of the bachelor course in Management engineering (industrial specialization or computer science), plus a cluster of generic requests.

At this point, a new textual analysis of the data was implemented. Any recurring word, concept or sector was identified and used to define another coding element, the “ambit of work”. Some examples of “ambit” are logistics and accounting office, or acronyms such as SAP, CRM or WCM, or tasks such as data analysis, client portfolio management or inventory handling.

More than one ambit was sometimes identified in relation to the same Education project. When a clear ambit was not identified, a warning was associated with the project, and the same warning was used when a project description was present but incomprehensible. After this first coding activity, the results were analysed by the complete team and some difficult interpretations were clarified. An iterative process was activated because any new interpretation of a project ambit often changed some codes of

other Education projects. In relation to the most complicated interpretations, a direct contact with the academic tutor of the student in internship allowed a clarification.

After these activities of data testing and coding, the Education project texts that resulted associated with the same specialization (industrial, computer science or non-specific) and ambit (or ambits) were grouped and re-analysed. A logical similarity between components of a group was defined and used to link them, translated in conceptual nodes of a logical graph (Norese and Salassa, 2014). A lot of graphs were created and comparatively analysed. Several analysis steps of the team reduced the 18 graphs to 12 (8 for the only industrial specialization) and then to 7 macro typologies of internship, in two cases with a limited correspondence with the competences acquired in the courses.

These results were used to better define the aims of some courses and their programs, and to clearly describe the management engineer professional profiles in the institutional documents and presentations for Open days and other events.

The analytical approach activated some years ago is becoming an annual procedure that aims to create and update a knowledge base that informs the College on which are the expectations of the territory stakeholders, in order to combine these expectations with the education objectives of our courses and to re-orient some of them towards new competences.

This analysis can be facilitated by machine learning techniques, such as Topic Modeling (Papadimitriou et al, 1998) or Probabilistic Latent Semantic Analysis (Hofmann, 2000), that the team is testing now, by means of some algorithms applied to 1799 Education projects, that is the total internship number of the last four academic years, which includes students of the Bachelor or the Master in Management Engineering.

4 Conclusions

University and multi-stakeholder partnerships can be facilitated by a dialogue that uses the digitalization approaches and processes as important tools. But the dialogue has to be generated, fed and improved by practises of networking, at different levels, both internal to the universities and in interaction with the territory stakeholders.

Knowledge can be obtained, used and shared in the networks that involve universities. The main result is a learning process that involves different stakeholders and produces a continuous upgrade of the university system, in terms of programs of the courses but also procedures, which have to control any risk without bureaucratise the processes, and a new language that generates a local and effective culture.

The COVID-19 emergency limited the knowledge exchange dynamics and heavily impacted any process. But the present constraints could and should become a new occasion to create and share knowledge. A quick development of the digitalization processes allowed the activation of several internships in remote. The word that was used to define these situations is “smart working”, but the next months should be used to understand the actual nature of these smart works, not only for the internships but also for

our society that adopted this way of working as the only urgent answer to the pandemic lockdown.

At the same time, the internal procedures of a university changed and only a parallel use of different communication tools allowed the decision process development in the last months. The questions become: how can these new dynamics improve internal and external communication, and are these tools something that slows down any decision process and makes the work heavier than in the past, or an important occasion for the future? There is a wide research space for all of us.

Abstract

The UNESCO site "Ivrea, industrial city of the 20th century" is a large urban area designed and developed under the leadership of Adriano Olivetti. It consists of more than 100 private buildings, valuable examples of Modern Heritage, and more than 60 elements related to public and private infrastructures and green areas. Currently the whole site necessitates to be redeveloped: the assets are mostly unused or underused and the streets and green areas condition does not foster the acknowledgment of the site's value, as well as its accessibility and enjoyment. Its enhancement and future management is a great challenge for the Municipality of Ivrea and a dynamic GIS developed, improved and implemented by the Politecnico di Torino over the last few years may effectively support this delicate phase. The aim of this paper is to highlight how the activation of a knowledge exchange process between the Politecnico di Torino and the Municipality of Ivrea may support the sustainable economic development of the Ivrea UNESCO site. In particular, it wants to demonstrate some potentialities of the GIS not only for the Knowledge Management, but also for the cost management of a series of redevelopment projects concerning both the buildings and the grey and green infrastructures of the UNESCO site. The redevelopment projects of streets, squares, car parks and public green areas constitute urgent and priority actions that the Municipality may quickly and directly activate in parallel with the ongoing mediation process with the buildings' private owners and other territory stakeholders. The positive impacts that the redevelopment of these infrastructures could generate go beyond the site's enhancement. Their improvement is able to foster the real estate market trends, supports the economic operators that currently operate in a rather fragile context and produce benefits for all the citizens (in terms of increase of the welfare, urban services equipment and the environmental condition).
The Municipality of Ivrea could steer numerous strategic actions in this direction by investing in public projects able to generate positive impacts on the community. To achieve this important and

ambitious goal, a knowledge exchange process should be activated between the Municipality of Ivrea and the Politecnico di Torino, which aims to be ever more proactive in its third mission activities, to further customize the current version of the GIS. By this way, the case of Ivrea could become a best practice of territory sustainable development and an example of fruitful collaboration between Public Administrations.

Keywords – Knowledge Management (KM), Geographic Information Systems (GIS), Economic-financial sustainability, grey and green infrastructures, Ivrea UNESCO site *(max 5 words)*

Paper type – Practical Paper

1 Introduction

The site "Ivrea, industrial city of the 20th century", inscribed in the UNESCO World Heritage List since July 2018, is a large urban area designed and developed under the leadership of Adriano Olivetti, in order both to expand his typewriter company and to create a model of a modern industrial city. It consists of more than 100 private buildings, valuable examples of Modern Heritage, and more than 60 elements related to public and private infrastructures and green areas. Currently the assets are mostly unused or underused, streets and green areas present lack of routine maintenance and the whole site necessitates to be redeveloped. The knowledge of the built heritage and its surroundings is rather fragmented and continuously changing, and it is hardly updatable with information about the buildings' and infrastructures' condition, transformation interventions and the subjects involved in the redevelopment processes.

The enhancement of this large unitary urban system of high historical, architectural and environmental value, represents a current big challenge for the Municipality of Ivrea, that is called upon to outline innovative governance strategies based on the constant monitoring and coordination of different redevelopment projects and by creating strategic partnerships and networks with numerous territory stakeholders and actors.

The creation, circulation and management of knowledge is an important condition for the enhancement of cultural heritage (Baca, 2003; Meyer et al., 2007; Dragoni et al., 2011; Eppich and Garcia Grinda, 2015; Sobrino et al., 2016; Soler et al., 2016;). When the analysed elements are buildings integrated in their surroundings and socio-economic contexts, the spatial dimension has to be used to support the Knowledge Management (KM). In the literature, several studies demonstrate the effectiveness of the integration of GIS in a KM finalized to the management of cultural sites (Kurtener and Badenko, 2000; Alavi and Leidner, 2001; Belsis et al., 2004; Balram, 2006; Jennex, 2008; Noor et al., 2019). A KM consists of the tools, techniques, and processes to collect, retain, analyse, organize, improve, and share understanding about data and information, and to use that understanding towards meaningful action (Wang et al., 2001).

Over the last few years the Politecnico di Torino studied the case of the Ivrea UNESCO site and designed a KM in order to lessen the issues that arise due to loss or lack of knowledge. In particular, during a Master of Science course in "Architecture for Heritage preservation and enhancement", it created and implemented a GIS, as a dynamic

system able not only to collect and visualise data at different territorial levels, but also to support the enhancement projects developed during the course (Barreca et al., 2017; Curto et al., 2018). The GIS was developed with the aim of structuring the knowledge base related to the UNESCO site, in order to:

investigate opportunities and weaknesses of the territory of Ivrea by analysing data on the physical characteristics of the built environment, as well as data on the territorial, socio-economic and cultural context;

analyse and monitor impacts and outcomes of possible redevelopment projects concerning the buildings located in the UNESCO site and the surrounding infrastructures and green areas;

support the Public Administration and the stakeholders in developing enhancement strategies, policies and actions.

Currently the Politecnico di Torino completed the knowledge structure of the GIS (Phase 1 of the KM - "Identification of Knowledge") and almost finished the implementation of a Knowledge Data Base (KDB) (Phase 2 of the KM - "Knowledge Generation"). Therefore, now it may transfer the GIS to the Municipality of Ivrea and effectively support the Public Administration in this pivotal phase for the UNESCO site enhancement and its future management (Phase 3 of the KM - "Knowledge delivery").

The aim of this paper is to highlight how the activation of a knowledge exchange process between the Politecnico di Torino and the Municipality of Ivrea may effectively support the sustainable economic development of the Ivrea UNESCO site. In particular, it wants to demonstrate some potentialities of the GIS not only for the knowledge management, but also for the cost management of a series of redevelopment projects concerning both the buildings located in the UNESCO site and the surrounding infrastructures and green areas. In this paper a particular attention is focused on the GIS potentialities in supporting the Municipality of Ivrea in the redevelopment and future management of streets, places, car parks (Elements of grey infrastructures) and public green areas (Elements of green infrastructures). In fact, they currently represent urgent and priority interventions that the Municipality may quickly and directly activate to foster the acknowledgment of the site's value and its accessibility and enjoyment (Curto et al., 2020). Moreover, it is worth mentioning the presence of the Virtual Museum of Modern Architecture of Ivrea (MAAM - http://www.mamivrea.it/), whose presence is currently not so evident in the site due to the lack of marked cycle-pedestrian routes, effective signs and suitable equipped areas. The redevelopment of the buildings of the site, which are almost all private assets, constitutes a crucial process that the Municipality of Ivrea has already started by dialoguing with the private owners and different stakeholders; nevertheless, it represents a big challenge that may be faced in parallel with the improvement of the surrounding infrastructures and green areas.

Today, the GIS developed by the Politecnico di Torino could effectively support this process, if the knowledge exchange process will be activated. The wealth of information that the KDB now contains enables a wide range of analyses finalized to describe the current situation, highlighting redevelopment potentialities and weaknesses. Moreover,

the GIS could also support future strategic development actions, such as the management of the costs necessary for the redevelopment and maintenance of the infrastructures and public green areas or the design and implementation of green infrastructure projects. The attention towards the redevelopment of grey and green infrastructures is fundamental to agree to the guidelines of the European Green Deal and to implement some principles of Green Economy and nature-based solutions (EC, 2019; Loiseau et al., 2016), By this way, the Municipality of Ivrea could concretely improve the environmental quality of the UNESCO site and, consequently, fostering its enjoyment, creating job opportunities, contrasting the negative trend of the real estate market and increasing the citizens' health, socio-economic condition and quality of life.

The paper proceeds as follows: Section 2 introduces the case of the UNESCO site "Ivrea, industrial city of the 20th century". The methodological approach is described in Section 3, while Section 4 discusses the results. The conclusions and discussion are presented in the final section.

2 The UNESCO Site "Ivrea, industrial city of the 20th century": an unitary urban system to be known, managed, enhanced and enjoyed

During the XX century Adriano Olivetti expanded the famous typewriter company founded by his father Camillo and created a model of a modern industrial city by redeveloping an extended urban area of the city of Ivrea, near Turin (Italy). His project was based on the innovative idea of "community" (Olivetti, 1945) and included not only the factory but also a series of residential buildings for the workers and managers, nursery schools, a leisure centre with playgrounds, a company canteen and a social services centre. Adriano Olivetti commissioned the works to famous architects, representative of the Italian "Modern Movement", with the idea of realizing high quality buildings closely integrated with their surrounding public spaces, green areas and infrastructures. The World Heritage Committee recognized the exceptional value of this large urban area, which in July 2018 became the 54th Italian UNESCO site, namely "Ivrea, industrial city of the 20th century" (see http://whc.unesco.org/en/decisions/7143).[1] Currently this site consists of more than 100 well-preserved buildings, which mainly need to be redeveloped or reused by changing their original functions. The 98% of them belong to private owners, except for two assets that are public properties belonging to the Municipality of Ivrea. Although the most part of the assets is private, the role of the Municipality of Ivrea

[1] *The candidacy process started in 2008, when the Adriano Olivetti Foundation, in collaboration with the Municipality of Ivrea and the Politecnico di Milano, promoted the inclusion of this site in the UNESCO WHL. In 2012 the site was included in the UNESCO Italian Tentative List of candidate sites and the UNESCO World Heritage Office of MIBACT set up a Steering Committee, which worked for four years to prepare the Application Dossier and Management Plan. The Steering Committee included the Municipalities of Ivrea and Banchette, the Adriano Olivetti Foundation, the Guelpa Foundation, the Piedmont Region, the Metropolitan City of Turin, the Superintendence of Archaeology, Fine Arts and Landscape for the Metropolitan City of Turin, the Regional Secretariat of MIBACT for Piedmont, the General Directorate for Architecture and Contemporary Art and Associated Organisations, private partners and owners or managers of the assets, cultural institutes of national relevance.*

is central, since it is responsible for the future management and enhancement of the UNESCO site. The great challenge, mandatory for UNESCO, is to enhance the cultural, architectural and environmental value of this outstanding tangible and intangible heritage by preserving the relationship between these three main components that constitute this large unitary system:

1. The architectural heritage: the UNESCO site includes numerous high quality buildings, which represent expressions of Modern Heritage (Galuzzi, 2016). The former Olivetti factory and all those buildings originally devoted to offices and to different types of services for the workers represent assets with large spaces, currently unused or underused, which need to be enhanced by identifying new compatible functions and by evaluating their economic and financial feasibility. Moreover, the site includes also several residential buildings, which require different enhancement strategies, mainly based on the buildings' preservation and on the improvement of the energy efficiency (Coscia and Curto, 2017).
2. The infrastructure and green areas systems: the architectural heritage of the site was progressively developed along Jervis street, in conjunction with the expansion of the Olivetti company during the XX century. Jervis street currently represents one of the most important and busiest road connection of the town. Public and private green areas, car parks and parks are all around buildings: some of them quite recently transformed the plan developed under the leadership of Adriano Olivetti, others, on the contrary, still highlight his original ideas. This is the case, for example, of the "Tribunette" area, where tennis courts and bowling greens are still present, and the park near the Company canteen, where Olivetti's employees could take advantage of fitness trails. It is worth mentioning that some green areas of the site constitute landscape heritage, such as the park designed by Pietro Porcinai, Annibale Fiocchi and gardeners of the Vivai Canavesani company in 1963-64, thus they already represent tourist attraction hubs.
3. The intangible heritage: the cultural and political Community Movement, founded by Adriano Olivetti, strictly influenced the setting up of the entire urban system. For this reason, additional intangible values of this heritage can be recognized as a testimony of his innovative approach and progressive vision about work, culture, society and human conditions.

The exceptionality of this site deserve to be enhanced and transmitted by considering buildings, green areas, infrastructures and their tangible and intangible values as integrated and not-separable elements in order to preserve and maintain the identity of the site.

3 Methodological approach

The enhancement of the whole UNESCO site, considered as a unitary system of buildings, green areas, infrastructures and tangible and intangible values, is possible only

by managing its complexity by means of a structured knowledge system. A research group from the Politecnico di Torino developed a KM based on three main phases.

During the first phase ("Identification of Knowledge") the Politecnico di Torino built the knowledge structure of the GIS, while during the second phase ("Knowledge Generation") created and implemented the Knowledge Data Base (KDB) (Barreca et al., 2017, Curto et al., 2018). This knowledge base supported the enhancement projects developed by students during the course "Architecture for Heritage preservation and enhancement", which was focused on the enhancement of this UNESCO site for three years (a.y. 2016/2017, 2017/2018 and 2018/2019). The results achieved at the end of the second phase now lay the ground to the third phase ("Knowledge delivery") that could be activated in order to transfer the GIS to the Municipality of Ivrea as a tool that could effectively support the Public Administration in this pivotal phase for the UNESCO site enhancement and its future management.

Each phase of the KM consists in different progressive steps, as Figure 1 shows. Each step is detailed below.

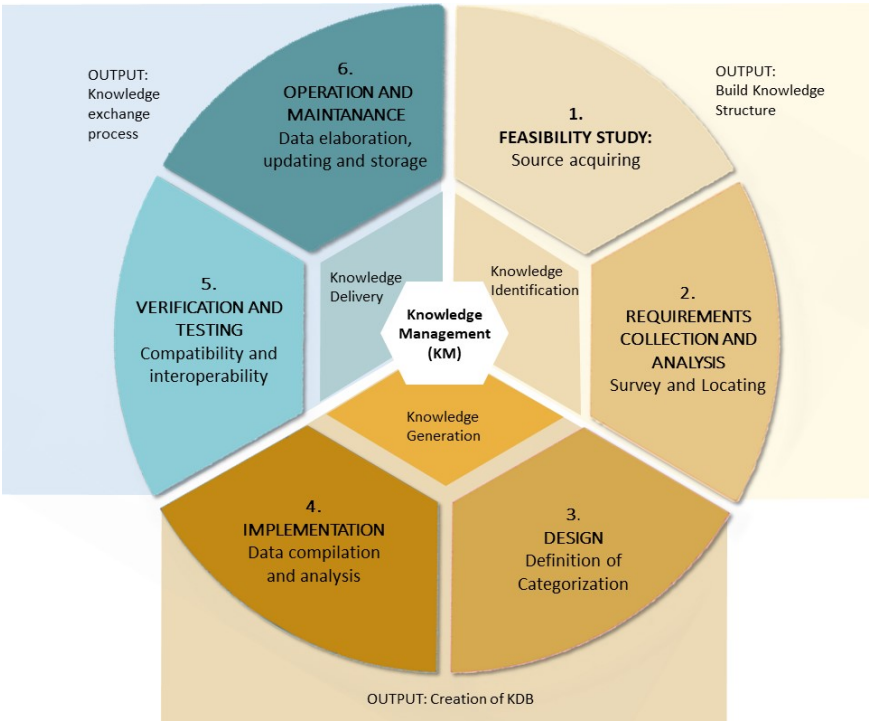

***Figure 1**: Knowledge Management Architecture for the implementation of the GIS developed by the Politecnico di Torino (Source: Authors' elaboration from Piccoli, 2007).*

3.1 Identification of knowledge

The initial identification of knowledge represents a crucial operation to guarantee a correct initial setting of the KM, to preliminary evaluate its feasibility and to analyse the main related requirements.

Step 1 - Feasibility study

The available data related to the UNESCO site and its surrounding territorial and socio-economic context were initially investigated (source acquiring) in order to evaluate the feasibility of the GIS development. Numerous existing data sources were consulted in this first preliminary step, such as the Geoportal of the city of Turin, the Geoportal of the Piedmont Region, the Real Estate Market Observatory of the Agenzia delle Entrate (OMI), and the Italian National Institute of Statistics (ISTAT). Moreover, other more specific data sources were consulted, such as the GIS of the Municipality of Ivrea, and a series of open data were downloaded and integrated into the KM.

Step 2 - Requirements collection and analysis

Important requirements to be considered for the future enhancement of the UNESCO site have to be investigated, collected, georeferenced and analysed (survey and locating). On this regard, the Management Plan for the UNESCO candidacy proposal constitutes a fundamental reference point (Municipality of Ivrea, 2012). Great part of the data and information reported in the Management Plan supported the creation of the knowledge structure and were included into the GIS. In particular, these data have to be analysed to formulate the Action Plans provided by the current MIBAC methodology (MIBAC, 2005) and necessary for the future management of the site: the Knowledge Plan, the Protection and Conservation Plan, Valorisation/Promotion Plan and Communication Plan.

3.2 Knowledge Generation

Once the knowledge base is preliminary identified and analysed, it is important to design and implement the KDB in order to generate a structured knowledge able to effectively support the site enhancement projects and processes.

Step 3 - Design

The identification of the site and off-site boundaries is the first necessary operations to design the KDB. Subsequently the most crucial step is the identification of the territorial classes and their mutual relations (definition of categorization). Some territorial classes were taken from the abovementioned Management Plan (the Buffer Zone, the Core Zone and Urban Contexts), while others were added by the Politecnico di Torino (Buildings, Cadastral Parcels, Elements of grey infrastructures, Elements of green infrastructures, Energy retrofit, Projects, Green and grey infrastructures projects and costs). The Buildings were assumed as the smallest territorial class and each element belonging to

this class was connected by means of a unique ID to an Urban Context and to a Land Parcel (Barreca et al, 2017). Moreover, each element was not considered separated from the others, but integrated in the unitary urban system that the UNESCO site represents.

Step 4 - Implementation

In order to implement the KDB it was firstly necessary to define its structure in detail, create a geodatabase and set up the data sheets. After that, a preliminary data compilation was possible, followed by the link of additional information and analyses, such as the survey of state of degradation and materials or archive documents (data compilation and analysis). An initial set of data (regarding only the Urban Contexts) was extracted from the abovementioned Management Plan (Municipality of Ivrea, 2012) and significantly expanded with additional information related both to the territorial and socio-economic context and to the buildings. A formal synthesis of many data on the different and heterogeneous urban elements of the site is very fruitful to set a new path of KM, to share knowledge with the actors who accept an involvement in the site enhancement process, to foster and monitor sustainable enhancement projects and to set performance and risk indicators. Therefore, the implementation included also a set of possible redevelopment projects with detailed analyses finalized to evaluate their economic-financial feasibility.

3.3 Knowledge Delivery

The third phase of the KM is fundamental to manage and control the knowledge exchange process between different subjects and systems, dealing with the complex issues related to interoperability, testing and data maintenance.

Step 5 - Verification and testing

After the KDB implementation, it is possible to proceed with its verification and testing of the integration of the new GIS with another existing structured knowledge base, such as the existing GIS of the Municipality of Ivrea (that currently does not include all the data related to the UNESCO site, which rather the Politecnico di Torino collected and analysed). An effective knowledge exchange is possible only if in the feasibility study the technical compatibility set is verified and a series of integration issues are tested and solved (interoperability).

Step 6 - Operation and maintenance

The KM becomes operational when queries, elaborations and updating of the data are properly manageable. In this phase all data can be integrated and jointly analysed for example by means of thematic maps or indicators calculation. The ongoing maintenance of the system is fundamental to guarantee its constant functionality, the access control and the storage and security process.

4 Results

The GIS was conceived in 2016 as a component of a structured knowledge base able both to accurately and preventively provide updated information about all the assets of the site and to support the governance of the urban area. It is a dynamic relational system able not only to collect and analyse geographical data concerning the territorial, socio-economic and cultural context and data related to the physical characteristics of the built environment (Urban Contexts, Cadastral parcels, Buildings, Elements of grey infrastructures, Elements of green infrastructures), but also to analyse, manage and monitor redevelopment projects and their impacts and outcomes over a long period of time.

The potentialities of the first version of the GIS were acknowledged by the Municipality of Ivrea in 2017, when it was used to support the candidacy proposal of the UNESCO site for the final evaluation, before the nomination.

Today, after three years, the GIS implementation has been considerably improved, so that it may be adopted by the Municipality of Ivrea to develop strategies, policies and actions for the enhancement and the governance of the whole UNESCO site.

In addition, to provide a complete, structured and updated knowledge of the actual buildings condition (owners, uses, fragmentations, structural and energy efficiency, restoration), the GIS could also support the management of administrative and cadastral practices, as well as of all those documentations useful for the regional UNESCO periodic reporting.

In this paper the attention is focused on the GIS potentialities in supporting the Municipality of Ivrea in the redevelopment and future management of streets, places, car parks (Elements of grey infrastructures) and green areas (Elements of green infrastructures). In fact, they currently represent urgent and priority interventions to enhance and to foster the acknowledgment of the site's value.

The results concerning these aspects are illustrated below, with a particular evidence on:

- the improvement of the structure of the KDB;
- the implementation of the KDB;
- analyses and future strategic development actions.

4.1 The improvement of the structure of the KDB

The conceptual framework of the GIS was defined in 2016 when the "Identification of knowledge" phase started (Barreca et al., 2017). The effectiveness of the structure of the KDB was generally confirmed, even if some improvements were made in the last three years during the "Knowledge generation" phase (Figure 2).

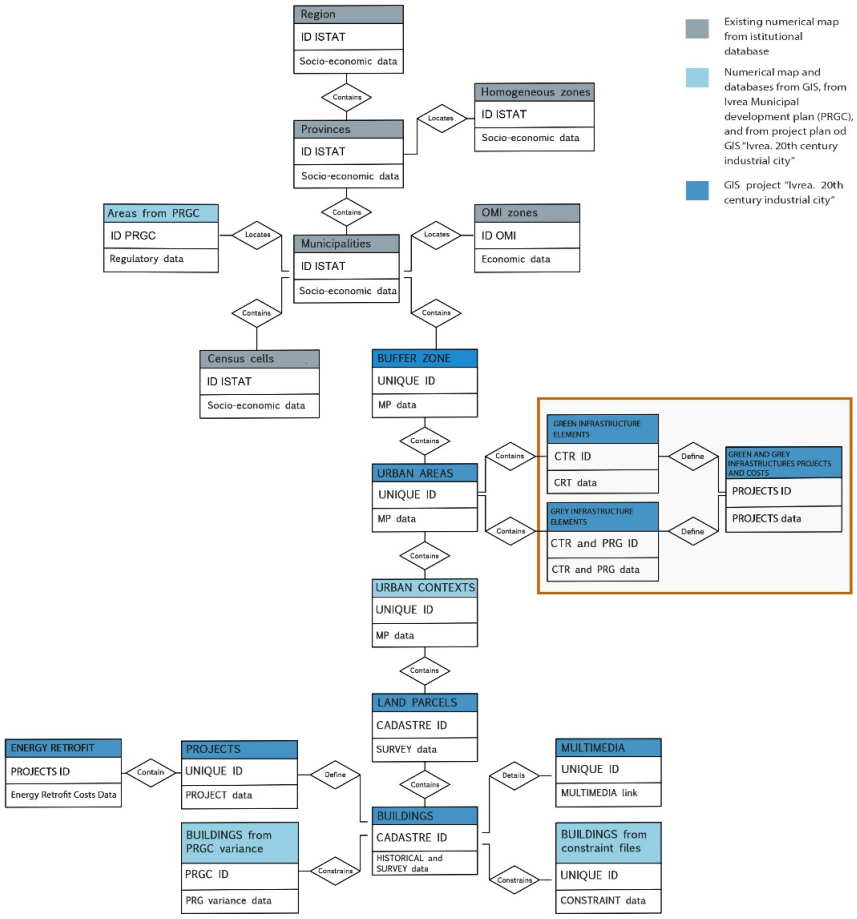

Figure 2: Conceptual framework of the GIS. (Source: Authors' elaboration).

In particular, some entities were added and joined to the Buildings, Elements of grey infrastructures and the Elements of green infrastructures, in order to better specify and manage important emerging issues. A particular attention was paid to improve the structure of the "Elements of grey infrastructures" and "Elements of green infrastructures" classes: several data were included in order to both to analyse the typologies of the single elements, their condition and the presence of car parks, sidewalks, playgrounds, equipped areas, street furniture and lighting. The improved metadata of these two classes are illustrated in Appendix A and Appendix B.

Furthermore, an important improvement was made by creating the new entity "Green and grey infrastructures projects and costs" with the aim of monitoring and managing the grey and green infrastructures redevelopment and maintenance projects and their related principal costs. Numerous aspects are to be considered for these purposes: in addition to the necessary specifications on the classification of the project type and its extension, it is

important, for example, to consider if the projects might reconnect the existing ecosystems or enhance the ecological corridors. Furthermore, it is strategic to identify and specify all those green urban features able to enhance the green percentage or to assist species movement (as compensation measures after the construction of a grey infrastructure), as well as all those multifunctional areas that can be openly accessed and enjoyed (kids playgrounds, equipped training areas, free Wi-Fi zones, recreation areas, areas with digital infrastructures, biodiversity protected areas, etc.). A particular attention was focused on the economic-financial aspects. On the one hand the main costs related to the grey and green infrastructures redevelopment projects were considered (for example: demolitions, excavations, consolidations, hydraulics works, technological plants, road signage, urban furniture) and on the other their principal maintenance costs (for example: one-off and ongoing costs, masonry, steel, protective coatings, road superstructures and pavements, road safety barriers, winter services, sowing and soaking, cutting, weeding, processing and various treatments). The metadata of this new entity are illustrated in Appendix C, while a possible future use of these data is illustrated in paragraph 4.3.

4.2 The implementation of the KDB

The infrastructure system of the UNESCO site was originally divided in 47 elements including streets, squares and car parks, while the system of green spaces was divided in 38 elements including both public and private green areas. Currently, at the end of the "Knowledge generation" phase, numerous data and information related to those elements were collected and joined into the GIS. The implementation results are synthesized in Table 1.

Table 1: Implementation results (Source: Authors' elaboration).

Entity	**Elements**	**Data implementation percentage**
Elements of grey infrastructures	47	89%
Elements of green infrastructures	38	79%
Urban contexts	29	55%
Buildings	114	76%
Cadastral parcels	93	80%

This structured, detailed and updated data collection represents an important result that could effectively support the Municipality of Ivrea in the future management of the UNESCO site. In particular, this data could be not only effectively integrated into the GIS of the Municipality of Ivrea, but it can also support a series of analyses and future strategic development actions aimed at enhancing and fostering the acknowledgment of the site's value.

4.3 Analyses and future strategic development actions

The wealth of information that the GIS developed by the Politecnico di Torino now enables a wide range of analyses finalized to describe the current situation, highlighting redevelopment potentialities and weaknesses related to the different abovementioned constituent elements of the UNESCO site (urban contexts, cadastral parcels, buildings, green areas, infrastructures, etc.). Figure 3 shows, for example, a possible analysis of data related to the presence of street furniture in the green areas and of the road signage in the grey infrastructures and may support the identification of the less equipped areas and to orient public investments to improve them.

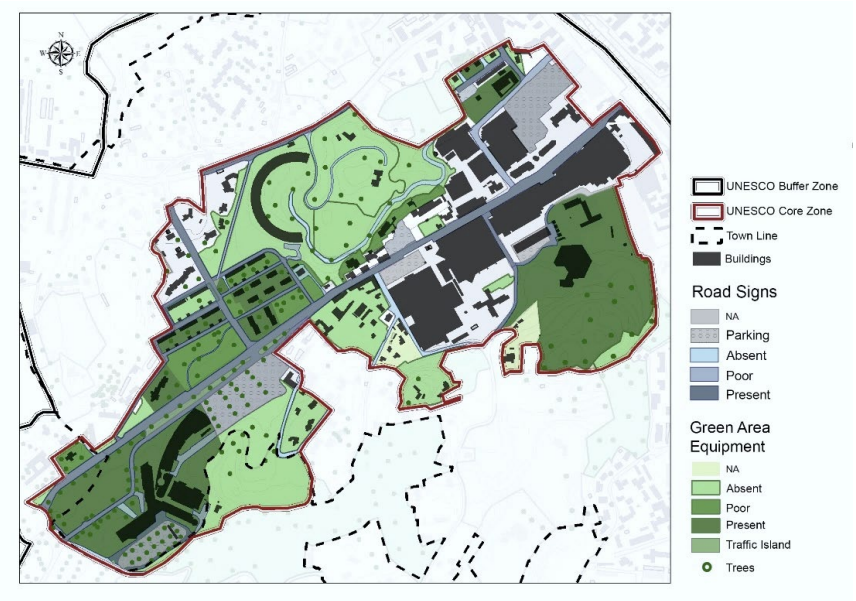

***Figure 3**: Analysis of the presence of street furniture in the green areas and of the road signage in the grey infrastructures: thematic map (Source: Authors' elaboration).*

In addition to these descriptive analyses, the current improved version of the GIS, with a particular reference to the new entity "Green and grey infrastructures projects and costs", enables also more specific and strategic development actions, such as:

- the management of the necessary redevelopment and maintenance costs related to the infrastructures and public green areas;
- the design, implementation and evaluation of green infrastructure projects.

Infrastructures design cost and value management

The creation of the new entity "Green and grey infrastructures projects and costs", illustrated above, laid the ground to important analyses that the Municipality of Ivrea may run in order to monitor and manage the principal costs related to the redevelopment and

maintenance of the elements of the grey and green infrastructures. These costs represent important items in the budget of a Public Administration, but in Ivrea a punctual and georeferenced estimation of their amount, at least at our knowledge, is currently absent. Therefore, the GIS may effectively support the Municipality of Ivrea not only in quantifying and in optimizing the necessary investments for each considered element of the UNESCO site, but also in estimating and managing the related future maintenance costs, respecting the current municipal regulations (Municipality of Ivrea, 2015; Municipality of Ivrea, 2017). The optimization of the public economic-financial resources is not the only benefit achievable through the GIS: in fact, this tool may also support the practical management of the redevelopment works and the future maintenance interventions, by optimizing the scheduling of the necessary activities and the involved resources. A rational scheduling and planning of actions has to be necessarily based on the uniqueness and transparency of the knowledge of each object and subject involved, over years, fostering accountability, efficiency and economic-financial sustainability of the enhancement interventions to be made in the site.

Furthermore, these data may also support the updating of the UNESCO site Management Plan, which currently includes an amount of 5000 Euro to be allocated for the public spaces maintenance (Municipality of Ivrea, 2017), while recent studies demonstrated that these costs are supposed to be much higher (Naumann et al., 2011; Pacella and Vianzone, 2019). The GIS may support an accurate estimation of the necessary works and also highlight the relation between the investment costs and all the positive impacts that those interventions may generate from the UNESCO site to the whole city of Ivrea.

Green infrastructures projects

Basic redevelopment projects to improve the current condition of the public infrastructures and green areas of the UNESCO site are certainly necessary but not sufficient. More specific and detailed green infrastructures projects may be promoted by the Municipality of Ivrea in order to concretely follow some green economy principles and deeply improve the quality of the public spaces and, consequently, foster the enjoyment of the assets located nearby these areas and the environmental quality (Loiseau et al., 2016). Green infrastructure is a strategically planned and delivered network of high-quality green spaces and other environmental features. It should be designed and managed as a multifunctional resource capable of delivering a wide range of environmental and quality-of-life benefits for local communities. Green infrastructure includes parks, open spaces, playing fields, woodlands, allotments and private gardens (European Environmental Agency, 2011). This network can deliver a wide range of ecosystem services such as air quality, water purification, space for recreation and climate mitigation and adaptation and therefore improve citizens' health and wellbeing.

Monitoring and evaluation are useful tools to assess a project’s success in terms of its achievement of the original objectives, benefits produced and cost-effectiveness. The

main drivers behind these actions are to assess the efficiency of the project (weighing the costs against the benefits obtained).[1]

In this perspective, the Municipality of Ivrea could promote strategic actions in order to generate positive impacts on the community of Ivrea, by opening public tender calls for the realization of protected areas, restoration zones, sustainable use areas, green urban features, natural connectivity features, artificial connectivity features and multifunctional zones (Naumann et al., 2011).

The new entity of the GIS "Green and grey infrastructures projects and costs" was created also for this purpose: by means of all the considered data (Appendix C) the green infrastructures elements can be analysed, monitored and evaluated. A possible influence generated by a hypothetical realization of a green infrastructure project is represented in Figure 4: a single scarcely equipped green area of the site, if properly redeveloped, is able to positively impact a whole residential neighbourhood (Castellamonte) and one of the iconic building of the UNESCO site (Olivetti new offices building).

***Figure 4**: Hypothetical realization of a green infrastructure project: positive influence on the Castellamonte residential neighbourhood and on the Olivetti new office building (Source: Authors' elaboration).*

[1] *A clear potential to integrate and boost green infrastructure projects throughout the EU is offered by spatial planning policies which, at the EU level, are comprised inter alia of the Strategic Environment Assessment (SEA), Environmental Impact Assessment (EIA) and Environmental Liability Directive (ELD). The SEA and EIA are considered as the most important legal instruments of horizontal European environmental policy.*

5 Conclusions

The enhancement and future management of the site "Ivrea, industrial city of the 20th century" is a great challenge for the Municipality of Ivrea, which is currently dialoguing with the private owners of the assets in order to coordinate the redevelopment projects, coherently with the Management Plan drawn up for the UNESCO nomination proposal. This delicate phase, as well as the future management of the site, could be supported by a structured and complete knowledge base about all the elements located in this area and to the environment and socio-economic context of Ivrea.

In this perspective, a fruitful collaboration between the Municipality of Ivrea and the Politecnico di Torino could start in the context of the third phase of a KM ("Knowledge delivery") activated over the last few years. The GIS developed, improved and implemented by the Politecnico di Torino could be transferred to effectively support the Public Administration in analysing different kinds of data, in identifying potentialities to strengthen or criticalities to solve over the whole site and in communicating with public and private stakeholders (Mason and Dragicevic, 2006). Several future developments of the GIS will be possible in order to address specific services for citizens, operators and the Public Administration itself (for example a collaborative GIS platform to interact with different stakeholders or specific operative tools able to support public policies for the land administration or the real estate taxation).

Focusing the attention on the grey and green infrastructures of the site, today it is evident a lack of routine maintenance: their condition does not foster the acknowledgment of the site's value, as well as its accessibility and enjoyment. The redevelopment of streets, squares, car parks and public green areas could be the driving force able to foster the enhancement of the whole UNESCO site. Therefore, these interventions constitute urgent and priority actions that the Municipality may quickly and directly activate in parallel with the ongoing mediation process with the buildings' private owners and other territory stakeholders.

Nevertheless, the positive impacts that the redevelopment of these infrastructures could generate go beyond the site's enhancement. Their improvement is able to produce benefits for all the citizens, in terms of increase of the welfare, urban services equipment and the environmental condition (air and water quality, ecosystem services, biodiversity, etc.). An improved quality of the surroundings positively impacts also the property values and, as a consequence, fosters the real estate market trends and supports the economic operators that currently operate in a rather fragile context. Therefore, strategic redevelopment actions on the grey and green infrastructures could indirectly improve the socio-economic equity and trigger important measures to contrast the current economic crisis.

Special attention deserve the design and implementation of green infrastructure projects, which are able to improve both the attractiveness and the environmental quality of the site. The Municipality of Ivrea could orient numerous strategic actions in this direction by investing in public projects able to generate positive impacts on the community: a network of healthy ecosystems compensates the construction of grey

infrastructures, offering benefits for all citizens. Furthermore, according to the carbon tax regulations, projects like the planting of trees generate both benefits and incomes for the Public Administration (green compensation for redevelopment works). Therefore, future researches can be addressed towards the cost-benefit evaluation of the green infrastructures projects, in order to support the Municipality of Ivrea not only in the management of the redevelopment and maintenance costs, but also in assessing the positive impacts that strategic enhancement projects could generate from the UNESCO site to the whole territory of Ivrea. To achieve this important and ambitious goal, a knowledge exchange process should be activated between the Municipality of Ivrea and the Politecnico di Torino to further customize the current release of the GIS. By this way, the case of Ivrea could become a best practice of territory sustainable development and an example of fruitful collaboration between Public Administrations.

Abstract

Universities play a crucial part in maintaining, creating and sharing knowledge in different ways for the society. Nowadays the amount and complexity of information required from different stakeholder groups for universities is increasing. In this context universities should be leaders in managing the knowledge within the institution. One way of doing that is to align the universities strategic priorities with the demands of the society, industry and government.

In this research paper the authors are focusing on understanding what is Knowledge Management (KM) in the university perspective, how it can be integrated in the university development strategies and how KM elements are structured and measured beyond universities. The purpose of this research paper is to find out how KM elements can be integrated into university strategic management systems.

The authors have conducted a literature review on KM, by analysing different definitions formulated by researchers. The definitions have been analysed in the context of university's role as a contributor to creating and sharing knowledge. The authors have analysed the main outcomes from integrating KM elements into university strategic management. In addition, the authors have contributed to this research by analysing strategic management trends of universities in Latvia and how they integrate KM elements, by analysing their institutional strategies.

The research includes universities in Latvia, at the European level only the requirements of the EUA were analysed and at the global level the requirements of THE World Rankings, QS World Rankings and U-Multirank were taken into account. This limitation was based on the availability of the necessary information and the scope of the study. Another limitation regarding the research is that only university strategic performance indicators were selected for in-depth analysis in this paper.

The research includes the analysis of previously defined KM definitions by researchers, compiles the main positive outcomes from KM integration in university strategies and gives insights to the

analysis of performance based indicator groups at the national, European and global levels. While identifying how KM elements are integrated the research also provides more insight into higher education strategic performance measurement systems.

Keywords – University, Performance measurement, Performance indicators, Knowledge management, Strategic knowledge management

Paper type – Academic Research Paper

1 Introduction

In the past decades universities have transformed and adapted to external factors showing their high capacities of change (Gibbons *et al.*, 1994). The changing role and scope of university impact is evolving. Universities as a significant contributor to the society and the economic development are still looking for new ways how to transfer the created knowledge within the institution to the industry more efficiently (Geuna and Muscio, 2009). For example, university and industry collaboration nowadays play an important role for the regional development (Gibbons *et al.*, 1994). As universities are faced upon new changes and challenges, those universities that are more flexible and adaptive has the most advantage. Researchers emphasise that universities which are keen on collaboration with the industry are more likely to adapt to change than those who do not (Gibbons *et al.*, 1994).

From the educational perspective the importance of KM in universities is being considered as linking created knowledge in education with practical implementation in the industry (Straujuma *et al.*, 2018). Nevertheless, from the strategic and operational perspective - developing, acquiring and applying KM activities can help to develop strategic and action-oriented goals for organization (Quintas, Lefrere and Jones, 1997). On the one hand, universities can be seen as knowledge-based organizations where knowledge creation and transfer occur, but on the other hand it can be used as a strategic advantage by introducing KM in an operational level at the university. Researchers emphasise that the KM that includes performance measurement analysis and benchmarking data has been considered as a strategic resource for the organization (Gonzalez and Massaroli De Melo, 2018). From the perspective of process management KM is beneficial for process innovation, re-engineering of processes to achieve continuous improvement for the organization (Quintas, Lefrere and Jones, 1997). Universities that are paying additional attention to how their KM system is being developed, how it integrates the analysis of the performance and how it resonates with the stakeholders, can be a beneficial source for sustainable development and competitive advantage of the university.

In the first part of this research the authors analyse the main contributions of KM to university strategic management. The second part of the research is dedicated to understanding how KM is integrated in university strategies and whether the groups of

strategic performance indicators reflected in the university strategies resonate with information requested and analysed at the national, European and global levels.

2 Defining Knowledge Management in Universities

To understand more in depth how KM activities are being defined in universities the authors compared different researcher interpretations of the definition of KM. Furthermore, indicating what positive benefits universities can gain from integrating KM in an operational level. These definitions allow understanding the importance of KM more comprehensively (see Table I).

Table I.

Year	Author (s)	The definitions of KM
1997	(Quintas, Lefrere and Jones, 1997)	KM is the process of continually **managing knowledge** of all kinds to meet existing and emerging needs, to **identify** and **exploit** existing and acquired **knowledge** assets and to develop new opportunities.
2000	(Mårtensson, 2000)	KM is considered a **prerequisite** for higher productivity and flexibility.
2001	(Alavi and Leidner, 2001)	KM involves distinct but interdependent processes of **knowledge creation, storage** and **retrieval**, **knowledge transfer**, and **application**.
2005	(Dalkir, 2005)	KM is the deliberate and systematic coordination of an organization's people, technology, processes, and organizational structure in order to add value. This coordination is achieved through **creating, sharing**, and **applying knowledge**.
2010	(Hung *et al.*, 2010)	The elements of KM are **knowledge creation, knowledge storage, knowledge transfer** and **knowledge application**.
2015	(Girard and Girard, 2015)	KM is the process of **creating, sharing, using** and **managing the knowledge** and information of an organization.
2020	(Dei and Bingle van der Walt, 2020)	The management of processes that govern the **collection, creation, storage, dissemination**, and **utilisation of knowledge** by merging the appropriate technologies, organisational structures and people to create the most effective and efficient learning, problem-solving, and decision-making in an organisation.

KM is being considered as the basis of operational performance (Mårtensson, 2000) as it plays important role in resource management (Dalkir, 2005). Researchers agree that KM is considered as an ongoing process that consists of using knowledge in different ways such as knowledge creation, storage and transfer (Quintas, Lefrere and Jones, 1997; Alavi and Leidner, 2001; Dei and Bingle van der Walt, 2020). Using the resources to create, share and apply knowledge (Dalkir, 2005; Hung *et al.*, 2010; Girard and Girard, 2015) is crucial part of the foundation of universities.

As universities are considered as an important player for knowledge creation and knowledge transfer to meet the social-economic needs (Geuna and Muscio, 2009) these definitions show the importance of KM as an integral process in the operations of the university. Overall the KM concept has evolved from meeting the existing and future needs (Quintas, Lefrere and Jones, 1997) to enhancing resources and technologies to ensure strategic decision-making and organizational learning (Dei and Bingle van der Walt, 2020). Most often researchers are discussing knowledge *creation, application, storage, transfer and sharing* as integral part of the KM activities in universities. Furthermore, by analysing the literature, the authors discovered the most commonly mentioned positive outcomes from developing the KM system.

2.1 Thriving innovation

KM within the orgnaization is being considered as a integral part of process of creation and innovation (Antunes and Pinheiro, 2019). Researchers have found that knowledge creation, integration, and application can facilitate innovation in the organization (Mardani, Nikoosokhan and Moradi, 2018), as nowadays universities play additional role in the society for knowledge transfer and creating innovation (Hu, Hou and Chien, 2019) it is considered as a beneficial opportunity. Researchers have found that the positive relationship between KM and organizational performance enhance innovation and open innovation in the organization (Lopes *et al.*, 2017; Mardani, Nikoosokhan and Moradi, 2018). Furthermore, KM in a organisational function perspective can improve innovation performance and by using different approaches enhance innovation even more (Ode and Ayavoo, 2020).

2.2. Performance effectiveness

KM that is linked with the organizational strategy and processes is considered as effective (Davenport and Prusak, 1998). There have been found links between KM activities such as knowledge creation and knowledge integration positively impacting organizational performance (Mardani, Nikoosokhan and Moradi, 2018). Furthermore, researchers mention that Strategic Knowledge Management system is beneficial for universities as it allows to manage knowledge more effectively and productively (Dei and Bingle van der Walt, 2020).

Some researchers discuss the positive impact of integrating KM with Total Quality Management (TQM) practices to manage knowledge throughout all levels of the organization (Grover and Davenport, 2001). Researchers also address the raising importance of KM integration with TQM being crucial part of organizations operations and innovation (Hung *et al.*, 2010).

2.3. Strategic advantage

Already in the 90ies KM was discussed to be a potential source for advantage for organizations (Quintas, Lefrere and Jones, 1997). Knowledge is defined as one of the most strategically important resources that systematically managed can be used as an organizational strategic advantage (Antunes and Pinheiro, 2019; Hu, Hou and Chien, 2019).

As nowadays universities are understanding more in depth their socio-economic impact on stakeholders (Geuna and Muscio, 2009) the management of stakeholders becomes crucial. Researchers also emphasise that Strategic Knowledge Management gives advantage for managing and leveraging the internal and external stakeholders. (Rubenstein-Montano *et al.*, 2001). Some researchers define knowledge within the KM as sustainable advantage, because it continuously gives and generates new returns for the organization (Davenport and Prusak, 1998).

2.4. Organizational sustainability

As organizational sustainability is the basis of any university strategic view, some researchers argue that there still has been little research on how universities through KM influences sustainable development and impact their stakeholders (Hu, Hou and Chien, 2019; Martins *et al.*, 2019). Although there have been researched links between KM, organizational sustainability and innovations as crucial part of sustainable development and innovations in the organization (Lopes *et al.*, 2017). Nowadays, KM is being mentioned as potential for universities to contribute more to achieving sustainable goals by managing and generating knowledge and innovation (Martins *et al.*, 2019).

From the literature review there have been identified four most commonly mentioned positive outcomes for universities which have implemented and continues to develop their KM system. These outcomes are:

- *Thriving innovation;*
- *Operational and process effectiveness;*
- *Strategic advantage;*
- *Organisational sustainability.*

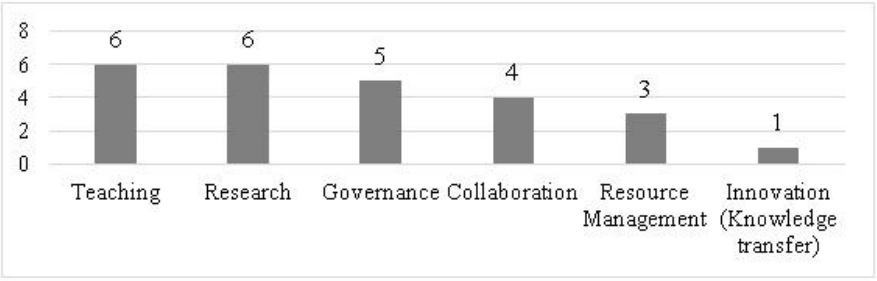
Previously identified positive outcomes are a result of KM integration within the university strategies. From the literature review it is concluded that by introducing KM system universities could enhance their performance in a variety of ways. The authors

continued the research to understand more in depth how universities nowadays are integrating KM elements in their development strategies.

3 Integrating Knowledge Management in university strategy and beyond

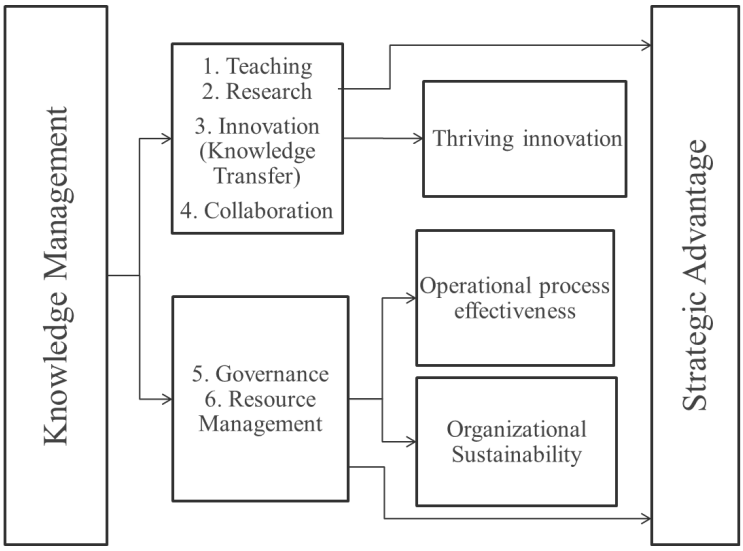
The competition, KM and quality assurance issues in the higher education sector in the world are increasing (Zheng, Yang and Mclean, 2010; Seyfried and Pohlenz, 2018). The competition in the Latvian higher education sector in the past years has increased, together with university autonomy and accountability (Broucker, Wit and Leisyte, 2016). This has led to the responsibility of universities to measure, analyse and report a variety of data and information, not only at the national but also international level. As in the previous chapter it was discussed that KM system can give positive impact on university organizational performance researchers find performance measurement part of that system. Universities are recognising the importance of well-structured knowledge management systems with accurate performance measurement indicators. The capacity of the system to process data into needed information is highly valuable for the university (Martins *et al.*, 2019).

In this research the authors analysed how previously researched KM elements are integrated in the university development strategies. Firstly, comparing the indicator groups defined, measured and reported in the strategies of Latvian universities with indicators required from universities at the national, European and global levels. At the national level the authors analysed the indicators and information required by the Latvian Ministry of Education and Science, at the European level – the European University Association (EUA) requirements and at the international level – Times Higher Education (THE) World Rankings and QS World Rankings indicators.



Graphic I. Latvian university strategic priorities (sorted by frequency)

As the graphic shows most emphasis in the development strategies is being put on the main university processes – teaching and research. Only one university in Latvia has included additional strategic priority – innovation in context of knowledge transfer and collaboration with the industry. The authors identified links between comparing the university strategic development priorities with previously identified positive outcomes from KM activities (see Picture I).



Picture I. KM link between university strategic priorities and positive outcomes

Universities that integrate KM within the strategic priorities can manage their resources and strategic priorities in a way that results in well-grounded and stable strategic advantage (Antunes and Pinheiro, 2019; Hu, Hou and Chien, 2019). From the operational view KM helps to continuous improve processes (Quintas, Lefrere and Jones, 1997). Furthermore, KM allows to manage university stakeholders in such way that ensures strategic advantage (Rubenstein-Montano *et al.*, 2001).

By analysing in depth the results, authors compared the university strategic priorities with priorities defined in three levels - country, European and international. In the country level the authors analysed Latvian Ministry of Education and Science annual reports for teaching and research; in the European level – European University Association (EUA) institutional evaluation program; international level - methodologies of the U-Multirank, Times Higher Education (THE) World University Rankings and QS World University Rankings. For each level there are identified indicators for which universities need to collect data and information. After identification the indicators were grouped and sorted in relevance. Each identified group contributes to understanding how KM elements are measured from university to international ranking levels (see Table II).

Table II. Indicator group comparison through different levels

University level	Country level	European level	World level		
University development strategies	**Ministry of Education and Science**	**European University Association**	**U-Multirank**	**THE WUR**	**QS WUR**
Teaching	Teaching	Teaching and Learning	Teaching and Learning	Teaching	Teaching
Research	Research outcome; income	Research	Research	Research influence	Research output
Governance	N/A	Governance; Quality Culture	General management of the university	N/A	N/A
Collaboration	Industry income	Internationalisation	Regional Engagement; International outlook	International outlook	Reputation; International outlook
Resource Management	Academic and research staff	N/A	N/A	N/A	N/A
Innovation (Knowledge Transfer)	Knowledge Transfer	N/A	Knowledge Transfer	Knowledge transfer	N/A

The table shows that teaching, research and collaboration activities are measured through each of the three levels, in contrast such priorities as university governance, resource management and organizational innovation are not. Governance as a priority is measured in all levels except country level, indicating gap between information flow from universities and government. Resource management is being considered as regional measurement, but organizational innovation consists of different indicators in each level, that could possibly duplicate with Research output measures. From the perspective of KM university teaching and learning, research and collaboration activities resonate with measurement of *knowledge creation, application, storage and sharing.*

The analysis of the groups of indicators also show that there is a weak link between performance indicators that results in variety of data and measures needed for university. The problem with data assessment is also identified in other countries where researchers see contradictions and wide gap between assessments in different levels (Turri, 2013). Other researchers argue that universities are focused on external evaluations and compliance to the requirements that lets them to forget about the university's strategic priorities (Sursock, 2012).

4 Conclusions

KM is being considered as a crucial part of university role and impact to the socio-economic development. The literature review identified that the most often discussed elements of KM are knowledge - *creation, application, storage, transfer and sharing.* Furthermore, by analysing the literature the authors compiled the main outcomes for universities which have implemented KM in their strategic management. Successful integration of KM for university could give the following positive outcomes - *Thriving innovation; Operational and process effectiveness; Strategic advantage* and *Organisational sustainability.* The authors identified links between Latvian university strategic development priorities and previously identified positive outcomes from KM activities.

The results of the research show that not only universities in Latvia define different performance indicators, but different performance measurement requirements also exist at the national, European and international levels. Only some of the previously defined groups of indicators can be identified in each of the levels.

Further research opportunities could be linked to analysing in depth the indicator groups to identify how diverse is the data and information collection. In addition, further contribution is needed for analysing the factors influencing successful integration of KM elements in different types of universities. As the second part of the research was based on analysing only strategic priorities and groups of indicators of Latvian universities it shows further research is possibilities by analysing different country example.

Abstract

Blood Supply Chains (BSCs) are a complex set of actors, facilities and relationships, whose role is to manage the entire flow of blood units, from donors to patients, and to ensure that the total demand of blood is met (i.e. the self-sufficiency goal). To this end, the support of Voluntary Associations (VAs) is crucial, as they contribute to new donors' recruitment and, possibly, can perform collection activities. In Italy, BSCs operate within the national health system. Data provided by the Central Government reveal that significant differences, in terms of self-sufficiency, exist across regions. In such a context, the scope of this paper is to investigate what are the organizational factors that can affect BSCs performance at the regional level. In particular, we focus our attention on two main aspects: i) the adopted organizational model, which can vary in dependence of the role played by VAs; ii) the spatial distribution of BSCs over the territory. Indeed, as blood is donated on a voluntary and non-remunerated basis, it is likely that the spatial organization of BSCs is fundamental to attract donors. With these aims in mind, we realize a field analysis, by interviewing regional managers from the main Italian association of donors. As a result, we identify the organizational models currently adopted by a sample of Italian regional BSCs. This classification is then used to perform a quantitative whose results highlight that regions adopting an Associative model, i.e. where VAs actively contribute to collection activities, tend to achieve better operational performances. Moreover, some preliminary findings from a spatial analysis seem to confirm that these performances are positively affected also by a widespread diffusion of collection

facilities over the regional territory. In practice, ensuring good accessibility conditions to potential donors, through an appropriate and coordinated organization of all the actors involved in the BSC, emerge as a consolidated recommendation to decision and policy-makers.

Keywords – Blood Supply Chain, Organizational models, Spatial Accessibility, Service availability, Public Service.

Paper type – Academic Research Paper

1 Introduction

Blood represents a vital resource in the context of national healthcare systems as it can be used for several medical treatments. Its efficient and effective collection, processing and distribution are, therefore, fundamental tasks. Countries throughout the world are facing serious challenges in making sufficient supplies of blood and blood products, while ensuring their quality and safety (Williamson and Devine, 2013). These aspects assume an even higher relevance in consideration of the scarcity of such a commodity and the necessity to serve the increasing needs of an ageing population (OECD/EU, 2018).

The Blood Supply Chain (BSC) manages the whole flow of blood products, from donors to patients. It is intended as a complex set of actors, facilities, and relationships whose main goal is to assure that blood components are readily available wherever and whenever they are needed. Worldwide, BSCs typically comprise public bodies belonging to the national health systems. In some cases, specific legislations and budget lines imposed by the Government may encourage third-parties' funding (WHO, 2016).

In this work, we specifically focus on the case of the Italian BSCs, whose organization is ruled by the Central Government (D.lgs. n.19/19.03.2018) in accordance with the guidelines set by the EU (European Commission, 2016). At the regional level, BSCs are articulated in two main types of facilities: i) *Blood Centers (BCs)*, performing blood collection and processing activities; ii) *Blood Stations (BSs)*, performing collection activities only. The main goal of regional BSCs is to ensure the satisfaction of the local demand of blood (*self-sufficiency*). To this end, regional BSCs are supported by *Voluntary Associations (VAs)*, i.e. private bodies that are essentially asked to increase people's awareness towards donations and are responsible for new donors' recruitment. Possibly, VAs can perform collection activities.

Clearly, blood collection performances can vary in dependence on their organizational models and, in particular, on the role of VAs. Indeed, regardless the fact that national self-sufficiency has been constantly guaranteed in the five-year period 2014-2018, data provided by the Central Government (Centro Nazionale Sangue, 2019) reveal that various regions are not able to satisfy their own demand of blood. In any case, the contribution of VAs is crucial in order to achieve the target of self-sufficiency: recent evidences report that VAs accounted for more than 1.3 million members and more than 2 million blood units collected, corresponding to almost 80% of the overall national need (AVIS, 2019). Therefore, in this work we try to understand the organizational aspects that influence the

system performances. These aspects include the adopted model and the actual territorial distribution of the facilities devoted to the collection process. In fact, as blood is drawn on a voluntary and non-remunerated basis, it is likely that the spatial organization of BSCs, as well as of VAs, may influence potential donors' willingness to donate blood.

In summary, the present study has a twofold aim: the first one is to identify the organizational models adopted by regional BSCs; the second is to investigate whether the spatial distribution of BSCs' facilities affect their operational performances.

To these ends, we realize a field analysis by interviewing regional managers of the main Italian VA, namely AVIS (Associazione Volontari Italiani del Sangue). Based on the retrieved information, we classify the organizational models currently adopted within a sample of Italian regional BSCs. Then, we introduce some quantitative indicators and perform a spatial analysis in order to evaluate, under the light of the identified organizational setting, the accessibility conditions of donors to BSCs' facilities: in particular, given the available data, we consider a restricted sample of Italian regions comparable in terms of territorial extension and population, as our case study. Chosen regions adopt similar models but present different performance levels.

We note that, in the extant literature, several methodological approaches have been proposed to measure spatial accessibility with applications to a wide spectrum of healthcare services (Neutens, 2015). However, despite the great research interest that the topic has stimulated in recent years (Bruno et al. 2019; Piraban et al. 2019), to the best of the authors' knowledge there are no papers dealing with the evaluation of spatial accessibility to BSCs. Moreover, we found no studies attempting to analyze spatial accessibility towards complex services, characterized by a plurality of actors, in dependence of the function they perform within different organizational models.

This aspect represents, undoubtedly, the main contribution of the present work. Finally, we also believe that the obtained findings may fruitfully support decision and policy makers in identifying proper strategies to manage BSCs, as well as and the interplay among all the involved actors, in a more cost-effective way while guaranteeing the fulfilment of the self-sufficiency goal. The remainder of the paper is organized as follows. In Section 2, we describe the current organization of the Italian BSC. In Section 3, we introduce the proposed framework for the classification of BSCs organizational models. Then, in Sections 4 and 5 we present the results obtained from quantitative analysis on a sample of Italian regions. Conclusions and directions for future research are outlined in Section 6.

2 The organization of the Italian BSC

In Italy, BSC is part of the national health system and its role is to ensure the availability of blood supplies to patients needing transfusions, in compliance with the European and National legislations (D.lgs. n.19/19.03.2018, European Commission, 2016). It is organized according to a three-layered structure, that we detail next. At the national level, the so-called *Centro Nazionale Sangue* is the public body, within the

Ministry of Health, leading the coordination and technical and scientific control of the entire BSC. Among the others, its main function is to define the yearly need of blood that every region has to achieve (i.e. the self-sufficiency goal). At the regional level, operational performances are supervised by coordination bodies, named *Strutture Regionali di Coordinamento*, whose role is to ensure that objectives of quality, safety and self-sufficiency of blood are achieved, by planning intra and inter-regional flows of blood units and derivatives, if needed. Finally, at the local level, *Transfusion Centers* oversee blood collection and processing activities. More specifically, they are articulated in two kind of branches: *Blood Centers (BCs)*, performing blood collection and processing activities; ii) *Blood Stations (BSs)*, performing collection activities only.

A deeper look into the performance of regional BSCs is given in Table 1, where we report the differences between the total production and the total consumption of blood units in the time span 2014-2018 (Centro Nazionale Sangue, 2019). As we can observe, strong asymmetries emerge across regions: some, like Lazio and Sardegna, exhibit significant shortages whereas others, especially the northern ones (Lombardia, Piemonte, Emilia-Romagna and Veneto), are strongly self-sufficient. Overall, we note that the self-sufficiency goal is reached in Italy: this evidence highlights the importance of inter-regional flows of blood units to counterbalance local deficiencies.

The above described scenario is completed by the presence of *Voluntary Associations (VAs)*, who help accomplishing the institutional purposes of the National Health Service through the promotion of blood donations and the protection of donors. Moreover, they can also carry out the collection of blood among their own members. In Italy there are various organizations of this kind: we focus, in particular, on AVIS (Associazione Volontari Italiani del Sangue) that is acknowledged as the largest voluntary association of blood donors. Indeed, AVIS is present throughout the national territory with a very articulated hierarchical structure, comprising one national office, 22 regional offices, 91 provincial offices and, approximately 3,400 municipal offices. Its crucial role is testified by the data reported in Figure 1, where we report, for each region, the percentage of donations coming from AVIS' associates over the total demand of blood. As we can see, AVIS contributed to 80% of the total national demand of blood in 2018. Notably, in some regions, its contribution was sufficient to satisfy the local self-sufficiency. Depending on the role played by Voluntary Associations and on the administrative level of the office eventually responsible for collection activities, various organizational models arise within regional BSCs. In the need of clarify these aspects, we performed a field analysis by interviewing regional VAs' managers whose results are reported in the next section.

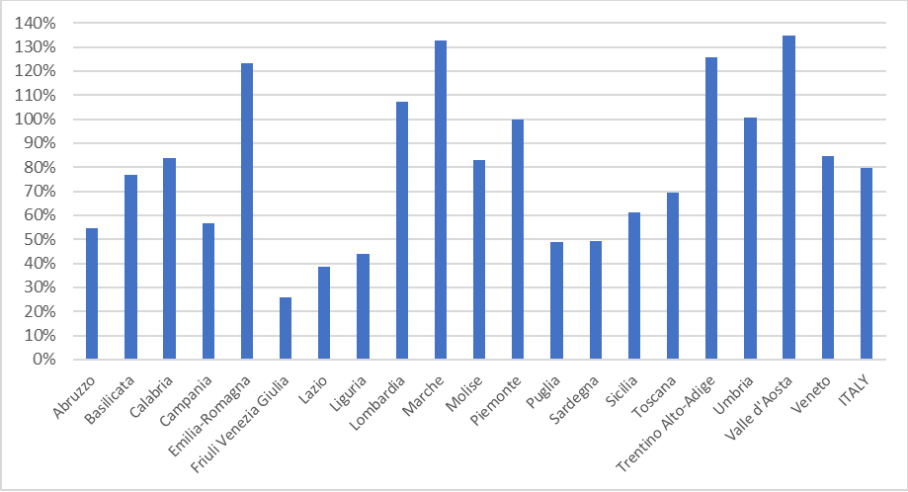

Figure 1. VAs' contribution to the regional demands of blood (source: AVIS, 2019)

3 A classification framework of BSCs' organizational models

At this stage, our analysis involved ten regions, i.e. ten regional managers from AVIS, who agreed to participate in the study. Details about the sample are reported in Table 3. All the semi-structured interviews were realized by telephone in June 2019.

It is worth reminding that Voluntary Associations (VAs) can perform two main kind of functions: sensibilization and new donors' recruitment, on the one hand; collection and donors' retention, on the other.

According to Saturni et al. (2013), their organizational models differ, in practice, with respect to two main dimensions: the first concerns the actual performance of the collection activities. In this sense, we therefore distinguish between: i) *Public models*, where only public facilities (BSs and BCs) collect blood units; ii) *Associative models*, where VAs actively support the collection phase.

The second lies in the in administrative level of the VA (municipal vs. provincial) responsible for each of the aforementioned functions. In particular, in the case of Associative models, we can further identify: *Decentralized models*, where all the activities (sensibilization and collection) are delegated to municipal VAs; *Centralized models*, where only provincial VAs perform collection operations. In this case, both provincial and municipal VAs perform sensibilization. A third model, that we denote by *Mixed*, emerges when there is a clear separation of these activities: provincial VAs perform collection, whereas municipal VAs are only in charge of sensibilization. We underline that, regardless the specific setting, collection is performed by special branches called *Collection Units*.

A similar distinction applies in the case of Public models. In this case, however, the third type (Mixed) does not hold. In summary, we identify five organizational models that are summarized in Table 2. In that Table we report, for each actor within regional BSCs, the operation they are responsible for (✓): Sensibilization (S) and/or Collection (C). The organizational model is then derived as a combination of the considered dimensions.

Table 2. Organizational models of regional BSCs

Actors	**Functions**									
	S	**C**	**S**	**C**	**S**	**C**	**S**	**C**	**S**	**C**
Transfusion Centers		✓		✓		✓		✓		✓
Provincial VA	✓				✓	✓				✓
Municipal VA	✓		✓		✓		✓	✓	✓	
Model	Public - Centralized		Public - Decentralized		Associative - Centralized		Associative - Decentralized		Associative - Mixed	

In Table 3, we detail the characteristics of the regions involved in our analysis. In particular, for each region, we show the number of Transfusion Centers (TCs), the total number of Voluntary Associations' (VAs) offices and the adopted organizational model,

according to the proposed framework. The reported data are useful for the quantitative analysis that are presented in the next section.

Table 3. Characteristics of the analyzed regions

Region	Population	Area $[km^2]$	No. of TCs	No. of VAs	Model
Campania	5,826,860	13670,95	17	67	Associative - Mixed
Emilia-Romagna	4,452,629	22452,78	12	332	Associative - Mixed
Friuli Venezia Giulia	1,216,853	7924,36	5	48	Public - Decentralized
Liguria	1,556,981	5416,21	10	64	Associative - Mixed
Lombardia	10,036,258	23863,65	42	661	Associative - Decentralized
Marche	1,531,753	9401,38	12	144	Associative - Mixed
Puglia	4,048,242	19540,9	21	134	Public - Decentralized
Toscana	3,736,968	22987,04	14	185	Associative - Decentralized
Umbria	884,640	8464,33	4	65	Associative - Decentralized
Valle d'Aosta	162,202	3260,9	1	22	Public - Decentralized

4 A deeper look into regional BSCs

In this section we deepen our analysis into the characteristics of regional BSCs, in light of the presented classification framework. Our goal, in fact, is to understand whether the organizational aspects, i.e. the adopted model and the spatial distribution of the facilities, affect the systems' performance. To this end, in the following, we discuss the results obtained by the calculation of some quantitative indicators.

In order to get a better understanding of the role of Voluntary Associations (VAs) within regional BSCs, in Figure 2 we depict the relative fraction (in %) of the donations coming from VAs' associates on the regional demand of blood in 2018. Actually, these values are those already shown in Figure 1: however, they are now restricted to the ten regions of the sample and thematized with different colours in dependence of the adopted organizational model. We recall that these values do not represent the actual amount of blood units collected by VAs; the latter, in fact, would be equal to zero in regions adopting a Public model. As expected, we can observe that the contribution of VAs is typically higher in regions characterized by an associative model (in green and cyan) rather than a public one (in red). In particular, we also note that higher peaks are reached in regions, like Emilia-Romagna and Marche, employing a mixed model (in cyan): this evidence seems to testify the relevance of a joint sensibilization effort by both municipal and provincial VAs. This result assumes an even higher relevance when comparing the number of VAs to regions like Lombardia. The above findings are confirmed also when looking at the so-called *donation rates*, i.e. the number of donations coming from VAs' donors, per 1,000 inhabitants. Indeed, from Figure 3, we note that a more capillary presence and a stronger engagement of VAs into collection activities seems to foster a higher propensity to donate blood.

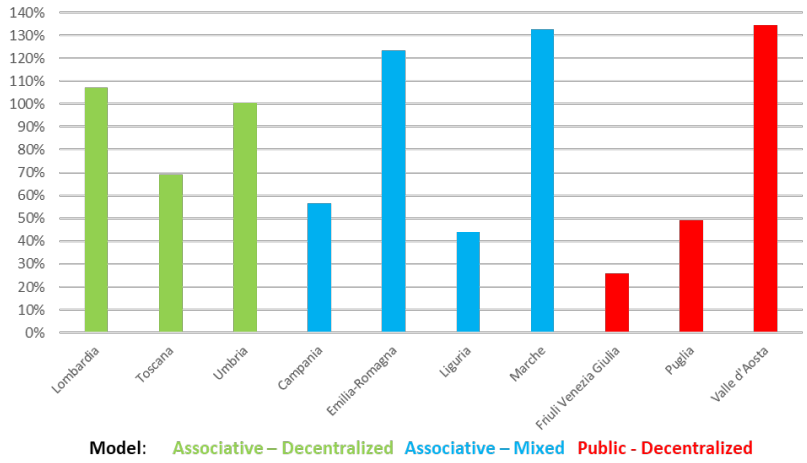

Figure 2. VAs' contribution to the regional demands of blood in the analyzed regions

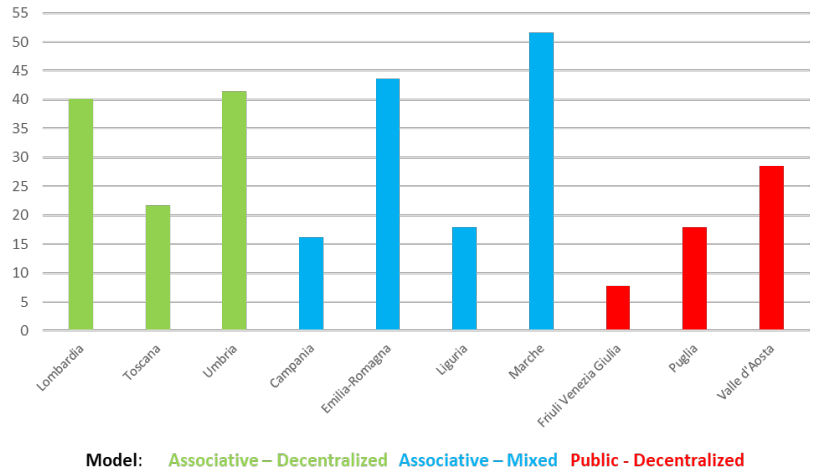

Figure 3. Donation rates in the analyzed regions

In such a context, an exception is surely represented by Valle d'Aosta: this result, however, can be reasonable explained if we consider that this region shows the highest number of VAs per 100,000 inhabitants, as we can observe from Figure 4. In the literature, this indicator represents a common accessibility measure which is typically referred to as *Provider-to-Population Ratio (PPR)* or *Container Index* (see Talen and Anselin, 1998). In that figure, each region is displayed as a point in a bi-dimensional space having the above indicator, calculated with reference to Transfusion Centers (TCs) and Voluntary Associations (VAs) on the axes. Besides, it is also worth noting that, in most of the cases, regions adopting an associative model tend to occupy the "northern" area in the graph: in practice, they are characterized by a higher availability of VAs, in

proportion to their population. In other words, they provide potential donors with a better accessibility, in terms of number of available facilities, to VAs.

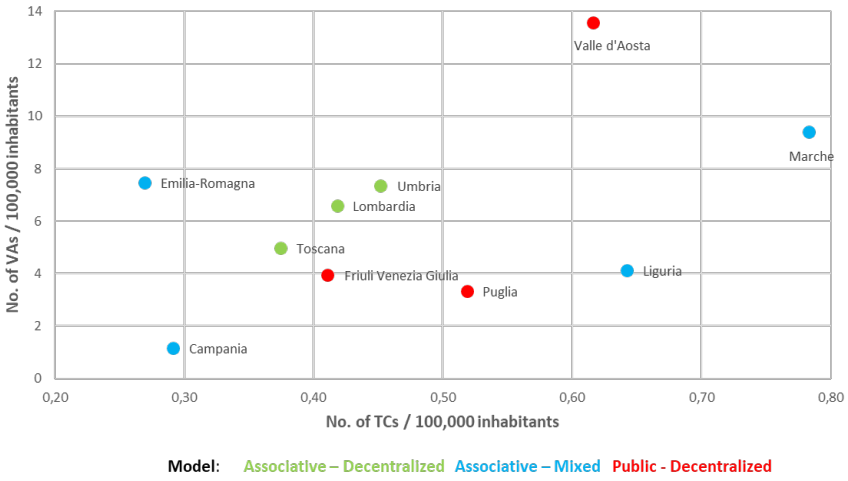

Figure 4. Provider-to-Population ratios in the analyzed regions

A similar analysis is reported in Figure 5, where we calculate two *spatial density* indicators, expressing the number of VAs and TCs per 1,000 km^2. These indicators offer a synthetic overview on the spatial distribution of these facilities over the regional territories.

What we note is that Campania keeps being the region with the lowest density of VAs, despite the organizational model adopted. This evidence may explain why this region is not able to reach the self-sufficiency goal (see Table 1).

The overall analysis is summarized in Table 4. For each region, we report: the adopted model; the fraction of donations (in %) collected by Voluntary Associations (VAs); the donation rate (number of donations per 1,000 inhabitants); the provider-to-population ratios (per 100,000 inhabitants) and the spatial density indicators (per 1,000 km^2), calculated for both Transfusion Centers (TCs) and Voluntary Associations (VAs); and, finally, the difference between the total production and the total consumption of blood units in 2018 (self-sufficiency). The latter indicator, if positive, indicates that a region is self-sufficient. Other than Campania, we observe that also Toscana does not satisfy its own demand of blood: interestingly, it presents an associative model and values of the calculated indicators that are in line with more virtuous regions. These results suggest a deeper look into the spatial organization of these regional BSCs, that is what we try to accomplish in the next section.

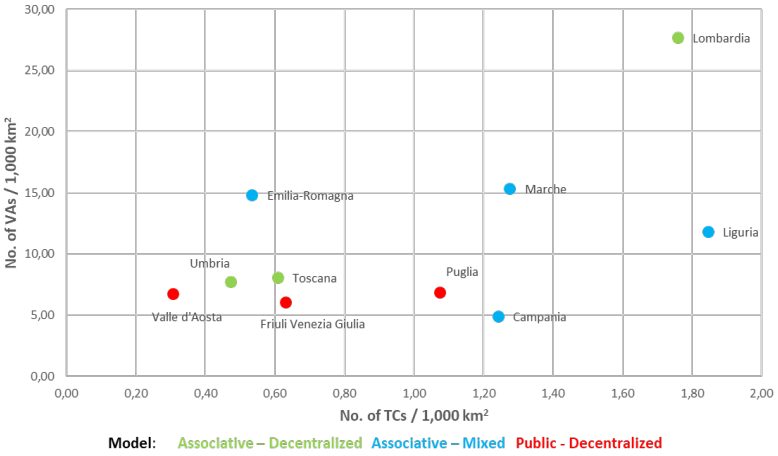

Figure 5. Spatial density indicators in the analyzed regions

Table 4. Results on the analyzed regions

				PPR		Spatial density		
Region	**Model**	**VAs contribution**	**Donation rate**	**TCs**	**VAs**	**TCs**	**VAs**	**Self-sufficiency**
Campania	Associative - Mixed	57%	16,20	0,29	1,15	1,24	4,90	-5952
Emilia-Romagna	Associative - Mixed	123%	43,57	0,27	7,46	0,53	14,79	10982
Friuli Venezia Giulia	Public - Decentralized	26%	7,70	0,41	3,94	0,63	6,06	8142
Liguria	Associative - Mixed	44%	17,86	0,64	4,11	1,85	11,82	1033
Lombardia	Associative - Decentralized	107%	40,12	0,42	6,59	1,76	27,70	21121
Marche	Associative - Mixed	133%	51,57	0,78	9,40	1,28	15,32	2282
Puglia	Public - Decentralized	49%	17,94	0,52	3,31	1,07	6,86	2277
Toscana	Associative - Decentralized	69%	21,65	0,37	4,95	0,61	8,05	-724
Umbria	Associative - Decentralized	101%	41,43	0,45	7,35	0,47	7,68	1082
Valle d'Aosta	Public - Decentralized	135%	28,48	0,62	13,56	0,31	6,75	1479

5 Spatial analysis

In this section, we realize a spatial analysis with the aim of highlighting key differences in the spatial organization of regional BSCs. In what follows, we first give some preliminary definitions on the concept of accessibility and on its measure. Then, we present the selected case study and the results obtained from the performed analysis.

5.1 Healthcare accessibility

The concept of *accessibility* refers to the relationship between the location of suppliers and the locations of clients, involving both spatial (e.g. travel times, distances) and non-spatial factors (e.g. demographic and socio-economic variables). More specifically, *spatial accessibility* expresses the relative easiness of a client to reach a facility from a given location (Wang, 2012). The literature is teeming of contributions dealing with methodological proposals to measure it (see Neutens, 2015). Among them, we refer to the distance from the closest service (Apparicio, 2008, Bruno et al. 2020): indeed, in the context of the present study, it is reasonable to assume that a donor is attracted by the nearest facilities to donate blood. In order to adopt this measure to the purpose of our work, some notation needs to be introduced. In particular, with reference to a generic study area, we assume the presence of a discrete set of nodes, say I, where potential donors are located. We denote by d_i the number of donors associated to each node $i \in I$. Then, we consider various sets corresponding to the actual locations of the facilities belonging to regional BSCs, namely: J_{TC}, representing the current locations of Transfusion Centers (TCs); J_{CU}, corresponding to the locations of Collection Units (CUs), i.e. facilities where blood collection are performed by Voluntary Associations; J_{VA}, corresponding to nodes where Voluntary Associations' offices (VAs), that do not perform collection activities, are located. Finally, we denote by c_{ij} the distances between each pair of donors' nodes and facilities. Therefore, the accessibility of donors $i \in I$ to a generic set of facilities K, can be assessed by means of the following indicator: $A_i = \min_{j \in K}\{c_{ij}\}, \quad i \in I$. Clearly, various accessibility indicators can be calculated in dependence on the set K. In the context of the present study, the latter can correspond to the specific sets above introduced (J_{TC},J_{CU},J_{VA}) or to their combinations (e.g. $J_{TC} \cup J_{CU}$, etc.).

5.2 Case study

We now present the data test used to perform our spatial analysis. In particular, we selected three regions, namely Campania, Tuscany and Emilia-Romagna as our case study. The rationale behind this choice lies in the results shown in the previous sections: these regions adopt a similar organizational model but present significant differences in their performance levels.

In order to perform our study, we apply the methodology proposed by Barbarisi et al. (2019). Accordingly, we discretized the study area by extracting the centroids corresponding to the regional census tracts (ISTAT, 2011), where we assumed that potential donors are concentrated. Then, we mapped the actual locations of the considered facilities based on data retrieved from our interviews and/or freely provided by official sources. Finally, the distances c_{ij} between the centroids and the facilities were determined as the shortest paths on the road network. Details about our study area are given in Table 5, where we present, for each region, the following parameters: the living population, the

number of census tracts (i.e. $|I|$), the number of Transfusion Centers (TCs, $|J_{TC}|$), the number of Voluntary Associations' offices (VAs, $|J_{VA}|$), and the number of Collection Units (CUs, $|J_{CU}|$).

Table 5. Characteristics of the regions under analysis

Region	Population	No. of census tracts	No. of TCs	No. of VAs	No. of CUs
Campania	5,826,860	21,050	17	53	14
Emilia-Romagna	4,452,629	35,551	12	172	160
Toscana	3,736,968	25,728	18	178	7

5.3 Analysis of the results

In order to better evaluate the spatial accessibility conditions of potential donors, we calculate the cumulative distributions of users' distances from the closest facility within each regional BSC. In practice, we define an accessibility function $\gamma = f(c) \rightarrow [0,1]$, representing the percentage of users γ having a distance from their closest facility not exceeding c. Conversely, $c = f^{-1}(\gamma)$ represents the accessibility condition of a given percentage γ of users, i.e. the distance c at which these users have at least one facility. In Figure 6 we report the accessibility distributions obtained by considering only the distance to the closest Transfusion Center (TC). As we can see, in the case of Campania, 70% of the population has the closest TC within 10 km ($\gamma(c = 10.00) = 0.70$). Within the same distance, only 40% of potential donors have the closest available facility in Emilia-Romagna. Overall, we can observe that the distribution obtained in Campania and Toscana dominate the one yielded in the case of Emilia-Romagna, which denotes better accessibility conditions to TCs in the first two regions. This is also reflected by the values of the average accessibility distances, reported in Table 6. In that table, we also show the accessibility distances corresponding to certain fractions of donors (i.e. $c(\gamma = \{0.25,0.50,0.75,1.00\})$).

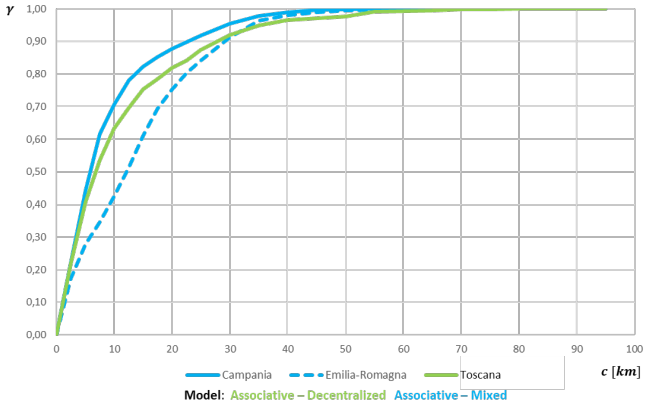

Figure 6. Distribution of the accessibility distances to Transfusion Centers

Table 6. Accessibility distances by fraction (γ) of donors

Region	$\gamma = 0.25$	$\gamma = 0.50$	$\gamma = 0.75$	$\gamma = 1.00$	Average accessibility [km]
Campania	2.77	5.80	11.37	63.46	8.93
Emilia-Romagna	3.93	12.13	19.84	71.31	13.63
Toscana	2.85	6.73	14.77	86.26	11.18

This scenario is completely reversed when considering donors' accessibility to both Transfusion Centers and Collection Units. As it also detailed in Table 7, we note that, in Emilia-Romagna, potential donors should travel, on average, only four km to donate blood; this value increases up to more than seven and 10 km in Campania and Toscana, respectively. Table 7 reports also information on the accessibility to Voluntary Associations (VAs) that only perform sensibilization activities. These values testify, again, a very dense presence of VAs in Emilia-Romagna. Ultimately, the obtained results seem to demonstrate that an effective spatial distribution of facilities over the territory, well-coordinated among the different actors of the healthcare ecosystem, can positively affect the operational performance of regional BSCs.

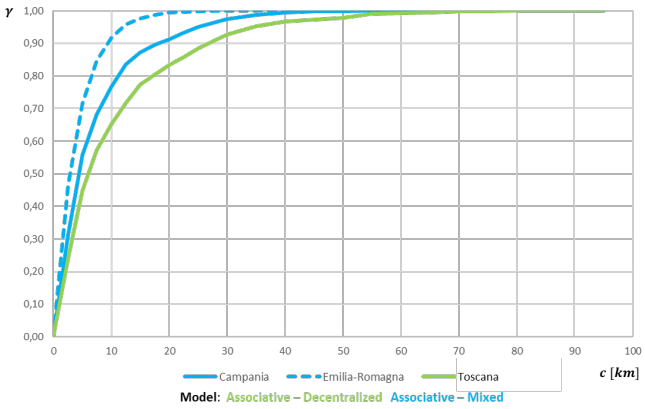

Figure 7. Distribution of the accessibility distances to Transfusion Centers and Collection Units

Table 7. Accessibility distances by fraction (γ) of donors and set of facilities

Set of facilities	Region	$\gamma = 0.25$	$\gamma = 0.50$	$\gamma = 0.75$	$\gamma = 1.00$	Average accessibility [km]
Transfusion Centers	Campania	2.77	5.80	11.37	63.46	8.93
	Emilia-Romagna	3.93	12.13	19.84	71.31	13.63
	Toscana	2.85	6.73	14.77	86.26	11.18

Transfusion Centers and Collection Units	Campania	2.02	4.21	9.40	63.46	7.21
	Emilia-Romagna	1.17	2.77	5.53	30.60	4.00
	Toscana	2.57	5.86	13.72	86.26	10.51
Voluntary Associations	Campania	1.58	3.05	6.23	58.03	5.24
	Emilia-Romagna	0.80	1.93	3.48	19.85	2.39
	Toscana	1.18	2.45	4.44	48.67	3.24

6 Conclusions

Blood Supply Chains (BSCs) are a complex set of actors, facilities and relationships, whose goal is to manage the whole flow of blood and its derivatives, from donors to patients. As blood is donated on a voluntary and non-remunerated basis the organization of this service on the territory is fundamental in order to attract donors and satisfy the demand of blood (i.e. self-sufficiency). In this paper, we tried to understand what are the organizational aspects that can affect the Italian BSC performance at the regional level. These aspects include: the organizational model adopted and the spatial of distribution of the facilities. With these aims in mind, we realized a field analysis, by interviewing regional managers from the main Italian association of donors. As a result, we classified regional BSCs within a framework comprising five different organizational models. The latter was then used to perform a quantitative analysis which highlighted that regions adopting an Associative model, i.e. where Voluntary Associations perform collection activities, tend to achieve better operational performances. Moreover, some preliminary findings from a spatial analysis seemed to confirm that these performances are positively affected by a widespread diffusion of BSCs facilities over the regional territory.

The present work, that is not free from limitations, opens to various further developments. First, it would be necessary to collect more real data and extend our study to other regional contexts in order to better validate the insights we obtained from our analysis. The spatial analysis could be enriched by employing and comparing various of the methods known in the literature, and by trying to account also for non-spatial factors, relevant to model donors' behaviors. In this regard, regression models could be exploited to explain BSC performances on the basis of a larger set of factors. Finally, novel strategies for the reorganization of existing BSC and/or for a more effective orchestration of their resources in regional contexts, could be also modelled and tested.

Abstract

The presence of comorbidities and multiple chronic diseases, and the related prescription of complex medications, as well as concerns in therapies changes, present many professional challenges in the clinical decision-making process. Multiple medications' use (i.e. polypharmacy),

is common in this population, and could be associated to adverse outcomes and presence of drug-drug interactions.
The present study aims at investigating the variables impacting on the clinical choice, and the potential support of digital innovation and other knowledge asset, such as InterchecкWEB and/or guidelines, to optimize the prescription decision making process in older and frailer patients, in polytherapy.
A review on the topic is performed for revealing the principal social and clinical factors, impacting on the clinicians' propensity to chance the patients' therapy. An observational study was conducted, involving head physicians and clinicians (N=35) referring to the Internal Medicine wards, of five Italian medium size hospitals. In June 2019, each clinician completed a questionnaire, aimed at evaluating 15 clinical cases, thus defining if in case of specific information derived from IT systems (such as INTERCheckWEB), they would have changed the patient's current therapy, during an Internal Medicine hospitalization.
Data were analysed considering three methodological approaches. i) Relationships between variables, were investigated to test the existence of correlations among them. ii) A hierarchical sequential linear regression model was implemented to define the predictors of the clinician propensity to change therapy. iii) A Qualitative Comparative Analysis – QCA, was implemented, in order to complement previous statistical approaches, with a comparative-configurational one.
Results reported that patient's age ($\beta = 0.505$, p-value = 0.000) and autonomy ($\beta = 0.303$, p-value = 0.000), as well as clinician's perception with regard to IT ease of use ($\beta = 0.298$, p-value= 0.043) and seniority ($\beta = 0.087$, p-value = 0.009), number of drugs assumed by the patients ($\beta = 0.541$, p-value= 0.000) and number of concomitant diseases ($\beta = 0.302$, p-value = 0.000) are factors influencing a potential change in the current therapy.
The QCA-crisp confirms the regression models results, highlighting that the number of drugs is a necessary factor being an active variable in all different configurations analysed.
The findings provide insight into factors influencing clinical assessment decisions, how a combination of them is related to the outcome, in order to suggest mechanisms to foster translation of research, into clinical practice.

Paper type – Academic Research Paper

1 Introduction

Clinical decision-making is the process of defining an informed judgment about the diagnostic and treatment pathways necessary for the patients (Hardy & Smith, 2008), and it represents the key point of health policy and medical practice (Kaplan 2005). Because health outcomes are probabilistic, most decisions are made under conditions of uncertainty: in particular, clinical decision-making is "a complex process involving information processing, evaluation of evidence, and application of relevant knowledge to select the appropriate interventions that provide high-quality care and reduce risk of patient harm" (Miller et al., 2020).

In this regard, the presence of comorbidities and multiple chronic diseases, and the related prescription of complex medications, as well as concerns in therapies changes, present many professional challenges in the clinical decision-making process. This is particularly relevant, since older adults (accounting for the 40% of outpatients - Olmos et

al., 2012; Maher et al., 2014) have a higher prevalence of multiple chronic health conditions, for which multiple medications are recommended as treatment (Charlesworth et al., 2015; Hajjar et al. 2007; Gurwitz et al., 2004). Consequently, multiple medications' use (i.e. polypharmacy), is common in this population, and could be associated to adverse outcomes (Field et al., 2004), such as drug-drug interactions (DDI) or drug-related adverse events. Approximately half of the elderly population is prescribed a non-suitable or non-desirable drug, this happens more frequently in polypathological patients: in some cases, the prevalence of potentially inappropriate medications can reach 71% in frail elderly people (Bjerre, et al., 2015; Récoché et al., 2017).

Difficulties in the management of such patients often happen in the clinical practice, since clinicians must monitor also drugs prescribed by other healthcare professionals. Usually, the clinical decision-process is guided by the knowledge assets based on experience and expertise of healthcare professionals that continuously look for new information and interprets it, to reassess the accuracy of his/her decision (Rudolph et al., 2009). Analysing the main decision strategies, with respect to task complexity and effort needed for accurate decisions, Payne et al. (1990) finds that individuals "selectively process a subset of the available information and/or selectively apply operations to that information that are easier to perform" (p. 4). It emerges that the decision-making process relies on effort reduction, since it examines fewer cues, integrates less information and examines fewer alternatives (Shah and Oppenheimer, 2008).

In the decision-making process the digital solutions can support the clinical process and the exchange of knowledge, in the evaluation of the therapy appropriateness. The above demographic changes put in evidence how a reduction of potentially inappropriate prescriptions for elderly patients in polytherapy, represents a relevant topic.

The knowledge assets of healthcare professionals' experience and expertise can be integrated by other knowledge assets, such as digital innovation and guidelines to support the clinicians towards an appropriate prescription. Digital innovation and guidelines could avoid that clinicians' judgment can be influenced by irrelevant information that can lead the individual to misinterpret the situation and make a wrong decision.

Although the availability of digital innovation to support the decision-making in polypharmacy, it remains poorly explored the factors that could prompt the clinicians to leverage on this digital solution to make a prescription for elderly patients in polytherapy. Given the multidimensional and complex nature of clinical decision making for treatment prescription in elderly patients, factors influencing it, may arise from multiple source, including both clinicians' behaviour and characteristics (individual factors) and non-clinical variables, such as task complexity (Smith et al., 2008).

The present study aims at investigating the factors impacting on the clinical choice, and the potential support of digital innovation and other knowledge assets, such as guidelines, to appropriately support the prescription decision making process, in older and frailer patients, in polytherapy. One of the most outstanding digital innovation is INTERCheckWEB, a Computerized Prescription Support System (CPSS), for helping

clinicians during their routinely clinical practice, improving the appropriateness of drugs prescription (Ghibelli et al., 2013). INTERCheckWEB is a user-friendly interface, enabling the clinician gather information on a specific drug or DDI and facilitating the evaluation of any possible therapy switches or changes. INTERCheckWEB stores useful information with regard to potentially inappropriate medications, anticholinergic burden and dose adjustment in case of renal disease and modality for drug withdrawals, thus relying on the most recent versions "Beers", and "START and STOPP" criteria (O'Mahony et al., 2015; AGS, 2019).

Coherently with these premises, the study addressed the following research question: "Which are the key factors determining the change in the treatment options in frail patients in polytherapy, in presence or in absence of specific information deriving from IntercheckWEB and guidelines?".

2 Research design and theoretical background

The factors affecting the decision-making in polypharmacy are grouped in variables related to clinicians and variables related to task complexity. Based on a literature review, we infer then main factors impacting on the clinicians' choice to change the patients' current therapy, in the management of elderly and polypathological patients, thus identifying a theoretical framework with the following hypotheses.

Clinicians' behaviour towards guidelines and clinical protocols

Despite the growing number of guidelines, their use in practice is slow and complex, and often not applied (Sheldon et al., 2004). In general terms, clinicians are prone to use guidelines and recommendations: they should be aware of a guideline and need to have some knowledge of their contents. Clinicians' knowledge and reliability of the guidelines influences attitudes, and attitudes affect clinical practice behavior (Welke et al., 2003). In the current clinical setting, the more the clinician is aware with regard to the quality of guidelines and clinical protocol information, the more he is influenced in changing the current clinical practice.

According to the above, the following hypotheses were developed.

Hp 1. The negative clinicians behaviour towards guidelines and clinical protocols has a negative impact on the clinical choice to change the patients' current therapy.

Hp 2. The positive clinicians behaviour towards guidelines and clinical protocols has a positive impact on the clinical choice to change the patients' current therapy.

InterCheckWEB usefulness

In the routine practice, the clinicians tend to use any innovative technology, such as InterChecWEB, only if they believe IT could improve daily activities and the proper use of the tool itself, aiming at the best quality and safety, for the patient (Venkatesh et al.,

2010; Holden et al., 2010). Hence the IT usefulness perceptions increase, the more the probability that this tool will help the clinician to make the most appropriate choice (Davis, 1989, Holden et al., 2010).

HP 3. INTERCheckWEB perceived usefulness has a positive impact on the clinical choice to change the patients' current therapy.

InterCheckWEB ease of use

InterCheckWEB ease of use should be defined as the lack of effort in understanding its functioning, thus leading the clinician to use this tool in the routinely clinical practice, in his/her decision-making process concerning the patients' therapeutic treatment (Davis, 1989, Holden et al., 2010). In particular, the greater the INTERCheckWEB ease of use, the greater the willingness to make different choice given the tool suggestions, with regard potential DDI.

HP 4. INTERCheckWEB perceived ease of use has a positive impact on the clinical choice to change the patients' current therapy.

Clinicians' seniority

Literature stated that clinicians with a longer seniority are more likely to use guidelines to address their clinical practice (Bochud et al., 2002). Additionally, the more the clinicians know about guidelines and protocol, the more the clinicians learn about the potential development of drug-drug interaction or adverse events, thus to a possible change of the current patient's therapy (Fried et al., 2011). In fact, literature stated that the clinical decision-making process is affected by several factors, such as clinicians' experience and ability, in making decisions regarding a given pharmacological treatment (Smith et al., 2008).

HP 5. The clinicians' seniority has a positive impact on the clinical choice to change the patients' current therapy.

Patients' polytherapy

Polytherapy refers to the use of multiple medications. Specific combination of various drugs administered to a single patient has the potential to result in an interaction (Montamat et al., 1989): as number of medications increase, the potential for drug interactions increases. In this view, the number of drugs administered could be an interesting topic to change the patients' current therapy, by stopping medication and thereby improving the patients' wellbeing (Pizzini., 2018; Schuljng et al., 2012).

HP 6. Polytherapy has a positive impact on the clinical choice to change the patients' current therapy.

Comorbidities

Patients suffering from multiple and concomitant diseases present a higher possibility to develop drug-drug interactions (Pizzini, 2018, Nobili et al., 2011), thus leading the

clinicians to deprescribing activities. Literature stated that multi-morbidity would suggest the clinicians to change the current therapy, in order to avoid the development of adverse events (Pizzini, 2018).

HP 7. Patient concomitant disease has a positive impact on the clinical choice to change the patients' current therapy.

In addition to the direct relationships between the above-mentioned independent variables and the clinical propensity to change the patients' current therapy (playing, instead, the role of dependent variable), the proposed framework also includes three moderators (two of them acting also as independent variables): patients' polypharmacy, quality of available patients' data, and clinicians' seniority.

With regard to patients' polypharmacy, literature (Vehoof et al., 2000) stated that the higher the number of concomitant diseases of a patient, the higher the number of drugs that the patients should assumed for the satisfaction of his/her health need. In this view, the number of drugs is assumed to strengthen the relationship between patients' comorbidity and clinician's propensity to change the current therapy.

HP 8. Polypharmacy positively moderates the relationship between patients' comorbidity and clinicians' propensity to change the current therapy.

The quality of available patients' data could be defined as the quality, appropriateness, and the presence of a large amount of detailed and complete information, recorded for a given patient. The lack of clinical information concerning a patient, or the absence of some anamnestic or comorbidities data, or the presence of potential errors in their collection, do not allow the clinician to identify a correct pharmacological treatment (Sorensen et al., 1996). This aspect is particularly relevant within the proposed setting, related to the patients in polytherapy management. According to the above, the following hypothesis concerning the moderator effect of the quality of available patients' data is displayed.

HP 9. The quality of available patients' data positively moderates the relationship between polytherapy and clinicians' propensity to change the current therapy.

In conclusions, clinicians' seniority, in terms of increasing experience over time, would strengthen the relationship among *i)* the positive clinicians behavior towards guidelines and clinical protocols; *ii)* INTERCheckweb ease of use; and ii) INTERCheckweb perceived usefulness, and the clinicians' propensity to change the current therapy. On the one hand, the higher the clinicians' seniority, the greater his/her knowledge with regard guidelines and protocol, with relevant consequences in terms of therapy changes (Smith et al., 2008). On the other hand, clinicians with a greater experience could present a low-level IT systems knowledge, thus negatively influencing INTERCheckWeb ease of use, and usefulness (Melas et al., 2011, Mohamadali et al., 2010).

HP 10. Clinicians' seniority positively moderates the relationship between positive clinicians' behavior towards guidelines and clinical protocols and clinicians' propensity to change the current therapy.

HP 11. Clinicians' seniority negatively moderates the relationship between INTERChekWEB ease of use and clinicians' propensity to change the current therapy.

HP 12. Clinicians' seniority negatively moderates the relationship between INTERChekWEB usefulness and clinicians' propensity to change the current therapy.

Furthermore, it should be noted here that for the creation of a comprehensive framework, the following set of control variables was assumed: patient's age, patient's autonomy and patient's body max index (BMI).

A synthesis of the research framework is proposed in the following Figure 1.

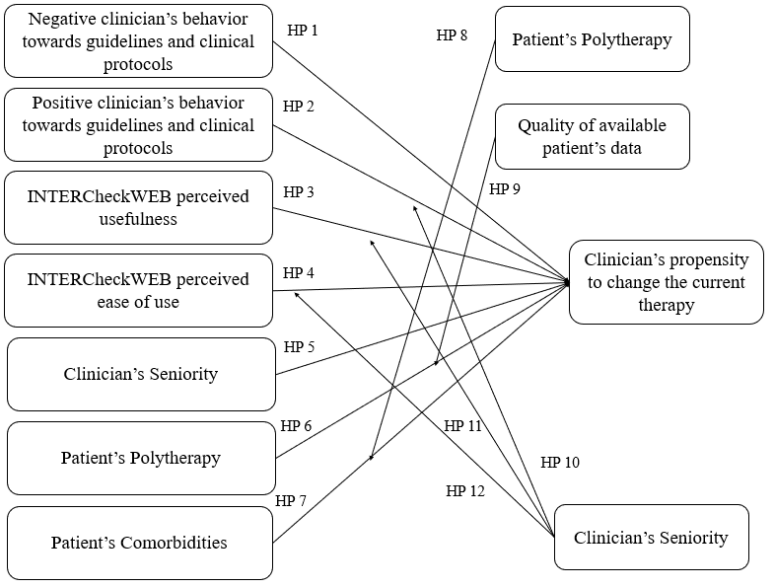

Figure 1 – Framework

3. Methods

3.1 Data collection

The study involved head physicians and clinicians (N=35) referring to the Internal Medicine wards, of five Italian medium size hospitals. In June 2019, each clinician completed a questionnaire, aimed at evaluating 15 clinical cases, thus defining if in case of specific information derived from INTERCheckWEB, they would have changed the patient's current therapy, during an Internal Medicine hospitalization.

At first a specific focus group (Basch, 1987; Beaudin, 1996; Rabiee, 2004) – composed of 6 clinicians and 2 researchers - was conducted, in order to define both the clinicians to be involved in the study and the clinical cases to be investigated.

On the one hand, the clinicians were determined on the basis of their seniority and their working position, thus selecting those who mainly are used to make clinical decisions under stressful and emergency conditions. On the other hand, the clinical cases were selected based on their clinical condition in terms of number of concomitant diseases and number of drugs administered to hospitalized patients (De Riu et al., 2013), assuming the time-horizon of 60 days before the institution of the focus groups.

After the selection of clinicians and clinical cases, a specific questionnaire was created, that was completed by all the professionals involved in the study, through an interview.

Besides the clinical information related to each patient (BMI, age, autonomy, number of concomitant diseases, number of drugs assumed, potential interactions emerged before INTERCheckWeb support), the questionnaire was composed to different evaluation scale aimed at gathering information with regard to the clinicians behaviour towards guidelines and protocol, as well as the INTERCheckWeb ease of use and usefulness. Once the clinician completed this first part, the results derived from INTERCheckWeb, in terms of development of potential interactions and adverse events, were shown to the clinicians in order to understand if this additional information would determine a possible change of therapy.

3.2 Statistical Analysis

Data were assessed by means of three methodological approaches.

- Relationships between variables, were investigated to test the existence of correlations among them.
- A hierarchical sequential linear regression model was implemented to define the predictors of the clinicians' choice to change the current therapy, establishing the impacts of independent variables and moderators respectively, previously defined. Three models were defined:
    - Model 1: Model composed of only the control variables.
    - Model 2: Model composed of Model 1, with the inclusion of the independent variables.
    - Model 3: Model composed of Model 1 and Model 2, with the inclusion of the moderator variable.
- A Qualitative Comparative Analysis - QCA (Ragin, 1987, Ragin 2000) was implemented, in order to complement previous statistical approaches with a case-oriented model that gives insights on the effects of variables in the context of investigated cases, and not in isolation, assuming the non-linearity of phenomena under investigation and basing on the principle of causal complexity.

QCA is an analytic technique that investigates about casual relationships through systematic comparisons. The aim is not to offer a single solution but to explain and discuss the complexity of the investigated phenomenon. QCA is an approach that operates

at the level of observed cases and processes each case as a holistic configuration of factors (Rihoux and Lobe, 2009). The basis of QCA's configurational approach is the analysis of sufficient and necessary causes to produce an outcome. A condition is necessary if it is present in all instances of the outcome. One condition will suffice if a particular outcome emerges whenever the condition is present (Ragin, 2008). However, there might be other conditions that lead to the same result; in other words, there could be multiple sufficient causes (Ragin, 2008).

In this work, a crisp QCA is applied. The criteria adopted in this research to dichotomize the factors, are based on the average value of each variable. What is important in this study is the set of combinations that can provide the output. We are looking for the features of variables that provide the output and for the combinations of inputs that do not provide the output.

4. Results

4.1. The sample under assessment

With regard to clinicians (N=35), the sample was mostly composed of females (63%). The average age of the clinicians involved was 45.23 years old, with a working experience of 16.14 years.

With regard to patients (N=15), the sample was mostly composed of females (60%), with an average age of 78.41 years old (range: 65.93). In general terms, the patients at the hospital admissions assumed on average 9 different drugs.

4.2. Results from the inferential analysis

The clinicians' behaviour towards guidelines and clinical protocols, INTERCheckWEB perceived usefulness and ease of use, clinician's seniority, patient's polytherapy and patient's comorbidities, were deeply analysed, in order to define their positive or negative impact on the dependent variable (clinician's propensity to change the current patient's therapy). In this view, both the strength and the linear relationship between variables were described.

Table 1 depicts all the potential relationships between variables.

It emerged that a higher clinician's propensity to change the current patient's therapy was strictly related to patient's age ($\beta = 0.110$, p-value = 0.011) and BMI ($\beta = 0.548$, p-value = 0.000). Furthermore, a significant negative relationship was reported between the negative behaviour towards guidelines and clinical protocols and the propensity to change the current therapy ($\beta = - 0.098$, p-value = 0.024). A clinician is more likely to change therapy if the patients assumed a greater number of drugs ($\beta = 0.211$, p-value = 0.000), as if the patients suffered from a higher number of concomitant diseases ($\beta = 0.511$, p-value

= 0.000). The moderator variables related to patient's data quality and polytherapy impacted on the clinical choice to change therapy.

Focusing on the relationships among the control variables and the independent variables, the following considerations emerged.

- Patient's age was strictly related to the development of concomitant diseases (β = 0.283, p-value = 0.000) and to polytherapy (β = 0.191, p-value = 0.000). In particular, the older the patients, the greater the number of comorbidities, and consequently the number of drugs assumed.
- A higher BMI was reported in patients suffering from multiple diseases (β = 0.568, p-value = 0.000) and assuming a greater number of drugs (β = 0.596, p-value = 0.000).
- A low-level of autonomy emerged in patients with a higher number of comorbidities (β = - 0.245, p-value = 0.000) and drug (β = - 0.486, p-value = 0.000).
- Clinician's seniority presented a negative relationship with the negative clinician behavior toward clinical guidelines and protocol (β = - 0.208, p-value = 0.000), as well as lower perceptions of INTERCheckWEB usefulness (β = - 0.094, p-value = 0.031) and ease of use (β = - 0.137, p-value = 0.002).

A regression analysis was conducted to test the hypotheses (Table 2). Inferential analysis demonstrated that younger patient's age (β = - 0.073, p-value = 0.048), autonomy (β = 0.303, p-value = 0.000) and BMI (β = 0.505, p-value = 0.000), as well as clinician's perception with regard to IT ease of use (β = 0.298, p-value= 0.043) and clinicians' seniority (β = 0.087, p-value = 0.009), number of drugs assumed by the patients (β = 0.541, p-value= 0.000) and number of concomitant diseases (β = 0.302, p-value = 0.000) are factors influencing a potential change in the current therapy. The moderator effects of both the data quality and polypharmacy (β = -0.661, p-value = 0.001), and the number of drugs and the number of comorbidities (β = -0.370, p-value = 0.000) were confirmed. The above aspects explained the 53.7% of the clinician's choice variance, to modify the prescription, reducing the number of treatments to be administered to the patients.

Table 1 – Relationships between variables

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16

4.3. Results from the QcA

QCA allows to analyse the outcome (change the therapy) considering also possible combinations of causal conditions. Table 3 contains the truth table generated for our model. Truth tables list the logically possible combinations of causal conditions and the outcome associated with each combination (Ragin and Sonnett, 2005).

Truth tables also indicate the proportion of cases in each configuration that are consistent with the outcome ("Consistency"). Consistency indicates how well the empirical cases are in line with the hypothesis that a condition (or a set of conditions) is necessary or sufficient for the outcome. Investigators select consistency thresholds for their analyses, based on their understanding of theory. We use 0.85 according to Ragin (2006).

In the Table 3, the column "out" indicates the output of the model (clinicians' propensity to change the current therapy).

Table 3 – Truth Table of the proposed model results

Clinician	Patient	Clinician experience	Usefulness	Easy of use	n. drugs	Positive behavior	Negative behavior	OUT

The Table 3 reveals interesting insights. Patients 1 and 3 are the most interested to the change therapy. These patients need a higher degree of polytherapy with respect to other patients. Moreover, the age and the autonomy of the patients are necessary factors in our analysis.

With regard to configuration, Table 4 clarifies that clinician's perception with regard to IT ease of use and seniority are factors influencing a potential change in the current therapy. Finally, number of drugs assumed by the patients, is a relevant factor due to it assumes positive value in all different configurations showed. Furthermore, a significant negative relationship was reported between the negative behaviour towards guidelines and the propensity to change the current therapy.

Table 4 - The configuration with clinician's propensity outcome

Configuration	**Clinicial Experience**	**Usefulness**	**Easy of use**	**Number of drugs**	**Negative Behavior**	**Positive Behavior**	**Output**	**Frequency**	**Consistency**
1	0	1	1	1	0	1	1	10	0,66
2	***1***	***0***	***0***	***1***	***1***	***0***	***1***	***9***	***0,93***
3	0	1	1	1	1	1	1	9	0,6
4	0	0	0	1	0	0	1	9	0,6
5	1	0	0	1	0	0	1	7	0,47
6	0	1	0	1	0	1	1	6	0,4

7	0	0	1	1	1	0	1	5	0,4
8	0	0	0	1	1	1	1	5	0,33
9	1	1	1	1	0	1	1	4	0,27
10	1	0	0	1	1	1	1	4	0,27
11	0	0	1	1	0	1	1	4	0,27
12	0	0	0	1	1	0	1	4	0,27
13	1	1	1	1	1	1	1	1	0,07
14	0	0	0	1	0	1	1	1	0,07
Sufficient configurations are in bold. The necessary configurations are in italics. The Frequency cutoff: 1.00 Consistency cutoff: 0.93									

Concerning the consistency and coverage, central measures within Qualitative Comparative Analysis (QCA), the table z shows that the configuration "Clinicians experience*Useful*˜Easy* *˜Positive Behavior" is the best consistent configuration. Authors would like to precise that coverage delineates the empirical relevance of a consistent solution. Furthermore, the symbol ˜ indicates that the factor is not present.

Table 5 - Best consistent configuration

		Raw Coverage	**Unique Coverage**	**Consistency**
Sufficiency	Clinicians experience*Useful*˜Easy* *˜Positive Behavior	0,13	0,13	0,93
Overall Solution		0,13		
Necessity		0,22	0,22	0,84
Overall Solution		0,22		

The consistency score of 0.93 indicates that 93% of the cases with this configuration have data consistent with the predicted outcome. Ragin (2006) holds that consistency scores below 75% undermine claims that a subset relationship exists, so this consistency score is encouraging.

Necessity analysis identifies the causal conditions without which a particular outcome will not occur.

The necessary condition explains 22% of the outcomes in the dataset, and 84% of the cases with this configuration have data consistent with the predicted outcome.

5 Discussions and Conclusions

Deprescribing is a new and emerging theme in the care of older adults living with multiple concomitant diseases, thus also including frail conditions. From a clinical point of view, deprescribing requires a comprehensive review of risk and benefits of a medication in the context of the quality of remaining life and patient and family priorities and preferences. More than 90% of inpatients are taking at least one inappropriate medication and up to 43% of medications taken by older patients lack a clear indication. Moreover, 5 to 11% of medications may be unintentionally prescribed for the same indication (Hanlon et al., 2004).

The present study investigated the setting of hospitalized patients, given the fact that approximately 45% of hospitalized older patients are discharged with five or more medications (Hajjar et al., 2005; Gamble et al., 2014). In this, view, it emerged that the clinical choice to change therapy is becoming relevant to decrease the incidence of drug-related adverse events and improve the adherence to medications, reducing the economic burden on the patient as well as on the health care providers. Despite the availability of many tools to minimize drug therapy-related problems, there is little guidance for the process of deprescribing, in general clinical practice.

In the investigation of the potential factors impacting on the propensity of the clinician to change the current patients' therapy (with a deprescribing approach), it emerged that having an IT system easy to use would be a facilitator to the clinical choice. Furthermore, the number of drugs and the number of concomitant diseases affecting a patient, play a key role in the potential current therapy changes (Figure 2). These results are confirmed by QCA analysis. In further research the analysis will be performed according to Fuzzy QCA.

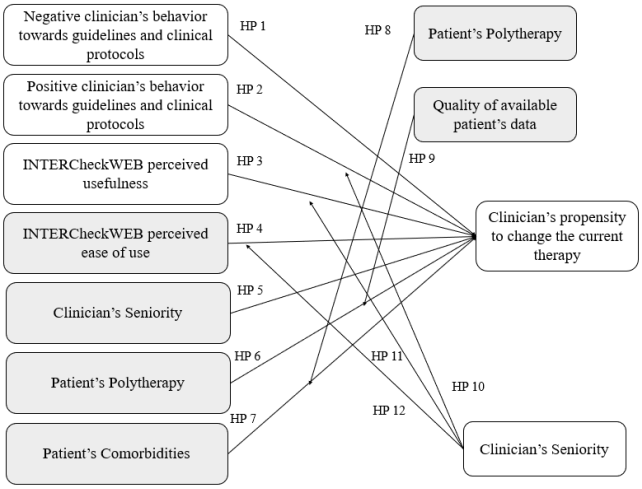

Figure 2 – Framework with verified hypotheses

The QCA confirms and complements these results, identifying the configuration "Clinicians experience*Useful*˜Easy* *˜Positive Behaviour" as the best consistent configuration.

Abstract

In recent years, the National Healthcare Services worldwide are forcing to implement spending review processes, to improve inefficiency areas and free up economic resources. Thus, the purchasing process, which have been centralized at regional and national level, require an in-depth optimisation. The present contribution aims at investigating the knowledge assets that might influence the design of a Complexity Index for Tender Procedures (CITP), useful to manage this topic in the public healthcare sector.
A literature review was performed for the identification of all the relevant assets to be considered in the design of a model for the CITP in healthcare. At first, a focus group, with 7 domains experts and 3 academic researchers was conducted, in order to define the variables affecting the CITP. A Delphi method was also implemented, to decline the variables and their relationships, thus defining the contribution of each variable and item, useful to develop the CITP framework. Once having created the CITP construct, a hierarchical sequential linear regression model was implemented to define the predictors of the dependent variables and validate the model. The evaluation of the robustness of CITP result was assessed by means of a bootstrapping approach.
According to the above, the presence of a tender preliminary phase, the number of batches and companies involved in a tender procedure, as well as the award criteria and the tender economic amount, were the main knowledge assets impacting on the CITP design. Results show the robustness of the CITP framework developed, with an Adj R^2 always higher than 80%: in particular, the tender preliminary phase, the number of companies, the economic amount, as well as the moderator effect of the criteria award on batches dependent variable and number of companies, mostly explained the complexity of tender. The CITP could be a useful support for any kind of technological batch tenders, given the variation lower than 5%, for any typology of batches. The

present study also confirmed the possibility to create validated scales by means of sum of items explaining the same topics as happened in other operational and innovation settings.

Keywords – Complexity Index for Tender Procedures, tender procedure, contracting authority, healthcare technology

Paper type – Practical Paper

1 Introduction

In recent years, healthcare systems have faced major organizational and costs challenges, particularly in the public sector. Hence, Governments worldwide launched programs of spending reviews aimed at cutting budgets, improving inefficiency areas (Radaelli et al., 2014).

Despite value-based healthcare, focusing on patient outcomes and costs of delivering these outcomes, can address both challenges, in this virtuous cycle, public procurement, in particular in Italian context, could represent a major barrier. In this view, the purchasing processes for public tender have been identified as a key component, for the improvement of healthcare systems performance (Busse et al., 2007), thus requiring an optimization.

Most hospitals and healthcare systems purchase medical products—including devices, supplies, and equipment—primarily, on the basis of the "up-front" purchase costs. The major concern related to the price-based approach to procurement, is that it addresses neither quality, nor the total cost of patient care. This failed to focus their attention on the needs of other stakeholders, such as patients, providers, healthcare systems, and society. Another technique used within the healthcare procurement process, is the Most Economically Advantageous Tender (MEAT), a value-based procurement framework, that paved the way to the introduction of outcomes, benefits, clinical and patients' point of view, significantly modifying the factors influencing pricing. By choosing the MEAT approach, rather than the cheapest option, decision-makers could be supported, in the procurement process, by a larger number of criteria, with a vision based on the entire care pathway efficiency.

In addition, another key element for improving the public tender efficiency and optimization, is represented by the centralization of purchasing processes at regional, and national level. Centralized procurement could be able to improve the achievement of many benefits through economies of scale (Karjalainen, 2009), decreasing the duplication of resources invested by different stakeholders. This approach enables for more efficient inventory control, reducing human resources and overheads costs. As result, a centralised purchasing process could affect the procurement tender speed, products' quality control and process flexibility (Racca, 2015).

Despite the growing interest in the role that strategic purchasing could theoretically have in empowering the cost-effective provision of healthcare services, while

simultaneously maximizing population health (Figueras et al., 2005), little is known with regard the aspects that could impact on its proper management, leveraging on complex and multifactorial issues.

In this regard, the Technical and Administrative Regional Supporting Agency – ESTAR (Tuscany Region, Italy) showed the need to define the complexity of each individual tender procedure, stratified according to the different product categories (administrative services, economic assets, medical devices, IT solutions, drugs and laboratory diagnostics and healthcare equipment). Moving on from these premises, the present contribution aims at investigating the knowledge assets that might influence the design of a Complexity Index for Tender Procedures (CITP), useful to manage this topic in the public healthcare sector. According to the above, the following research question was developed: "Which are the main factors leading to a higher complexity in the management of a tender procedure?".

2 Research design and methods

For the achievement of the above objectives, a theoretical framework with dependent and independent variables was accordingly developed.

A research design composed of the following phases was developed.

a) Identification of the variables affecting the complexity of tender procedures.

The identification of all the relevant variables to be considered in the design of a model for the CITP in healthcare was conducted, starting from a structured literature review (Tranfield et al., 2003) and an analysis of the purchasing processes items proposed in European and Italian laws (Directive 2014/23-24-25/UE; Legislative decrees 163/2006, 50/2016).

According to the above, a focus group (Dey et al., 2009) was conducted, involving 7 public tender experts and 3 academic researchers, in order to validate the pilot variables influencing CITP and derived from European and Italian laws. A Delphi method (Okoli and Pawlowski, 2004) was also adopted, to decline, quantify and create consensus concerning the list of variables and their relationships.

Thus, the tender complexity depends on all the variables that may have a dependent or independent influence on the following factors: *i)* the number of batches, *ii)* tender preliminary phase, *iii)* the economic amount and *iv)* the number of companies involved. Furthermore, the moderator effect of the adjudication criteria was identified (in terms of the lowest price, or the most economically advantageous tender – MEAT – as mentioned in the Directive 2014/24/EU of the European Parliament, Legislative Decree no. 50 of 18 April 2016), and studied as variable that could strengthen the relationships between the following variables: Batches Dependent Variable, Batches Independent Variable, Tender Preliminary Phase and Number of Companies, and the complexity of tender procedure.

b) Validation of the variables affecting the complexity of tender procedures and creation of the framework

A nominal group technique (Delbeq, 1975) was also implemented, involving 108 experts, to create consensus on the above assets, and to define their contribution in the development of the CITP framework, in terms of strength in their relationship. Once having defined the assets impacting on the CITP and their relative weights, the CITP was assessed using a sum approach as described in literature for other similar constructs (Wulf et al., 2010; Lubatkin et al., 2006), considering the tenders procedures related to the Technical and Administrative Regional Supporting Agency – ESTAR Tuscany, for the year 2018.

A synthesis of the research framework developed is proposed in Figure 1.

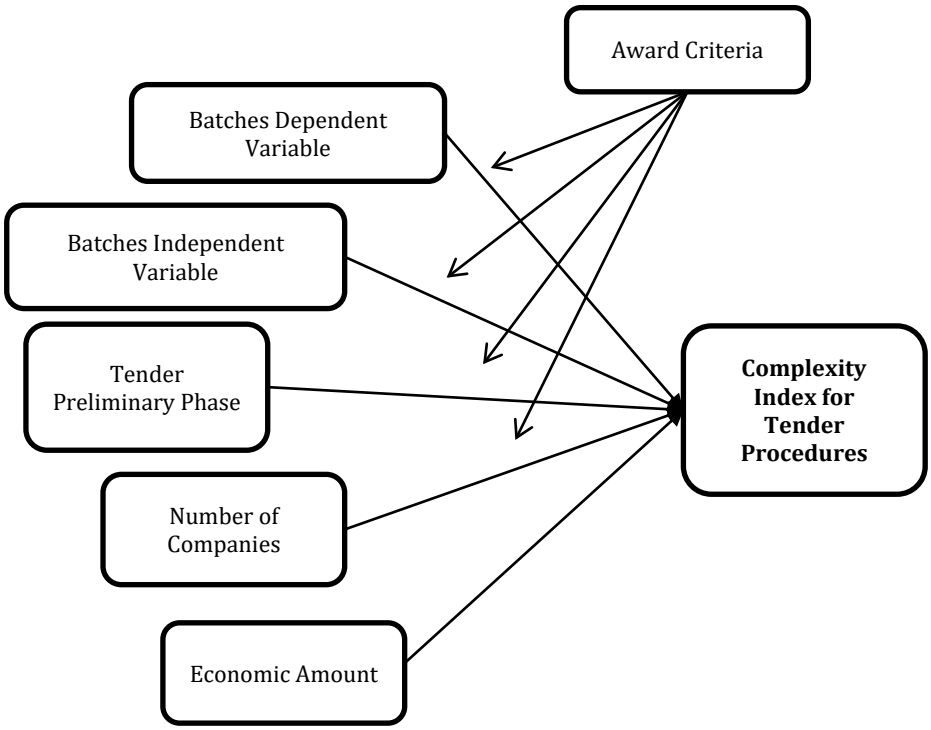

Figure 2 - Research framework

In the followings, the measures used for the creation of each variable are detailed. It should be noted here that all the variables and items considered in the study, are represented by scales with an incremental numerical value: the higher the value of the variable, the higher the related complexity with regard to the single item composing the general value of CITP:

Number of batches - Dependent Variables

- *Territory*, in terms of regional (2), local (1) and hospital (0) setting. The result ranged from a minimum of 0 (hospital context), to a value equal to 2 (regional).
- *N. hospitals involved*, in terms of number of hospitals involved in the tender process.
- *Technological and process innovation*: this variable identified the type of innovative technology for which the tender has been created, considering a scale ranging from 1 (services innovation), to 5 (innovative drug or service).
- *Sampling Exam*, in terms of number of sampling tests carried out on the product during the entire tender process.
- *Tender edition*, thus considering if the tender is a first edition (2) or not (1).
- *Presence of disposable device*: this item measured the presence of consumables or other services related to the life cycle of the product/service for which the tender has been created. The result ranged from a minimum of 0 (absence of consumables or other services), to a value equal to 2 (presence of consumables or other services).
- *N. of user points*, in terms of number of hospital departments requiring the specific tender object.

Number of batches - Independent Variables

- *Interoperability of Systems and Technologies.* This variable measured how much the technology/service can be integrated with the systems and technologies available in the hospital that required it. This item was evaluated, considering a scale ranging from 1 (high level of integration), to 3 (low level of integration).
- *Innovation Level,* in terms of technology degree of innovation. The result ranged from a minimum of 1 (obsolete technology), to a value equal to 3 (early stage technology).
- *High interference,* this variable would analyse how much the lack of a specific product could affect the routinely healthcare activities. The above item considered a scale ranging from 0 (absence of lockout of activities), to 3 (lockout of activities).
- *Reliability of Requirements*, for which both the quality and reliability of the requirements, were considered, ranging from a minimum of 1 (high-level of reliability), to a maximum of 5 (low-level of reliability).
- *Ease to find Requirements,* in terms of detailed information availability with regard to the requirements, according to an evaluation scale, ranging from a minimum of 1 (reporting a higher availability of requirements, reporting a low level of complexity), to a maximum of 5 (reporting a lower availability of requirements, with the highest level of complexity).

- *HTA Assessment,* on the basis of the need to conduct a prior Health Technology Assessment to compare and evaluate the technology. The variable considered a scale ranging from 0 (no need of HTA assessment), 2 (need of HTA assessment).

Preliminary phase of tender – Variables

- *Presence of Technical Commission*, in terms of presence (1) or absence (0) of the any Technical commission.
- *Preliminary consultations*, considering the number of preliminary consultations conducted. This variable was measured using the following scale: 0 (no preliminary consultations), 1 (one preliminary consultation), 2 (more than one preliminary consultations).
- *Presence of mixed contracts,* based on five characteristics: *i)* supply, *ii)* supply and services, *iii)* supply and installation, *iv)* services and installation, *v)* supply, services and installation.
- *Type of procedure, Acquisition Modality and Type of contract, in terms of the different arrangements for awarding the contracts performed by* the Technical and Administrative Regional Supporting Agency – ESTAR (Tuscany Region). Thus, multiple contracts are available in the Italian Setting, different based on their complexity to be managed.

Furthermore, the following variables were evaluated in terms of presence (1) or absence (0), with regard to i) aggregator able to unify the needs derived from several hospital; ii) social clause, in terms of social impact of the technology; iii) compliance with regional laws and iv) interreference risk assessment document, The variables were evaluated, considering a scale ranging from 0 (absence of the specific item), 2 (presence of the specific item).

a) *Validation of the CITP framework*

Once the framework was created, a hierarchical sequential linear regression model (with enter methodology) was implemented to define the explicative power (Adjusted R^2) of the variables considered, measuring the CITP derived from a prevision ("forecast CITP") of tender procedures, not yet awarded.

The robustness of the results was also verified, using the Bootstrapping technique (Efron et al., 1993). The sensitivity analysis was performed, in order to verify: *i)* the variation between "forecast CITP" and "final CITP", calculated after the tender adjudication; and *ii)* the possibility to implement the CITP for any kind of healthcare technologies, requiring a tender procedure (medical devices, drugs, ITs, administrative services, *etc*…).

In particular, for the forecast CITP and of the final CITP calculation, 376 and 41 calls for tender, respectively, were collected from the Tuscany Region in the year 2018.

All the analyses were conducted with a significant level of 0.05.

3 Results

The results of the nominal group technique revealed that the presence of a tender preliminary phase, number of batches and companies involved in a tender procedure, are the main dependent variables to be considered in the design of CITP, as reported in Table 1. In particular, the perceptions about the variables' priority in the definition of CITP revealed that the tender preliminary phase assumed the higher weight (0.4), followed by number of batches (0.3), economic amount (0.2) and number of companies involved (0.1).

Table 1 - Priority of the main variables of the framework

Main Variables	Priority	Weight
Tender preliminary phase	1	0.4
Number of batches	2	0.3
Economic amount	3	0.2
Number of companies involved	4	0.1

The above main variables were also declined, in detail, into other sub-variables or scales, as reported in the Methods Section (Table 2).

In particular, the perceptions about the specific variables' priority in the definition of CITP revealed that the territorial context phase assumed the higher weight among the dependent variables (0.25) and the integration of the awarded product or service with the systems and technologies available in the hospital assumed the higher weight among the independent variables (0.29). The presence of technical commission (0.18) and the request of one or more preliminary consultations (0.16) were the most relevant variables among the variables relate to preliminary phase of tender.

Table 2 - Priority of the sub-variables of the framework

	Priority	Weight
Number of batches - Dependent Variables		
Territory	1	0.25
N. hospitals involved	2	0.21
Technological and process innovation	3	0.18
Sampling Exam	4	0.14
Tender edition	5	0.11
Presence of disposable device	6	0.07
N. of user points	7	0.04
Number of batches - Independent Variables		
Interoperability of Systems and Technologies	1	0.29

Innovation Level	2	0.24
High interference	3	0.19
Reliability of Requirements	4	0.14
Ease to find Requirements	5	0.1
HTA Assessment	6	0.05
Preliminary phase of tender		
Presence of Technical Commission	1	0.18
Preliminary consultations	2	0.16
Mixed contracts	3	0.15
Type of procedure	4	0.13
Presence of Aggregator	5	0.11
Presence Social Clause	6	0.09
Acquisition Modality	7	0.07
Type of contract	8	0.05
Compliance with Regional Law	9	0.04
Presence of Interference Risk Assessment Document	10	0.02
Economic Amount		
< 500,000 €		
from 500,000 to 1,000,000 €		
from 1,000,000 to 5,000,000 €		
from 5,000,000 to 10,000,000 €		
from 10,000,000 to 20,000,000 €		
> 20,000,000 €		
Number of companies		
1		
from 2 to 5		
from 6 to 10		
> 10		

Once having defined the priorities and the weights related to each single variable and item, the method of calculation used to measure the CITP value was defined, as detailed in Table 3.

Table 3 – Method of calculation

1. Score of Dependent Variable: Weight * Value * Number of batches	**∑ Variables (1,2,3,5) * Value of Criteria of adjudication + ∑ Variables (4)**
2. Score of Independent Variable: Weight * Value	
3. Score Tender Preliminary Phase Weight * Value	
4. Score of Number of Companies Weight * Value	
5. Score of Economic Amount Weight * Value	

The results of the regression analysis, focusing on the "forecast CITP" indicated that difficulties occurring in a tender preliminary phase (β=0.138), a higher number of companies (β=0.245), a higher economic amount (β=0.278), as well as the moderator effect of the criteria award on batches dependent variable (β=0.499) and number of companies (β=0.283), were independent predictors of the complexity of tender procedure, thus explaining the 88.2% of the CITP variance. The same trend emerged considering the "final CITP", on the adjudicated tender procedures, reporting the robustness of the framework developed, with an Adjusted R^2 always higher than 80%.

Table 4 - Validation of the CITP framework

	Model 1	**Model 2**
Independent variables		
Batches Dependent Variable	0.260*	-0.095
Batches Independent Variable	0.174*	0.037
Tender Preliminary Phase	0.091*	0.138*
Number of Companies	0.259*	0.245*
Economic Amount	0.577*	0.278*
Moderator variables		
Moderator effect of award criteria on Batches Dependent Variable & CITP		0.499*
Moderator effect of award criteria on Batches Independent Variable & CITP		0.110
Moderator effect of award criteria on Tender Preliminary Phase &CITP		-0.177
Moderator effect of award criteria on Number of Companies & CITP		0.283*
R^2	**0.795**	**0.885**
Adj R^2	**0.792**	**0.882**
F Value	**286.126***	**313.000***
AR^2	**0.795**	**0.090**
F (AR)	**286.126***	**72.014***

Focusing on the "forecast CITP", the most difficult tender to manage is related to medical devices (value = 14.32), whilst the lowest CITP was assessed for IT system

(value = 4.83). Focusing on the final value of the tenders that were accordingly adjudged, it emerged that the most complex tender is related to Administrative Services (value = 13.25), followed by Economic Assets (value = 10.03) and Medical Devices (value = 10.25). Statistical analysis revealed the absence of statistically significant differences between the "forecast value" and the "final value" of the CITP (p-value > 0.05), confirming the robustness of the model. However, this showed the generalizability of the proposed CITP framework, as well as its effective predictivity.

Table 5 - Results

Priority	Types of goods to purchase	Median final value CITP	Median forecast CITP	p-value
1	Administrative Services	13.25	7.12	0.197
2	Economic Assets	10.03	8.84	0.119
3	Medical Devices	10.25	14.32	0.107
4	IT System	7.17	4.83	0.540
5	Drugs and Laboratory diagnostics	6.32	8.91	0.150
6	Healthcare equipment	5.56	7.66	0.164

Furthermore, bootstrapping technique confirmed, for both CITP values, the possibility to implement the framework for any kind of healthcare technologies, with a range of variability always lower than 5%. Hence, we concluded that the CITP could also be a useful support for any type of technological lot offer.

Table 6 – Bootstrapping Analysis

Technological Batch Tenders	Average Δ %	Minimum Δ %	Maximum Δ %	
Administrative Services	-2.80%	-3.95%	1.79%	**Δ % always lower than ± 5%**
Economic Assets	1.13%	-2.25%	2.96%	
Medical Devices	-0.56%	-2.55%	2.31%	
IT System	1.57%	-3.67%	4.93%	
Drugs and Laboratory diagnostics	-0.58%	-3.06%	2.71%	
Healthcare equipment	-0.22%	-2.21%	1.85%	

4 Conclusions

A centralized procurement authority exhibits a higher volume of procurement actions, both in terms of quantity and budget, due to aggregated demands as well as a more numerous and higher trained staff that arises from localization at one place and a related need for procurement specialists (Arnold, 1999). In this regard the Technical and Administrative Regional Supporting Agency – ESTAR (Tuscany Region, Italy) showed the need to define the complexity of each individual tender procedure.

Academically, public procurement has been a neglected area of study even though governmental entities and public procurement practitioners have diligently worked to improve public procurement practices (Thai, 2001), supported by methodological and structured approaches.

The present study could be considered as the first attempt to define an aggregate index, that could easily and effectively calculate the complexity of a tender, in terms of resources and time spent. In this view, the results provide practitioners with a CITP, raising new awareness on the variables that affected tender procedures and suggests interventions for its appropriate management, until its beginning, in terms of necessary resources, organization and communication, thus supporting the entire process.

Figure 2 depicts the CITP framework with verified hypotheses. According to the following, it emerged that the most important variable to be managed, in order to simplify the entire public procurement process in healthcare, could be represented by the tender preliminary phase, the number of companies involved, as well as the economic amount of the entire tender.

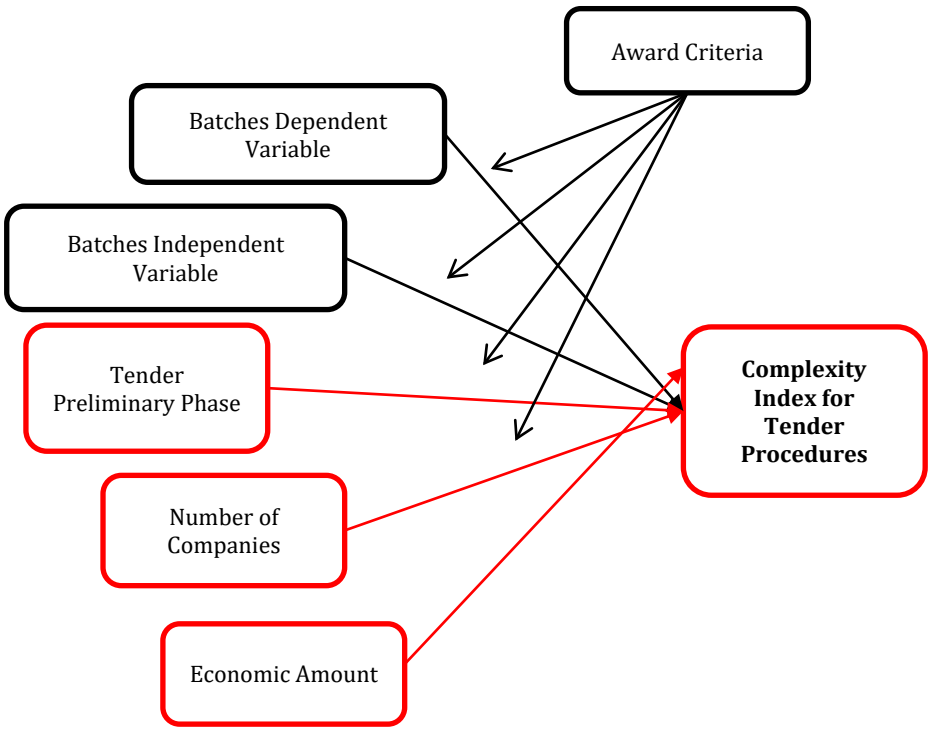

Figure 2 - Research framework with verified hypotheses

The CITP may also be useful in order to define realistically the standard schedule for each phase, in relation with the different complexity and product categories. The adoption of the CITP could support a more realistic planning of activities for contracting authorities' organization, thus identifying all the potential resources useful for the management of a tender process, with a degree of transparency not only towards the contracting authority, but also towards the staff who directly have to work on the tender. The ability to identify the process complexity at early stage, would provide better understanding, thus reducing risks and achieving a successful project management, due to better anticipation (Woord, 2008). This approach enables for more efficient process control, reduced human resources and overheads costs, as stated in literature (Cunningham, 2014). According to the above, it is possible to evaluate all the organisational and human resources management aspects, in order to include in the CITP development also these factors, forecasting the entire process complexity, and hypothesizing the time required to conduct all the necessary activities, forecasting the full time equivalent needed to implement and verify the tender procedure. The future logical step, useful for the contracting station, is to translate the complexity index, in an organizational complexity index.

According to the CITP robustness and replicability, thus being a useful support for any kind of technological batch tender, it should be noted that the present framework could be used by each Contracting Authority, in the definition, and in the scheduling of all the activities required for the tender procedure, thus forecasting the proper human resources, tasks and time needed to achieve the objectives. In this context, the Technical and Administrative Regional Supporting Agency – ESTAR (Tuscany Region, Italy) is implementing an informative tool to evaluate the complexity of each individual tender procedure, and to plan all the activities of its employees according to the amount of workload forecast. This tool is integrated with the ESTAR information system, in order to calculate the CITP automatically, when a tender is launched and after its award, as well.

From an empirical point of view, the results confirmed the possibility to create validated scales by means of sum of items explaining the same topics (i.e. batches dependent variable; batches independent variable; tender preliminary phase), as happened in other operational and innovation settings (Wulf et al., 2010; Lubatkin et al., 2006), thus creating a construct being more robust, solid and empirically superior. In accordance with the cited stream of literature, the CITP was created as the sum of multiple variables, thus being more consistent with the topic of research, in terms of creation a multidimensional synthetic indicator for tender complexity measurement combining more aspects.

The findings could contribute to enlarge the existing research, with regard to the use of real-world data in the healthcare sector, within the specific setting of the public procurement.

In conclusion, the adoption and the proper use of the CIPT framework could leverage on the, thus improving the internal processes, with important benefits, for Contracting Authorities, in terms of efficiency and effectiveness.

Abstract

In the last years, with the overwhelming explosion of medical devices and lack of resources in healthcare among scholars there has been an emerging and growing interest towards the medical equipment inventory management in hospitals. This paper aims at designing a tool of Replacement Priority Index (RPI) to measure the technical variables "technical RPI" through the development of a digital tool and the clinical opinions of users through the development of "professionals' Knowledge RPI" by means of structured elicitation of experts' judgement (clinicians). The technical RPI is based on literature review considering: *support availability; reliability; maintenance expenses; age; functional criticality.* The RPI based on professionals' knowledge of medical equipment resulted into an index consisting of information about the status (performance, quality, urgency), criticalities (uniqueness; faults; functional criticality), degree of use (frequency of use; volume of performance), ease of use (knowledge; degree of learning; interface), new equipment impact (staff availability, advancement of technology). The RPI tool has been pilot applied in a leading Italian hospital. The study offers an original and relevant contribution to the development of domain-specific knowledge and, as such, to fostering the diffusion of studies about Technology management in hospital in particular to facilitate the Investment Plan and guarantee the improvement of quality and safety of care.

Keywords – Technology obsolescence, Replacement priority index, RPI, Hospital, professionals' Knowledge.

Paper type – Academic Research Paper

1 Introduction

In the last years, with the overwhelming explosion of medical devices and lack of resources in healthcare among scholars there has been an emerging and growing interest towards the medical equipment inventory management in hospitals. There is a growing need to manage through automation processes the large amount of data in order to support with standardised procedures the process of decision making about the entire life cycle of the technologies. Some scholars emphasized the need of implementing predictive models for maintenance activities through a significant integration between technical performance evaluation and economic assessment (Seiti et al., 2019). In this context, the knowledge of professionals becomes essential during decision making process.

Despite its undoubted relevance and the growing awareness of the need for a systemic approach to medical equipment management in hospitals among practitioners and policymakers, in practice we are a long way from this approach. In fact, the initiatives and tools developed to manage the entire lifecycle of technology within hospitals have proved to be isolated, fragmented and not standardized.

The importance of professionals' Knowledge is particularly relevant for the phase of replacement of medical equipment. Among the different phases of the management of medical equipment in hospital, the one of replacement has always been one of the most critical because, unlike the others, it has not been systematized, nor have been established univocal criteria for general validity. Several authors encouraged the application of Replacement Priority Index (RPI) to medical equipment in hospital, recognising the benefits it brought to measure the urgency of decommissioning and renewal (Fennigkoh, 1992). However, the literature on RPI in healthcare is still scanty, and shows significant gaps at methodological level. First, there is no standard about what technical and organisational variables needs to be considered; second, only a very a limited number of RPI studies have implemented professionals' opinions (medical equipments' users) within an RPI tool which appear to be essential for an appropriate decision about replacement (Maggi, 2019).

2 Methodology

Literature review was used to identify and select the preliminary list of variables to be considered in the "technical RPI" and the "professionals' knowledge RPI". In the first phase, Scopus, PubMed and Web of Science are selected as scientific literature databases, being considered the systems with the highest number of articles in engineering and healthcare. A field study was carried out to develop, test and validate the RPI tool. The field study has been conducted in a leading Italian hospital in Lombardy. Moreover, the

tool has been validated through focus group and individual interviews with clinical engineers of the hospital.

For the professionals' knowledge elicitation, the questionnaire method was chosen to get responses from a large number of experts, and the data gathered may therefore be seen to generate findings with higher consistency and potential for generalisation. Moreover, the questionnaire allows to obtain new data that cannot be obtained from the technical evaluation, parameters that allow to objectify the real needs of each department considered.

3 Results

3.1 Development of RPI based on technical information

The literature shows a constant choice regarding the final formula of the IPS; in fact, as also shown in the first model proposed by Fennigkoh (Fennigkoh, 1992), the index is calculated as the sum of the scores of each criterion or sub-criterion, multiplied by its weight. The RPI can then be expressed as a linear combination, such as shown in the following formula (fig.1):

$$\text{RPI tech} = \sum \left(\sum_{i=1}^{n} \; \sum_{j=1}^{m} S_j \cdot w_j \right) \cdot W_i$$

Figure 1: RPI formula

where n and m are equivalent to the number of criteria and sub-criteria (if any) respectively chosen, Sj the score of the j-th criterion, while wj and Wi relatively the weight of the sub-criterion and the criterion. At this point, each parameter of the formula must be defined. It is convenient to start with the criteria and sub-criteria, since the attributes are actually indicative of the technical characteristics of each medical device. The development of a new classification algorithm, obtained the integration of existing models, with the introduction of some new criteria and measures. From literature review, 5 recurring categories have been identified: Availability of support", "Reliability" or "Downtime", "Maintenance Costs", "Age" and "Functionality" of the equipment. These criteria are then selected for the new model as the most representative for assessing the status of a medical equipment. In addition, it can be noted that for some criteria, such as "Age" or "Maintenance Cost", there are different calculation methods proposed by different studies, which differ for "Measure" and "Value." Therefore, it is necessary to choose the condition and the best scores for each parameter, justifying that decision. In the new model, it is preferred to adopt a fuzzy, non-binary methodology for use an approach that characterizes as much as possible the variables by selecting the conditions that offer the highest number of intervals and assignable scores. It is emphasized that this

part of the study should be carried out by comparison and aid from engineers and technicians, being aware of the specific hospital context, and its dynamics, the equipment present, the usable data and the measurements reasonable to use in a context of specific hospital.

For example, with regard to the age parameter, the assignment of more specific criteria is offered by the Capuano model (Capuano, 2010) with six intervals proposed i.e. 0, 3, 5, 10, 15 or 20 years or more. Nevertheless, comparing it with engineers' opinions, it is established that on average a piece of equipment can still be considered to be new up to five years to live. For this reason, the age ranges between 0 and 3 years are eliminated, maintaining the other ranges recommended by Capuano (2010). Before proceeding with the display of the new model, it is necessary to establish the value of each weight w and W. Among approaches identified during the literature review is identified as the best model Analytical Hierarchy Process (AHP) and fuzzy logic (Dondelinger, 2004). Among the articles that offer this type of procedure, the model of Faisal and Sharawi (Faisal and Sharawi, 2015) has been taken as reference because on the one hand, it proposes clear and available technical evaluation criteria which coincide with the 5 previously selected parameters. On the other, this model, compared with other AHP MCDMs, such as the Capuano (2010), Osman (2018), Taghipour et al. (2011) and Nobre (1999), offers a tested and precise study for as regards the allocation of incidence coefficients. In fact, as Faisal et Al. (2015) reports, in order to obtain the weighting of each criterion and sub-criterion yes comparative matrices are used, constructed on the basis of questionnaires placed with four decision-makers between clinical engineers, technicians and doctors. In addition, to strengthen the results there is also the consideration of the correlation between the various criteria. Here we reported the criteria chosen to be included within technical RPI:

Support Availability

As described by Faisal et al. (2015), "the availability of support is the most important indicator in the developing countries for replacement decisions'. The literature analysis shows that this criterion is assessed on the basis of the end-date life, called "End Of Life" (EOL), i.e. the "date defining the end of maintenance economic, engineering support or the further development of a product by the producer". As a condition none of those proposed in the literature is representative, since all assume that the date of EOL for each individual device is known, when in reality this is rarely provided by the manufacturer.

Reliability

A device can be considered reliable if it guarantees the correct operation, is based on its technical and manufacturing characteristics. This parameter, as emerged from literature, is measured through downtime, quantified in days, hours or number of failures in a specific time frame. In the new model this factor is divided into two sub-categories, as proposed by Faisal (2015). The criterion called "Efficiency Coefficient" remains unchanged.

Maintenance expenses

The maintenance expense is the total cost of maintenance and repair of each device. It is also considered reasonable to adopt the calculation offered by Faisal, i.e. by comparison with the purchase cost. The model proposes as a condition that, for optimal spending "the costs of maintenance over the last three years should not exceed 25% of the purchase cost of a device" (Faisal, 2015), a fact demonstrated in T. Clark's book "Health Care Technology Replacement Planning" and assumed in the new PRI model.

Age

In most of the models presented in the literature there is a parameter representative of old age. In fact, as Capuano writes, "the age in years of an equipment is an important factor because the components of the device can become susceptible to failure based on wear and age" (Capuano, 2010). As with the "Reliability" criterion, there are two sub-criteria for "Age". The first one, called "Age of the Device" is simply calculated as the difference between the current date and the test date. It represents the old age and therefore the score to the criterion is assigned according to its range, based on the ranges proposed by Capuano (2010), as previously mentioned. The second sub-criterion instead is presented by Coppola (1999) and the "Average Age", which compares the years of life of the individual machine with the average age of the devices of the same type, also called functional age and calculated according to the formula that follows:

$$\text{Functional Age} \quad \frac{\sum \text{Age}}{\#\ \text{medical devices}}$$

Functional Criticality

The function or application of the device may have a high effect on the decision substitute, as reported by many bibliographical articles, first of all by Fennigkoh (1992). Looking, for example, at life support devices which, regardless of the necessities, they almost always tend to receive preferential consideration over the other equipment. There are therefore 4 categories of devices with decreasing priority: lifesaving (e.g. defibrillator, kidney dialysis machine, electrosurgical device, etc.), therapeutic (e.g. laser, lithotripter, etc.), diagnostic (e.g. electrocardiograph, monitor, etc.). multi-parameter) and support or laboratory (e.g. centrifuge, printer, laboratory microscope, etc.).

3.2 Development of RPI based on professionals' Knowledge

This two-stage approach is not completely innovative but draws on the methodology first suggested by Caimmi et al. (2001), which was then taken up by other authors more recently (Maggi, 2019). The RPI based on Professional Knowledge, do not find a real explanation and analysis in the literature. What can be identified in the literature are general cues or topics on which to construct the questions to be asked to health care

personnel; however, to the best of our knowledge, there are no models dedicated. Evidence of literature gap can be taken, for example, from the article by Armisi et al. (2013), which proposes among the Professional Knowledge criteria the "Criticality of company management", described as "indicative parameter of the criticality on the basis of the indications of the company management, on the basis of which it is possible to facilitate certain Hospital Units compared to others, by virtue of the health policy orientation adopted" (Armisi et al., 2013). As can be seen, this explanation is theoretical and does not clarify how to obtain the parameter and how to evaluate it. The same applies to the publication of Topfer et al. (2016) which proposes as a subjective parameter the "Impact on health structure in case of equipment failure", without providing any explanatory information on this clinical criterion. These are the reasons why we decide to develop RPI based on Professionals' Knowledge model from scratch, starting with the framework, through to the formulas and the final calculation. First of all, it was decided to use as a means of data collection a questionnaire, addressed to hospital staff. The questionnaire provides the opportunity to obtain a homogeneous classification of the data collected, as the model is uniform for each interview and allows to ask the same questions in the same sequence.

At this point, it is necessary to choose the formula with which to obtain the RPI based on Professional knowledge. Considering that the calculation of the technical index previously presented by linear combination is practical and reasonable, it is decided to replicate it also for the subjective parameter, obtaining the following formula:

$$\mathrm{RPI}_{\mathrm{PK}} = \sum \left(\sum_{i=1}^{z} \; \prod_{j=1}^{k} V_j \cdot p_j \right) \cdot P_i$$

Figure 2: Formula for RPI based on Professionals' Knowledge

where z and k are respectively the number of criteria and questions, Vj the score of question j-th, while pj and Pi relatively the weight of the question and criterion. Also, in this case, as in the model of the technical RPI, the higher the value of the index, the higher will be the level of urgency to replace the device and therefore the new subjective and objective model can be considered consistent and aligned. Then it is necessary to define each element of the $\mathrm{RPI}_{\mathrm{PK}}$, from the criteria, the questions to be asked, the scores (V) of each answer, up to the choice of the weights to be assigned to each object (p, P). It should be noted that each professionals' knowledge "PK" data is chosen at the moment in which it identifies a new characteristic inherent to the device, information that cannot be obtained from the technical data available. Along with the selection of these criteria, it is necessary to determine the questions through which extract the data of interest. In order to understand how best to formulate these questions and to be understood by doctors, nurses and auxiliaries. Literature suggests study of Day et al.(2015) which offers some

interesting insights, including the fact that the data of interest can be obtained with several distinct formulations of the same question. In fact, if the question is too direct, there is the risk that the respondent understands the parameter to be extracted and is therefore influenced by his personal interest in answering it. Moreover, the cited article states the importance of explaining the details that might intuitively seem obvious to each question, in order to avoid any kind of misunderstanding or misinterpretation of the question. The only publication from which questions that can actually be used in the new questionnaire are those of the study of Ewertsson et al. (2015), concerning nursing practice. In particular, the aim of the article is to describe the new role of the nurse, who carries out activities of "technical competence and manages medical devices in different contexts", also going to "investigate their possibilities of continuous learning in this field".

Therefore, especially with regard to the criteria of "Impact" of the new technology and "Ease of use", Ewertsson provides an inherent tool. In all this, the comparison and continuous review of the questionnaire with engineers and technicians is indispensable, since they are aware of the useful subjective data that could be obtained through the questionnaire and the best approach to deal with medical staff, choosing together the best way to present the questions and make themselves understood. Here are reported in detail all the criteria chosen, with the related sub-attributions within the RPI based on Professionals' Knowledge:

Device status

The criterion that expresses the condition of the instrumentation because, although an evaluation of its state is already defined by means of the technical IPS, you need to know how the user believes it works. In order to develop this concept and acquire it by means of a questionnaire, 3 aspects are identified in particular: the "performance", i.e. whether or not the purpose for which the device has been produced, the "quality" of the result and the speed with which it arrives there and the level of 'urgency' of replacement attributable to the equipment, in the opinion clinical. Furthermore, in this last sub-criterion, it is possible to ask why it is considered a device to be replaced, in order to investigate deeper into the root causes that bring an equipment to the end of its life, according to the user's vision.

Criticality in the department

The second criterion identified is the "Criticality" in the department, with regard to both the risk related to the activity for which it is used, both the level of complications that can be come and create in case of failure or malfunction. Even if the technical data of "Functional Criticality", indicative of the relevance, exists of the scope and represented by the risk class (life-saving, therapeutic, diagnostic or analytical), it is considered necessary to introduce this new clinical parameter to assess the subject more specifically and precisely. This deepening can be explained through the 3 sub-attributions of which the criterion of "Criticality" is composed. The first of these is described as the "Uniqueness" of the device and allows you to record the number of equipment similar to

the one under examination actually available in the department, thus giving information about the backup equipment present. For the answer to this question, it is assumed that if there are no spare devices then the situation is critical and therefore the maximum score awarded, if there are more than 2 there should tend to be no risk of danger. The second sub-criterion is called "Fault" and expresses the degree of criticality in the department in the event of equipment failure, considering the possible consequences on the patients and user safety. Finally, the last sub-attribute coincides with the "Functional Criticality", parameter already entered in the technical model. However, it is also decided to put it as one of the arguments of the questionnaire to check what use is actually made of the device because it is not always coinciding with the risk class assigned in the technical documents.

Frequency of use

One criterion that cannot be evaluated using usable data is the degree of use, fundamental parameter to determine the wear of the instrumentation but which is not objectively available. It is therefore necessary to question the hospital staff, introducing a new subjective parameter, concerning the "Frequency of use", evaluating it from the point of view of the hours of use and volume of patients involved daily.

Ease of use

With the criterion called "Ease of use" we intend to collect in particular two aspects inherent in the interface between the user and the medical device. On the one hand, we want to record a factor that represents the operator's mastery in the comparisons of the equipment, through a self-assessment of its "Knowledge" to the regard and the way in which it arrived at it, through the sub-criterion of "Learning." On the other hand, the respondent is asked to comment on the "Interface", judging whether or not it is easy to use.

Impact of New Equipment

The last criterion you choose to evaluate is the "Impact" of a new equipment within a department, taking into account in the sub-attributions the "availability" of the personal in relating to an advanced and probably unknown instrumentation and of the "advancement of technology". In this last sub-criterion an open question has been inserted, asking the clinician if it is who knows of replacement models to suggest. This question does not have a score but may be of particular use to Clinical Engineering in order to better understand the needs of the staff and be able to invest in the appropriate and required equipment.

3.2.1 Weight assignment for the RPI based on Professionals' Knowledge

As far as the weights of the criteria are concerned, the contribution of all health professionals is of paramount importance. In fact, in order to attribute the weights to the various parameters it is decided to record the judgment of two engineers, one clinical engineering technician, one nurse and one doctor, so that they can express their own opinion on the matter.

Criteria	Weight
Status	0,3
Criticity	0,35
Frequency of use	0,2
Ease of use	0,1
Impact of new equipment	0,05

Figure 3: Weights assignment for the RPI based on Professionals' Knowledge

It appears that the greatest burden is placed on the "Criticality" and the "Status", the parameters, although deriving from a subjective opinion, they are indicative of the actual condition of the device. Then follows, at the level of relevance, the "Frequency of use" with a minor value. In fact, if we consider the pulmonary ventilators, we will have different equipment conditions comparing two contexts such as the operating rooms, where it is also used several times a day, and paediatric radiology, where it is used only on special occasions, tending to calm the patient, on average 2 or 3 times a month. Finally, the last 2 criteria are the least accidents, being considered the most subjective and easily changed and improved in case of bad judgment.

For both the "technical" and the "RPI based on professionals' knowledge" the algorithm is based on the weighted average of the assigned criteria, producing as output a ranking of equipment priorities.

3.3 Pilot application of the developed RPI tool

The technical RPI was tested for the entire medical equipment inventory, i.e. 8,153 medical devices, 7,723 "non-urgent", 375 "recommended" and 55 "urgent" for replacement. Therefore, analysing the 430 resulting "recommended" or "urgent" equipment, it is considered reasonable to use for the validation phase the equipment belonging to the most critical departments, i.e. Intensive Care, Neonatology and Neonatal Intensive Care, Anaesthesia, Dermatology, Gastroenterology and Endoscopy and finally Radiology. 81 questionnaires from expert clinicians in different hospital departments were then used for the quantification of the "RPI based on professionals' knowledge" for 68 medical equipment.

Once the RPI based on professionals' knowledge of the selected machine inventory had been calculated, the validity of the technical model was verified through the graphical comparison of the various results.

The comparison between the tools revealed that 69% of the devices considered have similar results for both RPIs. Nevertheless 31% showed differences. The investigation of these differences shows the relevance of tracing not only technical variables but also those related to users' clinical opinion. Indeed for 68 medical equipment, the "total PRI" has been calculated as a linear combination of the technical RPI and the RPI based on professionals' knowledge.

4 Conclusions

The study offers an original and relevant contribution to the development of domain-specific knowledge and, as such, to fostering the diffusion of studies about medical equipment inventory management in healthcare and in hospital in particular to facilitate the Investment Plan and guarantee the improvement of quality and safety of care. A future development that could be implemented, starting from the RPI model, can therefore be an assessment, carried out together with the Hospital Management, to establish what are the minimum standards of technology devices for each department, meeting the needs of each hospital's units, in terms of devises number and quality to be delivered to patients. Moreover, in addition to being a fundamental support for Technology Management in hospital, can be employed in other areas. It could in fact be used for the logistical management of warehouses to compare different technologies or to understand realistically the various needs of each hospital department.

The study suffers some limitations which open for further research endeavour. Although it has been developed thanks to the field study in hospital, the model needs a validation with a panel of experts.

Abstract

The present study investigates individual improvisation and perceived other person's affective passion and cognitive passion as predictors of short-lived co-creation in a dyad. The study takes a quantitative survey research strategy. Suggested research model was tested utilising SEM-PLS analysis with the dataset comprising 336 respondents. The data were collected from twelve co-creative events during 2017-2019, in which participants conducted a highly creative co-ideation task within limited time in dyads. The results show support for our hypotheses. Specifically, we find that individual improvisation and perceived affective and cognitive passion directly affect co-creation. In addition, we found that cognitive passion moderates between improvisation and that moderation is negative. We discuss theoretical and managerial implications of our results.

Keywords – Improvisation, Affective passion, Cognitive passion, Co-creation, Dyad

Paper type – Academic Research Paper

1 Introduction

Most knowledge creation and creative outcomes are collective endeavors. In the interconnected world, organizational members need to throw into various knowledge creation teams and events, in changing compilations of people, and often within limited time. Such a creativity is emergent and unfolding and relies of situational interaction and dynamics between participating individual (e.g. Bechky, 2006; Elsbach & Kramer, 2003; Cook & Brown, 1999; Nonaka et al., 2000). It is clear, that interpersonal dynamics between individuals rises as a fundamental source of new knowledge (e.g. Sawyer and

DeZutter, 2009). Earlier research on group creativity suggest that group characteristics and composition are important determinants of creative process and outcomes (e.g. Woodman et al., 1993; Gilson and Shalley, 2004; Cohen and Bailey, 1997). Despite the increasing research interest on collective knowledge creation (Harvey, 2014; Harvey, 2013; Hargadon and Bechky, 2006) and creativity as a process (Drazin et al., 1999; Gilson and Shalley, 2004; Thompson, 2018; Sawyer and DeZutter, 2009), we lack clear understanding on interpersonal determinants of temporary co-creation, that is, aspects that enable individuals to engage in joint creative process in order to integrate knowledge for a shared course within limited time.

We take an individual's perspective and investigate, which individual and other person factors affect co-creation in very short-lived face-to-face co-ideation event. A short-lived co-ideation differentiates from the long-term co-creation in terms of the given time as well as goals. The long-term co-creation aims to construct synthesis between diverse perspectives (Harvey, 2014), whereas short-term co-creation refers to collective improvisation and brainstorming to generate novel ideas within limited time. In this study, we investigate effect of individual improvisation and perceived affective passion and cognitive passion on dyadic co-creation. The co-creation is an individual's experience about the shared co-creation, and it describes the extent to which an individual experienced it to be participative and mutual. We suggest, that co-creation experience derives from both individual and perceived other person factors. Specifically, we investigate influence of individual improvisation and perceived other person's affective passion and cognitive passion as predictors of co-creation experience. We therefore ask, *what is the impact of individual improvisation, perceived affective and cognitive passion on co-creation in dyads*.

To test the research model, we applied a survey research strategy. We collected data (N=336) via survey instrument from twelve co-ideation events, in which participants conducted a highly creative co-ideation task within limited time in dyads. We used stimulated workshops to study factors affecting short-lived creative co-creation in dyadic interaction, because dyads are simplest target to study interpersonal dynamics (Bakeman and Beck 1974). The workshops were planned to mimic circumstances of temporary and unfolding co-creation.

Our study contributes to the research on knowledge co-creation by shedding ling on individual and other person factors affecting short-lived co-ideation in face-to-face dyadic interaction. Capacity and skills to engage into variety of co-creation in the digital era is central for all individuals, not to mention higher educated experts, who are potential entrepreneurs as well.

2 Theory and hypotheses

Theoretical bases of our study are on literature on collaborative creativity (Hargadon and Bechky, 2004; Sawyer, 2004; Harvey, 2014; Sawyer and DeZutter, 2009; Thompson, 2018; Drazin et al., 1999) and knowledge creation (Cook and Brown, 1999; Nonaka et al.,

2000). Specifically, we target our research on within interaction aspects of co-creation and exclude contextual aspects of creativity. We assume that in short-lived co-creation the within interaction aspects are in particularly central, as in an unfolding co-creation both the process and outcome are collectively built by the participating individuals, while they mutually contribute by sharing their ideas, perspectives, emotions, and building on other's ideas.

A short-lived co-creation is a specific kind of knowledge creation process, which lack a common frame of reference, past practices, familiar relationships, and shared group processes (e.g. Nisula and Kianto, 2016). Hence, we understand co-creation as a collective and unfolding process of knowledge creation. It occurs under interdependent, mutual relationship, in which participants can equally contribute to the course of event, and thereby engage in building the shared creative outcome (Vera and Crossan, 2005; Gray, 1989, Sawyer and DeZutter, 2009). Hence, both individual and other person factors affect the co-creation process, that is, interpersonal dynamics play important role in such a co-creation. While earlier studies relying on interactionist theory (Woodman et al., 1993) have investigated both individual and work environment factors affecting team creativity in organizations, the within interaction dynamics of temporary, short-term co-creation have received less research attention. Such a co-creation can take place only when participating individuals are willing to contribute to the course of co-creation.

A short-lived co-creation demands and is built by improvisation. Improvisation is spontaneous action, in which thinking and doing unfold simultaneously (Weick 1996). As such, an improvisation represents the most dynamic nature of human behaviour, that is, individual's ability to respond to unexpected events on the spot, which is a necessity in temporary co-creation. Indeed, in such a dynamic individual behaviour intuition, creativity and expertise converge in a moment, and enable immediate response emerging stimulus. In co-creation, improvisation is individual's contribution to creative endeavour and an important building block of creative process. Hence, we posit the following hypotheses:

H1: Individual improvisation is positively related to short-lived co-creation.

Co-creation is social process, in which participating individuals mutually influence and become influenced by one another's behaviour (Sawyer and Deutter, 2009; Kiesler, 1983), whether they are verbal or non-verbal (facial and bodily) behaviours. Specifically, perceiving one another behaviour individuals build beliefs for their own contributions. We suggest that perceived other person passion, constituting of affective passion and cognitive passion, provides important information about the other persons' engagement and interest in creativity endeavour at hand and therefore plays central role in short-lived co-creation.

Cognitive passion can be perceived in a dialogue as a coherence and logic of the content of speech (Chen et al., 2009). It is seen to refer to passion on the task or idea being explored and therefore cognitive passion reflects an individual's task-related

positive and intense engagement and attunes (Chen et al., 2009). In contrast, affective passion can be perceived in an individual's physical and non-verbal mirroring, like in cues, eye contact, facial echoes and bodily movements (Chen et al., 2009). We propose that in short-lived co-creation perceived affective passion and cognitive passion provide important social information about the other persons participation and engagement in creative endeavour at hand and thereby affect individual's experience of the co-creation. While perceived affective passion provides information about other persons enthusiasm and positive affect, perceived cognitive passion provides social information about other person's knowledgeability and task-related engagement. Thus, both affective passion and cognitive passion positively relate with co-creation. We therefore posit the following hypotheses.

H2: Perceived affective passion (a) and perceived cognitive passion (b) are positively related with co-creation

In addition to main effect, we propose that perceived affective passion and cognitive passion moderate the relationship between individual improvisation and co-creation. When an individual perceives other person enthusiastic and engaged (affectively passionate) and/or knowledgeable and engaged in task at hand (cognitively passionate) it might strengthen the relationship between improvisation and co-creation. Specifically, we propose that the higher the perceived other person affective passion and cognitive passion are the stronger the relationship between individual improvisation and co-creation will be. Therefore, we posit the following hypotheses:

H3: Perceived affective passion (a) and perceived cognitive passion (b) moderates the relationship between improvisation and co-creation

3 Methodology

3.1 Data collection

The data (N=336) were collected via survey instrument from the twelve co-ideation events, in which participants conducted a highly creative task within limited time in dyads. Specifically, we used stimulated workshops to study factors affecting short-lived co-creation in dyadic interaction, because dyads are simplest target to study such an interactional, within interaction, dynamics (Bakeman and Beck 1974). The structure and implementation of the workshops were planned to mimic circumstances of temporary and unfolding co-creation. Likewise, they were equal throughout the all cases.

The share of respondents in terms of demographic characteristics was as follows. Out of the 336 respondents, 62.2% ($n = 209$) were male, and 34.5% ($n = 116$) were female 3.3% (11) were missing values. A clear majority of the respondents, 77.7 % (n=261) said they had a master's level university education. Of the respondents 43.8% (n=147) had a

five or more years work experience, and 54,5 % (n=183) had a work experience less than five years. (1.7 % (n=6) were missing values.

3.2 Measurements

We used multi-item measures for the constructs, with a seven-point Likert scale (*1 = strongly disagree*, *7 = strongly agree*) for each construct, based on existing measures in the literature.

Improvisation was assessed with the individual improvisation scale by Magni et al (2009). We assessed *co-creation* with six-item scale adapted from Vera and Crossan (2005). The items were assessed in the form 'we', to target attention to dyadic, shared creativity within a dyad. We assessed *affective passion* and *cognitive passion* using the scales adapted from Chen et al. (2009), in which affective passion was composed of six items and the cognitive passion of five items.

In addition, we controlled for gender and age diversity in a dyad, as some scholars suggest that in short-lived interactions people draw draw from observable demographic characteristics, like age and gender (Levin et al., 2006; Harrison et al, 1998) and consider similar others more collaborative (Brewer, 1979; McAllister, 1995). Specifically, we controlled dyad members sameness/diversity in terms of gender (1=same gender, 2 = different gender) and age (1=same age and 2=different age), variables of gender, age, education, and nationality to rule out their influence on knowledge worker creativity on a virtual platform. Gender (1 = female; 2 = male). Age was assessed as a categorial variable (1 < 20; 2 = 21-30; 3 = 31–40; 4 = 41–50; 5 = 51–60; 6 > 50). Education captured the following education degrees, with the categories 1= basic education, 2= upper secondary education (vocational and matriculation examination), 3= higher education.

3.3 Analysis Methods

We used SPSS and partial least squares (PLS) (version 3.2.7 of SmartPLS; see Ringle et al., 2015) and the related procedures suggested in the literature (see, e.g., Hair, Sarstedt, Hopkins, and Kuppelweiser, 2014) for analysis and to test the hypotheses.

4. Results

4.1 Measurement model validation

We applied PLS for confirmatory factor analysis to assess the reliability and validity of the measurement model. Specifically, assessment of internal consistency and discriminant validity indicated that the model demonstrated good validity and reliability for the operationalization of the concepts of interest.

First, the construct reliabilities (CR) for all our constructs (Table 1) were above the threshold of 0.7 (Bagozzi, Yi, and Phillips, 1991). Second, the factor loading of each item was high and statistically significant, indicating that they were all related to their specific underlying constructs, verifying the relationship posited among the indicators and constructs (see Appendix I). Third, the values of the average variance extracted (AVE) exceeded the cut-off point of 0.5 (e.g., Fornell and Larcker, 1981) for all of our constructs (Table 1). In addition, each construct's squared AVE (diagonal in Table 2) was greater than the correlation between other constructs. This indicates a high level of discriminant validity (see Chin, 1998). In summary, considering the above discussed aspects of measurement reliability and validity, the measurements used met the necessary requirements for further analyses.

Table 1: Construct Statistics

Construct	Mean	SD	Cronbach's Alpha	CR	AVE
Co-creation	4.3776	.52063	0.869	0.902	0.607
Improvisation	3.6025	.61927	0.665	0.798	0.498
Affective passion	3.5584	.71086	0.881	0.910	0.627
Cognitive passion	3.9682	.59243	0.812	0.868	0.570

Note: SD = standard deviation; CR = construct reliability; AVE = average value extracted

Table 2: Latent Variable Correlations and Discriminant Validity

Construct	1.	2.	3.	4.
1. Co-creation	0.779			
2. Improvisation	0.245**	0.706		
3. Affective passion	0.297**	0.202**	0.792	
4. Cognitive passion	0.352**	0.212**	0.334**	0.755

4.2 Main effect model

We used structural modelling to test our hypotheses. First, we estimated a path model reflecting the posited direct relationships between the independent variables of improvisation (H1), affective passion (H2a), cognitive passion (H2b) and co-creation. The model was analysed with regression coefficients, and their significance was assessed with t-values obtained with a bootstrapping method (e.g., Chin, 1998). Our initial research model was able to explain 19.6% of the variance in co-creation. The results show that improvisation, affective passion and cognitive passion all effected co-creation.

4.3. Moderation model

We estimated a path models reflecting the posited moderation of affective passion (H3a) and cognitive passion (H3b) in relationship to improvisation and co-creation. As expected in Hypothesis 3b (Table 4), the moderating effect of cognitive passion was statistically significant (B = -0.117, $p < 0.036$). What is more, against our expectation the moderation effect was negative. Against our expectation in Hypotheses 4 moderation of affective passion was nonsignificant. Table x provides collected results of this study.

Regarding the effect of control variables, we found that the effect of the control variables was insignificant on the relationship between improvisation and co-creation. The model was able to explain 20.0% of variance in co-creation.

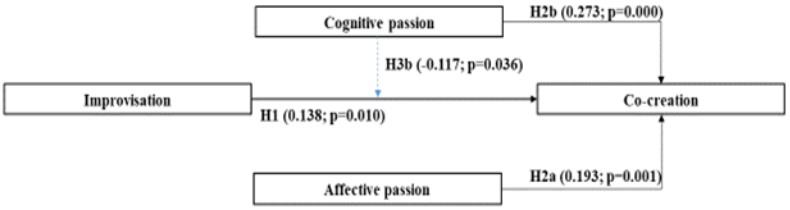

Figure 1: Results

5 Discussion and conclusions

The goal of this study was to extend the understanding of within interaction factors affecting short-lived dyadic co-creation. Building on literature on collaborative creativity, we took an individual perspective and focused on individual and perceived other person factors. In particular, we suggested that in short-lived co-creation individual improvisation and perceived other person's affective passion and cognitive passion affect co-creation, that is, the degree to which an individual considers co-creation being mutually participative, inspiring and successful. The empirical findings supported our hypotheses and showed that improvisation, perceived affective and cognitive passion positively and significantly affect co-creation. In short-lived co-creation participating individuals draw information for their contributions from other person's non-verbal and verbal behaviour. Such an interpersonal dynamics either build sufficient climate for individuals to contribute to the shared course or in worst case inhibits its. This is particularly important in unfolding creative endeavours, in which process the within interaction aspects are central sources of creativity.

We also investigated joint effect of cognitive passion and individual improvisation and found that cognitive passion moderates the relationship between individual improvisation and co-creation, and that moderation was negative. Thus, perceived high cognitive passion weakens the relationship between improvisation and co-creation, whereas low

level of cognitive passion strengthens the relationship between improvisation and co-creation. The finding can be explained by the nature of improvisation, that is, as a spontaneous and intuition dependent creative behaviour improvisation may suffer from task-oriented and rational attunement of another person. In contrast, low cognitive passion leaves room for improvisation and affects positively co-creation.

While focusing on within interaction aspects of short-lived unfolding co-creation, the findings of this study provide important contributions to the research on creativity as well as management of unfolding creativity. By showing the individual and other person factors, indeed, build temporary co-creation, this study adds to earlier research on short-lived co-creation and collective creativity (Drazin et al., 1999; Sawyer and DeZutter, 2009). Specifically, this study highlights the role of interpersonal dynamics of creativity, and suggest that individual's participating in joint creativity, should bear in mind, that positive and enthusiastic attunement is important driver of co-creation.

Abstract

This paper is examining investment and financing structures' effect on the return over equity. It also compares relevant financial indicators of the Ecuador Coast and Sierra regions. We analyze this effect from the resource-based visión (RBV). For this proposal, we use a sample of Ecuadorian food and beverage service companies. Different methods have emerged about potential factors that condition investment and financing structures. These conditions have a regulatory effect on profitability. Empirical evidence has shown that those theories are complementaries. Yet, financial management is systemic, and it follows the main aim of optimizing profitability.

To answer research questions, we use an unbalanced panel data sample of 146 companies into a period 2011-2017, specifically food and beverage services, located in Ecuador. We take data from reports published by the Superintendence of companies, securities, and insurance (SC) of that country. We test the hypothesis using multiple linear regression through the STATA program. Ecuador is an emerging country with little research around financial management, which seeks to boost private investment in the tourism sector as a development strategy.

This research helps to understand how the management of assets and financing structures influences the financial performance of the companies in the sector studied, exploring the behavior of their economic indicators over a specific time contrasting them according to the geographical location of the companies. Following other research focused on the effect of resources on business, we hope that the results will contribute to the theory of resource-based vision in the context of Latin America's emerging economies, specifically Ecuador.

By establishing the level of determination of the assets and financing structures on profitability, the importance of financial capital and the return on equity in differentiated areas, this research provides valuable information to both entrepreneurs as well as to domestic and foreign investors exploring financial performance trends to make investment decisions.

Paper type – Academic Research Paper.

1 Introduction

The resource-based vision (RBV) refers to business capabilities as a complex system of knowledge and skills applied to use productive assets in a coordinated way to achieve goals (Wernerfelt, 1984). Wernerlfelt (1984) argues that resources in each company are variable, and capabilities reflect different levels. Therefore, the sustainability of a company depends on the managerial ability to manage the system of resources and capabilities (Peteraf, 1993). In this way, the RBV into a firm leads to better financial performance through its resources and capabilities (Bharadwaj, 2000).

Gastronomy as a tourist attraction has taken on research relevance in recent decades. Nowadays is one of the main components that determine the experience of tourists (Sánchez-Cañizares & López-Guzmán, 2012). Research in the field of restaurant management service companies is diverse. On the one hand, there is research on menu design, quality of service, consumer behavior. So, there is research on business models, infrastructure, and finance (DiPietro, 2017). However, a preliminary review shows little research on financial capabilities as an asset structure and sources of financing, and their influence on profitability.

Empirical evidence sows that theories related to investment, financing, and profitability are complementary to each other (Reich, 1993), and try to explain the determinants of corporation development (Kumar, Colombage, & Rao, 2017). These theories have, in common, improve resource management. Research in the field of restaurant management has diversified, covering aspects such as menu design, business models, strategic management, human talent, quality in the service, including finances (DiPietro, 2017). However, a preliminary review by the authors shows research slightly about financial capabilities as assets structure and financing sources, and their influence on profitability.

We are more interested in contrasting the relationship between the assets and financial structures with profitability in the Coast and Sierra Ecuadorian regions because different contexts drive companies operating in different circumstances and resource disposition.

This article focuses on examining the importance of the assets and financing structures and their effect on the return on equity from the resource-based vision (RBV) approach, contrasting the two regions indicated. Therefore, we have established the following research questions: How does asset financing and profitability behave in Ecuadorian food and beverage services companies? Are there financial management differences between companies located in the Sierra and Coast Ecuadorian regions?

2 Conceptual background

2.1 Implications of the resource-based vision in Ecuadorian food and beverage services companies

Most emerging countries in the world try to improve tourism by emphasizing culture and gastronomy as relevant attractions. However, the food and beverage service business demands a set of resources that operate to make a synergy to strengthen tourism activity whit sustainable development.

Ecuadorian gastronomy is peculiar and different among its regions. A tour of the gastronomic routes makes it possible to know the commitment of Ecuadorian chefs to present the best dishes, raising competitiveness and culinary quality.

As culinary knowledge is an intangible resource, it needs other intangible and tangible support to create value for the food tourism business, like marketing, operation, productive assets, and financial capabilities (Bharadwaj, 2000; Kamboj, Goyal, & Rahman, 2015) and others. Business skill in managing the set of resources, including their self-experience and knowledge reflects the business culture of a country or region and influences its tourism positioning.

Capabilities are the basis of the company's success, and the organization processes its resources to generate value that contributes to sustainability, growth, and competitive advantage (Dierickx & Cool, 1989). In this way, assets and financial structures create value for companies by increasing return on capital, under specific activity scenarios, and adequate levels of operating profit (Assaf, Deery, & Jago, 2011), showing financial capabilities.

Despite the gastronomic richness of Latin America, some emerging countries as Ecuador show slow food tourism growth due to insufficient infrastructure and investment conditions. Due to geographical, socio-economic, and business integration characteristics, Ecuadorian companies could follow different financial behave in their quest to optimize productive resources to generate profits and increase capital. The combination of the asset structure, the level of activity of these, and the financial leverage should aim to maximize the capital returns (Mao & Gu, 2008).

CEO's perception of the environmental conditions and opportunities influences the management of the financial resources (Seo, Kim, & Sharma, 2017). The restaurant business, for its characteristics, demands continuous short-term financial decisions, exhibiting the influence of corporate decisions over market dynamism (Reich, 1993). Therefore, different contexts will have not similar economic indicators (Singal, 2015), and not identical financial management model.

As for long-term decisions, the food and beverage services sector is intricate to the location, indicating that investments in land and buildings are the most significant resources of the business (Lee & Jang, 2012; Seo et al., 2017), but could not be a constant in emerging countries. In Ecuador, investing in land and buildings depends on multiple

factors; frequently, the level of urbanization has an on-hand price that affects decisions. That implicates differences in capital needs and consequently affects the financing structure, assets structure, and the returns of investment.

2.2 Ecuadorian context of food and beverages service companies

Tourist spending is an essential economic indicator in destination countries. From this, it is known the economic spill that tourists generate during their stay. In 2018, UNWTO reported that international tourism revenues in destinations reached USD 1.448 billion. They estimate that 30% of tourism expenditure corresponds to the food and beverage segment (OMT, 2012). In Ecuador, tourism revenues reached USD 2,398.1 billion at the end of 2018 (MINTUR, 2019).

The cadastre of Ecuador's Ministry of Tourism (2019) registers 16,717 food and beverage service companies. This amount represents 67.6% of the total companies engaged in tourism activity. These companies are distributed in the four natural regions of the country. 47.2% are located in the Costa region, 47.8% in the Sierra region and the remaining percentage is distributed in the Amazon and Galapagos.

Regarding the distribution of spending in urban and rural households, Ecuadorians spend 22.6% of their food and beverage spending (INEC, 2012). 8.1% of the expenditure is spent on restaurants and hotels. These figures reveal the opportunity to enter and invest in food and beverage companies.

During the period 2012 to 2018, 40% on average corresponds to food and beverage companies. This average places them as the largest economic sector. On the other hand, when analyzing the country's business structure, we find that micro-enterprises account for 90.81% of the total existing enterprises, followed by small businesses representing 7.13% (INEC, 2019). This data places us in the context in which A&B companies in Ecuador are developed.

2.3 Financial factors derived from capabilities

The relationship between asset financing and profitability has transcended since the theoretical proposals placed forward by Modigliani and Miller (1958). From there, other specific theories developed on potential factors that condition the financing structure and have a regulatory effect on profitability (Ardalan, 2017; Wong, 2015; Bandyopadhyay and Barua, 2016). However, companies must demonstrate borrowing capability and then manage the financing resources according to their purposes and circumstances.

No less important is the working capital that must maintain the continuity of the operation. Consisting of current assets and short-term liabilities, the dynamism with which these resources move will justify fixed asset investments, external financing, and equity. This justification is reflected directly in the profitability of the transaction, leading to liquidity management.

We explore corporate financial indicators as a reflection of the CEO's decisions from different perspectives under RBV. The industry's financial indicators establish the characteristics that enable companies to compete in a specific context. Therefore, it is required to have a generalized view of some financial components through specific indicators (Mao & Gu, 2008). For this study, we selected a set of financial ratios associated with the resources management efficiency to generate profitability through the assets structure and the combination of long-term liabilities with capital. With those, we establish the following hypotheses:

H0: The region in which companies operate doesn´t influence their financial objectives.

H1: The region in which companies operate influences their financial objectives.

3 Research Methodology

3.1 Sample

Our study focuses on food and beverage service companies that reported operations for at least five years within the 2011-2017 period. The sample consists of 146 food and beverage service companies, 68 in the Coastal region, and 78 in the Sierra region. We obtain the information from the database of the Superintendence of Companies, Securities and Insurance of Ecuador, collected in February 2019.

We limit the sample to Ecuador-based corporate companies, which do not have lost data, are three years old at the beginning of the period observed, and have at least four years of operation in the same period. Economy deceleration from 2016 led to the suspension of activities of different companies (BCE, 2018; INEC, 2017), accentuating in the following years, an aspect that explains the difficulty of integrating a larger sample.

3.2 Main variables definition

Financial leverage

This ratio demonstrates the corporation's ability to manage long-term external financing and lenders' confidence in the business (DiPietro, 2017). A high level of financial leverage is adequate when increasing operating returns exceed the cost of debt (Fosu, 2013). The use of leveraged must be reasoned and depend on the level of operation and the cost of external financing (Öztekin, 2105). The relationship between financial leverage and business profitability has to be direct.

Liquidity

Corporate liquidity decisions are aimed at maintaining a level that ensures the continuity of the operation, avoiding the excess of current resources that could be considered unproductive (Chathoth & Olsen, 2007). Therefore, the relationship between liquidity and business profitability is inverse.

Assets turnover

The corporation expects to make the highest speed in producing and selling for profit using fewer assets (Shafi, Raza, & Zaheer, 2018). The relationship between asset turnover and profitability has to be direct.

Tangibility

Any company follows the objective of optimizing its fixed assets reducing idle production capacity due to investment and maintenance costs (Seo et al., 2017). The relationship between tangibility and profitability has to be inverse.

Operational margin

It reflects the corporation's ability to manage operating costs and expenses, reducing them until they do not adversely affect sales (Assaf et al., 2011). The relationship between operating margin and profitability has to be direct.

Return Over Equity

CEOs focus their efforts on overall value for companies through increasing the value of stocks, achieving that when the ROE is positive, sufficient, and growing (Hoskisson, Hitt, Johnson, & Moesel, 1993). However, this financial goal may behave differently due to each company's business context.

Because asset rotation directly influences the operating margin, and both variables don´t represent asset structure or financial structure, we create the multiple control variable called Moderator_1. We also include the variable dummy Region to measure its impact.

We describe the financial ratios and other indicators representing the dependent, independent, and control variables in Table 1.

Table 1. Variables description

Code	Name	Measurement	Type
ROE	Return Over Equity	Net margin / Equity	Dependent
E_LEV	Equity Leverage	Long term liabilities / Equity	Independent
OPER_M	Operating Margin	Operating margin / net sales	Independent
LIQ	Liquidity	Current assets / Current liabilities	Independent
ASSET_T	Sales turnover	Net sales / Total Assets	Independent
TANG	Tangibility	Fixed assets / Total Assets	Independent
Mod_1	Moderator_1	OPER_M x ASSET_T	Control
r1	Region	Coast = 1; Sierra = 0	Dummy

3.3 Method of analysis

We use a model in a data panel (unbalanced) to capture unobservable heterogeneity between study agents. We apply the following model of multiple line regression to estimate the impacts of the explanatory variables on the explained variable; in this case, it is ROE.

Model specification

$ROE_{i,t} = \beta_0 + \beta_1 E\_LEV_{i,t} + \beta_2 OPER\_M_{i,t} + \beta_3 LIQ_{i,t} + \beta_4 ASSET\_T_{i,t} + \beta_5 TANG_{i,t} + \beta_4 MOD\_OPERM\_ASSETT_{it} + \varepsilon_{it}$

Where i represents each observation; t represents each year of the period; β_i is the coefficient of each explanatory variable; ε_{it} is the error which is assumed to have a normal distribution.

4 Results

4.1 Descriptive Statistics

Table 2 show descriptive statistics. We calculate the average of each region and apply the *t*-test to determine the significance level of the differences.

Table 2. Descriptive statistics

			Differences	
Variable	**Coast mean** *(A)*	**Sierra mean** *(B)*	*(A-B)*	**p value**
ROE	0.4092118	0.3583008	0.050910	0.05
OPER_M	0.0576921	0.0518820	0.005810	0.32
E_LEV	2.8543376	3.1717186	-0.317380	0.09
ASSET_T	3.5686248	3.3334418	0.235182	0.13
LIQ	1.9353293	1.6451592	0.290170	0.05
TANG	0.3264936	0.3734197	-0.046926	0.02

The differences in the variables representing the asset structure (ASSET_T and LIQ) are significant at 95%. The variable representing the financing structure (E_LEV) shows a significant difference at 90%. The explained variable representing performance (ROE) shows a significant difference at 95%. Differences in variables related to the operation level (OPER_M and ASSET_T) are not significant. From another approach, in the Costa region, leverage is lower, while liquidity is higher. The alternative hypotheses H1 are not rejected because of significant differences.

Table 3 shows the results of the multiple linear regression. The t-statistic indicates that almost the independent variables seem statistically significant at a 1% significance level, other variables are significant at 5%, and r1 are significant at10%.

Table 3. Econometric model

ROE	Coef.	Std. Err.	t	P>|t|	[95% Conf.	Interval]
OPER_M	0.7892193	0.15717	5.02	0.0000	0.480761	1.097678
E_LEV	0.0385275	0.0040928	9.41	0.0000	0.0304951	0.04656
ASSET_T	0.0403501	0.0052869	7.63	0.0000	0.0299741	0.0507261
LIQ	-0.0116909	0.0051716	-2.26	0.0240	-0.0218405	-0.0015412
TANG	-0.0986021	0.037895	-2.6	0.0090	-0.172974	-0.0242302
MOD_1	0.3501049	0.0506151	6.92	0.0000	0.2507689	0.4494409
r1	0.0398038	0.022558	1.76	0.078	-0.0044679	0.0840755
_cons	0.0617505	0.0366906	1.68	0.093	-0.0102577	0.1337586

The variable E_LEV positively affects ROE, an increase of 1% will generate 3.8% in ROE. The LIQ and TANG variables negatively affect ROE, increases of 1% would generate reductions in ROE by 1.2% and 9.8%, respectively. Finally, MOD_1 positively affects ROE, an increase of 1% would increase by 3.9% in ROE. R1 represents the variable that differentiates the region. This variable is significant at 10%, implying that there are differences between regions. This variable positively affects ROE, indicating that the location in the Costa region generates higher profitability. Therefore the alternative hypothesis H1 is accepted.

All variables behave with expected, positive, and negative effects. We consider that the management of financial resources in the companies studied is consistent. The contrast between the Costa region and the Sierra region shows that the Costa region has a better effect on profitability.

5 Conclusion

The purpose of the study was to examine the importance of the asset and financing structures on the financial profitability of food and beverage services companies contrasting two Ecuadorian regions. With this, we make an original contribution to hospital management literature under the RBV theory. The analysis was done through financial indicators in two phases, in the first, we applied the student test to observe the differences between regions, and in the second, we used multiple linear regression.

The analysis shows that both assets structure and financial structure are significantly different between Ecuadorian regions studied. Although the Sierra region shows greater leverage, profitability is lower than the Coast. It could explain the difference in profitability between regions.

Besides, the study shows that the region has a significant effect on profitability behavior, showing a 4% greater in the Costa region. The sector studied reflects a margin of operation with an extremely high coefficient on profitability, demonstrating the high

sensitivity of financial profitability to operational management. These implicate that slight changes in operating profit produce significant changes in business profitability, either positively or negatively.

Also, the asset structure represented by tangibility and liquidity has a more significant effect than the financing structure measured by the impact of leverage, denoting trend to use less fixed assets, and caution or difficulty in the use of external financing as a strategy to improve profitability.

These findings are significant because it establishes the importance of regional contexts in business performance, strengthening resource-based vision theory regarding management capabilities to optimize available resources based on background.

We encourage investors and managers involved in this business segment to delve deeper into the analysis of asset and financing structures to identify substantive differences in financial management models that improve profitability.

The main limitations of this research are the sample size, and on the other hand, the type of business expressly referred to by corporate companies. The sample used may reflect instability in partner relationships, resulting in short periods of existence of such companies. In contrast, the non-inclusion of single-person enterprises is mainly due to the difficulty in obtaining the data.

It is possible that the limitations indicated will influence the results. However, a preliminary exploration of the overall business context between the regions studied suggests that the business dynamics in the Costa region is broader than in the Sierra.

Due to the difference in results between the study regions, we recommend future studies to use cross-sectional samples that can facilitate a larger sample size and period time.

Abstract

Long-lasting family businesses are usually equipped with dense storytelling about the foundation and the development of the firm. These narrations are implemented through various techniques and carry on much information about heritage, values and people who made the longevity and the success of the firm. From the cultural point of view, family businesses are particularly interesting organisations as their operations are strictly linked to personal stories of owners and founders. In this vein, we performed a qualitative analysis to understand how women's role is described in narratives of firms.

The research aims to analyse such narrative information to (1) verify the presence of a description of women's role, (2) individuate the temporal location of women's role narratives (period and/or business phase), (3) understand which values (e.g. ethical, human, etc.) are currently linked the women's role.

The first step of the research consists in the selection of a panel of long-lasting family businesses. For this purpose, we considered Italian firms associated with the Henokiens (https://www.henokiens.com/index.php) an international association between bicentenary family companies. The Henokiens Association has been founded in 1981 to promote the concept of family businesses as a viable alternative to multinational corporations; it currently gathers 49 members (12 Italians, 15 French, 9 Japanese, 4 German, 3 Swiss, 2 Dutch, 2 Belgian, 1 English and 1 Austrian).

The (qualitative) research is designed as a multiple case study by using secondary sources (websites, papers, newspapers, magazines, etc.).
Limitations: The research only considers firms that are associated with the Henokiens Association but other long-lasting family businesses (at least bicentenary firms) may likely exist over the countries represented in the association.
Further perspectives: The research considers Italian family businesses. Further developments may include an analysis of the other countries' perspective as well as a comparison between them.

Keywords – Long-lasting family businesses; women; successful; narrative

Paper type – Academic Research Paper

1 Introduction

The study of family firms has been an object of profound efforts by scholars involved in the study of SMEs. Such companies have great adaptation aptitudes to market changes, thanks to their creativity and flexibility (Mustier, 2018). However, relational dynamics of the family can disrupt balances and compromise the business; indeed, one of the most critical phases of family businesses is that of succession, a step that is essential for lasting for a long time (Le Breton-Miller and Miller, 2009; Lumpkin and Brigham, 2011).

With this contribution, we aim to understand which is the role played by women within the long-lasting family business. Moving from the belief that long-lasting firms should provide consistent information about their story and their heritage, we seek to collect narrative information about women's role concerning the following points: (1) verify the presence of a description of women's role, (2) individuate the temporal location of women's role narratives (period and/or business phase), (3) understand which values (e.g. ethical, human, etc.) are currently linked the women's role.

Following a qualitative approach, we performed a narrative analysis of data presented in the form of stories (Pentland, 1999; Riessman, 1993; Dawson & Hjorth, 2012; Merriam, 2009). We considered Italian firms member of the Henokiens (https://www.henokiens.com/index.php), an association among bicentenary family companies. Data are collected from company websites, newspapers, magazines, videos, interviews and social networks.

Findings are consistent respect to our aim and show that in 4 of the 12 firms investigated, women play a relevant role in the management of long-lasting firms, also by successfully managing the generational transaction.

After the introduction, section 2 reviews the relevant literature, section 3 synthesize the methodology, section 4 presents our findings and 5 presents discussion and conclusions.

2 Literature review

Family firms are considered fundamental, both in terms of numbers and capacity to adapt more easily to market changes, thanks to their creativity and flexibility (Mustier, 2018). From what has been said, it can be stated that family business is vital to the well-

being of an economy (Hisrich and Fülöp, 1997). But, during the life of a Family Firm, some events can compromise the business. One of the critical phases of family business' life is represented by the succession, sometimes considered as a major problem (Hnátek, 2012); indeed, it is also defined as a strategic challenge (Scranton, 1992). The succession is necessary to assure the continuation of the life of the company, as well as to concretize the possibility that these of lasting for a long time; furthermore, this is one the main concerns of the family (Le Breton-Miller and Miller, 2009) because this type of firms typically have a long-term orientation (Lumpkin and Brigham, 2011). Consequently, such conditions led to a relevant focus on succession or generational transaction in the family business (Cadieux et al., 2002).

To adequately manage the transition, a key role is played by the proper planning of the ownership shifting to the next generation. Indeed, in this type of companies, is extremely important to consider some peculiarities: these companies are a reflection of its founder, and frequently there is a coincidence between ownership and management (Cesaroni et al., 2017); furthermore, it is necessary to take into account the emotional perspective of the owner influencing the decision-making process (Hnatek, 2012).

Usually, the succession is divided into four different phases (Cadieux et al., 2002), that are: i) choice of who will be the successor (Matthews et al., 1999); ii) owner-manager brings his or her successor into the business; iii) official entry of the successor into the business (Stravou, 1998); iv) official retirement of the predecessor and the complete transfer of responsibilities (Churchill & Hatten, 1987). As can be guessed from the synthetic description of the sentences, what is relevant for this study and which can be considered the critical phase is the first one, that is the moment in which one identifies and chooses who will be called to succeed in the management company. It is common that, in family businesses, the choice of the successor falls on male children, leaving the female daughters in the shadows or involving them in marginal activities (Dumas, 1992; Curimbaba, 2002; Garcia-Alvarez et al., 2002; Vera e Dean, 2005; Hamilton, 2006; Haberman e Danes, 2007; Cesaroni e Sentuti, 2014; Cesaroni and Paoloni, 2016). Very often, this choice is conditioned by the stereotypes of the society (Kubíček and Machek, 2018) in which, towards women, various biases are foud, (Galiano and Vinturella, 1995) and for any person, there is an incompatibility between the "family" and the "business" role (Cole, 1997). But the decision to let a man rather than a woman take control and run a firm could be a mistake because women could represent strength for family businesses (Salganicoff, 1990) as they can make a unique contribution to family businesses, especially about management. This is due to the woman's particular characteristics and qualities that are, sometimes, vital to the success of the business (Salganicoff, 1990) and that allow them to face challenging opportunities in the family business (Frishkoff and Brown, 1993). Thanks to their psychological characteristics they can enhance, at the same time, both the private aspects of family life and those of family business professional life (Curimbada, 2002), contrary to what is claimed by some scholars. The peculiar psychological characteristics of women mean that women in charge of a company tend to

be loyal to the company and sensitive to the needs of others to be able to define them as competent in peacekeeping (Salganicoff, 1990) or in the resolution of problems and conflicts that may arise between family members (Cole, 1997).

When processing corporate's information a clarification is needed for the understanding of the concept of narrative. Scholars involved in this field separate reporting and disclosure, where the concept of disclosure tends to be used to refer to the previously undisclosed information (Dumay, 2016, p. 178). Another important classification has to consider the level of the factuality of the information; some authors (Campbell e Rahman, 2010) divide factual information, based on concrete events, from perceptions, that are (at most) purely narrative.

The lifespan of family businesses is a relevant issue for SMEs scholars (Moy and Luk, 2003; Masurel and Van Montfort, 2006), and the major focus is on factors affecting the success of such firms (Feindt et al., 2002; Saad et al., 2006). Usually, long-lasting firms are equipped with a dense heritage (Kyriakidou and Gore, 2005; Kreiser et al., 2010; Brettel et al., 2015) that is generally communicated to stakeholders through a narration (Rae, 2005; Whyte and Classen, 2012) of facts and people that affected the success of the firm. Such a process, most of the time, involves the adoption of various storytelling instruments (Sadik, 2008; Shook et al., 2017) such as websites, interviews, videos and so on.

Such narrations are implemented through various techniques and carry on much information about heritage, values and people who made the longevity and the success of the firm. However, no previous contributions focused on women's role in long-lasting firms; in this vein, we focus on narrative (Beach, 2010) information (Healy and Palepu, 2001) on women's role in long-lasting (Ward, 2016) family businesses, (1) verify the presence of a description of women's role, (2) individuate the temporal location of women's role narratives (period and/or business phase) and (3) understand which values (e.g. ethical, human, etc.) are currently linked the women's role.

3 Methodology

To achieve the above-mentioned aims, we undertook, towards a qualitative approach, a narrative analysis of data presented in the form of stories (Pentland, 1999; Riessman, 1993; Dawson & Hjorth, 2012; Merriam, 2009).

Two main problems affect research based on long-lasting businesses: (1) the definition – in terms of longevity – of the long-lasting attribute and (2) the identification of a proper panel of firms to analyse. To overcome these issues, we considered Italian firms members of the Henokiens (https://www.henokiens.com/index.php). The Henokiens is an international association between bicentenary family companies founded in 1981 to promote the concept of family businesses as a viable alternative to multinational corporations; it currently gathers 49 members (12 Italians, 15 French, 9 Japanese, 4 German, 3 Swiss, 2 Dutch, 2 Belgian, 1 English and 1 Austrian).

Therefore, the Henokiens represents a reference point that enables us to incorporate - from the associationism - a definition of long-lasting firms (bicentenary) and, at the same time, automatically provides us with the panel of firms to perform the analysis.

The analysis consisted of the following steps:

1. verify the presence of women in the ownership/management bodies, having a parental link with the company;
2. verify the presence of narrative information describing the commitment of such women within management/operations of companies;
3. manual collection of available sources (company websites, newspapers, magazines, videos, interviews, social networks);
4. manual sift of collected sources;
5. individuate the temporal location of women's role narratives (period and/or business phase);
6. identify values (e.g. ethical, human, etc.) linked to the women's role.

Hence, the study consisted in documental research (Corbetta, 2013) using open-access information, like websites, papers, newspapers, magazines, etc.. The analysis is done with regards to different firms, defining this study as (qualitative) multiple case study (Yin, 2014).

4 Findings

The analysis conducted on the 12 Italian members of the Henokiens association revealed the presence of relevant results for 4 of the companies, where women's role is recognisable.

Table 6 - Relevant sources

Company	Industry	Women Current presence	Nickname	Women past presence
Amarelli	Sweets	Pina Amarelli	Lady liquirizia	None
Ditta Bortolo Nardini	Spirits	Cristina Nardini	None	None
Guerrieri Rizzardi	Wine	None	None	Maria Cristina Loredan Rizzardi
Vitale Barberis Canonico	Textiles	Lucia Bianchi Maiocchi	None	None

While in Amarelli, Ditta Bortolo Nardini and Vitale Barberis Canonico companies there is a current presence of women in within governance bodies, in Guerrieri Rizzardi we've been able to recognize the past role of Maria Cristina Loredan Rizzardi.

Within Amarelli the relevant personality is Pina Amarelli who has been engaged in the business after the decease of her brother-in-law Giorgio, becoming, at that time, the first business leader woman leader in Calabria. Such decision brought her to leave her academic career as a jurist to devote to her husband's family business.

Overcoming the cultural biases liked to women's traditional role in family care, she has been the promoter of Amarelli turnaround, with famous initiatives like the introduction of Amarelli's famous metal box. Over the Milan EXPO of 2015, a statuette of Pina Amarelli is exhibited among the superheroes of sustainability to commend her effort to such value.

Several values emerge from the analysis of content related to Pina Amarelli's role. First of all, she outlined the difficulty for women to gain a foothold in the business world. Over an interview, she highlighted women's role in the processing of liquorice, where they were prominent in the manufacturing of the final product, with men intervention only in the processing of raw material. Furthermore, she outlines the difficulties of generational passages, where families try to force the introduction of family members, while it would often be better to rely on a manager.

Within Bortolo Nardini the relevant personality is Cristina Nardini. She represents, after more than 200 years of history, the first female figure at the top of the company. After studies and work experiences that brought her away from his family, the needs of the company, combined with the desire to be back home, entailed her to join the company.

She represents a revolution for the history of the company: since the 1940s the company was handed down to male heirs only, while women were liquidated in cash. The first exception dates back to 1943 when a cousin of Cristina Nardini's grandfather, having no male heirs, transferred his shares to his daughter, who never had an active role in the management of the business. In this vein, what emerges for the interview is the importance of the gender revolution.

Within Guerrieri Rizzardi the relevant personality is Maria Cristina Loredan Rizzardi, no longer at the guide of the company. She started at the side of her husband Antonio and in 1983 is charged with the management of the business, further developing the production of the wines.

In 1968 she was the promoter of the foundation of the Bardolino consortium, being one of the pioneers of such kind of initiatives. Such a decision had a very important strategic impact because it was the way to make the products of the Bardolino area known all over the world.

In this sense, by the analysis of available sources emerges a strong orientation towards corporate foresight, outlining, at the same time, the value of the gender revolution.

Within Vitale Barberis Canonico the relevant personality is Lucia Bianchi Maiocchi. She represents the new generation of female entrepreneurs, with a great engagement in sustainability policies. In July 2019 the company released the first sustainability report, voluntarily made by the company.

5 Discussion and conclusions

We undertook the present study with the aim of (1) verify the presence of a description of women's role, (2) individuate the temporal location of women's role narratives (period and/or business phase), (3) understand which values (e.g. ethical, human, etc.) are currently linked the women's role.

Following a qualitative approach, we performed a narrative analysis of data presented in the form of stories (Pentland, 1999; Riessman, 1993; Dawson & Hjorth, 2012; Merriam, 2009), analysing Italian firms member of the Henokiens (https://www.henokiens.com/index.php).

The analysis confirms that long-lasting firms widespread, especially towards company websites, but also by interviews, several narrative information. Findings show that in 4 of the 12 firms investigated, women play a relevant role in the management of long-lasting firms, also by successfully managing the generational transaction.

Temporal location of women's role refers both to the past and to the present and is linked to several motivations: need to manage and economic activities and start turnaround processes, but also the will to return to the family context. In this vein, such results are consistent respect to previous literature on women's motivation (Cesaroni and Paoloni, 2016a, 2016b).

Concerning values emerging from the manual sift of narrative contents, women's role appears linked both to classical and up to date concepts. Particularly, innovation, foresight and family ties seem prevailing; also sustainability issues are perceived as important themes both four young and older female entrepreneurs.

The current version of the research has some limitation; indeed, we only considers firms that are associated with the Henokiens Association but other long-lasting family businesses (at least bicentenary firms) may likely exist over the countries represented in the association. Further developments may include an analysis of the other countries' perspective as well as a comparison between them.

Abstract

In the wave of upper echelons theory, scholars have devoted an increasing interest towards the implications of top managerial characteristics on company outcomes, especially in terms of professional expertise and experience. However, less attention has been paid to the contribution that the female managers' background can offer to the board decision-making. With this in mind, the aim of the paper is to explore whether and how the functional expertise of female directors affects the company innovation. By relying on the classification of functional expertise provided by Hambrick and Mason (1984), the article empirically examines a sample of Italian firms belonging to technological industries through ordinary least squares regression analyses. In particular, it tests the effects of the expertise of female directors in throughput, output and peripheral functions on innovation in terms of R&D. The empirical evidence documents that the functional expertise of women directors influences firm innovation in given circumstances. More specifically, female directors with throughput functional background increase company innovation, while peripheral functional expertise of female directors limits R&D. Different results are reported for the output functional expertise, as female directors with such background seem to not affect company innovation. The paper enriches the existing debate on the managerial expertise of female directors as it disentangles the effect of the three specifications of managerial functional expertise for innovation. At the same time, the paper has significance for practitioners as it suggests companies to promote the appointment of female board members directors according to their functional expertise.

Keywords – Female directors, Functional expertise, Board, Innovation.

Paper type – Academic Research Paper

1 Introduction

In the last decades, scholars and practitioners have emphasized the importance of female directors for innovation (Nielsen and Huse, 2010) by suggesting that they can support board decision-making (Galia and Zenou, 2012) and contribute to the generation of innovative solutions (Torchia et al., 2011; Saggese et al., 2020).

However, previous research has proposed that the ability of women to affect corporate boards activities may depend on their qualifications (Peterson and Philpot, 2007). In this regard, it is important to note that female managers differ from male peers because they present a professional background in human resources as well marketing and sales business divisions, while they lack of working experiences in the financial and administrative fields (Saggese and Sarto, 2019; Ruigrok et al., 2007). Thereby, understanding how the female directors' expertise can affect company innovation is relevant to advance the debate on the topic.

According to the upper echelons proponents (Hambrick and Mason, 1984), the company activities reflect the background/expertise of their managers as it is able to drive the firm strategic orientation, thus affecting company outcomes such as firm innovation (Khanna et al., 2014; Sarto et al., 2020; Bermiss and Murmann, 2015). In this regard, there seems to be unanimity among scholars on the relevance of directors' functional expertise for top management and board decision-making (Datta and Guthrie, 1994; Beal and Yasai-Ardekani, 2000; Tyler and Steensma, 1998; Roach and Sauermann, 2010). The anecdotal evidence also witnesses the importance of appointing managers with a specific functional expertise. Indeed, literature suggests that, in the past, some functional backgrounds have been preferred to others due to business contingencies (Beal and Yasai-Ardekani, 2000). In particular, between early 1920s and 1950s, companies tended to appoint CEOs characterized by backgrounds in the field of operations and manufacturing (Newcomer, 1955), while between 1960s and 1970s, they often chose financial experts (Fligstein, 1987). Differently, from 1980s until early 1990s, the evolved business environment prompted the appointment of executives with functional expertise in operations (Ocasio and Kim, 1999), while to date there seems to be a trend towards the selection of directors with a heterogeneous background (Sarto et al., 2020).

Building on these premises, the aim of this paper is to explore the effects of different specifications of women directors' functional expertise on firm innovation. More specifically, by relying on the classification of functional expertise provided by Hambrick and Mason (1984), the article investigates the functional expertise of female directors in terms of working experience in throughput, output and peripheral business divisions (Hambrick and Mason, 1984).

We tested our predictions on a sample of Italian telecommunications, information technology and electrical/electronic furnishings firms through ordinary least squares (OLS) regression analyses. We focused on such settings as, in these contexts, innovation is especially relevant (Ruiz-Jiménez et al., 2016). Moreover, we examined Italian

companies because the Golfo-Mosca Act has fuelled the debate around women on board (Saggese et al., 2020).

Findings document that the functional expertise of women directors matters for firm innovation in given circumstances. More specifically, the empirical evidence provided by our study shows that female directors with throughput functional background increase company innovation, while, in the presence of peripheral functional expertise, they limit R&D. Different conclusions apply to the output functional background, as female board members with such expertise seem to not influence innovation.

The article is structured as follows. First, we present the theoretical background and the literature review. Then, we illustrate the statistical method and present the findings of our study. Lastly, we conclude by discussing contributions, implications and limitations of our research.

2 Theoretical Background and Literature Review

In the wave of upper echelons theory (Hambrick and Mason, 1984), academics have devoted an increasing interest towards the influence of top managers' characteristics on company innovation. In this regard, the functional expertise is one of the top managerial feature that has attracted much attention by scholars (Buyl et al., 2011; Wang et al., 2015; Herrmann and Datta, 2005; Ocasio and Kim, 1999; Beal and Yasai-Ardekani, 2000).

The functional background refers to the company departments in which managers are employed during their professional path (Hambrick and Mason, 1984). In this respect, literature suggests that the managers' functional experience influences their job as it directly shapes how information is processed and problems are perceived (Beyer et al., 1997; Bermiss and Murmann, 2015), thus affecting strategic choices (Hitt and Ireland, 1985) and company performance (Gupta and Govindarajan, 1984; Bell et al., 2011). Indeed, managers with a professional experience in a specific business function develop an orientation proper of such division as they are exposed to related relevant information (Chattopadhyay et al., 1999; Tyler and Steensma, 1998; Roach and Sauermann, 2010). Indeed, the skills and knowledge gained through the experience in a functional area help managers to properly evaluate the decisions to make through the lens of the prevailing business division thinking (Finkelstein and Hambrick, 1996). In this regard, having previous working experience in specific functional areas might differently affect firm outcomes, especially in terms of innovation (Dalziel et al., 2011; Kor and Misangyi, 2008; March and Simon, 1958; Rajagopalan and Datta, 1996).

In this regard, a useful classification to explore the implications of functional expertise for company outcomes is provided by Hambrick and Mason (1984), who suggest that the functional background can be divided into three categories on bases of the features of the departments in which managers have mainly developed their professional experiences. These three categories include "throughput function", "output function", and "peripheral function" (Abebe, 2010; Zhang and Yuan, 2011). While the throughput one includes production, technical and R&D functions, the output function encompasses marketing and

sales. Differently, the peripheral function refers to supporting functions, such as law, finance and accounting (Hambrick and Mason, 1984). Studies have mainly focused on the heterogeneity of managers and directors' functional background, but less attention has been paid to disentangle the effect of the above-mentioned specifications on firm innovation.

As far as the throughput functional background is concerned, scholars enlighten that managers with this kind of professional experience are familiar with production and core technologies and are equipped with engineering skills (Wang et al., 2015), thus giving priority to quality improvement as well as technology and innovation development (Zhang and Yuan, 2011; Elsaid et al., 2016). As a result, executives with throughput functional expertise tend to be more committed to innovation strategies (e.g. equipment updates, production automation and technology upgrades) (Sun and Jia, 2009), and are often associated with production invention and improvement (Wiersema and Bantel, 1992; Balta et al., 2010). At the same time, the managerial professional experience in firm technologies effectively drives and addresses the innovation initiatives issues (Sarto et al., 2020; Sundaramurthy et al., 2014; da Mota Pedrosa et al., 2013). Indeed, executives with professional expertise in firm divisions devoted to innovation processes are better able to effectively identify priorities and reach innovation goals (Sarto et al., 2020). Moreover, they are willing to forgo the efficiency and cost-containment targets in order to support innovation investments (Finkelstein and Hambrick, 1996; Barker III and Mueller, 2002).

In line with this conclusion, a number of empirical studies provide insights into the positive implications of director throughput functional background for firm innovation. Some studies find that executives with a work experience in R&D and engineering tasks tend to implement innovation strategies increasing R&D spending and the value of patents (Tyler and Steensma, 1998; Valenti and Horner, 2020; Sarto et al., 2020). Other studies document that firms characterized by CEOs with throughput background present higher level of R&D expenditures (Datta and Guthrie, 1994). Finally, still other research highlights that firms directed by top executives presenting experiences in throughput functions tend to foster innovation development (Jensen and Zajac, 2004).

Similar arguments apply to the output functional background, because literature suggests that managers with specializations in marketing and sales tend to support innovation ideas and initiatives (Musteen et al., 2006). In this regard, top managers with output functional backgrounds are more sensitive to market and more likely to get the inspiration for new elements. Besides, top executives with output functional expertise usually have more external social capital which is positively related to corporate innovation performance (Zhang and Yuan, 2011). At the same time, CEOs with substantial marketing experiences lead the company to obtain higher levels of performance because they tend to confer to their products and services an image of originality (Beal and Yasai-Ardekani, 2000). Moreover, top managers with output functional expertise follow more innovative strategies which entail greater change, thus resulting in high R&D spending (Barker III and Mueller, 2002; Thomas et al., 1991).

Opposite conclusions can be drawn when shifting the attention to the peripheral functional expertise. Indeed, research claims that managers with professional background in financial and legal affairs lack of proper knowledge in firm technologies and production processes and are more committed to limit legal and financial risks (Wang et al., 2015; Thomas et al., 1991). In this regard, since they tend to neglect technology and production issues, they usually do not have much influence on innovation initiatives (Wang et al., 2015) but they pay more attention to financial issues (e.g. debt and financial performance) (Minton et al., 2014; Mizruchi and Stearns, 1994; Naranjo-Gil et al., 2009; Garcia-Sanchez et al., 2017). At the same time, scholars emphasize that directors with peripheral expertise can be less favourable to too risky and costly innovation opportunities as they put more emphasis on improving efficiency and cost containment (Hambrick and Mason, 1984). The empirical evidence supports these arguments showing that directors expert in peripheral areas limit innovation and growth opportunities (Jeanjean and Stolowy, 2009; Allemand et al., 2017; Dalziel et al., 2011).

When it comes to the functional expertise of female directors, it is interesting to assess what happens when women board members have an expertise that is close to their own skills (i.e. output functional expertise) and/or the one that is far from them (i.e. peripheral and throughput functional backgrounds) (Hillman et al., 2002; Singh et al., 2008; Zelechowski and Bilimoria, 2004).

Thereby, building on these premises, we examine whether and how all the three specifications of functional expertise of female directors can influence company innovation.

3 Statistical Method and Results

We explored the influence of the female directors' functional background on company innovation by focusing on a sample of 149 telecommunications, information technology and electrical/electronic furnishings Italian firms, examined for a 4 years observation window (i.e. 2012-2015). We investigate such contexts because innovation is especially relevant to these settings (Ruiz-Jiménez et al., 2016) and, in Italy, the debate around women on board has been fuelled by the Golfo-Mosca Act (Saggese et al., 2020).

As described in Table 1, we gathered governance and financial data from the AIDA database, hand-collected information on the functional expertise of female directors from their own CVs, the company websites and LinkedIn.

Table 1. Source of data

Type of data	Source
Governance data	AIDA database
Financial data	AIDA database
Data on functional expertise of female directors	Hand-collection from CVs, company websites and LinkedIn

Our research approach was based on OLS regression analyses. In this regard, we focused on company innovation as proxied by the ratio between total annual R&D expenditure and total sales. In addition, following prior literature (Hambrick and Mason, 1984; Abebe, 2010; Zhang and Yuan, 2011), we classified the functional expertise of female directors in three categories according to their working experience in: (i) throughput functions, (ii) output functions and, (iii) peripheral functions. We caught the throughput functional expertise of female directors by the proportion of female board members expert in R&D and engineering functions (Female R&D/Engineering). At the same time, we proxied the output functional expertise of female directors (Female Marketing/Sales) by the percentage of women board members with a professional background in marketing and sales functions. Similarly, we measured the peripheral function of female directors by the proportion of women executives with a functional expertise in accounting and finance (Female Accounting/Finance). We completed our regression models by including the percentage of women appointed to the board (Female Percentage), the board size (Board Size), the company size (Company Size) and the leverage (Leverage) as controlling variables (Saggese et al., 2020; Campbell and Mínguez-Vera, 2008).

The descriptive analyses document that the majority of female directors in our sample is characterized by expertise in accounting and finance (i.e. 7.6%). Differently, a lower proportion is expert in marketing and sales (i.e. 3%), while only 0.34% presents a professional career path in R&D and engineering functions.

Shifting the attention to the regression analyses, Table 2 reports the relationship between the expertise of female directors and company innovation. More specifically, Model 1 shows that the coefficient for the percentage of female directors with a professional background in R&D and engineering functions is positive and statistically significant ($\beta = 0.680$, $p < 0.05$), thus suggesting that female directors expert in R&D and engineering functions improve the company innovation. However, as illustrated in Model 2, although the coefficient for proportion of female directors with functional expertise in marketing and sales is positive, it is not statistically significant. Different findings are reported for the presence of female directors with professional background in accounting and finance divisions. Indeed, Model 3 documents that the percentage of female directors with such functional expertise is negatively and significantly linked to our proxy for company innovation ($\beta = - 0.032$, $p < 0.05$).

Table 2. OLS regression analyses on the relationship between female functional expertise and company innovation

4 Conclusions

The paper aims to explore the influence of the functional expertise of female directors in terms of working experience in throughput, output and peripheral functions on firm innovation by relying on a sample of Italian firms belonging to technological settings.

Findings show that the functional expertise of women directors matters for firm innovation measured by R&D/sales. In particular, in line with previous studies (Valenti and Horner, 2020; Sarto et al., 2020; Jensen and Zajac, 2004), the regression analyses document that women board members with throughput functional background enhance company innovation. Indeed, as suggested by the literature, managers with such professional experience are especially concerned with technology development and are more committed to take innovation opportunities consistently with the prevailing thinking of their business division (Finkelstein and Hambrick, 1996; Wang et al., 2015; Elsaid et al., 2016; Sun and Jia, 2009). At the same time, they are better equipped to identify innovation priorities and goals (Sarto et al., 2020), thus supporting innovation investments (Barker III and Mueller, 2002).

Opposite results are reported for the peripheral functional expertise, as our article shows that female directors with such professional background hamper the level of R&D. This result confirms previous evidence suggesting that directors expert in finance and accounting functions give priority to financial issues (Minton et al., 2014; Mizruchi and Stearns, 1994; Naranjo-Gil et al., 2009; Garcia-Sanchez et al., 2017) to the detriment of technology and production matters (Wang et al., 2015). In this way, they put more effort into efficiency improvement and cost containment, thus limiting risky and costly innovation initiatives (Hambrick and Mason, 1984; Jeanjean and Stolowy, 2009; Allemand et al., 2017; Dalziel et al., 2011).

Differently, the empirical evidence provided by our study documents that women board members expert in output functions do not matter for firm innovation. This result is in contrast with prior research suggesting that directors expert in marketing and sales support innovative initiatives in order to provide their products and services with an image of uniqueness (Beal and Yasai-Ardekani, 2000; Musteen et al., 2006; Zhang and Yuan, 2011; Barker III and Mueller, 2002).

On the basis of these premises, our research extends prior literature on managerial background as it suggests whether and how the functional expertise of female directors can affect the company innovation. Moreover, it advances the debate on female directors background by disentangling the effects of the three specifications of functional expertise (i.e. throughput, output and peripheral functions) for innovation. At the same time, our findings recommend practitioners not only to foster the gender diversity on the board but also to include specific functional expertise. Indeed, by emphasizing the positive (negative) implications of throughput (peripheral) functional expertise of female directors for company innovation, our research advices firms to promote the appointment of female directors according to their functional expertise.

Despite these contributions, our study is not free from limitations as it focuses on homogenous industries. Therefore, future research should explore how the effect of the functional expertise of female directors changes in multiple and heterogeneous sectors. At the same time, our research investigates only the influence of one kind of female top managerial position (i.e. directors). Thereby, additional efforts could be addressed to examine how the functional background of other managerial figures (e.g. CEO, TMT members) can contribute to firm innovation.

Abstract

The study of company dynamics is increasingly influenced by the role that the analysis of cash flows assumes, as these play a central role both for the company's economic performance and in predictive terms. However, the literature on the predictive capabilities of cash flows is scarce both in terms of number and depth of research, the samples that have so far been analyzed have limited dimensions. Taking advantage of the power and opportunities offered by digitization, which allows immediate access to data and information in ever greater quantities, our work has the aim of studying the relationships between cash flows (of different management areas) and the economic performance of the company using a complete sample of Italian listed digital firms in the 2008-2019 period with more solid statistical tools compared to previous studies. The choice of the database, to collect all the necessary balance sheet data, fell on Amadeus of the Bureau van Dijk platform, which already shows reclassified and easily comparable balance sheets. To assess whether our cash flow proxies could be strong predictors of future cash flow and, consequently, of business performance, we will use correlation analysis and multiple regression.

Keywords: Earnings, Cash Flows, Forecasting Future Cash Flow

1 Introduction

The financial statement plays an increasingly important role in both the Italian and international business dynamics. It is the only document that directly provides data on the company's liquidity and solvency, on the change in assets, liabilities and net worth and it is able to highlight the provenance of resources relating to different management areas, as well as the total management of the company. While the balance sheet provides information on stock values at a given instant, such as a photograph taken periodically (quarterly, semi-annually, annually) and the income statement shows flow quantities based on economic dynamics, the financial statement is able to highlight the provenance of resources relating to different management areas, as well as the total management of the company. The sentence "cash flow don't lie" is motivated above all in comparison with the magnitudes of the income statement, where many items can divert or disguise the real results. On the other hand, it should be emphasized that even cash flows are not totally free from possible manipulations by the editor of the financial statements of a company, that can determine misleading influences on all analyzable quantities.

The principal objective of financial statements is to enable users to assess the firm's ability to generate sustainable future cash flows for decision-making purposes (IASB, 2001). The International Financial Reporting Standards (IFRS) suggest two options, namely the accrual basis and the cash basis of accounting. The importance of cash flows for the life of the company cannot be underestimated, as it is similar to the role played by blood to keep living creatures alive and, therefore, its role is crucial in the decision-making process of users (Nasrollah and Hassan, 2013).

Several studies have examined the correlation between the results and future cash flows (Finger, 1994; Dechow et al., 1998; Barth et al., 2001).

Some of them have shown that both accounting earnings and cash flows can forecast future performance. Others have supported the assertion of FASB, emphasizing the superiority of earnings in relation to cash flow (Jordan and Waldron, 2010; Ebaid, 2011; Takhtae and Karimi, 2013, Moeinaddin et al., 2013, Jemâa et al., 2015).

By contrast, for others, it is the cash flow that has the most interesting predictive power (Farshadfar et al., 2008; Habib, 2010; Al-Debie, 2011; Senan, 2019).

Based on traditional literature on the predictive ability of cash flows, this research will focus on the study of the predictive ability of cash flows with respect to company performance measured by a specific indicator, ROA.

The research question of this research will be the following: can the company's cash flows predict the company's future economic performance?

2 Literature Review

Forecasting cash flows is a key element in the life of companies, used by owners to plan future cash movements to remove any threat from insolvency and illiquidity crises (Barth et al., 2001). Javedan and Largani (2014) claim that it's through predicting cash

flow that the most important information is provided to the users inside and outside organizations. Taking as a starting point the FASB assertion about the ability of earnings to act as a predictor towards future cash flows (1978), scholars have focused on the study of prediction of future cash flow by using cash flow and earnings as a predictor variables and prediction of future cash flow by using cash flow, earnings and accruals as a combined predictor variables (Mulenga and Bhatia, 2017).

For this reason, several research findings collected from the existing literature on the comparative abilities of accrual-based earnings versus operating cash flows in the prediction of future operating cash flows are mixed, contradictory or inconclusive.

Table I shows a summary of the results of the studies that assessed the predictive ability of operating cash flows, while Table II highlights the studies that measured the predictive ability of cash flows through earnings and accruals

Forecasting cash flows through earnings and accruals	Aggregate earnings have superior predictive ability of future cash flows than current cash flows.

2 Research Methodology and expected results

The intent of the authors is to investigate the ability of cash flows to predict future cash flows, providing, in this way, a valid support to the tools offered by digitization to allow people inside and outside the organizations to obtain useful information on investment decisions and to measure prospective business performance. The study will limit the analysis to the Italian market, focusing on Italian listed digital companies in the 2008-2019 period.

We expect that cash flows components can influence the firm performance (ROA). In the null form the research hypothesis will be the following:

H1. Return-on-assets (ROA) of year N is influenced by cash flow (CF) N-1

Our key variable will be an accounting-based proxy for cash flow. The choice of this proxy variable is supported by prior cash flow forecast ability research.

The database we will use to collect all the balance sheet and income statement data will be Amadeus database of the Bureau van Dijk platform, which already shows reclassified and easily comparable financial statements. The greatest advantage of using this reclassification with respect to the use of financial statements in a civil law format, such as those available on the Aida database of the same platform, is that the reclassification allows a quicker reconstruction of the cash flow statement using the indirect method, starting from the flow variables of the income statement and changes in the balance sheet stock sizes. The selection of the sample has objective and replicable criteria: the selected company must be active and listed on a regulated market, as well as based in Italy. We expect, however, that the rigidity of the parameters required for the selection of companies within the sample will contrast with respect to the availability of balance sheet data. For this reason, any company that does not have fundamental data for subsequent analysis for several consecutive years will be removed from the sample.

We intend to use an accounting measure as proxy for firm performance which has been widely used in previous research related to cash flow forecasts, i.e. ROA:

ROA (Return on Assets) = Net income/total assets

The independent variables relating to the identifiable management areas will be the followings:

- Cash flow for investments in fixed assets (CFI)
- Cash flow related to corporate dynamics (CFS)
- Cash flow from financing (CFF)
- Cash flow for extraordinary components (CFXC)
- Global net cash flow (CF)

The Cash flow for investments in fixed assets (CFI), is obtained as the sum of the change in the capital assets of fixed assets, including tangible, intangible and financial assets and the Financial Revenue income statement item, as this last component is generated by the financial assets held as fixed assets and is therefore relevant to investment management.

The Cash flow related to corporate dynamics (CFS) is obtained by subtracting the variation in the Shareholder Funds item from the profit for the year. It indicates the net result from the point of view of liquidity, obtained following any increases in paid-up share capital or the distribution of profits to shareholders.

The Cash flow from financing (CFF) indicates if the company has opened or redeemed loans during the year, and the value is obtained based on the change in the balance sheet items relating to short-term debts and long-term debts.

The Cash flow for extraordinary components (CFXC) indicates the impact on the extraordinary management fund captured using the Extraordinary Profit/Loss income statement item.

The Global net cash flow (CF) is obtained as a sum of the components described above and coincides with the change in the balance sheet item called cash and cash equivalents.

The regression analysis will consist in a regression equation (model), to explores the relationship between the cash flows available in the financial statement and the future economic performance of the company:

$$\text{Model: ROA1417}i = \beta 0 + \beta 1\ \text{CF1013}i + \beta 2\ \mathcal{C}FI1013i + \beta 3\ \mathcal{C}FS1013i + \beta 4\ \text{CFXC1013}i + \beta 5\ \text{CFF1013}i + \varepsilon i \quad (i = 1 \ldots 176)$$

Having proposed a research hypothesis in null form, the results that we expect to obtain could be in line with one of the two positions present in the literature, i.e. accrual-based earnings versus operating cash flows in the prediction of future operating cash flows.

3 Conclusions

The aim of the research will be to provide evidence of a significant link between the cash flows available in the cash flow statement and the future economic performance of the company.

In doing this, the results we obtain may be in line with the assumptions of those who claim that cash flows are a better predictor of future cash flows (Finger, 1994; Al Attar and Hussein, 2004; Farshadfar et al., 2008; Habib, 2010; Al Debie, 2011) or, on the other hand, with the arguments of those who claim that earnings are the best predictors for measuring future cash flows (Dechow et al., 1998; Barth et al., 2001; Kim and Kross, 2005; Ebaid, 2011; Jemâa et al., 2015; Frank, 2018; Nguyen and Nguyen, 2020).

Furthermore, the research will produce evidence of a significant link between the cash flows available in the cash flow statement and the future economic performance of the company, and it could be useful, if interpreted and contextualized, for external and internal users of the company. The research will therefore be potentially useful to analysts who try to predict the future performance of the studied company, analyzing the flows of the various management areas and the typical characteristics of the company, as well as the internal subjects, where the results may constitute a possible comparison benchmark with the model studied on the Italian companies of the sample. A limit of the present research work could be represented both by the reduced size of the sample used and by a database of financial reports not elaborated directly by the companies, which therefore could be not free from errors or imperfections.

Any future developments of our research could concern further analyzes to be carried out by observing the differences between companies in different sectors, for example between manufacturing and service companies, or between *capital* and *labor* intensive

companies. In this way, even more peculiar links could be identified between cash flows and economic performance.

The research field is insidious and the analyzed variables can be influenced by external elements that are not taken into consideration in this paper; therefore, the analysis will be conducted with the awareness that this work is free from any presumption of completeness and that the results that will be shown are not definitive and impeccable.

Abstract

The term eHealth includes multiple components, like the Mobile Health (mHealth), the Health Information Systems (HIS), the Telemedicine and the Distance Learning (eLearning). With the aim to explore some of the main eHealth governance issues at stake and the challenges faced at national and global levels, for the purposes of this paper, authors propose an integrative review on crosscutting eHealth governance issues and call for the development and adoption of appropriate policies and an international well-coordinated governance.
Although eHealth projects and initiatives are growing, worldwide scenario is still one of piecemeal implementation often lacking a system approach at national level and coordinated governance internationally.
The trend toward Health 4.0, extending eHealth to the Internet of Things in health, will require a deeper analysis on what is really at stake in terms of human rights, universal access to health services and further commodification of health needs, in that sense due to the global nature of the Internet, national policies will necessarily need to be part of a global governance framework based on solid international cooperation.

Keywords – eHealth, health determinants, health care, health policy

Paper type – Academic Research Paper

1 Introduction

Interconnectedness is a defining feature of globalization, and the development and worldwide diffusion of information and communication technologies (ICT) are at its roots.

The exponential use of the internet and electronic devices over recent decades has been associated with documented cases of excessive use and negative health consequences, reaching in some countries the magnitude of a significant public health concern. Consequences on health of excessive use of internet has mostly been studied and discussed under the lens of behavioural addictions and a variety of physical, psychosocial and socio-behavioural pathologies, which in many cases still need further study due to the recent emergence of the phenomenon.

However, the Internet and in general the digital society do not only represent a radical innovation of technology and tools, they also have a disruptive impact on the relationships established within the health care system. Compared to the theoretical strands of the past, it can be said that the digital society, and digital health in it, is made of a combination of "disruptive innovation" and continuous improvement. As such it comes with multiple challenges.

The World Health Organisation (WHO) uses eHealth as a generic term including distinct but related applications of digital health, such as: mobile Health (mHealth); Health Information Systems (HIS); telemedicine and distance Learning (eLearning) (Lewis et al., 2016).

More in general eHealth has been defined as the use of information communication technologies (ICT) in support of health and health-related fields, including health-care services, health surveillance, health literature, and health education, knowledge and research (WHO, 2005).

Digital technologies contributed among others to reduce the information asymmetry between health professionals and patients. In the past, the doctor was the almost absolute holder of the knowledge and skills related to health and played the dual role of interpreter of the need and provider of suitable services and services. In the network society the patient has autonomous access to a lot of information about health, although not necessarily the interpretative tools, and the possibility to share this information through the social media for additional opinions. This on the one side allows the patient to interact with the professional on a more balanced level, but on the other side it also exposes him to a number of risks.

Telemedicine has partially modified "access" to consultation, diagnosis and to a limited extent therapy and rehabilitation. The Internet has become the most important vehicle of a cross-border supply of health services to individual consumers.

New technologies may allow highly personalised therapies and monitoring of patients' conditions in real time (e.g. according to the instant measurement of blood glucose level in diabetics). mHealth linked devices and applications in the Internet-of-things (IoT) through their capacity to individualize access and use of health information and services,

promises to revolutionize health systems, eventually becoming a key component of universal health coverage (UHC), toward what some authors already envisaged as Health 4.0 (Comptesse, 2017).

The collection of data into large shared databases and easy access to health data by patients and professionals contributes to health system integration across different healthcare facilities and levels of complexity. Big data systems may contribute to speed-up research and the development of new therapies.

Nevertheless, in addition, to access to valuable services, the internet also channels new types of exploitation and fraud, including the sale and use of health data of individuals and the illegal promotion and sale of medicines and other products, posing severe risks to both individual and collective health and undermining legitimate trade and correct functioning of health systems (WHO, 2016).

The possibility of fraud and illegitimate data collection may also seriously affect research ad its credibility. For example, in May 2020 the WHO decided to suspend the COVID-19 trials with hydroxychloroquine over concerns about drug side effects published on the Lancet. However, later on, evidence emerged about authors' fraudulent data collection and the study was retracted, leading WHO to resume trials (Mehra et al., 2020).

This leads to rising concerns on policies and an international governance that should be addressed to ensure the cost-effective and secure use of health-related information communication technologies (ICT).

While much research and studies have analysed the impact of new digital technologies on single aspects of health care systems, we rather take a systemic approach aiming at exploring some of the main eHealth governance issues at stake and the challenges faced at national and global levels. This paper is guided by the following research questions: - Does eHealth contribute to increase equity in health systems? Does it contribute to worldwide cooperation and increase access to universal care? Is national and global governance effectively addressing eHealth issues?

We examine the existing international policies and governance challenges dealing with the risks that inevitably come with innovation and a progressively digital borderless society, including aspects such as protection of sensitive data and privacy, cyber security (interference and data theft), conditioning of behaviour through fake news with the related issues of certification of sites that give clear and correct information to patients.

We conclude calling for the development and adoption of appropriate policies at national level and an international well-coordinated governance.

2 Methods

To identify the governance challenges posed by the eHealth revolution at global level, we propose and short integrative review involving a mapping exercise of the literature. The search included peer reviewed research and discursive literature on main eHealth

barriers and governance issues at stake and the challenges faced at national and global levels published between 2000 and 2020.

Evidence came from systematic reviews (6 studies), non-randomized controlled perspective studies (4 studies), qualitative research, including assessment reports (9 studies). Authors used as source of evidence electronic databases, scientific journals and international organizations reports (WHO, EC).

3 Results

3.1 Determinants in achieving a successful eHealth intervention

Directing and coordinating eHealth development, achieving consensus on policy, protecting individuals and groups and assuring oversight and accountability in the various aspects relating to use of ICTs are relevant part of an eHealth governance function at the national and global level.

The governance of eHealth initiatives requires traceability of many requirements and design decisions.

Costs represent the main driver to effectively achieve successful eHealth interventions across the health system. Indeed, some of the common barriers (workload, role definition, undermining of face-to-face communication, workflow disruption, alignment with clinical processes and staff turnover) require huge efforts both in terms of direct and indirect costs (e.g. opportunity costs) (Granja et al., 2018).

Ross et al. (2016) identify as factors important for the eHealth policy and implementation: individual eHealth technology (e.g. innovation characteristics), the outer setting (e.g. external policies and incentives), the inner setting (e.g. compatibility between the e-health intervention and the organisation) and the individual health professionals (e.g. attitudes and beliefs) as well as the process of implementation. (Ross et al., 2016).

Among high-income countries, Norway has a long history of using telemedicine, especially for geographical reasons. Despite this, telemedicine use in Norway from 2009 to 2015 remained very low, not exceeding 0.5% of total outpatient activity at regional level and 0.1% at national level. Three major themes affecting implementation and utilization of telemedicine in Norway emerged: (i) governance and strategy; (ii) organizational and professional dimensions; (iii) economic and financial dimensions. For each theme, a number of factors and challenges faced at different health care levels were identified. (Alami et al., 2017).

3.2 End user acceptance

We investigated the end user level of acceptance toward eHealth.

For instance, a recent study revealed how in Bangladesh the successful adoption of eHealth solutions is influenced by social reference, advertisement, attitude toward the system and perceived system effectiveness (Hossain et al., 2019).

Harst et al. (2017) identified theoretical predictors that influence the acceptance of telemedicine. Characteristics of the technology, such as its usefulness, as well as attributes of the individual, such as his or her need for social support, inform end-user acceptance. (Harst et al., 2017).

Kligenberg et al. (2020) found a significant relationship between compatibility-usefulness and usefulness-attitudes among the factors that influence health care provider's attitudes toward m-health technology for emergency care of burn patients in Tanzania.

Afghanistan piloted a multi-stakeholder people-centred eHealth systems governance approach at provincial district health level over a six-month period, reporting a 20% increase in access to care (Kligenberg et al., 2020).

Botswana, like many developing countries, has also recognized the need for eHealth implementation. The mHealth in Botswana seems more costly compared to other countries such as South Africa and east African countries. This is because of several issues, including the need to import devices, the lack of attention to developing market needs, the ongoing trend of mHealth being smartphone dependent, and the inability of the populace to afford such devices (Mauco et al., 2018).

3.3 Assessment, Standardization and Interoperability

Almost all European countries have a sort of national body directly responsible for eHealth standards development or for overseeing standards development and implementation. The vast majority of the Member States adopt HL7 V2 and V3 (Health Level 7, version 2 and 3) as international standard, followed by CDA R2 (clinical document architecture, release 2, an HL7 V3-based standard) and ISO 13606 for electronic health record communication.

Unfortunately, these standards are most of the times not specific enough to assure interoperability, neither across the same region. Although in principle they allow for interoperability at various levels, further agreement on more detailed specifications, testing, and certification of solutions are required to ensure a cross-border implementation (Stroetmann et al., 2011).

Furthermore, the lack of a harmonized assessment method for eHealth technology between Europe and US make it difficult to perform a comprehensive summary of available evidence to help plan and undertake eHealth implementation (Mackey et al., 2014).

In Africa, the WHO in partnership with the African Union and major Donors/UN agencies, supported the implementing e-Health in African countries (e.g. Telemedicine Task Force, the Pan African e-Network). However, the major challenges were the programmes sustainability and the harmonization of their assessment (WHO, 2010). The

absence of a strategic systemic approach to the development of eHealth is another clear challenge.

Kenya reported myriads of eHealth projects, mainly in the mHealth strategic area and focusing mostly on primary care and HIV/AIDs. However, the lack of evaluation and the exclusion of marginalised areas and least urbanized counties – known for the highest health care needs – cause a difficult scale up of the interventions, beside the evident lack of a systemic approach (Njoroge et al., 2017).

Portugal was an early adopter of telemedicine to overcome both its geographical barriers and the shortage of healthcare professionals. The Pediatric Cardiology Service (PCS) at Coimbra University Hospital Centre (CHUC) implemented a real-time communication and the sharing of clinical information, including with overseas partners improving access to specialized care both in Portugal and Africa, representing a successful example of the international collaboration as well as of interoperability across multinational health systems (Maia et al., 2019). In this case also, the bilateral collaboration lacked a systemic view.

In Ethiopia the vast majority of the population lives in remote areas, with limited access to modern health services. The lack of health care budget, systematic shortage of health care workers and limited incentives to retain those in remote areas further jeopardize the national health care delivery system. Recently, the application of ICT to health care delivery and the use of telemedicine have raised hopes. Unfortunately, recent findings showed that due to its premature phase of development in Ethiopia and other sub-Saharan African countries, it remains difficult to talk objectively about measurable impact of telemedicine, even though it has demonstrated practical applicability beyond reasonable doubts (Shiferaw et al., 2012).

3.4 Health literacy and Digital divide

An element of concern for the eHealth implementation is about eHealth education. For instance, half of the nursing students in Sri Lanka have inadequate eHealth literacy skills, preventing them to identify trusted health resources and using this information in health decision making process (Ref).

In Israel, Neter et al (2012) measured the health literacy across the population, documenting differences between respondents high and low in eHealth literacy in terms of background attributes, information consumption, and outcomes of the information search. The association of eHealth literacy with background attributes indicates that the Internet reinforces existing social differences. (Neter et al., 2012)

3.5 Governance and regulatory framework

For the first time in 1998, the WHO Executive Board (EB) tackled the potential impact on health of the advertising and promotion of medical products via the internet (WHO 1998).

In 2005, the World Health Assembly (WHA) passed its first resolution on eHealth (WHO 2005a). An eHealth unit was created to promote and strengthen the use of ICT in health development, from applications in the field to global governance.

That same year, WHO launched the Global Observatory for eHealth (GOe), to support countries in developing and managing national eHealth strategies.

Since then "the potential impact" of the advances in information and communication technologies on health-care delivery, public health, research and health-related activities for the benefit of both low- and high-income countries expanded considerably, together with new challenges. Through the GOe WHO has been updating since 2010 an online directory of eHealth-related national policies and strategies from Member States. To date, 58% of countries have established an eHealth national strategy (WHO, 2018).

At European level, only six countries (13%) have a national policy or strategy

regulating the use of big data in the health sector and four countries (9%) have a national policy or strategy regulating the use of big data by private companies. Furthermore, 73% (33 Member States) do not have an entity that is responsible for the regulatory oversight of the quality, safety and reliability of mHealth applications.

Many Latin American and Caribbean countries are committed to reform their telecommunications systems. Rodrigues et al. (2013) analysed all the 33 Latin-American countries, reporting 19 ICT interventions; among these, 7 eHealth policies have been studied. The study found that there has been considerable progress in the establishment of ICT policies in the LAC region, but less so for eHealth policy specifically (Rodrigues et al., 2013).

At the national level, comprehensive legislation will need to address a long list of issues that many low-income countries will find difficult to introduce and sustain autonomously. The list of regulatory issues relevant for eHealth identified as key includes: access to and ownership of data, security and access to clinical information systems, privacy and confidentiality, informed consent for data use, access rights, integrity of data, patient safety, secure transmission of patient data, electronic and physical security, reliability of electronic portable medical devices used with eHealth, accuracy and reliability of online information for patients, sustainability of accuracy and integrity of electronic patient medical records, validity and reliability of clinical decision support systems, quality of care using eHealth processes, availability of efficient and effective communication systems, and reliability and dependability of telemedicine and telemonitoring. It has been argued that regulatory priorities for eHealth development should focus on privacy, confidentiality, security and standards (WHO, 2016).

Clearly, eHealth governance covering multiple areas mentioned above is a challenging issue of our times and needs requires input from global policy-makers.

At the global level, eHealth standardization has been also on the International Telecommunications Union (ITU) agenda since 2003.

Later the ITU felt the need to build on the collaboration with the WHO to create a global, open environment for the development and promotion of eHealth standards. In 2012, the 12th World Telecommunications Standardization Assembly (WTSA-12) adopted a resolution regarding ITC applications and standards for improved access to eHealth. Among issues needing global attention in order to ensure the successful adoption of eHealth applications, responses that were considered were: the conformity with standards to increase interoperability among systems, the safeguarding of privacy and security and the reduction of the cost of devices through economies of scale.

Health related internet domains have also been among the issues debated at global level.

In 2013 the WHA recognized the need for health data standardization as part of eHealth systems and services, and the importance of proper governance and operation of health-related generic top-level internet domain names (gTLDs), including ".health" (WHO 2013).

Regulating the .health domain was considered key in ensuring the internet can play its proper role in supporting global public health. The privatization of .health domain elicits concerns about the effects on health information access and quality and calls for global safeguards and policies to protect consumers. Indeed, due to the global nature of the internet, national legislators will have difficulty in ensuring that the management and operation of .health and other health related gTLDs will be consistent with public health goals (Missoni et al. 2019)

Many other technical aspects are also examined in collaboration between International Institutions, mainly the ITU, and private stakeholders such as the Personal Connected Health Alliance (PCHA), which is an international not-for-profit industry organization whose members are prominent ITC, health technology and pharmaceutical companies. ITU recognises the PCHA promoted Continua Design Guidelines, as the international standard for safe, secure, and reliable exchange of data to and from personal health devices (Missoni et al. 2019).

Indeed, legal, ethical, cultural, and economic issues are continuously debated between ITU and WHO. Furthermore, many of the regulations at the international level have been developed mainly due to trade in health services in the context of transnational data flows; one example is the United Nations Conference on Trade and Development (UNCTAD)'s Data protection regulations and international data flows (UNCTAD, 2016).

Complex issues concerning Big Data in health are specifically analysed by the UNESCO International Bioethics Committee (IBC) concerned with the protection of individual rights and fostering public good. Regarding governance UNESCO stated that in relation to Big Data, governance systems should aim at protecting the fundamental rights of the persons from whom the data originates, protecting sharing of data from exploitation, manipulation and improper control (UNESCO, 2017).

It is worth to mention that the eHealth information governance played a key role in the COVID-19 pandemic emergency. However, the difficulties associated to pseudo-anonymization of data for internet-based epidemiology as well as the risk that large amounts of data will be gathered by private companies are top concerns in Europe (European Commission, 2020).

4 Conclusions

Although eHealth projects and initiatives are growing, worldwide scenario is still one of piecemeal implementation often lacking a system approach at national level and coordinated governance internationally.

Most of the eHealth tools are not embedded within the health care system. eHealth tools that use multimodal content and provide the possibility for direct communication with providers have a higher adherence among vulnerable groups. However, eHealth tools are usually focused on specific problems, such as diabetes or obesity. Hence, they do not provide comprehensive services for patients. This limits the use of eHealth tools as a functional component of existing health care services.

eHealth programmes should be part of a national strategy as an integral plan for health system strengthening, taking into account countries' specific socio-economic contexts, including sustainability in terms of human and financial resources and normative environment.

The diffusion of eHealth goes hand in hand with the digital divide theme, thus calls for policy categories and issues that enhance the use of eHealth among populations who most need improved health services. These should include policies and guidelines to regulate the penetration of telecommunication companies, such as mobile companies, Internet service providers, integrated services digital network providers, and satellite vendors. Together with access to information and communication, eHealth must be recognised as a public good that cannot be left unregulated to the market. It is a governmental and intergovernmental responsibility to ensure that benefits reach also the poorest countries at affordable costs, providing universal and unlimited access to the Internet, and allowing for appropriate use of eHealth as part of the global effort toward universal health care, and the attainment of the relevant Sustainable Development Goals (SDGs) of the global Agenda 2030 (UN, 2015).

In this sense, the development of adequate global governance mechanism should go hand in hand with assisting national health systems in the development of eHealth and encouraging a global commitment for funding eHealth programs.

The policy goal-setting theme includes policy categories and issues that can guide the process of defining policies for eHealth that cannot be disconnected from policies to encourage appropriate growth of the telecommunications sector in a well-regulated framework.

This would include policy issues such as encouraging development and use of open-source technologies, increasing access to technology, increase connectivity in remote

areas, reducing cost, building local capacity, encouraging appropriate and sustainable innovation and developing governance and management structures.

Institutional policy issues, such as ensuring universal standards of care, and allotting and distributing the workload for health care providers and technical and managerial staff, are also included under this theme (Khoja et al., 2012)

The power of digital technologies structurally changes behaviour and above all the relationship between knowledge and perception. In other words, it poses the problem of the relationship between science, knowledge and behaviour. Digital technologies represent a great step forward in improving knowledge and possible concrete applications. Especially in the health care system the problems are represented on the one hand by the speed and flexibility of adaptation of supply structures and on the other by communication. Even using digital technologies science has to get out of its ivory tower to communicate and involve patients and thus regain credibility in society.

The trend toward Health 4.0, extending eHealth to the Internet of Things in health, will require a deeper analysis on what is really at stake also in terms of human rights, universal access to health services and further commodification of health needs, in that sense due to the global nature of the Internet, national policies will necessarily need to be part of a global governance framework.

Abstract

The fight against both air and water pollution has become an obligation for OECD Countries. Particularly, waste collection and disposal are becoming a social problem to be tackled by worldwide Public Administrations through new models able to go beyond accounting for financial inputs and towards outputs (outcomes, impacts and service quality) by a dynamic co-productive scheme. Accordingly, recycling policies based on "door-to-door" collection have become widespread. Nevertheless, changes in waste management (WM) are consequently modifying waste collectors' working activities, transforming also the risks of accidents at work. Musculoskeletal systems of WM employees are deeply exposed to high bio-mechanic and ergonomic risks caused by repeated movements; thus, WM workers tend to develop a higher risk of both injuries and occupational diseases.

In this context, Digital Technologies (DT) seem to be an extremely useful element to optimize public service provision preventing working accidents, and related costs. Thanks to digital wearable health technologies, it is possible to monitor workers' gestures and correct, in case, their wrong postures taken on during their tasks. This would bring to prevent injuries and its related losses of productivity.

Given that no literature has arisen yet about DT impacts on occupational accidents, this study aims at investigating how DT could contribute in improving the WM field, particularly for what regards the prevention of accidents at work together with a reducing of service setbacks. Specifically, this manuscript intends: i) to investigate if DTs allow a better governance in Public Agencies performance by reducing social security costs and by guaranteeing a better continuity of services to citizens; ii) to examine which structural change would be requested in order to make operative this predictive risk model in the real working context.
To achieve these goals, this study developed a qualitative inquiry based on face to face interviews with two high-qualified experts about DTs and wearables e-tools.
Findings demonstrate a positive impact of DT in detecting critical operating issues in WM services. Particularly, information obtained by digital infrastructures allow management to make more efficient the work of the organization, reducing potential loss due to waste of time and/or physical resources; moreover, wearable technologies allow to prevent injuries by modifying the workforce management (work shifts, rests, tasks).
Finally, this contribution fosters the debate about the potential role of digitalization in Public Administrations and Policies. Particularly, this research shows how innovations based on Internet of Things could potentially improve the whole value-chain of public services' provision.

Paper type - Academic Research Paper

1 Introduction

Defined as "the contamination of the physical and biological components of the earth/atmosphere system to such an extent that normal environmental processes are adversely affected" (Muralikrishna and Manickam, 2017), environmental pollution represents one of the major problems for worldwide modern economies.

In the last decade, the fight against both air and water pollution has become an obligation for OCSE Countries, so much so as to represent one of the most important issues among the development goals, recently released by the United Nations (UN-SDG 9, 12, 13).

In the Italian context, in particular, waste collection and disposal are becoming a social problem to be tackled by waste management and recycling policies addressed by the Public Administration. Hence, in the lens of health prevention (Reed et al., 2013), both local and regional governments have emphasized the introduction of environmental policies which address the challenge of pollution reduction through a rethinking of public service delivery processes (Osborne, 2006).

Moreover, it must be considered the relevance of the public role in this field, which has seen, in the last years, the shift from government to governance (Stoker 1998), leading to a recourse to contracting out in waste collection practices, with a distribution of services, not merely technical, but leading to the raise of questions about the power exercised through regulation, contracting and monitoring (Clarke, & Newman, 1997). This shift was associated with the necessity, by the public, to formalize performance measurements able

to go beyond accounting for financial inputs and outputs, thus including the outcomes, impacts and service quality (Slater & Aiken, 2015). Indeed in considering the waste collection in a local community, the relevance remains to the public, the payment is made by taxes from citizens, the collection and disposal are in charge of a private organisation (being it for profit or even not profit) in a complex dynamic of co-production scheme (Osborne et al., 2014; Pestoff, 2014), where it is not important to have not only a service at a right place, but it is also important, by the public, to regulate activities in order to avoid any possible risk of pollution and/or law respect of hygiene rules.

For this purpose, the improvement of a proper waste management policy seems to be an effective solution. In particular, recycling policies based on "door-to-door" collection have become widespread. This is also confirmed by the document issued by the European Commission in 2018 which identifies the recycling procedures as basis for circular economies.

However, the changes in waste management accordingly changed also working activities of waste collectors thus transforming also the risks of accidents at work. Indeed, a preliminary aspect regards the necessity to design and implement, innovative work behaviours by waste collectors, in order to reduce the risk of accidents. An innovative work behaviour is "the intentional generation, promotion, and realization of new ideas within a work role, work group or organization, in order to benefit the role performance, the group or the organization" (Janssen, 2003: 348). In this sense it is important to consider, when thinking about an innovative change behaviour by employees, also the ability, by managers to design and implement actions within a transformational leadership style, able to make employees capable to transcend their self-interests, through the development of a proper vision, adequately communicated to the employees, in order to have them as implementers of the change (Jasper & Signe, 2019).In the European Union in 2017 accidents at work were about 3.32 million (Cioca and Ivascu, 2017), representing a loss of productivity (European Union, 2013) of about 146 million of working hours/year (OSHA E, 2001). Workplace disruption costs account for €10 billion and loss of quality of life is estimated to €60 billion (Rikhardsson and Impgaard, 2004).

Moreover, waste management workers tend to develop a higher risk of both injuries and occupational diseases in comparison with other fields (+2% - Eurostatat, 2015).

In this scenario, musculoskeletal systems of employees involved in modern "door-to-door" waste collection and recycling activities, are deeply exposed to high bio-mechanic and ergonomic risks caused by repeated movements (INAIL, 2014 and 2016).

In this context, digital technologies seem to be an extremely useful element to both optimize public service provision and, especially, prevent working accident. Particularly, the Internet of Things (IoT) applications and devices, by allowing the connection of anyone, anytime, anywhere, to any service, devices and network can contribute to completely re-define how devices and people (clinicians and patients) interact with each other (Rhgiuou, 2018).

Accordingly, IoT applied to healthcare environment (Terry, 2016) relates to the following aspects which involve public service improvements:

1) Clinical. The possibility of remote monitoring vital signs of individuals, making them supervised without long interruption and checking also their adherence to follow-ups and prescription.

2) Organizational. The impacts of IoT on the internal process in service delivery regard the way in which biomedical information and hardware technologies, connected each other, transmit data which are able to change the behaviour of individuals (providers and users) in their role within service providing.

3) Economic. The individuals' management by IoT could radically change financial charge on service providing. By precise information availability both the service time burden and resource wasting can be decreased; thus, costs decline. Moreover, staff monitoring could prevent their working accident; as a consequence, future costs will decrease as well.

As a contrast, limits at IoT employment relates to human resource issues (i.e. staff skills), legal and ethical factors (i.e. liability, confidentiality, data protection, and patient privacy), and culture norms and practices (i.e. doctors' expectations regarding face-to-face patient interaction), along with organisational business strategy (Qi et al., 2017).

Potential setbacks regard prevalently the following aspects:

a) Technical. This regards the complexity of technology usage, installation and its intuitiveness-usability.

b) Effectiveness. This relates with the lack of strong evidences of IoT employment efficacy. This limit is mostly due to the fact these technologies are at the beginning of their life cycle, and not so many trials have been successfully concluded yet. This brings to an impossibility to declare their complete reliability in the real context. Besides, the continuous misclassifying between medical devices (CE stamp, FDA declaration of conformity, etc) and wellness devices (i.e. smartwatches, smartphone apps, etc), contributes to feed doubt about IoT affordability within users.

c) Cyber-Security. This regards mainly the protection of health and sensible information. These limits refer with the architecture of data mining, the way in which data are collected, registered, stored. The way in which date are sent, received and processed; the way to encrypt and unencrypt them, in order to make them available also for the owner and the responsible of their management. Also, in the lens of the General Data Protection Regulation (GDPR).

With specific regard to the waste management, in order to decrease both those risks incidence and related costs, according with the clinical risks predictive models based on biomedical signs monitoring (Orchard, 2018; Zhao, 2017), a possible solution could be found in the correction of wrong postures taken on by employees during their tasks (Guercio et al, 2013). This strategy should be taken starting by a precise knowledge of each individual's body movements during his/her working performance which is made

possible by digital health technologies designed for continuous human activity recognition (Mukhopadhyay, 2014).

The aim of this biomedical monitoring of waste collectors is to identify those employees who need to improve gestures during working activities with the goal to prevent injuries and related risks of loss of productivity.

However, while it has been demonstrated that the continuous advancement of health technologies (HT) - often derived from sport and wellness fields - makes possible the continuous human activity recognition (Mukhopadhyay, 2014), no literature has arisen yet about their impact on the prevention of accidents at work.

In particular, or waste management employees, the bio-mechanic and ergonomic risks of injury can be detected through Electromyography (EMG) and Electro-Kinesiology (EKG) investigations, which can be obtained in their real working context by simply "wearing" medical sensors enclosed into bracelets or a suit.

Therefore, with the goal to minimize risks of working injuries for waste collectors, wearable technologies are able to record data and communicate them to a service desk which: i) analyse obtained information, ii) compute health-related risks, iii) give feedback to employees aimed at working risks prevention.

This risk-detecting model seems to work in a way similar to the Hub & Spoke model in healthcare (Elrod and Fortenberry, 2017) and with general flow charts of a common Telemedicine service providing (Ranalli and Palozzi, 2019). Accordingly, this process should positively impact on detecting and reducing risks of accidents, injuries and diseases caused by repeated and wrong gestures during the working activities of waste collectors; this should also contribute in training and teaching employees about a correct improvement of their physical working tasks.

However, experiences about the effective execution of this model are scarce and mostly theoretical.

Given the above, this study aims at investigating how Digital Transformation could contribute in improving the waste management field, particularly for what regards the prevention of accidents at work together with an increase in working productivity, by reducing service setbacks.

Particularly, this work wants to analyse how digital wearable technologies can be accepted as an investment on social-security within the waste management field.

Therefore, this manuscript would like to investigate if DT and Internet of Things (IoT) allow a better governance in Public Agencies performance: on one hand, by reducing social security costs; on the other hand, by guaranteeing a better continuity of services to citizens.

As a secondary endpoint this work wants to examine which structural change would be requested in order to make operative this predictive risk model in the real working context. In particular, this work would like to examine for working practices:

- potential changes of workforce management;
- investments in digital technologies and infrastructures needed for this change;

- flow-chart of information "from" and "to" employees.

To achieve its purpose, this paper follows the following outline: after this brief introduction, including the main background about the theme, the second section explains methodology followed to answer the research issue. Particularly, we used an interview-based qualitative pilot case study (Patton, 2002; Yin, 2014) aimed at intercept opinions of experts about the employment of digital and wearable technologies in WM field. The fourth presents analytical findings of the interviews; while the last section discusses results obtained and provides some consideration about the potential impact of digital tool in health prevention of workers in arduous work field.

2 Methodology

In order to better understand the impact of digital transformation in the waste management, we decided to analyse a specific application of digital technologies, the so called: *wearables*, that is specific tools able to detect risks of potential accident for employees while they are working. Coherently with the qualitative "explorative case sampling" [Patton, 2002], we inquired the potential impact of these innovations within its real-life context by intercepting information-rich key informants, who are well-situated and competent people involved in the critical issues (Yin, 2014) of digitalization projects.

With the purpose to intercept some insights from high-qualified experts, the research has been designed on "face to face" interviews (Said et. al, 2017) to two experts (E1; E2), who can be considered two of the most important specialists in the field of electronic engineering applied to healthcare and people protection field.

The interviewees hold the following job-position within their organization:

1. Head of the National Center of Innovative Technologies for Public Health – National Institute of Health (ISS), Italy (E1);
2. Professor of Electronics at the Department of Electronic Engineering, University of Rome Tor Vergata, Italy, and Coordinator of several research on Electronic Engineering applied to bio-medical field (E2).

The enquiry intends to intercept opinions of those "key" experts belonging to the fields of health & security policy, biomedical engineering and waste management about the effective employment of ICT and digital tools (Qi et al., 2017) in the protection of workers' health of.

We developed the theoretical rationales for the interview protocol by drawing on digital transformation literature and particularly on the pillars of digital portfolio for digital innovation framework (Schreckling and Steiger, 2017).

The basic Schreckling and Steiger (2017) framework considers the following key dimensions related to digital transformation:

- Customer centricity (i.e. the expectations, preferences, engagement, issues and problems related to customers-patients in terms of digitalization adoption);

- Leadership and strategy (i.e. the reasons why organizations should focus on digital initiatives);
- Culture (i.e the people mindset for digital adoption);
- People (i.e. skills and obstacles for digital business);
- Structure and governance (i.e. roles and authority mechanisms);
- Processes (i.e. the objects of digitization);
- Technology foundation (i.e. the importance of new technology infrastructure and applications);
- Business model (i.e. the importance of innovate business by new offerings and products)

Given the on-going, iterative process of data discovery and comparison, we decide to exclude two pillars of the digital framework, namely Technology Foundation and Customer Centricity, as they were found not meaningful for the context of the pilot project we wanted to analyze.

Accordingly, Technology Foundation is a less informative topic for our research as the technology (in particular IoT applications) is already present in the analyzed context, differently from what suggested by the framework, which questions the need for having new technology infrastructures, systems and application for digitalizing business. Moreover, we do not consider the Customer Centricity topic as we focus on the effect of the innovation on service providers rather than users, which, in the waste management field, have to adapt themselves to the rules of the community they belong to.

Moreover, in order to have an exhaustive overview also for the technological issues that represent one of the main drivers of our research, we further enrich our theoretical basis for the interview protocol by drawing on the insights of Technology Acceptance Model (TAM) theory (Davis, 1989; Davis et al., 1992) and its modification (Dutot et al., 2015), especially for having a guide about the understanding of how operationalize questions related to technology acceptation and use in the specific context of waste management as direct derivation of the healthcare sector (the field from wearable technologies arise).

According to TAM, several factors can influence users' intention to use a new technology which prospectively could turn into an actual behavior. Such factors are contextual since they relate to both characteristics of individuals (e.g. motivations, attitudes, resistance, demographic attributes, and user type), technologies (e.g. types of innovation) and organizational environment (e.g. types of setting, processes, and conditions)

Accordingly, we framed our interviews as open, semi-structured questions, related to the pillars by adapting such framework to our case and thus having the following questions (Table 1):

Table 1: Framework for qualitative assessment of digitalization in the Waste Management Field

	PILLARS	QUESTION (s)
Impact of Digital Transformation	1. Leadership & Strategy	What is the role of digitalization in a waste management/recycling organization?
	2. Business Model / Policy	-Referring to a waste management field, who would be responsible for investments in digital transformation? -Investments would be supported by public agencies, or by private service providers, or both? What would be the investment goals?
	3.Process	-How do waste management services change through the use of information obtained by digital tools?
	4. Structure & Governance	-How employees are involved within do digitalization process? -How do employees accept this change? Positively, negatively, Why?
	5. People & Skills	-Which kind of employees could mainly benefit from that kind of digital technologies? - There would be a need for new professionals who allow these digital tools to permeate / be used within the organization?
	6. Culture	Which staff personal variables (e.g. age, gender, level of education, work experience, etc.) can accelerate / slow down this digitalization process?
Structural Change	a. How much the information obtained by digital wearable technologies could affect the workforce management? b. Which would be the specific investments in digital technologies and infrastructures? Could you describe them? c. Which would be flow-chart of information "from" and "to" employees? Could you sketch them?	

Source: Authors'. Elaboration inspired by the Schreckling and Steiger (2017) framework

3 Results

From the verbatim transcription of interviewees' opinions, we collected around 100 raw concepts, about 20 pages, which contributing in reporting insights about the potential adoption of digital technologies from companies operating in the waste management field.

Thus, the section follows the questionnaire structure with the goal of intercepting how digital transformation impacts on business operating and which leverages of change are interested.

3.1 Impact of Digital Transformation on Organization

3.1.1. Leadership & Strategy

"What is the role of digitalization in a waste management/recycling organization?"

This question highlights the potential impacts of digital technologies in waste management. "Many!" has answered the E1 interviewee; "Many! Because DT allows company to trigger a continuous communication between staff and leaders; this "feedback to feedback" relationship allows both leaders and staff in changing the strategy in order to provide better services". For instance, E1 continues, "monitoring of working activities and efforts provided by staff could allow company to:

i) changing work-shifts;

ii) managing service with less or more personnel and/or machineries;

iii) making this debate between staff and leaders a Research & Development moment of activities".

Particularly, for the correct exploitation of gestures during working activities, digital technologies allow experts to monitor activities and subsequently correct the wrong gestures with the result of a potential reduction of working accidents.

"In a service process with a high level of standardization, the punctual observation of information by digital technologies give company the possibility to protect health of workers" (E2) and to improve the service provided, by decreasing the level of absenteeism and related service breakdowns.

In particular, according with E2, wearable technologies allow experts to objectively observe and register gestures provided by workers during service activities for several times. The correctness of gestures is defined by a rule (e.g. Italian Law n. 626) which establishes when the working position and operating process is safe.

As shown in the following illustrative Figure 1, wearable technologies can replicate, by an avatar, the movements of a subject. This allows to judge if the singular gesture exposes employees to specific bio-mechanic risks. If the gesture is wrong the counter is red coloured, if it is correct the counter is blue. Surely the parameters are judged depending on the kind and the intensity (number of gestures, speed, power) of the observed working activities.

Source: Captks s.r.l., Italy, http://www.captiks.com

Figure 1: Avatar for gesture correctness analysis

From the analysis of repeated gestures, it is possible to correct each employee's movements (by a feedback received by an expert – e.g. a Security Manager), with a subsequent reduction of the risk of a working accident.

3.1.2. Business Model / Policy

"Referring to a waste management field, who would be responsible for investments in digital transformation?" and "Investments would be supported by public agencies, or by private service providers, or both? What would be the investment goals?"

About this point, both interviewees agreed that in the WM field the investments in digitalization should be taken from both public agencies and service providers.

E1 highlighted that these two subjects should contribute in the investments coherently with their own role in a long-standing business plan. In particular providers *"should purchase equipment needed for the internal process"* (E1), while, public agencies "*should be charged by those infra-structural investments related with the digital transformation functioning within the Country (e.g. the 5G technology)"*. Moreover, with particular regard to the basic need of wearable technologies for monitoring working activities' E2 clarifies that "*this kind of investment is very inexpensive. With* (about) *10.000 € it is possible to purchase a complete 10-sensors Kit, software included* (the same discussed in the previous point)*, for the total-body monitoring of working gestures*". This kit, specifies E2 "*can be used by several employees in different moments with the goal to:*

1) monitor gestures;

2) understand those possible mistakes that could bring to working accidents;

3) teach employees how to improve gestures and reduce working risks".

3.1.3. Process

"How do waste management services change through the use of information obtained by digital tools?"

The IoT-based strategies in waste management allow service providers to save resources; in particular, as highlighted by E1 "*if you can monitor things (or people) you can understand the efficiency of the service; for example: if you were able to know if a garbage bin is effectively full, you can't waste time in checking each one; or: if you could add a "R-fid" sensor on specific kinds of rubbish (for example those plastic made), you could know if someone is putting the wrong rubbish in the garbage bin. Or, again, if you can monitor by a GPS all the vehicles involved in waste collection, you could potentially understand if they are correctly operating or they take too long stops during the work-shift. If you are able to know what it is expected to find in a garbage bin, you can better organize the collection, being more efficient and safer (for example employees could wear special protection if they would know they are picking-up an infected waste)*". According to E1, the DT can completely change public service, by changing operating activities together with staff involvement.

With specific regards to wearables employment for working accidents reduction, E2 specifies that if it is possible to know the specific complexity of a service (e.g. the high of a garbage bin or a vehicles), it is possible, as well to train and then adjust gestures of the employed staff in order to save them from injuries.

3.1.4. Structure & Governance

- How employees are involved within do digitalization process?

- How do employees accept this change? Positively, negatively, Why?

Generally, "in order to get involved employees in a business change, you should motivate them by adequate training and information" (E1). "*Every kind of working monitoring should be known and well accepted by the worker, in order to allow him/her in understanding all related personal benefits and limitations*"; E1 continues: "*for example, if a WM company monitors the operation time both of worker and the vehicle that s/he is using during the service, it can probably discourage breakdowns and waste of working time; as a result, if the provided service were effectively more performing, the employee should receive a prize*". In E1's opinion the matter is not the kind of employee involved in the digital transformation, but how this change is perceived by the subject within an incentivizing mechanism.

This is valid also for wearable technologies aimed at preventing working accidents; these technologies have to be understood by the employees (and Unions as well) as a "strategic leverage for job security and not as a monitoring for personal productivity" (E1).

There is no answer about the positive or negative effect of digitalization by employees; it depends on how much this change is shared within the organization, together with its pros and cons.

Accordingly, E2 underlined that "nobody can accept to be monitored for a long time while working"; if the monitoring is for a short time and specifically aimed at health protection can be perceived, by the workers, as a "value-added" ; otherwise it would be suffered as a constriction.

3.1.5. People and Skills

"Which kind of employees could mainly benefit from that kind of digital technologies?"

and "There would be a need for new professionals who allow these digital tools to permeate / be used within the organization?"

E2 underlines that all employees could gather a benefit from an observation (by wearable digital technologies) of their working activities in the working place: "*not only the operational employees* (those that in WM are involved in waste collection), *but also the clerical ones, that often spent 8 hours per day sitting on a chair*". The administrative employees, could indeed suffer due to occupational diseases on musculoskeletal systems well as those workers with operative jobs. Clearly, who is more involved in physical

activities will tend to overcharge the musculoskeletal system, with the consequence of higher risks of injuries and muscular fatigue (E1).

With regards to professional figures, needed to foster digital technologies within WM organization, both interviewees agree upon that Security Managers should be mainly involved in the process of acceptance of wearable technologies as a tool for improving their tasks of health protection.

3.1.6. Culture

Which staff personal variables (e.g. age, gender, level of education, work experience, etc.) can accelerate / slow down this digitalization process?

No specific personal features of employees seem to be related to their inclination in using digital technologies; usually youngers and higher educated seems to have a proclivity for innovation (E2). But this is not related to the specific WM field.

On the opposite, E1 notified that most of employees are male; he added that this is due to a "legacy" of the specific field; thus, no connection between gender and propensity to digitalize has been highlighted.

3.2 Structural Change

a. How much the information obtained by digital wearable technologies could affect the workforce management?

From interviewees' opinions, this information changes a lot the possibility to manage the workforce management in waste collection. Particularly, E1 highlights that if it is possible to know about the physical effort and physical stress of an employee while s/he is working, it is possible to "*change work-shifts, in order to reduce his/her effort and prevent occupational accidents*"; accordingly, E1 continues saying "*during a door to door garbage collection shift, an operator could repeat 3/400 times the same gesture with an arm, or s/he gets in and get off 200 time from the truck. These repetitive movements implicate specific risks that wearable technologies can mitigate by, analyzing:*

- accuracy of gestures;

- speed of gestures;

- number of gestures;

If you measure these variables related to physical efforts, probably you can modify the work-shifts (e.g. reducing number of hours by increasing their frequency), *with the result of reducing risk of accidents at the musculoskeletal systems*".

"*Moreover*", E1 specified it with an example: "*if during a night shift, the operator collects 100 garbage bags but replicates the gesture of bag grasp for 200 times, it means that something wrong happened during the service*". Thus, the digital technology become a performance tool able to monitor also the service management as a whole.

Moreover, E2clarified that the monitoring of working gestures makes sense only for a short period of time, two, three working days. The employee carries out his/her tasks

while is monitored; his/her gestures and activities are firstly recorded and then automatically analyzed by a software. The result is a personalized teaching about the improvement requested to make the gestures safer.

b. Which would be the specific investments in digital technologies and infrastructures? Could you describe them?

Both interviewees agree that, in order to digitalize waste management activities, with the specific goal of decreasing risk of accidents, are requested the following resources:

a) capital investment in hardware equipment (wearables, transmission system);
b) capital investment in software infrastructure and cloud computing;
c) operating expenses for data analysis and feedback providing to employees.

No references about costs were discussed by interviewees.

c. "Which would be flow-chart of information "from" and "to" employees? Could you sketch them?"

Both interviewees confirmed that data flows "from" and "to" employees are exactly the same of a telemedicine service of biomedical monitoring.

Data start from the employee, while s/he is wearing the technologies; information are deposited to a cloud where are processed and analysed by a software; once data are analysed and understood by a professional, the feedback is transmitted to the employees. This feedback should include corrections to wrong working gestures, repeated movements and their speed.

The same feedback is also sent to the Human Resource Management and to the Security Manager in order to evaluate if it is requested a change of work-shifts, in order to reduce risk of accidents and increase occupational security.

4 Discussion and Conclusion

The study findings demonstrated a positive impact of digital technologies in detecting critical operating issues in waste management services. Specifically, interviewees highlighted that digital technologies could potentially represent a tool for an alignment of operational behaviors to business strategic goal (Ferreira & Otley, 2009). In particular, information obtained by digital infrastructures allow management to make more efficient the work organization, reducing potential loss due to waste of time and/or physical resources.

Moreover, wearables allow to intervene on the service production chain, thus having direct consequences on occupational accidents; in particular: the monitoring of the musculoskeletal system of waste collectors, during their working activities, allows to prevent their injuries by modifying the employee management (work shifts, rests, activities, physical training, etc.) and by providing employees with instructions about the

correct gestures that have to be hold during their working activities. This second point, we underline, is coherent with rule prescriptions about occupational safety.

This approach allows business in a "*quite continuous R&D aimed at maximize operational efficiency, and minimize risks in the daily activities, where planning and control represent a continuous cycle*" (E1). Digitalization, in fact, makes on-line (and strongly interconnected) these three pillars of strategic management (Kaplan & Norton, 1992):

1 Gather information
2 Provide internal communication
3 Monitoring service provided

If managers and employees can share information one to each other, through digital infrastructures and sensor, it becomes possible to easily adjust business strategy at the operative contingencies and, moreover, every change becomes better explained within the institution and better accepted from individuals. This surely improves the decision-making about operating activities (Lippa et al, 2017).

This structural change requests resources comparable to every digitalization project which implicate a direct data collection on physical subject in their working (or domestic) environment; such it happens for any telemedicine-based remote monitoring system. Thus, according to the literature about this theme (Davalos, 2009; Kairy, 2007; Ramkumar, 2018) the requested resources can be summarized as follows (Table 2):

Table 2: Costs of Digital Transformation in the Waste Management Field

Investment costs	*Operational and service costs*

Hardware:
• Personal device:
  ○ Wearable or Ambient sensor
  ○ PDA/ Smartphone
• Office Devices
	Personnel:
	• Technical/IT
	• Administrative
	• Security Manager
	• Specialist

Software: • License	Staff education: • Continuous training • Upgrade training
IT infrastructure: • Server • Internet / Utility lines • Privacy Security	Service hardware: • Depreciation of personal devices or • Rental medical of devices

Data Center Equipment	Organization hardware:
	• Depreciation:
	  ○ Office devices
	  ○ IT infrastructures
	  ○ Data Center Equipment

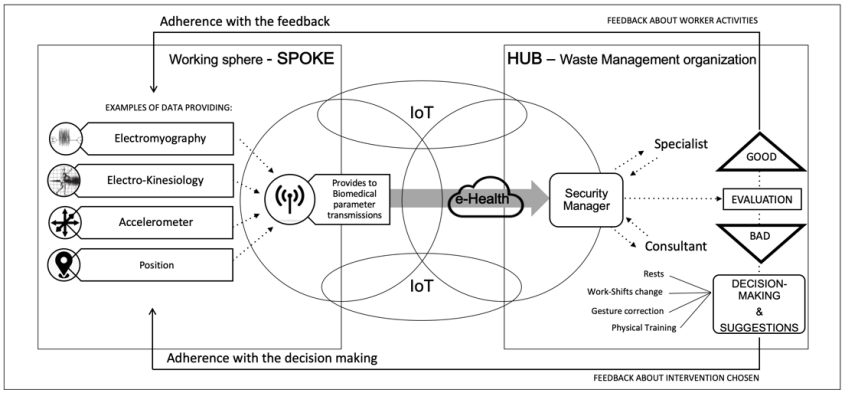
Set-up costs: • Operative Flow-chart • Privacy Rules	Software: • Amortization: • License.
Personnel: • New Hiring • Training	Staff support: • Enrollment • Training • Consulting

	Direct material: • Medical consumables • Office consumables
	Utilities

Source: Adapted from Palozzi et al., (2020)

Nevertheless, with particular regards to the technology necessities, a company has to pay attention to wastefulness of resources; very often, many operational information can be detected by an alternative use of technologies already owned by the organization. An easy example, on the specific context, was provided by E1: "*for instance, if the company wants to monitor if its waste collector is standing or fallen, the accelerometer with which, the employee's smartphone, is already equipped, represents a perfect* (and free) *solution* (as long as the smartphone is positioned on the back of the individual)".

In addition, this study confirms that information flow of a digital infrastructure aimed at monitoring employees' activities is based on "one to one" relationship between the worker (SPOKE) and his/her institution (HUB) (coherently with the Elrod and Fortenberry (2017) model. In particular this flow can thus be represented as a general model for the delivery of a telemedicine service, as shown in the following Figure 2.



Source: Authors' illustration, adapted from Ranalli and Palozzi, 2019.

Figure 2: Operating Model for Waste Management collectors monitoring system.

Nevertheless, as underlined by the interviewees, the most critical issue is represented by the "quality" of the feedback provided to employees within the business environment. Differently from the "clinical" field of telemedicine, where feedback to patients is provided by a specialist physician (who holds both the specific knowledge and the responsibility for patients' outcome), in the context of a waste management organization, the feedback mechanism would be potentially managed by an administrative employee with specific tasks on security management. This is very risky in order to effectively align workers' behaviors. About this matter, both E1 and E2 highlighted that this feedback moment is pivotal, because it "includes" (or "excludes") the operative worker within the

decision process which aims at the service improvement. The feedback, in other words, is the moment where there is a transfer of knowledge within the organization (Edmondson et al. 2001), that would be able to both increase business performance and decrease occupational accidents. This process follows a top-down flow, but on the base of bottom-up information gathered by digital (wearable) technologies.

Limitations of the study are those implicit in a qualitative method: first, in terms of its replication, it would result less reliable than quantitative ones, for the interpretive role of researchers, and limited extension of data. Nevertheless, the prestige of our interviewees reduces such a limit. Secondly, given that this research is moving its first steps, the study can be considered as a pilot, given its original level. This explains why our interviews involved only two experts.

Moreover, another limitation is implicit to the specific topic addressed by this study; it regards the limited specific literature background on digital technologies employment in occupational accident prevention: this literature is prevalently belonging to the engineering and healthcare fields, with few strong interconnections with managerial ones.

This limitation, however, poses this study as a contribution for fostering the debate by both scholars and practitioners about the potential role of digitalization in Public Administration and Policies. Particularly, this regards insights about those potential benefits, for Communities, related to the digitalization of public service in modern economies. Although digital technologies are still prevalently considered as a support for administrative activities and process controls, this research shows how innovations based on internet of things (Brous et al. 2019; Terry, 2016) could potentially improve the whole value-chain of services' provision (Bermann and Marshall, 2014), including organization of work-shift, operative tasks, and workforce management.

Abstract

The paper proposes a plan for introducing digital transformation into the estimates of the spending on drug-related healthcare, by identify the models currently available in scientific literature to make bottom-up estimates of the costs of providing treatment to substance abuse. The authors performed a scientific review of the literature, complemented with the snow-ball method, and applied a qualitative method of content analysis. Authors do not rule out the possibility that additional cost calculation tools may exist, because many methods are published in grey literature by public or private entities in charge of monitoring drug treatment. These studies are not always possible to capture in scientific reviews of the literature. Finally, the paper contributes to set the theoretical framework required to apply methods to estimate the costs of providing substance health care, in a digital context.

Keywords – Methods, Costs of treatment, Substance abuse treatment, Digital ecosystem, Illicit Drugs, Smart Public Administration.

Paper type: Academic Research Paper

1 Introduction

In 2018, over 92 million people used illicit drugs. Moreover, alcohol remained the third risk factor for disease and mortality in Europe (OECD, 2018). According to McLellan et al. (2000), the abuse of illicit drugs is a chronic condition which often lasts the whole life of a patient. This requires practitioners, health economists and policy makers long-term treatment and innovative strategies to handle costs.

Two main approaches are commonly used to estimate the costs of providing healthcare. The top-down and the bottom up approaches. The top-down applies pre-defined criterion to disentangle specific costs within wider budgets. Here, the relative value units (RVU) or for instance the number of days that patients stay in hospital are commonly used metrics (Chapko et al., 2009). Data are frequently provided by national or international entities (Rubin, 2017).

The bottom-up approach aims to estimate the total cost after estimating the cost of providing one unit of treatment, and multiplying it by the number of treatments administrated (Olsson, 2011).

As shown in Chen (2010), the bottom-up approach is desirable to evaluate health programmes. In fact, once a methodology has been identified, the same method can be generalized, enabling to estimate total costs and to make cost-effectiveness analysis, because this method allows a rigorous evaluation of the relationship between the costs of each intervention and its outcomes.

Over the years, several studies have been carried out to calculate the costs of treating the abuse of illicit drugs (Cartwright, 2008; EMCDDA, 2017). However, methods applied are still too diverse and results are not comparable (EMCDDA 2017). It is therefore important to promote consensus-based improvements in the estimation methods and to work towards defining best practices.

One solution for bridging this knowledge gap and to developing suitable methods, could be to reinforce the use digital technology in this field. As indicated by Agarwal et al. (2010), the application of health information technologies (HIT) increases the quality of the health provided and reduce its costs. These authors stress that adopting specific HIT to the different scales of operation, increases the knowledge of costs and allows better analysis.

In the same vain, the European Parliamentary (2017) refers that digital transformation can give a better contribution to tackle substance use disorders. It mentions that there are some improvements that should be operationalized. It stresses i) increased interoperability between e-Health solutions, ii) more transparency in the use of data collected; iii) harmonization of the national and regional access to ICT services; iv) promotion of standard guidelines; v) promotion of reimbursement schemes for digital health services; vi) lowering the costs in setting-up e-Health systems and e-Applications; vii) reducing regional differences in acceding ICT services. The study of Buccioli et al. (2014) stresses the need to introduce digital transformation in this sector, because of its beneficial impact both on the decision-making processes and on the control of costs.

The use of digital technology is frequently applied in two main areas. The first uses e-Health applications to treat patients. It includes web-based environment for self-care, Information and Communication Technologies (ICT) for therapy, Artificial Intelligence and virtual therapeutic software and the therapeutic use of social media (Barak et al., 2009; European Parliamentary Research Service, 2017; Litvin et al., 2013). Digital technology is also used is to manage the operational components of Health provision, with e-Health applications. Buccioli et al. (2014) and Fritz et al. (2015) stress the benefits of e-management to reduce the costs of providing health services, especially in an era of scarce resources, responding to cost-effectiveness concerns.

Despite the political, social and economic relevance of this topic and the advantages of linking costs to digital transformation; a systematic digital processing of costs does not seem to have been systematically applied to drug-related healthcare yet (neither for treating illicit drugs nor alcohol abuse).

Therefore, an additional the aim of this study is to analyze the compliance of the models used to estimate the costs of drug-related healthcare with digital ecosystems.

This study is organized as follows. Section 2 investigates the elements required in a digital ecosystem when applied to drug-related healthcare, considering the results of the European Agenda for the treatment of substance abuse. Section 3 describes the methods used to search literature and to analyze the cost models of treating substance abuse in a digital ecosystem framework. Section 4 describes and Section 5 discusses the models available in literature. Finally, section 6 concludes by presenting the elements necessary to create and develop a desired digital ecosystem in this field.

2 Digital transformation and ecosystems

Digital transformation in healthcare is a broad concept. We consider digital transformation the transition from a setting with analog or non-digital procedures to a setting where procedures are mostly operationalized in a digital ecosystem.

As Ricciardi et al. (2019) stressed, digital transformation in health care is difficult to define because it is complex and it ca be applied in multifaceted ways. These authors suggest that "*digital transformation indicates that health services and systems are in a transition in which more health services and processes will be digitalized*". Agarwal et al. (2010) point to the potential use of mobile health; Klinker et al. (2019) discuss the system of Augmented Reality for Hands-Free Service Innovation and; Menachemi et al. (2007) suggest the systems of Electronic Health Record (EHR).

So, on the one hand, one can consider the appliance of digital transformation as a support to diagnosis or to the measurement of prevention processes (Agarwal et al., 2010; Biancone et al., 2019); or, on the other hand, one can apply digital transformation to services provided to patients and to back-office operations in health services (Meskò et al., 2017).

As Jacobides et al. (2019) referred, digital transformation in healthcare needs to be framed within a good orchestrated digital ecosystem. Therefore, we will also explain what we consider a digital ecosystem.

Jacobides et al. (2018) say that "*An ecosystem is a set of actors with varying degrees of multilateral, non-generic complementarities that are not fully hierarchically controlled*". Iyawa's et al., (2016) defined a digital ecosystem as a "*[…] network of digital health communities consisting of interconnected, interrelated and interdependent digital health species, including healthcare stakeholders, healthcare institutions and digital healthcare devices situated in a digital health environment […]*".

Therefore, we consider that a digital ecosystem is composed by community, content, practice, technology, biological species, economics species, digital species, digital environment, security, and trust (Table 1). These components are useful to frame digital transformation and should be defined when designing a digital ecosystem (in healthcare).

Table 1. Components of digital ecosystems

Components / Sources	**Description**
Community	Community is the entire set of actors/species available within the digital ecosystem environment. There are three different types of species: biological, economic and digital.
Content	Content contains the information or services used by species.
Practice	For the different species to be comfortable and operate freely, practice is required.
Technology	Technology refers to hardware and software responsible for the information interchange.
Biological species	Persons who participate in the digital ecosystem.
Economic species	Companies and institutions which participate in the digital ecosystem.
Digital species	Digital devices, software and hardware used by people, companies and institutions participating in the digital ecosystem.
Digital environment	The platform on which digital species interact.
Security	The protection of resources and species in the digital ecosystem.
Trust	The believe that all species want to achieve the same goal and the same level of security.

Source: Iyawa's et al. (2016)

This study will assess if the bottom-up methods used to estimate the costs of drug treatment operate in a framework of digital ecosystems, according to the pre-defined conceptual framework required. This assessment is made verifying their compliance with the criteria identified in Table 1.

3 Methodology

3.1 Review of literature

A review of literature was performed to identify the tools and methods used to estimate the costs of treating the dependence of illicit substances to be used by European policymakers, researchers or health care managers. The authors searched for studies

which applied a bottom-up approach. One outcome of the literature review is that the number of models is small. Below, authors describe the process applied in the literature review.

In order to review the existing methods available, this study used a multiple-case study approach. It gives an overview of other currently on-going initiatives and an understanding of their implementation.

The analysis was carried out by investigating the methods applied to estimate the costs of treatment programmes targeting substance abuse. In order to reduce contextual variation, authors selected a set of countries with high health care expenditure (OECD, 2019). Therefore, the selection of the cost-accounting methods was made among the top 12 countries with highest expenditure, out of the 37 countries monitored by the Organization for Economic Co-operation and Development (OECD). Data was extracted from the OECD database, with data published for expenditure on Health Capital (HK) as a percentage of the Gross Domestic Product (GDP)[1].

Authors used the follow online search engines: EconLit, and PubMed. In particular, the EconLit engine is recognized as the primary research tool for Economic analysis (Smith, 2009). PubMed was also used because it offers functionalities such as searches 'limited by specific search keys' or 'citations from identified sources' (Shultz, 2007).

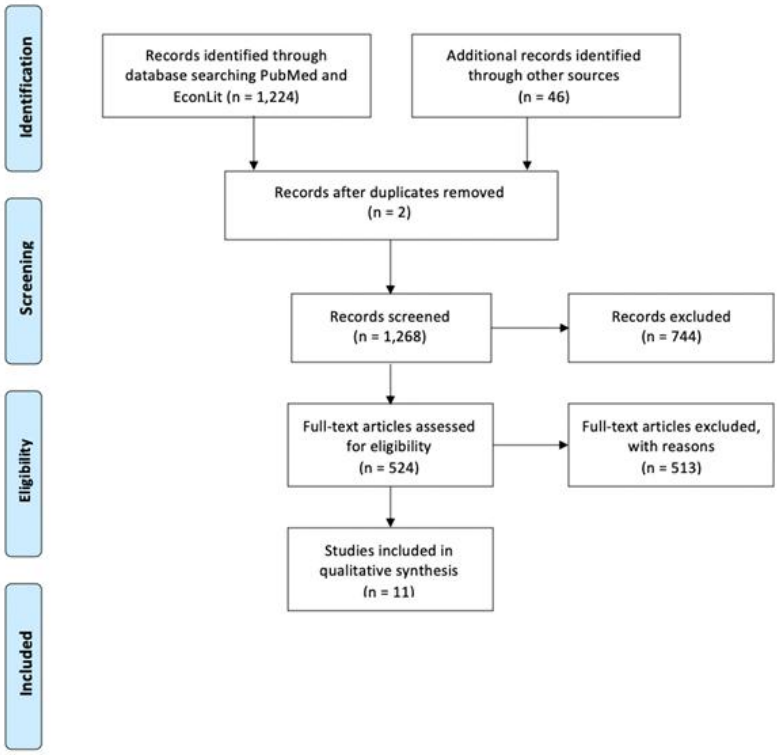
In this literature review the keywords used were: "treatment", "costs", "addiction"; "economic", "evaluation", "drug", "abuse", "methods"; "EHR", "calculation", "analysis", "digitalization", 'illicit drugs', 'cocaine', 'heroin', 'cannabis', 'methamphetamines', 'harm reduction' and opioid substitution treatment (OST)'. The review of the literature was complemented with a snowball procedure (Lecy & Beatty, 2012), because the number of studies resulting from the first search was small. In fact, the description of the methods applied to estimates of the costs of treatment with a bottom-up approach has been most published in grey literature. Therefore, models are better traceable through references.

Further, this review complied with the following criteria: (1) studies and documents published in English; (2) availability of full text and; (3) studies used a bottom-up cost calculation approach in the area of illicit substance dependence. Additionally, all the authors independently perform the analysis in the search engines reading the titles and the abstracts of each source. After this step, they share the knowledge flow and when opinion differed, a final decision on inclusion of exclusion of the source was made after an in-depth discussion of the topic.

Consequently, authors have reviewed all studies that proposed a complete method to estimate these costs. Authors considered scientific peer-reviewed papers, institutional reports, case studies and health-programmes evaluations.

The outcomes of the literature review were classified according to the PRISMA method (Liberati et al., 2009). Figure 1 presents the flow of the search, the method, the number of results obtained and the final number of papers considered.

[1] *Data extracted from the OECD Database: https://data.oecd.org/healthres/health-spending.htm, April 2020.*



Source: authors' elaboration on Liberati et al. (2009)

Figure 1. The PRISMA flow

3.2 Content analysis

Subsequently, the authors carried out a content analysis. The aim was to identify in each study the cognitive schemas, accounting methods, categories used, readiness and easiness to apply to a wide spectrum of European countries and compliance with a digital context. This objectives were used to review the literature and to compare methods and accounting categories applied, as well as the different periods of time and institutional frameworks (Flick et al., 2004). This study implemented a deductive content analysis in three phases: first, preparation; second, organization and; third, concluding remarks (Elo & Kyngäs, 2008).

As shown in Fig. 2, the first step consisted in defining the unit of analysis applied to the cost methods. The second step, the organization, consisted in developing a structured matrix to test two hypotheses with the pre-defined criteria. Criteria were applied to analyze and compare the costs methods (Kyngäs & Vanhanen, 1999). With the support of this matrix, authors reviewed the studies founded. Table 1 displays results. The third step comprised the analysis of the information, i.e., testing compliance with the digital ecosystem framework.

The following two hypotheses were tested:

H_1. The literature provides sound methods to account and estimate the costs of treating substance abuse, with a bottom-up approach;

H_2. The bottom-up methods used to account and estimate the costs of treating substance abuse are possible to implement within the framework of a digital transformation and comply with a digital ecosystem.

Figure 2. The qualitative process of content analysis

4 Results

4.1 Cost analysis

The survey of the literature reveals that eleven methods were used applying a bottom-up approach to estimate the costs of treating substance abuse. These methods are listed below (Figure 2). Their main features are briefly summarized. The feasibility/cost of

collecting the data and the adequacy to a European framework are assessed. Their fit to a digital ecosystem is evaluated also.

DATCAP (The Drug Abuse Treatment Cost Analysis Programme) is an instrument to collect data on the costs of treating drug abuse, using a specific accounting method. This method provides summarized operational guidelines and has been applied empirically several times. It aims to provide a tool to estimate the costs of providing substance abuse treatment in an outpatient and inpatient environment. In particular, DATCAP targets specialized drug treatment units, low-threshold agencies, general and mental health agencies, hospital-based residential treatment units, residential drug treatment units and therapeutic communities. One of its advantages is the completeness of the data designed for being collected. It accounts for expenditure on compensations of employees (*e.g.* wages and social contributions); services and materials (health care services, health care goods such as pharmaceuticals, non-health care goods and non-health services) and; fixed capital. Additionally, it includes the contribution of voluntary resources, provided as labor or as building expenses. An additional advantage is that DATCAP considers not only traditional accountancy data but also opportunity costs. Data collection is based on face-to-face interviews. Each interview requires more than 8 hours (Roebuck et al., 2003). The website of the United States National Institute on Drug Abuse (NIDA) used to have a link to this method (https://www.drugabuse.gov/research/research-data-measures-resources and http://www.datcap.com/index.htm).

BRIEF DATACAP (The BRIEF Drug Abuse Treatment Cost Analysis Programme) is a simplification of the DATCAP. It is suggested to use when there is limited time and money/personnel to collect data. It provides an estimate of accounting costs net of depreciation and other related economic costs. Compared to DATCAP, it needs less data. It does not account, for instance, spending on buildings, facilities and equipment (French et al., 2004). Data collection continues being based on face-to-face interviews and each interview requires approximately 4 hours. As compared to DATACAP, its BRIEF version reduces the data collection time by 50%. Additionally, authors refer that the degree of accuracy is only reduced by less than 2%.

CLIENT DATACAP (The Client Drug Abuse Treatment Cost Analysis Programme) estimates the cost of receiving treatment in the perspective of patients. There are two types of Client DATACAP programmes (Salomé et al., 2003). The Client DATACAP-I includes open-ended and multiple-choice questions, measuring costs of inpatient treatment facilities (*i.e.* inpatient detoxification, short and long-term residential care, hospital inpatient and therapeutic communities). The Client DATACAP-O includes 25 questions measuring costs of outpatient treatment frameworks (outpatient detoxification, outpatient drug-free, methadone maintenance, day treatment and intensive outpatient modalities).

SASCAP (The Substance Abuse Services Cost Analysis Program) is a theoretical and empirical method to estimate the costs of treating substance abuse. It estimates the costs of the various phases/types of healthcare service. It diseggregates estimates by the

spending on the initial assessment of patients, treatment planning, initial medical services; individual treatment, couples' treatment, family counseling, group counseling, ongoing medical services other than methadone, case management, quality assurance and methadone. Data collection is based on interviews to clinic directors, requiring less than 4 hours (Zarkin et al., 2004).

ADSS (The Alcohol Drug Services Study) is a method with a theoretical and an empirical base, which allows estimating the costs of providing drug and alcohol treatment in specific settings (hospitals and residential treatments units). The model requires data on revenue, costs of personnel and counseling activities. The number of clients is also necessary. Data collection takes a three-step approach: first, a telephone assessment; second, a face-to-face interview and; then a follow-up (SAMHDA, 1999).

TCAT (Treatment Cost Analysis Tool) is a method to estimate the costs of providing specialized drug treatment in outpatient frameworks. It is a theoretical and empirical method which accounts for accounting costs (direct and indirect) and economic costs. To avoid interviews and save time, it permits direct data entries (Flynn et al., 2009).

US (Uniform System) is an empirical method which estimates the costs of outpatient and inpatient units. It is applied for an initial assessment of individual situations, individual counseling, group counseling and mental health treatments. Data comes from daily data of treatment programmes, outpatient programmes and methadone maintenance programmes (CCC, 1992).

DATACAP&US combines previous approaches considering treatment service costs which include patient case-load information and time analysis to determine the use of resources. Estimates are made by service category, collecting supplemental program expenditure and patient caseload information. Estimates provide the unit cost of services and result from an interview with health staff (Anderson et al., 1998).

CPPOA (Cost-Procedure-Process-Outcome Analysis) is a theoretical method which allows estimating the accounting costs with a wide range of variables (direct services provided, material, supplies, transportation, communication and financial data). It estimates the costs of outpatient and inpatient services. Finally, using the value of resources used in the healthcare process, the method estimates the social cost of drug dependence (Yates, 1999).

TSR (Treatment Services Review) is a theoretical and empirical method which considers the costs of 96 units of treatment of drug dependence and related services and; estimates the social costs of the addiction phenomenon (French et al., 2000).

SROI (Social Return on Investment) is a method to estimate public expenditure and social costs of alcohol and of drug use, developed in England. It also estimates the social return of treatment applied to both substances. SROI is an empirical method which considers mainly the costs of providing prevention, treatment and recovery interventions. The main difference from the other methods is that it is focused on identifying specific economic and social costs more relevant to English stakeholders. Additionally, it is

concerned the the costs of inequality and it promotes wellbeing in the provision of these treatments (Banke-Thomas et al., 2015; Public England Health, 2015).

4.2 Digital ecosystem

This study aims to assess if these methods can be automated and applied in a digital ecosystem. The characteristics of a digital ecosystem applied to cost estimates are listed in Table 2.

In a digital ecosystem, practitioners and healthcare managers are required to work closely together in order to estimate the costs of drug treatment. As stated by León et al. (2016), a digital ecosystems model should consider a structured approach. It means that the analysis has to take into account the contextual characteristics of treatment provision. In another words, analysis has to consider factors such as technological context, legal framework or the existence of economic asymmetries prevailing in electronic services.

Additionally, if the chronicity of patients requires multidisciplinary approaches (McLellan et al., 2000), as in drug treatment; in a digital ecosystem, cost estimates require the participation of complete health teams. The medical community (doctors, nurses, psychologists and health managers) should participate in the process, in close cooperation with economists and IT system managers.

Table 2. Components of digital ecosystems: a conceptual framework for estimating costs

Components / Sources	**Description**
Community	Health communities: doctors, nurses, psychologists, and health managers.
Content	Costs calculated with a bottom-up approach.
Practice	Application of the model to pilot projects, and gradually increasing the availability into larger frameworks.
Technology	Cost-Kit able to input and account data for raw costs and providing an automated calculation of cost of treatment.
Biological species	Health Department for cost-benefit and cost-effectiveness analysis.
Economic species	Health authorities, IT companies, universities and research centres for subsequent data analysis.
Digital species	Management software for the management of health/costs data provided by public or private institutions.
Digital environment	Electronic Health Record (EHR) as a storage of data related to drugs, services and treatments provided and medical programming using common data lake.
Security	Take maximum data protection measures based on internal or cloud storage. Provide data centres in those realities with many patients or share security standards within a geographical region.
Trust	Create a business model based on the scientific accountancy of data that can provide estimates to policy makers, operational management, citizens and researchers in the drugs field, medical and management area.

Source: adapted from Iyawa et al. (2016) framework

5 Discussion

The literature review listed the most commonly bottom-up methods found in literature and applied in the last decade to account for the costs of treating dependencies. Now, we will assess their compliance with a digital ecosystem framework, according to pre-defined criteria (Table 2).

The analysis of the compliance of each cost model to the 'community' criteria, í.e., to the criteria that the whole community handling the treatment provision should be involved in the process reveals that none approaches involves a representative proportion of the health community when estimating costs. For instance, excluding the SASCAP and CCPOA which don't require the involvement of a significant proportion of qualified personnel, all the other methods are based on the assessment of 'qualified personnel'. For instance, the DATACAP and its variants (Brief DATACAP and Client DATACAP), as well as the TSR, require qualified personnel to collect data. They are based on collecting an extensive set of data; with different cost components; and using automated spreadsheets as a data collection tool. Indeed, these models require that training is provided to data collectors and in collaboration with health care staff (which are accounted in the process of data collection). Therefore, despite these methods result in a comprehensive set of data collected on costs and allow a complete cost analysis, they can be difficult to implement in real life, because of the time they require on training and on implementing surveying costs. This fact makes it difficult to health professionals to collect and manage costs.

Even considering practices, we state that all methods are applied to selected contexts and start by designing pilot projects. This fact favors the adoption of a digital ecosystem, since it complies with the criterium 'applied technology'. In fact, both the DATACAP and the TCAT are empirical accounting tools supported by a theoretical framework. Therefore, they comply with this criterium of digital ecosystems. The Brief and the Client DATACAP too. Additionally, these models comply with the 'digital species' and 'digital environment' criteria also. In fact, these four methods appear to be applicable to digital ecosystems since they are conceived in standards 'Excel' worksheets. The application of data collection tools and of linked accounting methods in digital user-friendly contexts, which are supported by mobile applications, allows to simplify the routine data collection and the estimates of costs. Further, this tends to reduce errors and the time required to perform the different tasks. Finally, the methods such as the SASCAP, ADSS and SROI are feasible and consistent with digital platforms.

As indicated by Ford et al. (2010), the evolution towards electronic data processing with Electronic Health Record (EHR) offers a system consistent with the spirit of public health service, because an enhanced information systems is able to provide accurate data mining and allows the monitoring of costs. However, the different models were linked to any EHRs.

Considering the "security" criteria, the content analysis did not reveal any specific element neither in the scientific contributions nor in the application documents. This can

be explained by the fact that models only allow data exchange between those who have access to it.

Concerning the compliance with "trust" criteria, i.e. the belief that all species want to achieve the same goal and the same level of security, our analysis shows a wide empirical use of methodologies such as the DATACAP or SASCAP and; that models like the DATACAP&US and CCPOA are less used. This could eventually be improved if users would trust more on these models, considering the network and the community in which they are applied. For instance, the creation of a simple and transparent business model based on the scientific accountancy of data, which could provide accurate estimates, would be useful to policymakers, operational management, citizens and researchers in the drugs field: Moreover, the medical and management community would be supported (Biancone et al., 2019).

Finally, considering the geographical analysis of the sources, except the SROI, the other methods were primarily applied in the United States. Nevertheless, as shown by (Chronaki & Vardas, 2013), there models like the DATACAP which could be adapted and applied also to some European healthcare realities. In Europe, health systems are characterized by a higher proportion of public healthcare interventions and have specific reimbursement mechanisms.

6 Conclusion

The results of this study allow us some conclusions and to draw some future implications.

To summarize, in this study started by surveying the literature. Authors searched studies which used a bottom-up approach to estimate the costs of treating drug dependence. Eleven methods were found. Then, authors analyzed which methods were used as tools to estimate costs and, then, their compliance with a digital ecosystem.

As Iyawa et al. (2016) stresses, digital cost ecosystem requires the cooperation of the community of professionals . Agarwal et al. (2010) adds that the estimates of health care costs must use consensual criteria, accepted by accountants, health care professionals, economists and policymakers. Among the methods analyzed, the DATACAP, SASCAP and SROI have these required characteristics. Nevertheless, when comparing these studies, we conclude that it is still necessary to reduce the heterogeneity of accounting methods applied and agree upon a commonly accepted methods to collect data and estimate costs.

The World Health Organization, jointly with the Organization for Economic Co-operation and Development and EUROSTAT, have developed the System for Health Accounts (SHA). The SHA provides a comprehensive conceptual framework to account for health financing systems. Its purpose is to help accountants and policy makers to obtain a clear and transparent picture of their health financing systems, which is comparable by international standards (OECD et al., 2017). Therefore, the introduction of the SHA concepts and classification system are a desirable feature to introduce.

Most systems of drug treatment provision are funded through several complex arrangements. While many European countries purport to have universal healthcare coverage, the reality is that most patients pay some form of co-payment and/or are privately insured. Notwithstanding, that differs frequently with funding healthcare systems. Differences have been considered in the SHA classification system, but data published accordingly are still scarce. Data concerning expenditure on the treatment of substance abuse is generally not available.

Therefore, all in all, even if the SHA could provide valuable guidance on the mapping/accounting structure and should be used in estimates of drug-related spending. Respecting the SHA structure would assist the mapping process and would help to ensure completeness of estimates and comparability of results. But, the SHA still does not provide a specific framework for classifying drug treatment. Therefore, estimators may feel the need to develop additional and more detailed classification systems (if possible in the respect of the SHA).

Only when international consensus exist it will be possible to use an agreed method and its results. Then, cost estimates will be safe to use in cost/efficiency analysis and in the support of policy and practice.

Additionally, this study aimed to assess the cost models in the light of their applicability to automated calculation procedures, in digital frameworks. According to the information collected, only six of them assume an automated calculation method (CCC, 1992; M. T. French et al., 2000; Michael T. French et al., 2004; Public England Health, 2015; Roebuck et al., 2003; Salomé et al., 2003).

As a suggestion for further research, and to conclude, as a result of the analysis of cost models and of the analysis of digital ecosystem frameworks, we conclude about the utility of developing an European framework, where accounting rules and procedures would respect the SHA and would be applicable to the field of substance abuse treatment. The suggestion would be to push for developing a toolkit, where objectives would be such as managing data collection and aggregation data, as well as permit automatic calculations certain types of treatment costs. This concept should be designed considering the integration between different areas of care and with the possibility to add internal or external projects, as widespread in the field of dependency care. This would be particularly useful to develop cost-effectiveness analysis (McLellan et al., 2000).

Last but not least, an implication of the current analysis is the need to develop methods which benefit from more intervention of digital technology, and in respect of digital ecosystems, better considering elements such as the community, content, practice, technology, biological, economic and digital species, digital environment and security practice. Safety remains one crucial factor which has been neglected consistently in the current methods developed. The support of pilot projects would be a desirable way to proceed.

Furthermore, this paper was written considering the perspective of health managers, policymakers who need to plan and implement budgets. This way, we aim to contribute to

the development of better models and more reliable estimates of costs, allowing a fair discussion on the cost-effectiveness of various types of treatment for substance abuse.

Abstract

Digital Transformation is one of the most important drivers for the progressive changing of a broad range of health care sector. Digitalization allows organizations to radically improve their performance by providing consistent opportunities to disrupt their value creation process and, therefore, by creating new customer relationships through digital infrastructures. ERP and SAP are currently analyzed in healthcare as tools for change and success in the digitization of control and management systems. At the same time, the IPSAS principles supporting NPFM tools direct the organization towards a single integrated system aimed at guaranteeing the decision-making processes that hospital structures need in the face of a significant incapacity of Italian healthcare companies to have a overview in real time. Two theoretical approaches guide the reading of the case and allow to highlight the impact of the digitalization of the control and administration system. The analysis of the Bambin Gesù of Rome (Italy), a polyclinic of pediatric excellence, guides the analysis, and allows some innovative observations. The study uses an empirical research method that integrates case study analysis, structured interviews, analysis of hospital documents and interventionist approach. The case study was analyzed between 2017 and 2020 to identify changes and principles that have changed the company's management and organizational approach,

confirming the basic theoretical model. The heads of the organization and management control of the Hospital were questioned through a survey on the identified theoretical elements. The analysis was triangulated through interviews and analysis of internal management reports in order to confirm what emerged. The Interventionist approach was realized thanks to the involvement of two of the authors in the progressive change of the organization and the internal control system, guaranteeing direct observation and a refutation of the opinions gathered by the internal experts. The introduction of NPFM tools, such as the SAP management control system and IPSAS accounting principles, has led to a standardization of accounting processes relating to clinical and research activities. The adoption of new control instruments and adhering to the accounting approaches referred to by the NPFM is currently applied and has led to an increase in efficiency, effectiveness, and quality of services with greater transparency expressed in the financial statements. The possibility of obtaining reports in real-time, the standardization of processes, homogeneity of data management associated with the characteristics of data quality guarantee support for decision-making processes and respond to the aim of the research.

Keywords – Digital Transformation, ERP, SAP, IPSAS.

Paper type – Academic Research Paper

1 Introduction

Digital Transformation is one of the most important drivers for the progressive changing of a broad range of health care sector (Cech & Tellioglu, 2019; Hanseth & Bygstad, 2015). Digitalization allows organizations to radically improve their performance by providing consistent opportunities to disrupt their value creation process (Biancone et al., 2019) and, therefore, by creating new customer relationships through digital infrastructures (Faggini et al., 2019). ERP and SAP are currently analyzed in healthcare as tools for change and success in the digitization of control and management systems (Streitz, 2018; Kraljić & Kraljić, 2018; Kuhn, 2019). Before developing an ERP process and adequate IT management tools, the health structures must have reached an adequate level of internal maturity that involves all the key processes and takes into account the characteristics of a series of processes capable of reflecting the effectiveness and repeatability in key processes of the organization (Williams et al., 2019). These elements lead to the definition of procedures, practices, and communications aimed at the internal improvement that consider different aspects and radically change internal policies and organizational elements (Williams et al., 2019) with an impact on the accounting system with a change in the internal drivers and external outputs (Bae & Ashcroft, 2004). In the healthcare sector, there are several examples in which the ERP approach and the SAP software management tool have improved the quality, efficiency, and effectiveness of the production and management processes in healthcare (Marcu & Popescu, 2012; Kraljić, A., Kraljić, T. & Delismajlović, 2013; Poba-Nzaou et al., 2014; Syafiraliany et al., 2019). At the same time, the introduction of the IPSAS accounting principles pushes the organization to define processes aimed at increasing accountability, transparency and a real vision of the structure capable of supporting the internal decision-making process.

However, there is no evidence in ERP approach and SAP using regards healthcare structures following the application of accounting harmonization in Italy and new IPSAS accounting approaches. The absence in the literature of the observation of the phenomenon highlights a lack of attention in the Italian context, which pushes healthcare towards the latest innovations without analyzing reality and contributing to a real change with a deeper understanding of the context and theme (Ricciardi, 2019; Ricciardi, 2015). The study aims to investigate the impact that an ERP approach using SAP software has on the health organization and the efficiency of the structure that applies IPSAS principles. The study integrates two approaches that observe the same phenomenon. The study uses an empirical research method that integrates case study analysis, structured interviews, analysis of hospital documents and interventionist approach (Argento et al., 2019). The method confirms and expand what is defined by the literature on ERP and SAP solution in healthcare. Williams et al. (2019) guides case analysis based on the theories highlighted by the ERP literature. The accounting approach and the outputs of SAP software allow to analyze the degree of innovation within the organization, confirming and expanding the existing literature on digital transformation. The case study is significant in that it represents a hospital of excellence of Bambin Gesù Children's Hospital of the Vatican – Rome (Agenas, 2018), therefore the data obtained will not be conditioned by organizational and managerial inefficiencies (Moullin, 2007; Hussey et al., 2009). The international accounting standards of the public sector, Ipsas, and the information tools of the private sector, Sap, can help the structure to be more effective in reporting and to direct investments in innovation with a rational administration based on the most aware budget. The adoption of IPSAS accounting principles and a digital transformation approach through the ERP approach is capable of leading to a significant increase in supporting quality output in healthcare (Biancone et al., 2017).

2 Literature review

2.1 IPSAS and NPFM tools

The adoption of international accounting standards represents a moment of change in the functioning of each organization. Accounting changes have animated literature for many years (Carruthers, 1995; Dambrin et al., 2007; Libby and Waterhouse, 1996; Nahapiet, 1988). They have been followed by many approaches to understanding evolution, causes, trajectories, and paths of these changes in different types of organizations. The application of international standards is closely related to New Public Financial Management NPFM (New Public Financial Management), which deals with identifying the most correct technical and accounting instruments to be applied (Guthrie et al., 1999). NPFM, according to Gurthrie et al. (1999), involves several approaches, the main ones being accrual accounts, performance indicators, delegated budget, devolved budgets, full costs, output groups, outcome statements, accrual output-based budgeting

and fiscal responsibility statements. NPFM is related to new managerial control approaches applicable to all public interest companies, including hospitals; Jackson and Lapsley (2003: 362) identified three areas of analysis: budgeting, accounting costs, and performance measurement. Each of these three categories is further divisible into potentially practical techniques: for example, budgeting includes zero-based budgeting, resource management, and activity-based management; cost accounting includes the target costing, activity-based costing, and strategic cost management; while performance measurement includes functional analysis, key performance indicators, and the balanced scorecard. The presence or absence of such tools leads Jackson and Lapsley (2003) to consider organizations advanced in terms of managerial control. NPFM brings the organization to five significant changes, the first related to a reporting system change, accrual-based financial statements across departments, and reliance on professionally accounting set accounting standards. The other changes involve the development of commercially minded, market-oriented management systems and structures to deal with the pricing and provision of public services, with emphasis on cash management, contracting-out arrangements and internal and external charging/pricing mechanism, development of a performance measurement approach, including techniques such as financial and non-financial performance indicators, devolvement/decentralization or delegation of budgets and changes to internal and external audits (Guthrie et al., 1999; Olson et al., 2001; Lapsley, 1999). The approaches are closely linked to management systems capable of supporting change, management, control, and economic and financial output (Destri, 2013). It is precisely on the output of the accounting system that the IPSAS is based, guaranteeing a different approach aimed at guaranteeing real transparency on different balance sheet items, which become more significant in healthcare structures and require more considerable attention than others.

2.1 SAP and information system

The acronym E.R.P. (Enterprise Resource Planning) identifies the integrated management systems, sets of integrated software applications, which manage all the relevant information of the company in a single centralized database and which allow managing in a coordinated way a multiplicity of activities of the company (Gargeya & Brady, 2005). The acronym E.R.P. it was coined in the early 1990s to indicate new integrated management systems for manufacturing companies, and then spread to the management of all production activities, including healthcare. SAP is an E.R.P. system (Jacobs & Whybark, 2000). According to the literature, it can make quantitative and qualitative improvements to the management, control, and programming systems. Nahet al. (2001) identifies 11 characteristics that E.R.P. they must possess, and which become part of the theoretical frameworks applied to all systems of this type, including SAP. The E.R.P. system must be able to change the company's programming and culture and depends on the composition of the corporate team. Due to a cultural change, the corporate

vision also undergoes an evident change with an impact on communication systems. These changes support top management in the definition of choices and re-engineering processes with performance evaluation systems and standardized levels. The processes are able to guarantee adequate business information with a personalization of the software to the necessary reports and controls. The 11 characteristics lead to tangible and intangible improvements represented in table 1 based on Nah et al. (2001), Themistocleous et al. (2001) and Stratman and Roth (2002).

Table 1 tangible and intangible benefit of E.R.P.

Tangible benefit	Intangible benefit
Inventory reduction	Information visibility
Personnel reduction	New/improved processes
Productivity improvements	Customer responsiveness
Financial cycle improvement	Cost reductions
Revenue/profit increase	Integrations
Transportation/logistics cost reduction	Standardization
Maintenance reductions	Flexibility
On-time delivery improvements	Globalization
	Supply/demand change
	Business performance
	Dismantling inefficient legacy systems

The results obtained from the study by Poba-Nzaou et al. (2014) indicate first of all that the performance motivations underlying the adoption of ERP systems in healthcare organizations are of a technological, managerial (operational and strategic), clinical (operational and strategic) and financial nature. However, these organizations differ in the ERP management or clinical advantages that are privileged considering the core business of these organizations. The analysis also highlights the impact of efficiency and effectiveness linked to the use of ERP systems. Furthermore, the management of clinical elements associated with economic elements and developed information systems has already allowed an increase in the quality and appropriateness of the treatments linked to the adoption of SAP systems in various structures through a first management development phase linked to the back office and a second base which combines elements related to the healthcare services provided. Williams et al. (2019), have defined a theoretical framework that incorporates the two aspects highlighted by putting a system of maturity based on the system's key process area, activities, variations, and maturity of the subjects involved in the use of the data. The analysis framework is based on eight steps. In the first, the context's digital maturity levels are identified. The second step defines the area of technological processes associated with functional outcome-based technologies and services (transport, collaboration, security, mobility, and data center). The third step includes defining each domain in functional activities strictly related to subdomains of the second step. In the fourth step, outcomes are identified for each capability (key practices). The fifth step involves evaluating the activity outcomes and associating each level's maturity with the technological capacity produced. The infrastructure's capacity leads to critical elements and non-critical analyzes of the results associated with the service

provided; this is mapped in the sixth step. The final step concerns the weight given to each capacity by attributing weight to critical and non-critical elements. It refers to the impact that the SAP system can give to the organization for the achievement of clinical and administrative objectives.

3 Method

The applied method investigates the same phenomenon through two different but necessary perspectives to explain the complex organizational reality (Mayer & Sparrowe, 2013). The two theories are dealing with the same phenomenon, i.e., technical tools for identifying an approach that leads to efficiency, effectiveness and quality of services within the hospital, guaranteeing a control system and real transparency in decision-makers. The phenomenon is analyzed through two perspectives, one linked to the theoretical framework of the development of an outcome-based infrastructure which also considers the maturity assessment connected to the SAP application (Williams et al., 2019), the other approach linked to the accounting principles that identify management control tools through NPFM and redefinition of balance sheet items based on IPSAS principles (Jackson and Lapsley, 2003). Both approaches deepen the management control tools that direct towards a higher management capacity linked to the digitalization of the control itself. Without applying one of the two approaches, it would not have been possible to solve the management problems encountered. The theme is complex and needs several keys. The study uses an empirical research method that integrates case study analysis, structured interviews, analysis of hospital documents and interventionist approach (Argento et al., 2019). The case study of the Bambin Gesù in Rome (Italy) confirms what has been defined theoretically (Dul & Hak, 2007; Yin, 2017). The case study was analyzed between 2017 and 2020 to identify changes and principles that have changed the company's management and organizational approach, confirming the basic theoretical model. The heads of the organization and management control of Bambin Gesù Hospital were questioned through a survey on the identified theoretical elements. The analysis was triangulated through interviews and analysis of internal management reports in order to confirm what emerged. The Interventionist approach was realized thanks to the involvement of two of the authors in the progressive change of the organization and the internal control system, guaranteeing direct observation and a refutation of the opinions gathered by the internal experts who will be called internal actors.

3.1 Case Study

The Bambin Gesù is the largest Polyclinic and Pediatric Research Center in Europe with 2,600 doctors, researchers, nurses, hospital technicians and employees and over 1,600,000 health services provided every year to children and young people around the world.

The belonging body at the Vatican operates in the Italian state for the effect of Law no. 187, that has ratified and executed the specific Agreement between the Italian government and the Holy See of February 15, 1995, to regulate relations between the hospital itself and the Italian National Healthcare system. The structure has also adopted an accounting system based on IPSAS accounting principles to guarantee a higher quality of accounting output (Mhaka, 2014). The structure has also introduced an SAP system capable of managing the structure's control, management, and administrative delivery system. The current stage of development has not yet directly affected the management of clinical data. Furthermore, Bambin Gesù Hospital is significant because it is among the first in terms of efficacy of results in care technical assessment and health research (Ruggieri et al., 2019; Andellini et al., 2019; Angelico et al., 2019) therefore, it is not influenced by inefficient results at the time of the analysis.

3.2 Results

The Bambino Gesù Pediatric Hospital needed to re-engineer its information system and integrate it with a more structured solution. The objective also expressed through the interviews was to manage all the information necessary to optimize the quality and speed of the services offered directly from a single terminal: accounting, pharmaceutical warehouse management, coordination in shift work, management control of research orders. The project proposed by Technis Blu and supported by the management of the Bambino Gesù Hospital was divided into several steps. The company that developed the control and management system focused on:

• The processes of the Bambino Gesù Hospital (and not on individual areas), with a view to greater integration;

• The use from the initial stages of a pre-configured solution, which contained within it the main responses to the needs expressed by the healthcare company, drastically reducing implementation times for the final project.

Both aspects have proved particularly useful not only at the organizational level of the entire project. In fact, they have allowed operators to get in touch since

immediately with the new system, without waiting for the final implementation. This has obviously translated into a speeding up of staff training times.

The members of the administrative and management control offices in 2017 identified several elements that led the company organization to find it difficult to define programmatic and control tools. There was no standardized system in the hospital's administrative management, and there were several difficulties in defining applicable common accounting standards and difficulties in finding updated data capable of defining reports and associated policies. All the interviewees point out the problems and the need for organizational and managerial change. The change occurred in 2018 thanks to the adoption of ERP systems based on SAP software, all the actors' highlight that they have identified the program thanks to a study of the best management systems adopted in the

private sector. The instrument was fully adopted in 2019. At the same time, the components of the administrative and management control offices had identified some problems relating to the quantification of fixed assets, which require a fair value to guarantee the correctness and enhancement of equipment and instruments that are vital within the company structure, given the clinical implication of the same (Miniati et al., 2011). The managers need a tool capable of determining the achievement and definition of policies through performance by basing the elements on financial factors. Each aspect of the process leads to an enhancement that must be quantified in real-time to bring about the correct definition of elements (Biancone et al, 2019). The direction of Bambin Gesù from 2017 needed to define policies based on target costing, activity-based costing, and strategic cost management. The adoption in 2018 of new accounting standards and the ERP system required the implementation of a training course for all subjects suitable for understanding the functionality and the possibility of adopting accounting standards. Through the company actors, it is possible to identify various advantages, including the ability to coordinate processes in a centralized and automated way through an agile infrastructure. The functions guaranteed by SAP allow dynamic management of resources with a high level of collaboration services in resource management. The main positive aspects identified concern the traceability of documents and registrations, greater internal transparency with immediate accessibility to the accounting documents of the entire company, and more exceptional ability to trace company passive flows. All respondents stated that IPSASs increase the level of accountability and transparency with a relative increase in the quality of the financial reporting and internal control system However, the corporate actors identify an often-excessive rigidity in correcting accounting errors and the management of employees' wages and contributions. To date, SAP has not yet managed the clinical procedures which remain separate from the administrative management, although they are linked and conditioned. The players note a change in the efficiency and effectiveness of business processes justified by the introduction of accounting principles and the SAP system with higher planning capacity. Considering the tangible and intangible benefits, the interviewees recalled all those highlighted in table 1.

4 Discussion

The IPSAS accounting principles have pushed towards a more excellent application of management control techniques and systems to increase transparency, efficiency, and effectiveness within the organization among decision-makers (Brusca et al., 2018). In particular, the NPFM has introduced a reform of new frameworks of accountability, new management systems and processes, and new accounting practices and procedures (Jakson & Lapsley, 2003). Geroski (2000), considering the changes brought about by the OECD, has started in all countries, including Italy, an innovation of the means available to manage accounting and public-interest organizations. New techniques such as activity-based costing, resource management and key performance indicators have been introduced into public interest organizations. Bjornenak (1997) is one of the first to talk

about the transmission of tools spread in the private sector applied to organizations of public interest, the introduction of ERP systems and the SAP system is configured just like a new approach that had not been applied until then. Alter, and Hage (1993) also demonstrated that the use of new techniques based on the grouping of processes and definitions of performance leads to a reduction of risk and uncertainties. Axelsson and Easton (1992) introduce the theme of the relationships between internal and external subjects necessary to improve the quality of the service thanks to the market and make improvements in the relationships provided by the network, for this purpose a control system suitable to respond to this new need it becomes necessary. As recalled by the interviewees and by the analysis of the information found in the internal reports, the IPSAS principles increase the level of accountability and transparency with a relative increase in the quality of the information present in financial reporting; the characteristics have already been highlighted in a study conducted by Ababned and Porretta (2019) on the United Nations agencies. The study also highlights the impact of the control system in supporting the results obtained thanks to the IPSAS. The infrastructures supporting the information systems with the digitization of information becomes a critical element for the survival of the healthcare organization in the face of new management needs (Walsh & Rumsfeld, 2017). The quality of the information together with the standardization of the processes is recalled in the adaptation of the new ERP processes (Bernal-Delgado, 2017). The investigation has continued to highlight that the data quality dimensions were mapped before initiating the structural information change, these concern the complexity (coverage, density, relevancy, and sufficiency), the relevancy (current, timely, correct, and sufficient), usability (usefulness consisting of relevance accuracy and completeness, easy to use and organized, the availability (accessible, compatible, interretable, and locatable), reliability (unbiased, reputation traceability including data source, credibility, consistency) and security (supports all other dimensions) (del Pilar Angeles & GarcĂa-Ugalde, 2012; Biancone et al., 2019a). The approach applied in the clinic follows the framework identified by Williams et al. (2013) on accessibility and on the definition of the value of the processes. In particular, the entire organizational extension part of the definition of the level of maturity that measures the key process areas defines the objectives, identifies the standardizable practices in activities and the common characteristics that have an impact on the policy, on standardized processes, on procedures, on tools and training. The questionnaires, interviews, and analyzes of the business processes identified in the new ERP infrastructure confirm the elements of the theoretical framework. Comparing the characteristics of each objective grouped by activity theology leads to a continuous improvement of the key processes. The key processes of Bambin Gesù are at the same time purely clinical activities and those strictly related to scientific research, in both cases the need for activity-based analysis through appropriate budgets is essential in defining and defining the clinical outputs that are already mapped through protocols. In this case, the ERP guarantees a dual process and scientific project vision, guaranteeing the interpolation of specific data to support

empirical evidence. Although the structure is only at an initial level of maturity in which the elements are managed at an administrative and tactical level, there are maximum usable levels of information, as the information is reliability when requested, it is usable and present in an adequate format and appropriate for use, they are relevant in that they respond to the requests of the tasks and are complete and capable of allowing decisions by the actors. The interviews allowed to identify the main activities confirmed both by the social report of the Bambin Gesù and by the report of the health and scientific activity. The measurement of the associated activities and performances made it possible to identify the main processes and measure the outcomes by assigning a weight of priority based on each activity. In the internal strategies defined, management control becomes functional to support the direction of decisions and oriental key practices. Precisely the theme of accounting principles, highlighted by respondents, is referred to the obsolescence of the equipment supporting the structure and supports decisions. According to IPSAS 17 "property, plant and equipment" after recognition as an asset, an item of property, plant and equipment whose fair value can be measured reliably shall be carried at a revalued amount, being its fair value at the date of the revaluation less any subsequent accumulated depreciation and subsequent accumulated impairment losses. Revaluations shall be made with sufficient regularity to ensure that the carrying amount does not differ materially from that which would be determined using fair value at the reporting date (IPSAS 17, 44). The analysis has shown that from 2019 an evaluation of fixed assets is active with the new fair value method, which, within a context-oriented towards excellence and innovation on new analytical accounting systems, leads to real improvement. The budgeting and planning, programming, and control process, there is still the absence in the standardization of autonomous clinical IT applications. Although the administrative and accounting processes and the diagnostic clinical ones are closely related and it is possible to intertwine the results, the organization has preferred not to standardize these processes in part because already guided by clinical protocols in part because subject to experiments that lead to an innovation of the cures that would be too conditioned by imposed management poles.

5 Conclusion and remarkable

Through interviews, analysis of internal documents, and public documents, the study highlighted the confirmation of what has been highlighted in the literature on management control systems linked both to ERP systems based on SAP Software and to the effects of the NPFM and IPSAS principles. The introduction of NPFM tools, such as the SAP management control system and IPSAS accounting principles, has led to a standardization of accounting processes relating to clinical and research activities. Although the structure has not yet reached an advanced technological maturity level, the system reflects the theoretical framework referred to by Williams et al. (2019). The adoption of new control instruments and adhering to the accounting approaches referred to by the NPFM is currently applied and has led to an increase in efficiency,

effectiveness, and quality of services with greater transparency expressed in the financial statements (Jackson and Lapsley, 2003). The possibility of obtaining reports in real-time, the standardization of processes, homogeneity of data management associated with the characteristics of data quality guarantee support for decision-making processes and respond to the aim of the research. The aspects were confirmed both through interviews and through internal hospital documentation. Adopting a framework that embraces business processes and adopting NPFM tools is oriented to investigate the same results and allow a reading of the same phenomenon. The analysis introduces some elements of reflection, including the theme of technological innovation and the need to keep the asset recorded in the balance sheet under control to determine its use and obsolescence with an impact on care. The issue needs to be investigated further and guides future research in this direction. Also interesting is the dichotomy between the theoretical framework proposed, which requires the adoption of systems under control standardized through SAP, and the need for research-oriented centers that need management freedom to register and keep under control the clinical data. This aspect should suggest that the service's digitalization process must take into account the differences between the types of clinical structure. This aspect also requires future investigation.

Abstract

Recent studies on EU public procurement showed how an increase in public accessibility of procurement data can raise the likelihood of having competitive bidding processes, increase the number of bids per contract, and facilitate market entry by new vendors.
According to OECD, the application of Open Government principles emphasizes governmental accountability and legitimacy; nevertheless, these principles foster collaboration and engagement between civil society and public administrations.
In the context of public procurement, the adoption of Integrity Pacts – a signed contract between public authorities, companies bidding for a contract and a Civil Society Organisation (CSO) acting as independent monitor – represents a viable solution so far applied in many countries for enabling governments to gather and mobilize public support for their programs and to avoid the high cost in loss of reputation attached to occurrences of corruption in highly sensitive projects. Beside Integrity Pacts, open contracting data standard – a scheme that provide shareable, reusable, machine-readable open data across the entire cycle of public procurement – has the potential to foster the achievement of open government principles, i.e. transparency, participation and accountability.
This paper explores the extent to which the dissemination of Integrity Pacts and the adoption of innovative digital solutions (OCDS) might build shared knowledge and enable a real transition to Open Government principles in public procurement.

Keywords – Public Procurement, Open Government, Integrity Pacts, Open Contracting Data Standard.

Paper type – Academic Research Paper

1 Introduction

Public procurement (PP) represents a crucial pillar of public sector efficiency and community well-being, as it accounts for a substantial portion of taxpayers' money and contributes to achieving pressing policy goals such as environmental protection, innovation, job creation and the development of small and medium enterprises (OECD, 2015). PP has a multi-faced and holistic nature and it encompasses the key strategic and managerial dimensions of state and local governments.

The burden caused by mismanagement of public funds and corruption in public procurement, raised the awareness of a growing number of actors about the need of ensuring transparency along the whole public procurement cycle.

The spread of COVID-19 pandemic among EU has so far determined a brutal shock that worsened the economic and social condition of several countries. EU is now setting the agenda to revitalize the internal markets and to boost the resilience of State members. The Commission announced the aim to invest 1.85 trillion euros for the EU's long-term budget to build a "next-generation EU". A major portion of these funds will be spent through public procurement.

In light of these elements, data availability and legibility represents an issue of major concern for the fair and effective management of public procurement among EU countries. At this regards, a recent study from academics at Yale and MIT Sloan found that the publication of procurement data on the EU's Open Data Portal had major social benefits that range from (Duguay et al.,2019):

- the number of bids received increased per call for tender published as open data (the initial analysis in the paper suggests this was by approximately 12%);
- public officials were more likely to award government contracts to new vendors after the increase in open data accessibility and;
- prices for contracts with open data publication decreased (by approximately 8% in the initial analysis).

Coherently with these data, a report from the European Bank for Reconstruction and Development (EBRD) shows that open procurement data lowers barriers to entry and the cost of doing business for SMEs. After Ukraine enacted public procurement reforms based on Open Contracting Data Standard (OCDS), the country saw significant gains, - i.e., US $1billion in savings and around 80% of businesses using the procurement portal were SMEs; among them, 75% won at least one public contract in 2016.

Digital solutions are of pivotal importance in order to address a wide range of public policy issues as they have, among others, the power to reshape interactions between public institutions and other external key stakeholders.

Standardized open data that links all different stages of procurement (from planning to implementation), enables smarter contract management, red-flagging, efficiency monitoring, auditing capabilities, and even quicker transactions. More external monitoring of procurement can reduce levels of corruption and inefficiencies.

The European Commission's Directorate-General for Regional and Urban Policy and the Civil Society Organisation "Transparency International" runner a joint program since 2015 aimed at promoting the use of Integrity Pacts (IP) to increase transparency and accountability, enhance citizens' engagement and trust in public institutions, bring cost savings and improve competition and promote awareness and better understanding of public procurement (EU Regional Policy Website).

Integrity Pacts are signed contracts between public authorities, companies bidding for a contract and a Civil Society Organisation (CSO) acting as independent monitor. Contracting authority and bidders commits to open all the process-related documents for facilitating monitor oversight on all the procurement phases.

Many countries have so far adopted Integrity Pacts (Ips) as viable solutions for enabling governments to gather and mobilize public support for their programs and to tackle the high reputational risks (Carpenter and Krause, 2011, 27) linked to corruption phenomenon in highly sensitive projects of public administrations.

Despite a growing debate on the specific relations between transparency, accountability and participation in public procurement, (Schnequa et al., 2012; Mabillard and Zumofen, 2020), and although there is a broad consensus at the EU level on the adoption of Integrity Pacts, public management literature has so far devoted narrowed attention at addressing the role of Integrity Pacts within public procurement.

This paper explores the extent to which the dissemination of Integrity Pacts and the adoption of innovative digital solutions (OCDS) might build shared knowledge and enable a real transition to Open Government principles in public procurement.

The remainder of the study is structured as follows: section 2 presents some theoretical background; section 3 describes design and method applied in the research; section 4 shows the preliminary results of the analysis; section 5 discusses the results; section 6 is devoted to concluding remarks.

2 Theoretical background

According to Matheus and Jansenn (2019), transparency is aimed at overcoming discrepancy in information, thus enabling the public to view what is happening within the government.

Many authors framed transparency within the context of the principal-agent theory (Broadbent et al., 1996), as one of the instruments available to a "principal" for controlling that its "agent" does not engage in "shirking", i.e. activities which promote its

own interests rather than the interests of the principal (Soudry, 2007; Lindstedt and Naurin, 2010).

Mancini and Lambroglia (2017) provide an in-depth review of the literature concerning transparency in the public sector and its multiple relations and connections with other key concepts of public management discourse i.e. accountability (Ezzamel et al., 2004; Kudo, 2004; Hood, 2010; Meijer, 2014; Fox, 2018), ICT and accounting systems (Rodriguèz Bolivar et al., 2015).

Beside the need for transparency, PP has to ensure effective stakeholder participation, coherently with Open Government and SDGs principles which encourage responsive, inclusive, participatory and representative decision-making process at all levels.

Open government principles influence the political arena in which "social forces external to the government claim a larger role in the society animated by progress in IT" (Pyrozhenko, 2017, 1495). The application of Open Government principles emphasizes governmental accountability and legitimacy; nevertheless, these principles foster collaboration, engagement and participation of civil society with governments (Lee et al., 2019). The extent to which local communities and other key stakeholders can monitor and influence government decision-making arenas (Meijer et al., 2012) – both in terms of policy definition and service provision – greatly depends on the level of government transparency and openness.

From a public value perspective (Benington and Moore, 2011), the aforementioned principles are 'substantive value' that deliver specific benefits to individuals, groups and organizations (Harrison et al., 2012).

Transparency and participation in public procurement can be properly achieved by using digital technologies for a wide range of purposes (i.e.: to allow visibility of the flow of public funds, to facilitate access to public tender for potential competitors, to apply monitoring and control mechanisms which support accountability throughout the public procurement cycle, etc.).

Recent studies on EU public procurement (Duguay et al.2019) demonstrate how an increase in public accessibility of procurement data can raise the likelihood of having competitive bidding processes, increase the number of bids per contract, and facilitate market entry by new vendors.

3 Design and Method

To investigate the topic of this study, researchers assumed a qualitative methodology based on semi-structured interviews which involved projects coordinators of the main CSOs (Monitoring). Project coordinators have been selected for interviews because of their knowledge of the entire Integrity Pacts process. A total of five hours of interviews were carried out, and interviews were carried during online calls. Interviews were semi-structured and in the form of a colloquial conversation to allow interviewees to be at comfort, with questions designed to gain understanding of both the methodology behind the monitoring activities and the chosen drivers. Questions asked during the interviews

are related to some key concepts such as coordination with contracting authorities, citizens' participation and outcomes of the process especially in terms of reporting issue.

Tables n.1 Description of Interviews

Organization	Interviewees' role in the project	Duration of the interview	Format
Transparency international Italia	Project coordinator	100 minutes	Online call
ActionAid Italia	Project coordinator	100 minutes	Online call
Amapola	Project coordinator	100 minutes	Online call

The Dg Regio Pilot Program "Integrity Pacts, Civil Control Mechanism for Safeguarding EU Funds" brings together government agencies, private sector and civil society in 11 EU countries to ensure that 18 major public contracts are designed and implemented to the highest possible standards of transparency, accountability and efficiency, according to the public interest.

In addition, this project aims at engaging communities, social groups and professional associations directly affected by a specific public contract. As a result of the first four years of the DG Regio project, the Italian cases seem to be those which showed the best degree of citizens engagement during the Integrity Pacts implementation. Among other evidences (number of citizens involved, public events organized, monitoring schools etc.), this is testified by the specific DG Regio decision to host in the "Civic monitoring and Citizens Participation" stand at the 2020 High Level Conference "Engaging Citizens for a Better Governance in Cohesion Funds", held in Brussels in February, only the Italian projects by Transparency International Italia, ActionAid Italia and Amapola together with a dissemination example provided by an autonomous initiative of IP implementation born in Sicily and patronized by the Municipality of Palermo and Parliament Watch Italy.

3.1 Coding approach

The research team analysed the interviews isolating the relevant information according to the research objectives. We extrapolate from the selected case studies a series of quotes that are representative of the main dimensions identified i.e. "transparency", "participation" and "accountability". The analysis concerns the following cases:

"*Museo Archeologico Nazionale della Sibaritide e Parco Archeologico di Sibari"*

Sybaris (in Calabria), 2,800-year-old Greek city, had recently become a lost city. In the mid-20th century archaeologists rediscovered the old ruins. Now the Ministry of Cultural Heritage is undertaking two projects, "Museo Archeologico Nazionale della Sibaritide e Parco Archeologico di Sibari", funded by PON Cultura e Sviluppo FESR 2014-2020, to preserve and rejuvenate Sybaris and the archeological site. Worth a combined €2 million,

the first project involves the modernisation of Sybaris' Museum; the second project will allow visitors access to a Roman-era religious temple known as the "White House". ActionAid Italy is monitoring both procurements using an Integrity Pact, to make sure that ancient history is truly persevered and that local communities can benefit economically and socially from their heritage.

"Metropolitana leggera di Cagliari"

Infrastructure is one of the most exposed sectors to corruption in public procurement in Italy. In Cagliari, Sardinia's main city, the Sardinia's Transport Agency is working to the construction of the final 2.5 km extension of the city's tram service to connect with six new stops the tramway with the transportation hub of the city. In collaboration with local civil society, Transparency International Italia (henceforth TI Italy) is implementing an Integrity Pact on the project "Metropolitana leggera di Cagliari" and organizing workshops and a civic monitoring school to engage citizens in monitoring the €20 million project.

"Madonie Resilienti: Laboratorio di Futuro"

In Sicily 21 municipalities joined a Union called "Unione Comuni Madonie", to share resources and public services. The Union is the contracting authority of a €39 million development project of the National Strategy for Inner Areas (SNAI) called "Madonie Resilienti: Laboratorio di Futuro". Amapola is implementing an Integrity Pact to monitor public procurement procedures selected from two crucial development areas: energy efficiency and education. Amapola is targeting the local youth with awareness-raising activities: students are involved in the monitoring of procurement processes and are provided with tools to become active citizens.

Tables n. 2 Key Information gathered during the interviews.

Driver	**Interviewed Organisation**		
Knowledge Building	Transparency International Italia	ActionAid	Amapola
	1)"For the contracting authority, among the motivations to sign the Integrity Pact there is the occasion to apprehend from a direct contact with the independent monitor, thus experimenting a new and more sophisticated version of the IP." 2) "Although there wasn't any reporting of irregularity, the IP benefits from technical remarks,	1) "The Ministry of Culture has all the procurements information on a platform named Community Mibact. They have granted us access and we had the possibility to acknowledge all the tender documents." 2) "We have done a single reporting of irregularity (done by the previous project	1) "To understand the reason of our procurement's delay we crossed the information given by the contracting authorities with those in possession of DG Regio, addressing the person in charge of the management of Sicilian funds." 2) "We issued about ten recommendation to highlight things that required more attention. Major issues concerned the need to improve the use of transparency and methods of publishing information on-line. Pas have to start publishing having in mind who is going to read the documents."

	comments and suggestions that arise from the dossiers done by experts." 3) "We have sent to the contracting authority about 20 reporting in the form of recommendations. They have been communicated through emails, calls, meetings and can be found on the report published on monitorappalti.it" 4) "Furthermore our monitoring activities can be tracked by the project's verification indicators' which are available into the dossiers published on monitorappalti.it" 5) "For every procurement's phase we have done a technical report and a simplified one, directed to the wider citizenry."	coordinator). 3) "We made several requests for access to information, document integration. The document requested have been integrated timely and also clarifications have been provided promptly." 4) "We made training initiatives on Ips and open data both to the wider citizenry and to the contractor."	3) "All the procurements are published on *portaleappalti.ponmetropalermo.it.* As monitor, we had a read-only access and we can see some classified information. For example, we can see the profile of the candidate for the evaluation commission before the publication." 4)"We keep track of all the reporting into a register shared only with DG Regio and TI Secretariat. The reporting are shared during meetings or via emails." 5) "At the beginning we thought that the timing to deliver reports would have been rigid. During the process we understood that we should have delivered a report every time that there was something valuable to share. We have started to build a monitoring protocol and we have an document that we will submit as the entail of our experience."
Participation	1) "The contracting authority has always rigorously answered to our recommendation, even if technicalities and bureaucracy have always delayed the suggested solutions." 2) "The recommendation that contributed more to ensure the IP's participatory value was about a better and more regular organization of the activities to inform citizens on the project. The contracting authority organized an open soiree to discuss with citizens the multiple stages of the project.	1) "From the digital platform "ALAC", *Advocacy and Legal Advice Centre* there were no reporting; after the meeting with local community there have been a lot of "vis à vis" request of clarification about the procurement." 2) "The external channels of communication have been website and mailing list. For regular participants we activated a chat. We also arranged meetings (4 school events and 2 site	1) "We have received a reporting through ALAC, not on our project, but on the Madonie area. Once the person who made the report was asked for more information, he/she disappeared. Anyway, the reporting seemed not to be accurate." 2) "We made various (5) initiatives to involve the municipalities in disseminating the IP core concept at various levels (i.e., schools).

	They also showed the model of the final project." 3) "There wasn't any reporting of irregularity. We made recommendations, as it would has been difficult for citizen to do a technical recommendation, without a full sharing of all the document and information of the monitor." 4) "We use external communication channels: monitorappalti.it, social media page of Transparency International. Press office on single events. Live meetings and events."	visits) with the aim of communication and sensitization. The meetings have been attended also by key actors like, the Project Manager, the Director of the Museum, the Contractor and the Municipal Secretary." 3) "We worked with the contracting authority in arranging the meetings and events and a representative of local government was always attending."	
Digital Accountability	1) "As monitor we devoted a section of our website to build infographics using .xml data collected from various websites that were compliant with the Italian Transparency Law 190/2012, showing data in a more comprehensive and clear visualization."	1) Many data were already open (i.e. the Italian Investment financed by the EU Cohesion funds). We tried to understand if data related to subcontracting could have been released but the State General Accounting Department was not ready and our technological partner had difficulties; so it was impossible to release those data.	1) "We wondered if was useful to gather and release data for publication or to follow some standard for disseminating open contracting data… This was not the main focus of the project but I still don't have the answer on which dataset is better or really useful for "live" IP monitoring… or how can it be used? I think there is a lot of rhetoric and very few clarity on it."

4 Discussion of results

Under the dimension of knowledge building, TI Italy referred that the contracting authority motivation to sign the IP was driven by the desire to acquire direct experience from the monitor. In fact, more than the function of reporting – only one (minor) occurrence across the three cases – collaboration with external expertise, during a

continuous peer review process, has been highlighted as a key driver and, moreover, a common trait of the three cases selected. To this end, the big majority of reporting coming from the monitors were requests of document integration and recommendations.

Another common trait among the cases considered refers to the form of reporting. Interviewees said that reporting have been made informally to the contracting authority, by emails, meetings, calls, following a procedure that confirm the will to strengthen teamwork and collaboration more than the application of a mere evaluative control. While recommendations and suggestions are informally communicated to the contracting authority, and all the reporting are kept in an internal register and shared with the managing authority of the program (DG Regio) and the apical NGO which is presiding the program as civil society stakeholder (TI secretariat), thus realizing direct exchange of knowledge and enabling vertical oversight by the central administration and the "mentor".

Relevant part of this information is opened to the wider public through the project website monitorappalti.it which host a resumé of the entire process and the relevant documents that allow to follow step by step the IP's implementation.

Furthermore TI, for every procurement phase, have diversified the communication doing a technical report and a simplified one directed to the wider citizenry.

The monitor of the second (ActionAid) and the third case (Amapola) exploited a read-only access to the governmental platform containing relevant information on the procurement management. In this regard, Amapola project coordinator states that through this access they had the possibility to know and evaluate the profiles of the evaluation commission's members before the officialization of the composition.

About third parties involvement, ActionAid have organized a preliminary training on IP mechanisms and values focussed on the contractors. Finally Amapola stated that they have learned by the process itself – as should be in a pilot – what monitoring a procurement can mean and during the process they drafted a "living document" that will be the entail of this first experience to be shared with those who are interested in understanding, reflecting and further applying IP practices.

Driver n. 2 "Participation" collect all the sentences where monitors referred a participation to the process in the form of a concrete contribution to the end of the project and especially all the attempt to establish operative relations or to raise citizen's awareness.

PAs answers have been overall considered by the monitors timely and satisfying even if, in two case of the three cases examined, was highlighted how technicalities and bureaucracy slow down operationalization of solutions.

Recommendations safeguarded IP values. For example, TI Italy recommended to the contracting authority an improvement in the way citizens should be informed about the bidder offer. The contracting authority organized an open soiree to discuss with citizens how the works have proceeded and at which stage were arrived giving the idea of the whole project showing a model.

In all the three cases the monitor involved the contracting authority and facilitated its relation with other stakeholders and with the wider citizenry through the organization of a range of events. The range of events is wide and goes from public meetings that have mere cognitive purposes, to focus groups which involve the key stakeholders (contractors, members of public administration and relevant institutions), to school lessons, seminars and site visits.

The Monitors have been using for external communication not only off-line meetings and press involvement but also web, social media and tools. Citizens had at disposal the s.c. "Advocacy and Legal Advice Centre" (ALAC), a digital system issued by Transparency International for collecting reporting of irregularity, whistleblowing or anything that deserve the monitors attention. Only in a single case (Madonie Resilienti-Amapola), ALAC received a reporting.

Furthermore, the reporting was not sufficiently detailed and after a request of explanation there wasn't any follow up. This reveal the difficulty for citizens in expressing, through digital sources, a qualified opinion. For the same admission of TI Italy, it would has been difficult for any citizen to provide a technical recommendation, without sharing all the document and information owned by the monitors. More than giving a concrete push to the monitoring work, citizens have been encouraged to acknowledge and understand what was done by contracting authorities and contractors. In doing so – ActionAid refers – citizens involved, once gained confidence and established a direct relation through meetings, asked directly several explanations and expressed legitimate doubts. Apart from ALAC, a clear mechanism for feedback collection from the citizen's involved was not structured.

Finally, major relevance has been devoted to students' engagement, which has been unanimously considered as one of the more fruitful civic monitoring participatory dimension able to foster civic education and shared values.

The third driver "Digital accountability" was chosen to understand if the IPs had any impact under the profile of releasing/analysing open procurement data, and understand if there has been a reflection on the role of data in "live" civic monitoring.

TI Italia proceeded to a collection of data scattered in various sites and proposed in its website infographics and a more comprehensive and clear visualization.

ActionAid tried to release the data regarding subcontracting but without success because this required a more systemic efforts involving state general accounting department. For Amapola, it is still unclear the role of data in facilitating live civic monitoring through IP.

Notwithstanding the empirical evidences on the contribution that standardization of contracting data provides in enhancing the overall performance of the procurement cycle, our results show that reflections on data standardization in NGOs implementing IP has barely started. This highlights an implementation gap in the adoption of OCDS in public procurement monitoring that should be solved in the next future even considering the

systemic efforts that the EU Commission and governmental agencies made in this direction.

5 Final Remarks

The aim of this paper was to explore the extent to which the dissemination of Integrity Pacts and the adoption of innovative digital solutions have built shared knowledge and enabled a real transition to Open Government principles in public procurement.

The results which arise from the interviews confirmed that IPs play an important role in the reconstruction of a link between PA and citizens, enabling raise of awareness on public investments – and thus on local development through local investments –, in the exchange of knowledge and operationalization of solution that might foster innovation in PAs and to push forward open governance agenda.

In this regard, the monitors function as intermediate bodies that facilitate and safeguard this relation, determines at least a twofold effect:

- knowledge building for PAs. Providing solution and supporting public bodies in their operationalization, the monitors act as specialized agencies that ensure the compliance of the whole public procurement process with the law and the IP values. The role and functions performed by the monitors provide useful examples and insights about new procedures and protocols that allow better performance from civil servants.
- knowledge sharing and community engagement around IPs and its underlying principles. Focusing on the needs behind the procurement, on how the designed project answer to these needs, on the principles that ensure the lawfulness of the whole tender procedure and engaging citizens in an ongoing oversight of the implementation steps, the monitor contribute to the raise of citizens awareness.

However, it might be said that, even if the interviewed consider satisfactory the degree of knowledge and collaboration between the PAs and monitors, a big part of the participatory potential of the IPs has still to be deployed. Even if the efforts made to guarantee citizens participation is appreciable for its innovativeness, the full achievement of Open Government principles (above all, transparency and participation) requests a step forward from fostering citizens' acknowledgement and understanding – which is an initial way of empowerment – to delegating citizens, under monitors supervision, specific tasks and responsibilities of the monitoring process, i.e. document analysis, reporting, etc...

In our belief, the full transition to Open Government asks for a shift in monitors role' that enables a more coral and systemic contribution of multi-stakeholder monitoring entities, thus boosting mutual exchange of knowledge and expertise.

Looking at the impact of Integrity Pacts on digital accountability, the analysis provides us few information, mainly concerned with a better organization of existing data. The provision of comprehensive and standardized open contracting data requests a broad and

systemic effort from the key actors involved in the governance of investment funds. This efforts have started as testify by recent initiatives developed in many countries and business sectors.

This shared effort determines positive effects on the dissemination of IPs, also in terms of strategic assessment and advocacy. On the other hand, IPs act as platforms where citizens greatly benefit from the full legibility of procurement data which is a key asset for ensuring effectiveness and openness of data itself.

Abstract

Framed within researches underlying the appliance of digitisation in public administrations, this paper analyses the relevance of investigating barriers and enabling factors present in the "grey area" which ranges from the positive test of digital innovation trials to their generalisation in all the different bodies of a public administration. Having a double step of analysis, the research starts from a systematic literature review looking at how, digital transformation in the public sector, is considered and analysed in academic journals in order to look at how much failures and barriers about wide-spreading and diffusion of it were already investigated and depicted. Starting from the analysis of the literature review – in which it was found a lack of analysis upon the aspects we intended to investigate – we executed a qualitative case study upon three Italian local public bodies dealing with the full implementation of digitalised tools for the interaction with end-users and citizens in general. Findings seems to suggest that the actual wide-spreading of the implementation of a "new" tool thanks to digital transformation, requires years and it is not devoid of obstacles and costs, which should lead both researchers and practitioners to "reconceptualise" the analysis of strategies and efforts for the full implementation of a "smart" digital transformation in the public sector.

Keywords – Digitalization; Public service innovation; Knowledge Transfer, Digital Technologies

Paper type – Academic Research Paper

1 Introduction

Digital Transformation has been generally seen, in the last years, as an important driver for the progressive positive changing of public administrations, being considered a tool able to radically improve their performance, by providing opportunities to advance their value creation process in different ways, creating new relationships among providers, organisations, and end-users, through digital infrastructures.

There is a general consensus about the fact that innovative technologies can positively reshape the way we conceive public administration, and its interactions with citizens and other organisations (public, private, and non-profit) because, the availability of digital innovations, has the leverage power to positively convert public service delivery processes.

Starting from the above mentioned assumptions, we reflected on the fact that, in studying any innovation in the public sector, it is necessary to consider also that it is not achieved per se in a blink, it is rather the result of a process locally embedded: in a specific context (such as a specific policy sector with specific state and governance traditions); in a specific time; within specific power relations (Bekkers et al, 2011).

In the case of digital transformation, recent technological and societal developments need new innovation models such as "open innovation" or "user innovation" in order to empirically grasp and adequately theorize the complex interrelationship between technology developers and technology users (Chesbrough 2003).

Starting from the above mentioned assumptions this paper is focused on the analysis of aspects regarding the path, which allows the overall dissemination of a digital transformation, from experimental trials to a general agreed proper effective use.

It indeed starts from the consideration that we usually analyse, in the academic field, stories of successful experimental innovation rather than failing ones. Moreover it must be considered that, in the specific case of public administrations, their organisation is huge, and composed of several layers and bodies, from national to local ones, as well as sectors, ranging from national governmental to local levels, which deliver different services, from administrative to health services, passing through education and police. This means that, a positive technological innovation developed in some bodies, takes time to transform, a benchmark developed in a unit or a component, in a generalised practice for all bodies and branches.

Founded upon the above considerations, this study focuses upon the barriers and enabling factors present in the "grey area", ranging from the positive test of digital innovation trials to their generalisation in all the different bodies of a public administration. In particular we aim at answering the following research question: Is it always true that an innovative successfully digital transformation trial leads to a general advancement of the whole bodies of the public administration in which it was preliminary tested? And if yes, is time a relevant barrier?

In order to answer our research question we decided to run our research on two steps. We firstly carried out a systematic literature review on how digital transformation has

been considered and analysed in public management academic journals, in order to look at how much failures and barriers about wide-spreading and diffusion of it were analysed.

In a second step, starting from the analysis of the results of step one – in which it was found a lack of deep analysis on the aspects on which we were running our investigation – we decided to run a qualitative case study with interviews to workers of local public bodies, dealing with the full implementation of digitalised tools for the interaction with end-users and citizens in general.

The paper is structured as follow: the next section reports about the first step, presenting, after a description of the issue, the literature review results. In section three we report about the case study, whereas, in the last one, we present concluding remarks upon the whole research, giving some indication for further more tailored analysis about the topic.

2 Research topic and literature review results

Since the beginning of the new millennium, several scholars highlighted that public sector, thanks to the development of new enabling technologies, was entering a new phase, allowing more effective and agile approaches in public services delivery and consumption (Franda, 2002). Later on, Dunleavy et al. (2006) even named this new phase as Digital Era Governance, characterised by changes inside government, engaged in answering to the advent of new phenomena and even able to be a quasi-paradigm for government on the Web (Margetts & Dunleavy, 2013). This new era was perceived as able to create a powerful dynamic situation, driving to a disintegration of traditional techniques and services, traditionally organized around systems integrators and departmental structures, for arriving at their re-aggregation around the citizen in the form of services (Fishenden & Thompson, 2013).

Considering that more than a decade passed from these first announcements and declaration about the birth of a new era, we had to be now, in a new efficient world in which public service design and delivery had to be much more efficient and effective than what they were at the end of the twentieth century. But can we surely affirm that we are living in such a new successful era in the public sector? The answer cannot be absolute. Indeed many things (procedures, tools, relations) changed, but not all of them seemed going in the same direction of a more efficient and effective public sector. What did go wrong?

In order to answer these questions, we firstly decide to look back to find some of the not initially foreseen causes which did not allow such an expected improvement in a technologically based public sector. We therefore decided to run a literature review aimed at looking for causes which were unpredicted in the ten years ago forecast analysis.

2.1 Method

We based it on a systematic review, compromising several steps (identifying relevant publications, selecting eligible studies, extracting data from them and synthesizing the results (Liberati et al., 2009). We made this choice because, differently from traditional literature reviews, it involves the use of standardized ways to identify all the likely relevant aspects (Moher et al., 2009) and considering that we were not looking for theoretical frameworks interpretations, rather than we were interested in finding causes, we found it as the most appropriate tool.

We selected our object of analysis using Scopus and searching for journal articles and books in publish in English from 2015 to beginning of 2020, having the strategy represented in figure 1

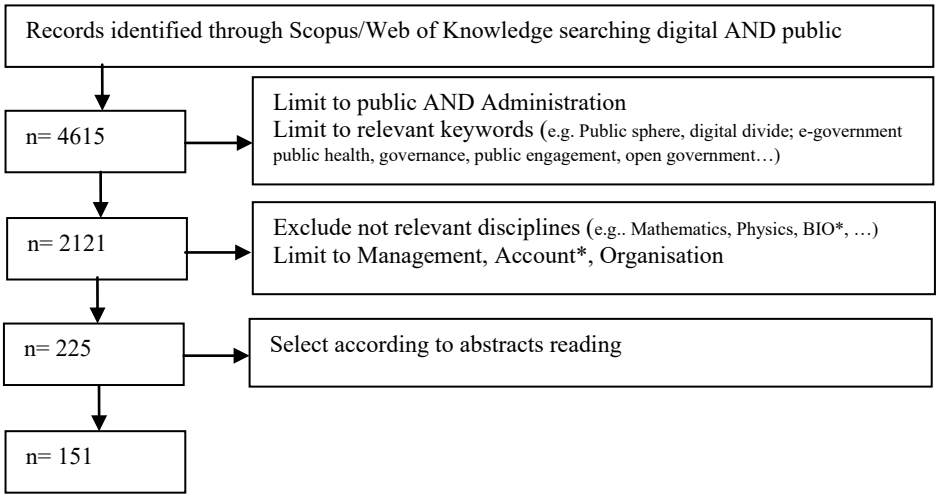

Figure 1 Flow diagram of the research

2.2 Results

According to the analysis of the 151 selected journal articles, it seems that technological innovation process in public sector is still an ongoing one and researchers are still engaged in illustrating its potentialities, through their analysis, forecasting new challenges regarding: the relevance of big data analysis, the protection of sensible data, the necessity of regulation as well as sensitise about ethic issues. In synthesis most of the research appeared to be proactive towards the future, although being aware about risks regarding intentional disinformation.

Few problems seemed to be tackled about the wide-spreading of innovation derived by the advent of the digital era: the challenging of a multi-stakeholder approach, difficult to be managed, but anyway considered a great opportunity for re-designing public services

in order to achieve greater effectiveness in the relations with users; the lack of infrastructures and the digital divide (especially in aged people). Anyway they were both considered as problems to be faced for a full integration of disadvantaged territories and of a small portions of users.

Indeed only 1 out of the 151 selected articles was dealing with the aspects of our analysis. A reflection about the article (Tate et al. 2018), which we deeply analysed after the conclusion of our study case (presented in paragraph 3) will be traced in paragraph 4 describing the alignments of our qualitative case study with what depicted by the authors.

3 The "bugs" in the widespread implementation of digital innovation processes in public administration

The above reported results appeared to give an indication referred to a digitalised era, which is facing new challenges about data protection and engaged in integrating disadvantaged territories and users, but it is anyway full embedded in delivering services in an effective and efficient way. In synthesis it seems that our question reported in paragraph 1 found a positive answer in the fact that we are living in a new successful era in the public sector. Was our premise wrong or is there something we are missing in analysing the effectiveness of digital innovation in public sector?

We considered that in the specific case of public administrations, innovation is not a unique linear process, rather than it is a sum of several different components, considering the specificities of the public sector as one composed by several layers, bodies branches, traditions, delivering very different categories of services. It is thus important to consider the influence of the specific environment in which any public innovation process takes place, bearing in mind that any innovation process is locally shaped, and thus dependent on institutionally embedded exchanges among relevant actors (Osborne and Brown, 2011). It can, thus, be argued that innovation processes should be studied from an ecological perspective (Bekkers & Homburg, 2005; Bason, 2010; Osborne & Brown, 2011). Moreover OECD (2010) reported about the fact that successful reforms in the public sector, often take several attempts before arriving at a wide-spreading able to re-design a structure.

Starting from the above reported considerations we decided to look at digital innovation in public administrations from a different perspective. Instead of looking for the validity of an innovation, we decided to concentrate our analysis upon the specific dissemination process, looking at a not fully analysed aspect, that is the implementation path which goes from a positive trial, in a unit or a branch, to the full accomplishment of innovation in all the different units of a component of the public sector.

3.1 Qualitative research design and method

Considering the above reported aspects about the complexity and multi-layering of public sector, we thought to concentrate our analysis upon a digital innovation which had

to be as "generalised" as possible as well as not too "recent". Therefore we had to look for an aspect which had no specific issues and was not specifically related to a particular service. All the above considered, together with the fact that we were running our study case in Italy, we decided to analyse the general application of two overall communication services: the digital protocol register of documents (Titulus) and the certified email (PEC). These two services started their experimental phases, in Italy, at the end of the first decade of the new century, becoming "supposedly" fully generalised, after the publication of specific memos by the regulatory national offices, in 2013. So we thought to analyse, after seven years since the actual regulation, if and how these digital services have positively affected internal public sector management and the relations of the different bodies with end-users and citizens in general.

We thus decided to run a case study, aiming at addressing 'why' and 'how' questions (Yin, 1994). In particular, considering that the topic was not deeply explored yet, we decided to execute exploratory targeted qualitative interviews (Bailey, 1987) to privileged witnesses able to be informative as experts of the area (Weiss, 1995) thus we interviewed, from October 2019 to January 2020, 6 officials working in three local public administrations based in Abruzzo, a region of the centre of Italy. Interviews were conducted in interviewers and interviewees native language (Italian). The verbatim transcriptions were translated into English and finally analysed having a content analysis (Bauer & Gaskell) of them for the redaction of this work.

3.2 Results

By the content analysis (of the different interviews we depicted four constraining factors whose descriptions are reported hereafter:

The initial perception of the digital tool as a burden

A first important aspect which emerged from our analysis was that, especially in a first phase, the implementation of the two digital services, was perceived as an additional task to be accomplished, rather than a facilitating instrument. All the interviewed people were working in their administrations much before the 'advent' of the new digitalisation (with a range going from 5 to 15 years before the enactment of the new rules in 2013), so, by their points of view, the processes, regarding the exchange of documents and information, were perfectly suitable using traditional mailing and protocols. Therefore, the change was perceived more as a burden rather than an opportunity. Indeed they declared they had been trained, but by their points of view, training was perceived as time subtracted to working hours, rather than an opportunity. But, above all, they all declared that although trained, it was not easy the shift to the new system.

The result was that two administrations delayed the actual application of the new system for more years after 2013, waiting for all personnel to be ready and instruments to be fully available. The other one adopted a kind of mix strategy, which instead of

fostering the process, had the opposite result of extending its time and especially making it much more complicated. In this sense what was reported, by an interviewee, about PEC application, is eloquent. “At the beginning the municipality declared the accomplishment of the PEC system (…) but in reality there was only one PEC address. So the process was that, the specific office received the PEC-mail, printed it, protocolled it, send the paper and related attached documents to the office to which the PEC was addressed (…) the internal protocol of the office registered the arrive of documents (…) documents finally arrived at the unit and person to which they were destined”. In synthesis, instead of facilitating the process, the application of PEC, in this case, resulted in a lengthening of both times and costs, because of the necessity to print all documents, a task which, with traditional mailing, was in charge of the sender.

Lack of proper digital infrastructures

Another important obstructing factor was found in the lack of proper digital infrastructures, not much referred to devices (which were anyway accounted by all interviewees as obsolete) rather than in the functionality and speed of the connection to internet. This aspect was not referred to the two observed innovations, but rather it was reported as a basic prior obstacle for any kind of innovation regarding the digitalisation of their administration. In this sense one of the interviewees affirmed: “when we arrived at pick hours we couldn’t work properly (…) Sometimes (…) we remained after 6.00 p.m. in order to be able to work in a proper way when we had to respond to users, sending official documents which had heavy attachments regarding scanned documents, because we needed a lot of time to upload the attachment official scanned copies”. We found anyway that, although the effort in training by the involved public administrations, interviewed people still had not a proper language and knowledge in talking about digital tools, as if they were an adding problem to be solved rather than tools to facilitate their work.

Process digital divide and consequent difficult interaction with users

As we highlighted in paragraph 2, digital divide is still seen as a barrier to be tackled, especially for older people. In our analysis we found that there was also a digital divide in the interaction between each public administration and their citizens and stakeholders in general. We defined it a process digital divide, indeed we found that there was not a specific problem regarding basic knowledge about the use of digital tools, rather than there was a lack in the communication and information about the functioning of the new digital tools, which disoriented both officials and users. All interviewed people reported about citizens asking to fix an appointment to ask how to use the new tools to digitally interact with the administration. One interviewed said: “At the beginning (…) it was really a mess, they claim for an answer but they did not save the protocol number, it was impossible to refer a request to any administrative file”; another one affirmed “many citizens were complaining, they had to request for the intervention of a consultant because

they have no knowledge of the system". But the greatest evidence of the augmented distance between administration and citizens was found in the following case reported by an interviewee "It even happened that two or three times people arrived in my office complaining for the lack of an answer to a specific request sent with a PECmail following the procedures as read on the municipality's website (…) we did not use that procedure anymore because internal organisation had changed (…) but the website had not been updated so people were still using a procedure putting a code which was not valid anymore but which had not been cancelled".

Different knowledge and systems between administrations and end-users as well as among different levels of Public Administration

A great barrier was found in the lack of shared standards. This aspect regarded, more than the PEC and Titulus, the validity of the digital signature on most sent official documents. Indeed three interviewees referred about two initial obstructing factors regarding: the impossibility to read the file because of the lack of proper reading software; and, especially, a difficult in interacting with other offices because of time differences in the wide-diffusion of the system. In this sense one affirmed "People were digitally signing with XYZ because it was cheap and very easy to be used, but the administration did a tender with HJK, so we hadn't the software to open most of the signed documents". Regarding the augmented distance between administrations' levels one interviewed stated "it was easy for them [the officials at ministerial level], they asked us to send digitally signed documents (…) only the director had the machine to digitally sign, so we had to wait for his signature (…) it was impossible to work if he was out of office". But another example really eloquent about the distance between government levels was found when we were told about interaction with EU Offices to apply for tenders to use EU funds "fortunately we receive sometimes offers by local consultants to create a partnership for a tender (…) they know all about creation and sending of an application for a project (…) without them it would have been impossible for us to participate (…) EU electronic platform is too complicated and completely different from our on line schemas".

4 Discussion and Conclusions

Aiming at finding the relevance of digital innovation upon different public sector components, the present study concentrated its analysis on the discrepancy between the issued analysis upon public services effective and efficient re-design and the actual daily wide implementation of them in all the different components of a public administration.

The work undoubtedly has limitations. First of all, the systematic review should be both enlarged in the number of analysed search engines (thus not limiting it only to Scopus) and much more refined in its selection and analysis process. A better full content analysis of the already selected articles should absolutely be done. Also the qualitative analysis has limitations, being based on a case study regarding three administrations of a

single region of a single country. Nevertheless, it clearly shows that there are aspects that need much more analysis. It is indeed impossible to look at digital innovation as a decontextualized element, it is important to consider all influencing factors. Qualitative research findings seem to suggest that the actual wide-spreading of the implementation of a "new" tool, thanks to digital transformation, requires years and it is not devoid of obstacles and costs, thus leading us to think that it might be necessary to "reconceptualise" the costs of the full implementation of a "smart" digital transformation in public bodies. Indeed all interviewees were referring their situations using the past tense, stating that all the reported issues and problems had then been solved. The point is that it requested time and efforts which were initially not considered, highlighting that, what we defined "grey area" in paragraph one, should be properly considered when working for the actual implementation of a digital innovation in a public administration. We should reflect on the fact that, as stated by Rogers (2009), an innovation is "an idea, practice, or object perceived as new by an individual or other unit of adoption"; nevertheless, the diffusion is defined as "the process by which an innovation is communicated through certain channels over time among the members of a social system". Thus, in Newman et al.' opinion (2016) the factors which are able to influence the uptake of an innovation are three: relative advantage; technical complexity; technical capability. Thus there is much to investigate from the inception of a digital innovation, to its diffusion.

In this sense our case study seems to confirm what affirmed by Tate et al. (2018) in the only article we found relevant for our study in the systematic review we run. Indeed they depicted a methodology for carrying out open innovation for digital public services, concentrating their analysis on what has been defined, by Gassmann & Enkel (2004) the fuzzy front end, that is the fuzzy zone between the time in which an opportunity (or need) is known and the time when serious effort is devoted to the development project, where there is the challenge of analysing good ideas, for deciding which one to pursue. In particular their methodology was outlined starting from the consideration that digital innovation in the public sector has to face more challenges than what it is for the private one. They depicted, in the digital innovation life-cycle for public administrations, 9 challenges to be faced to be transformed in opportunities and 8 barriers to be overcome.

Now, with respect to our research, not only the article (although the only one we found in the literature review) confirmed that our premises were not wrong, but above all, we found that, some of the barriers they depicted, were in line with the results of our case study. In particular: disconnect between citizens and officials; digitising without transforming; internal culture barriers; lack of shared standards.

In conclusion, our analysis seems to show that the premises that led us to run this exploratory research are important both at theoretical and practical level and should be adequately addressed in the near future. At theoretical level, more researchers could be progressed in order to better enucleate the issue, whose basic preliminary little theoretical foundations, was found only in one article of a bit more than one year ago. The relevance

of studying this aspect is of pivotal importance for practitioners, who ought to be aware, in the designing phase before arriving at the actual implementation, that, in the public sector, the wide-spread dissemination and diffusion of a digital innovation already tested in several trials, requires time and especially a proper strategy as well as adequate resources, otherwise the results, for an initial period which could last for years, might be even worse than the previous status quo.

Abstract

In modern society, municipalities and cities are accountable for various societal service missions. In addition, cities and municipalities are expected to take a responsible role in solving the wicked problems such as climate change and ageing of population, coupled with sudden challenges, like the COVID-19 virus, together with the government. This kind of development has increased the role of municipalities and cities as decision-makers in global and social challenges and their ability to use information has become a critical success factor in modern society. By systematically exploiting information use possibilities in the public sector, it is possible not only to make more informed decisions, but also to serve the citizens better and use resources more effectively.

The purpose of information and knowledge management is to collect, process, organize, store, share and utilize information in a way that enhances individual and organizational decision making and operations. The current trend of digitalization in the cities and municipalities is changing the way these activities can be carried out. At present, public organization's ability to manage its

information and knowledge resources is critical and there are still many lessons to be learnt in taking the best out of digitalization. In this study, a maturity evaluation instrument (Jääskeläinen et al., 2019) based on Choo's knowledge management model (2002) is used to evaluate the status of information and knowledge management in a large municipality organization. The aim of the study is to increase our understanding on the status of information and knowledge management practices used in the digital era governance of public sector. Theoretical part of the paper analyses and combines research literature related to digital era governance and knowledge management in order to find out connections between these research areas for the empirical analysis of this study. The empirical context of the study is a large Finnish municipality that has gone through a large scale administrative and managerial system reform a few years ago. A survey will be used to gather the empirical data for this study. Around 300 responses representing all the branches of the municipality were received. The results show that organizational information and knowledge management requires improvement especially in relation to organizing and storing knowledge, knowledge acquisition and information products and services. However, performance benefits of information and knowledge management can be obtained only through successful knowledge usage.

Keywords – Digital-era governance, Knowledge management, Information management, Maturity analysis, Public sector

Paper type – Academic Research Paper

1 Introduction

The start of 21st century has contributed to a new model of public management called Digital-era Governance (DEG). According to Dunleavy et al (2006), handling digital change effectively required a new macro-theory for public sector governance that considered the changed contextual aspects of organizational governance and placed digital technologies at the center of public administration. According to Dunleavy et al. (2006, 217) "government IT changes are no longer peripheral or routine aspects of contemporary public management and public policy changes, but increasingly important and determinant influences upon what is feasible." However, it is noted that the most significant impacts of digitization processes are not achieved without changes in organizational culture and structure inside the public sector alongside behavioral shifts by civil society.

Considering the ever-changing landscape prompted by digitalization in modern society, municipalities and cities are accountable for various societal service missions, like provision of social and healthcare services, development of industry and urban structure, including digital transformation of services. Coupled with the expanding role of digitalization, the role of cities' and municipalities' in managing and tackling climate change and other environmental issues have become increasingly important. This development along with urbanization has increased the role of cities as decision-makers in global and social challenges. Due to these changes, public sector organizations have identified the need to develop their management systems and thereby their ability to manage its knowledge resources has become critical.

The role of knowledge management in municipalities require detailed evaluation. Earlier literature presents maturity models in many different managerial fields such as information management, knowledge management, strategy and performance management (e.g. Aho, 2012; Becker et al., 2009; Hsieh et al., 2009; Jääskeläinen et al., 2019; Jääskeläinen and Roitto, 2015; Kruger and Johnson, 2010; Pee and Kankanhalli, 2009; Poeppelbush et al., 2011, Teah et al., 2006; Van Aken et al., 2005; Wettstein and Kueng, 2002). These models can be used as tools to evaluate organizations to increase the understanding of management practices and to improve the performance of organizations by presenting desirable characteristics for operations (Bititci et al, 2015; Jääskeläinen and Roitto, 2015).

In this study, a maturity evaluation instrument (Jääskeläinen et al., 2019) based on Choo's knowledge management model (2002) is used as a tool to evaluate the status of information and knowledge management in a large municipality organization. This will increase our understanding on the status practices of information and knowledge management used in the public sector. More specifically, this research attempts to investigate the following research question (RQ): ***How does a municipality organization deliver performance connecting to knowledge management within the emerging context of DEG?*** Theoretical part of the paper analyzes and combines research literature related to digital era governance and knowledge management in order to find out connections between these research areas for the analysis of this study. The empirical context of the study is a large Finnish municipality that has gone through a large scale administrative and managerial system reform a few years ago. A survey was used to gather the empirical data for this study. Around 300 responses representing all the branches of the municipality were received.

2 Literature review

2.1 Digital-era governance

Digital-era governance (DEG) is a movement towards digitalization in a society, not only about digital changes within governments. DEG signifies complex societal changes, which according to Dunleavy et al. (2006), have IT and information-handling changes at their centre. According to Margetts (1999) digital technologies were marginalized in the era of New Public Management (NPM), as governments' IT operations were outsourced to global computer services providers, resulting in digital expertise going out of government, and fragmenting data sources (Margetts, 1999). From the 1980s to the early 2000s, the NPM model was dominant in public management reforms involving disaggregation of large-scale departments, increased competition within the public sector, and the incentivization of public officials along business lines (Pollitt & Bouckaert, 2011; Dunleavy & Hood, 1994). Research has not yet provided empirical understanding on the developments and impacts of digital-era governance and its practices. Digital-era

governance practices can be categorized under three main themes: 1) reintegration, 2) needs-based holism, 3) digitization changes.

Reintegration can be seen as a reaction or even an antithesis to NPM practices. It emphasizes bringing back together the distinct functions and clusters of expertise that "under NPM were separated into single-function agencies and fragmented into complex inter-organizational networks". (Dunleavy et al. 2006, 227-228.) The main components in reintegration are the rollback of agencification and fragmentation, joined-up governance and re-governmentalization, reinstating or re-strengthening central processes, reducing production costs, re-engineering back-office functions and service delivery chains, procurement concentration and specialization, shared services on a 'mixed economy' basis as well as network simplification and 'small worlds'. (Dunleavy et al. 2006). Reintegration has expanded into more fundamentally reengineering services and removing duplicate service delivery chains. One of the most significant trends for reintegration is the development towards an 'intelligent centre'/ 'devolved delivery' (IC+DD) design in the allocation of functions across the organization. The design is adapted from big private companies entailing the generation and analysis of big data, both from a government's own administrative operations and from citizens' activities (Margetts 2014). Further, reintegration includes intelligent centre and decentralized delivery design, single tax and benefit systems (using real-time data), big data analysis, and reintegrative outsourcing (Margetts et al 2013).

Needs-based holistic reforms seek for simplification and change in the relationship between agencies and their clients by building larger and more encompassing administrative blocs, which are connected to re-engineering of processes and sorting out unnecessary steps. The main components in needs-based holism are interactive information-giving and seeking, client-or needs-based reorganization, one-stop provision, ask-once processes, data warehousing, end-to-end service re-engineering and agile government processes. Flexible directorate structures have fostered more IT and cloud-based central service arrangements. As the pressure to create for more agile government structures has increased, holism has brought up phenomenon including extensive client and needs based reorganization, co-production of services and single benefits integration in welfare states as well as development of 'social web' processes within online government. Furthermore, there is a trend to cooperate with citizens in service creation (Dunleavy et al., 2013; Margretts et al. 2013).

The third theme, *digitalization,* means the adaptation to electronic delivery and placing it to the centre of the government's operations wherever possible (Dunleavy et al., 2013). On a concrete level digitization entails electronic service delivery, automatization and simplification of processes, decreasing service channels and centralizing those into digital formats (ibid.). In fact, the trends related to DEG's digitization theme, like radical disintermediation, automated processes and channel reduction, have expanded rapidly lately (Margretts et al. 2013). Digitalization includes the following new components: '100% online' channel strategies and government cloud, free storage and comprehensive

data retention, offering public information for reuse (open data initiatives) and pervasive computing. In addition, big data approach is seen to offer significant potential as a catalyst for improving mutual government–citizen understanding, and supporting efficiency, effectiveness and responsiveness of public organizations (Margetts & Clarke 2014) Both holism and digital changes aim to move towards open-book government and building on open data initiatives (Margretts et al. 2013)

2.2 Information and knowledge management as a cycle

There are several process models that aim to support knowledge management and thus, knowledge-based value creation (Laihonen 2013). One of the best-known models is Choo's process model (1995, 1998, 2002). In Choo's information management process model, information management is described as a continuous cycle, in which six closely related but separate stages can be detected. The information management cycle begins with the *definition of information needs*. The information needs are first identified so that they can later be met as well and efficiently as possible. Information needs refer to gaps between the existing knowledge and the knowledge that is required to make decisions or to conduct certain actions. Effective knowledge management prerequires an accurate description of information needs (Choo 1995). The second phase is *information acquisition* stage, where information is obtained and collected both from external sources, such as competitors and customers, and from internal sources, such as operational databases and information systems. The data collected will be then stored in the organization's archives and possibly analysed in combination with other data sources. This means the stage of *analysing and organizing* the information, which facilitates the next stages of the process, i.e. the stage of *information distribution and knowledge sharing*. A wide distribution of information and sharing of knowledge enhances organizational learning as the aim is to enable information from multiple sources that is processed by multiple people to be synthesized in order to generate deeper insight (Choo 1998). Furthermore, in information and knowledge sharing it is essential, that reliable information in the right format reaches the right user at the right time and place (Choo 2002). For this to be realized, the knowledge sharing model has to meet the end-user's information utilization preferences and habits. This will enhance the ultimate aim of the information management cycle, the *information and knowledge utilisation,* as information is valuable only when used. At best, information and knowledge are used actively in decision-making and operational development leading to real changes in the organization's operations. By *measuring* and verifying the changes that have taken place and learning from what has happened and thereby identifying new development needs, the cycle starts from the beginning. Choo (1998) argues that this requires information processes and methods, which provide a high degree of flexibility in the representation of information and facilitates exchange and evaluation of multiple representation among individuals.

2.3 Linking the DEG framework to the knowledge management evaluation

This section links DEG framework and the evaluation of information and knowledge management based on Choo's model (Jääskeläinen et al., 2019), consisting of the following segments: vision and strategy, administrative structure and organization, information needs, information acquisition, information organization and storage, information products and services, information sharing, information usage and indicators (see Appendix 1).

Organizing and storing knowledge emphasize integration, flexibility and consistency of IT architecture and data storage and organizing. Daddieco (2004) states that one often overlooked asset for organizing and storing knowledge is that knowledge embedded within and between records and legacy record keeping systems is lacking government-wide documentation management systems and, thus efficient retrieval of relevant records is not possible. This segment can thus be linked to holistic efforts of data warehousing and digitization efforts to enhance the creation of free storage and comprehensive data retention. Organizing and storing of knowledge can also be connected to DEG's aims of reintegration since organization wide and integrated storing of knowledge can benefit organizational effectiveness and efficiency. This segment is also linked to open and big data initiatives, in the way that systematic storage and organizing of data is a basis for effective utilization of big data and open data.

Knowledge sharing includes communication with employees, delivery and sharing of information and open data. The integration theme of DEG focuses collaboration across agencies and joint-up governance. Creating agile government processes and co-production of services can be influenced by efficient knowledge sharing (see e.g. Bolivar et al. 2015; Riege & Lindsay, 2006). According to Barzki and Reid (2004), a difficulty in both the creation and maintenance of horizontal networks across organizations can be caused by an embedded culture of not sharing information and knowledge between departments in governments. DEG's integrative component to simplify networks is thus an important factor for intra- and inter-organizational knowledge sharing. Holistic aims to create client and needs-based structures can be seen to require knowledge sharing across sectors and between organizations. Knowledge sharing is also linked to initiatives of opening public information for re-use and moving towards open-book government.

Information products and services emphasize performance and quality of analytical information services. Within DEG's holism theme to create agile government processes and the digitalization theme (automated processes) essentially relate to sufficient information products and services (Dunleavy et al. 2006). Furthermore, the integrative aim to re-engineer back office functions rest heavily on functioning information systems (Dunleavy et al. 2006). Redesign of back-office functions often aims to system integration and streamlining of processes, meaning that government agencies need to scrap historic processes and systems that are lacking present day rationale. (Dunleavy 2006). Maintaining and developing sufficient information products and services is also linked to the development of e-government (e.g. Dunleavy et al. 2006; Lappi 2019) as

well as intelligent centre/devolved delivery (IC+DD) design, which builds on effective information products and services that allow data to be stored, analyzed and managed efficiently (Dunleavy et al. 2013, 8). As Zaharova et al (2004) state, advanced information analysis can help to identify customer needs and, thus help to create client and needs-based structures.

Knowledge acquisition examine the effectiveness, automatization and clarity of data collection processes and the variety, availability and usability of information. These can be linked to DEG's integrative initiatives of building governmental intelligent center/decentralized delivery (Margetts et al. 2014). Creating data warehouses and turning big data into benefits requires well-functioning data collection processes. To be able to make strategic decisions based on knowledge as in the IC-DD design, one could presume that gathered information should be in a "readily available" and "easily usable form". As stated by Dunleavy et al. (2006) interactive information exchange is fundamental to all elements of needs-based holism. Information searching could also be understood as information acquisition. Thus, creating agile government processes, client-based or needs-based reorganization, co-production of services, one-stop provision and ask-once processes could be seen to benefit from efficient knowledge acquisition.

Knowledge usage deals with knowledge being used to evaluate and measure performance and knowledge use in decision-making. Evaluating knowledge-based decision making is connected to DEG's IC+DD design and data warehousing initiatives, that aim to help public servants to make strategic decisions based on acquired information. Furthermore, the key elements to agility of structures and processes are real-time monitoring, forecasting, and prediction systems, that are cutting unnecessary time for decision-makers (Dunleavy et al. 2006). And thus, the effective utilization of information in decision-making is crucial for agility of processes.

The table 1 illustrates identified connections between DEG framework and knowledge management evaluation model (Jääskeläinen et al. 2019). For the most of the segments of evaluation model, connections were identified. However, for the segments vision and strategy, administrative perspective, information needs and indicators, one could not detect adequate similarities with the DEG framework to coherently say that contents could be evaluated within the framework. To conclude, knowledge management evaluation model seems to capture many aspects related to digital era governance.

Table 1. The research framework of this study

Reintegration	Evaluation model	Holism	Evaluation model	Digital changes	Evaluation model
Rollback of agencification and fragmentation, joined-up governance (JUG)	Organizing and storing knowledge, Knowledge sharing	Client-based or needs-based reorganization	Knowledge usage, Knowledge sharing, Information products and services	E-government	Information products and services
Re-engineering of back-office functions	Information products and services, Knowledge sharing	One-stop provision, ask-once processes	Knowledge acquisition	New forms of automated processes	Information products and services
Shared services on a 'mixed economy' basis	Knowledge sharing	Data ware housing	Organizing and storing knowledge, Information systems and products, Knowledge acquisition	Radical disintermediation	Knowledge acquisition, Knowledge usage
Network simplification	Information products and services, Knowledge sharing	Agile government processes	Knowledge sharing, Information products and services, Knowledge acquisition	Moving towards open-book government	Knowledge sharing (open data), information products and services
IC+ decentalized delivery (DD)	Information products and services, Knowledge usage	Co-production of services and single benefits integration	Knowledge sharing, Knowledge acquisition	Freeing public information for re-use	Knowledge storing and organizing, Knowledge sharing (open data)
Single benefit systems (using real time data)	Knowledge sharing	Development of 'social web' processes within online government, and field	Knowledge sharing	100% online' channel strategies (covering all contacts and transactions) and related modernizations	Information products and services
		Interactive information seeking and giving (present in all of the above)	Knowledge sharing, Knowledge acquisition	Free storage, comprehensive data retention	Knowledge storing and organizing

3 Methodology and empirical research

The data for this study was collected with an online survey, where respondents were asked to evaluate presented statements on a likert-scale from 1 to 5. The survey was sent to 1281 respondents working in a large municipality. Respondents worked as managers

(30%), department/unit leaders and supervisors (18%), and experts (52%). The respondents represented central administration (29 %) and sectoral committees including the committee of education (22 %), committee of city environment (14 %), committee of culture and leisure (13 %) as well as the committee of social services and health care (16 %). Other departments covered 6% of the respondents. Most of the respondents had been worked in the municipality for more than 10 years. The survey got 379 respondents, representing a response rate of around 30%.

IBM SPSS Statistics 26 and SmartPLS 3.0. were used in data analyses. PLS-SEM is an estimation method maximising the variance explained and does not include assumptions regarding data distributions. PLS is specifically powerful in predicting and explaining the variance of examined constructs (Reinartz et al., 2009). Bootstrapping of 5,000 rounds was used in the analysis. The constructs of the model were created by using reflective constructs in SmartPLS analysis. Reliability and validity of the constructs were analyzed by using factor loadings, composite reliability (CR), Cronbach alpha and average variance extracted (AVE). Loadings of all items in the constructs were above 0.6 and mostly over 0.7 which is satisfactory. Composite reliability varied between 0.884 and 0.917 exceeding the threshold of 0.7. AVE values were between 0.524 and 0.694 which exceeds the 0.5 level threshold. Also, the Cronbach alphas were more than 0.7, which is satisfactory. Appendix shows more detailed results as well as the items used for evaluating the constructs of the research framework. Furthermore, descriptive statistics including mean comparisons with a one sample t-test and distribution of results on the likert-scale were examined.

4 Results

To describe the overall state of how the case municipality is performing in the areas of knowledge management linked to DEG, descriptive statistics were examined by comparing the means of constructs created through PLS algorithm. Table 2 presents descriptive statistics of means and standard deviation of these constructs. To see whether there are statistically significant differences among the means a one-sample t-test was performed, comparing each of the construct mean values to the other. The one sample t-test measures the statistical significance of differences in results based on a null hypothesis. The results show that all of the means except “Information products and services” and “Knowledge acquisition” ($p = 0{,}709$) as well as “Organizing and storing knowledge” and “Knowledge acquisition” ($p = 0{,}690$) differentiated on a significant level (when using the level $p < 0{,}05$).

Table 2 Descriptive statistics of the key constructs

Report						
	Organising and storing knowledge	Knowledge sharing	Open data	Information products and services	Knowledge acquisition	Knowledge usage
Mean	2.4022	3.2075	3.4304	2.5029	2.5200	3.0445
N	287	327	327	285	339	312
Std.dev.	0.79250	0.76092	0.91528	0.77058	0.78946	0.76609

The mean of the variable "Organizing and storing of knowledge" that measures integration, flexibility and consistency of IT architecture and data storage and organizing has the lowest status with an average of 2.4. Also the result of information products and services which emphasize information service analytical performance and quality, was considerably low, with a mean of 2.5. Furthermore, the state of knowledge acquisition, that measures effectiveness, automatization and clarity of data collection processes and the variety, availability and usability of information, is considerably low with the mean of 2.5. The means of "Knowledge usage" that deals with knowledge being used to evaluate and measure performance and information use in decision-making, "Knowledge sharing" that takes into account communication of information for employees, delivery and sharing of information as well as "Open data" that measures the provision and use of open data are relatively higher. When looking at the standard deviations it appears that there are most differences in responses regarding the practices of open data.

Figure 1 presents the results of PLS-SEM analysis which shows relationships between the constructs of the analysis framework in alignment with Choo's (2002) model and further in relation to performance benefits for the organization. As noticed, not all of the studied constructs relate to organizational performance directly. Knowledge sharing ($\beta = 0.437$, $p < 0.001$) and knowledge use ($\beta = 0.272$, $p < 0.01$) have a direct link to organizational performance. Other constructs have only indirect relationships to performance. Organising and storing knowledge ($\beta = 0.516$, $p < 0.001$) and open data ($\beta = 0.223$, $p < 0.001$) are supportive to knowledge use. Knowledge acquisition has a strong positive link to organising and storing knowledge ($\beta = 0.725$, $p < 0.001$). Finally, information products and services are strongly linked to knowledge sharing ($\beta = 0.546$, $p < 0.001$).

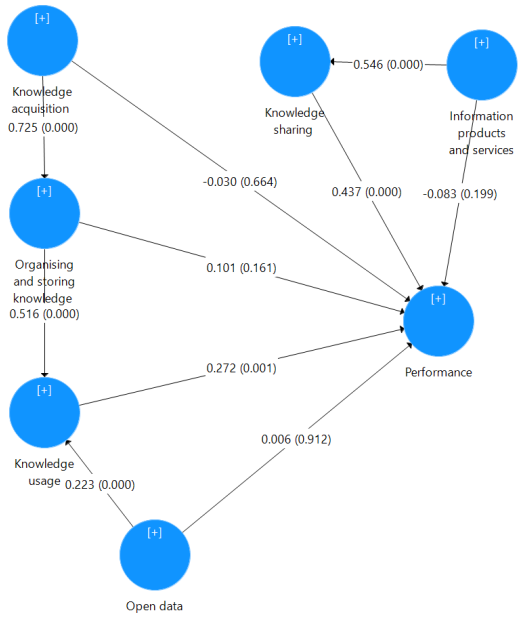

Figure 1. PLS path model

Table 3 further opens up the statistics underlying the PLS analysis. The path model explains around 44 % of the variance in organizational performance, 30% in knowledge sharing, 41% in knowledge use and 53% in organising and storing of knowledge. Multicollinearity was evaluated with variance inflation factor (VIF). The outer VIFs are between 1.0 and 3.0, which are well below the cut-off level of 10.

Table 3. Detailed results of the path model

	β	**VIF**	**t-value**	**Significance (p-value)**
Antecedents to organizational performance				
Organising and storing knowledge	0.101	2.724	1.414	0.157
Knowledge sharing	0.437	2.301	5.816	0.000
Open data	0.006	1.402	0.110	0.912
Knowledge acquisition	-0.030	3.047	0.431	0.667
Knowledge usage	0.272	2.797	3.502	0.000
Information products and services	-0.083	2.757	1.252	0.211
R^2	0.434			
R^2 adjusted	0.425			

Antecedents to knowledge sharing				
Information products and services	0.546	1.000	15.942	0.000
R^2	0.298			
R^2 adjusted	0.296			
Antecedents to knowledge usage				
Organising and storing knowledge	0.516	1.185	12.358	0.000

R^2	0.407			
R^2 adjusted	0.404			
Antecedents to organising and storing knowledge				
Knowledge acquisition	0.725	1.000	26.298	0.000
R^2	0.526			
R^2 adjusted	0.525			

5 Conclusions

This study contributes to the literature by evaluating the status of information and knowledge management through the lens of DEG framework and by empirically demonstrating how performance benefits can be obtained through the activities of information and knowledge management. The results suggest that the investigated activities are relevant for organizational performance improvement by explaining 44% of the variance in organizational performance. Most notably, performance benefits require a process where knowledge is first gathered, stored and supported by information products and services. These activities are relevant for sharing and using knowledge, but they require appropriate practices of sharing and using knowledge in order to reach performance benefits.

The studied municipality is performing quite poorly (2.4/5) within "organizing and storing knowledge". It can be interpreted that by developing these activities, the city could achieve de-fragmentated data warehousing, opening up data, creation of free storage and comprehensive data retention that reflect the contents of digital-era governance in the areas of holism and digital changes. Referring to Dunleavy et al. (2006), storing information in separate, incompatible systems has been the conventional administrative situation in many countries. This seems to be the case also in the empirical context of this study. Data warehousing or the contemporary phenomenon of data pooling is seen as a desirable path of development (e.g. Dunleavy et. al. 2006; Margetts et al. 2014). Both, Choo (2002) and Dunleavy et al. (2006) stress that data warehousing should contain information from several sources throughout the organization, that is structured in a way that is meaningful for the end-users and meets their needs. Moreover, the overall system requirement should be flexible in architecture as well as in capturing multiple forms of information, linking together data and supporting multiple users' needs.

"Information products and services" measured maturity of analytical capabilities and quality. The results show that the municipality was also performing quite poorly (2.5/5) in this area. Within the DEG framework this could be linked to the formation of automated processes. This may also hinder the agility of government processes as they require

adaptiveness and flexibility of systems as well as real-time monitoring, forecasting, and prediction systems (Dunleavy et al. 2006). Furthermore, both incompetent analytical performance of information products and systems and the low level of effective, automatization and clarity of data collection processes can affect the generation and analysis of big data. According to Margretts (2014) these aspects affect the implementation of the IC+DD model to further create knowledge-based client and needs-based structures and strategic decision-making. Furthermore, if the municipality is aiming for automatization of its service supply, developing projects and strategies should pay attention to developing sufficient analytical tools and services.

Furthermore, both knowledge acquisition and knowledge sharing, can be interpreted to influence the creation of holism within structures and processes of public organizations, as those require interactive information seeking and giving (Dunleavy et al. 2006). The low results within “knowledge acquisition” can affect the move towards DEG´s co-production of services and single benefits integration and one-stop provision. Poor knowledge acquisition may also affect negatively to the creation of client and needs-based processes, following the reasoning of Wimmer (2004), who emphasizes the access to information and knowledge resources in achieving the goal of citizen-oriented service delivery. If a municipality aims to move the organization towards DEG´s client-based delivery, processes to foster "information seeking and giving” as well as the creation of “detector mechanism” have to be in place.

The results within “knowledge usage” can be considered as fairly satisfactory (3.0/5). As the variable deals with knowledge being utilized in decision making, and measuring and evaluating performance, developing this area could particularly affect the adoption of the IC+DD model, were data is utilized for strategic decision-making. The results of “knowledge sharing” were also on a satisfactory level (3.2). The creation of agile government structures and processes to respond with flexibility to fast emerging cross boundary issues is influenced by the organization´s ability to share knowledge. To further enhance knowledge sharing capabilities within the municipality, the de-fragmentation of organization structures and creation of inter- and intraorganizational networks could enable information from multiple sources and processed by multiple people to be synthesized in order to generate deeper insight of issues at hand (Kim & Lee 2004; Choo 2002).

Notably this study also showed the importance of knowledge use and sharing in creating performance benefits. However, it is evident that practices of using or sharing knowledge are eventually not enough if the activities of producing knowledge are insufficient as in the investigated municipality.

The municipality´s is performing relatively well (3.4/5) within “open data”. Thus, the municipality´s current status within this factor can be seen to reflect the trend of open-book governance and freeing public information for re-use within DEG. It also demonstrates the pursuit for the ideals of smart city opening up data for citizens, companies and other stakeholders (Argento et al., 2019). However, this study

demonstrated that open data is not as such enough for organizational performance benefits.

Although it appeared that there are not major differences between the municipality divisions studied, a further study could be implemented, for example in a different region, in order to improve the external validity of the results regarding the status of information and knowledge management. The analysis of this study was mainly descriptive and explorative and a further study could move further towards theory testing and more detailed statistical analyses with the data.

Abstract

As knowledge intensive organisations, higher education (HE) organisations also face a challenge of creating value from data and utilising knowledge in decision-making. However, in many HE organisations, knowledge management practices and culture are not very evolved. Overall, knowledge-based management is not yet widely recognised in HE-context. The aim of this research was to study knowledge-based management in HE context through a case study of a Finnish technical university. This research was conducted as a qualitative single case study and research material was collected by 19 thematic interviews consisting mostly of upper and middle management personnel. The results are analysed through a Framework of information and knowledge management. Based on a vast analysis, some suggestions were made of how the knowledge-based management could be improved in the organisation.

Keywords – knowledge-based management, higher education, case study

Paper type – Academic Research Paper

1 Introduction

The mission of higher education (HE) organisations is to provide high quality education and research, and to serve the society. Even though the goals of a HE organisation differ from many other organisations', they also create a vast amount of data and information in their operations. HE organisations are knowledge intensive environments by creating knowledge through research, by transferring knowledge with businesses and other parties and by offering higher education to students (Fullwood et al., 2013). However, currently many HE organisations do not take full advantage of the

information available. For example, Fullwood et al. (2013) say that universities knowledge strategies tend to be passive or inconsistent even though as knowledge intensive organisations that should not be the case.

There is a growing demand to better utilise data to support decision-making in HE-sector (Aljawarneh, 2016; McNaughton et al., 2017). Like other organisations, HE organisations need to distinguish what data is relevant, how to refine it, how to share it within the organisation and if needed, to other stakeholders, and how to use it in decision-making (Choo, 1998; Kaivo-oja et al., 2015), and furthermore, in creating value for themselves and/or other stakeholders. In addition to developing their own operations, HE organisations face the challenges of globally increasing competition (Pucciareli and Kaplan, 2016; Scholtz et al., 2018).

Using data and information is necessary for organisations to understand the dynamic operational environment and to be able to develop their own operations and so on to create value for the organisation. Organisations need efficient ways and practices to manage data and information from various sources to gain understanding about organisations' environment and main partners to support decisions that are met for achieving the objectives of an organisation. In this paper, we refer this knowledge-based management. It is viewed as an approach to collect, refine and use information to support decision-making and strategic development of an organisation. Organisation's culture and attitudes towards knowledge-based management are also an important factor to be considered.

Since knowledge-based decision-making has been found to be highly beneficial in HE-context (McNaughton et al., 2017), the purpose of this research is to study knowledge-based management in a HE organisation in Finland. Our study illustrates practical challenges in relation to research literature from knowledge management literature. The study points out beneficial issues for the development of knowledge-based management in the case organisation. In addition, the findings contribute to research in the HE sections where knowledge-based management is not very widely studied.

The structure of the paper is the following. At first, the theoretical premises of the study are presented, focusing on knowledge-based management and the process model of information management (Choo, 1998) in the context of higher education. In the empirical part of the study, we discuss the methodological choices and the research setting. We have interviewed the management personnel of a Finnish university and have analysed the results using Choo's process model as analytical lenses for the empirical study. Conclusions and future research end our study.

2 Theoretical setting

2.1 Knowledge-based management

The amount of data is growing at exponential rate and there is a need to distinguish what data is relevant to organisations and how to use it (Hellsten and Myllärniemi, 2019). In literature, this phenomenon has been approached by using concepts like business intelligence (Shollo and Galliers, 2016), data-based value creation (Xie et al., 2016) and knowledge-based value creation (Laihonen and Lönnqvist, 2010). Common for all is the way they refine data and information to form and use that are more meaningful.

This paper focuses on knowledge-based management, i.e. knowledge and knowledge processes. Knowledge-based approaches, like the concepts listed above, aim to understand and explain how organisations internal and external knowledge resources contribute to organisations' competitive advantage (e.g. Grant, 1996; Myllärniemi et al., 2012; Salonius and Käpylä, 2013; Myllärniemi et al., 2019). Knowledge-based management may be seen as synonymous for the concepts mentioned above. It is an approach to collect, refine and use data and information to support the decision-making and strategic development of an organisation. In our research, we stress knowledge-based development aspects as well as cultural and strategical issues which are not emphasised, for example, in the concept of business intelligence.

We refer to knowledge as the outcome of human action that takes place in decision-making situations. It is based on information, know-how and experiences. It is refined from information and data and therefore it is more valuable for decision-makers. Information, on the other hand, is data in the structured form. Data is unstructured facts that have the least impact for managers. (Thierauf, 2001). Knowledge management considers the processes and activities supporting the utilisation of knowledge resources (Wiig, 1997), and further, information and data. One common way to structure knowledge processing and related activities is the process model of information management (Choo, 2002). Choo's model, presented in figure 1, is widely used in knowledge management research. We used it as a theoretical framework when studying the case organisation's knowledge-based management.

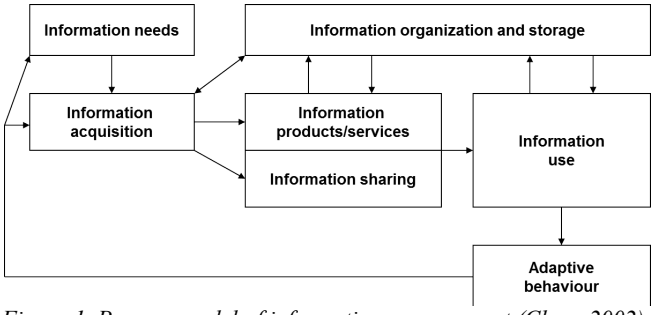

Figure 1. Process model of information management (Choo, 2002)

The model includes six stages. First, information needs are defined so that they can be later satisfied as well and efficiently as possible. Based on this, information is then acquired and gathered both from external sources, such as competitors and other partners, and from internal sources, such as operational databases and personnel. This is followed by the phase of information organisation and storage where the aim is the creation and build-up of an organisational memory. This facilitates not only latter phases such as information analysis for systematic and advanced information products/services, but also the phases of information sharing and information use. Information gets its final meaning when it is utilised for instance in decision-making, and changes in the organisational activities take place. By utilising and adjusting organisational operations, the cycle starts over.

Like said, HE organisations do not take full advantage of the information available. In order to do so, the broad understanding about knowledge utilisation is necessary. This means that knowledge-based management must be studied also from broader organisational perspective including cultural and strategical aspects. Therefore, we used the approach of Jääskeläinen et al. (2019) to cover these aspects. Jääskeläinen et al.'s (2019) framework of information and knowledge management leverage Choo's model by the aspects of governance and organisation, measures, and strategy and vision. In doing so, we could take into consideration the softer side of humans related to knowledge and the viewpoints of the employees and the organisation.

2.2 Higher education organisations and knowledge-based management

HE organisations have been acknowledged as knowledge intensive organisations for a long time (Fullwood et al., 2013; Sharimillah et al., 2013). New knowledge is created constantly through research, teaching and learning. Through these operations, also a vast amount of data is created which could be utilised to develop the organisation and support decision-making. Based on Gartner's (2017) research, the state of digitalisation in higher education organisations is lower than in other industries. It is widely recognised that the data is not utilised to support decision-making at least in the scale that it could be done (Aljawarneh, 2016; McNaughton et al., 2017; Scholtz et al., 2018).

In the HE sector, organisational structures can be either an enabling or restricting factor when it comes to knowledge-based management (Veer Ramjaewon and Rowley, 2017). HE organisations are often quite hierarchical and HE organisations tend to have challenges adapting to rapid changes, for example, due to inflexible organisational structures (Pucciareli and Kaplan, 2016). In knowledge-based management perspective, the stiffness of organisational structures can also cause a major barrier for knowledge sharing for HE organisations (Fullwood et al., 2013). Besides structural challenges, also strategic management (knowledge strategies tend to be passive or inconsistent), leadership in general and funding related issues have been mentioned as reasons behind challenges HE organisations come across.

Finnish HE organisations face these same challenges. The Ministry of Education and Culture of Finland coordinates the activities of higher education organisations and acts as their main financial source, so the organisations are performance guided (The Ministry of Education and Culture, 2020). These set a pressure for management, as well as, for example, for functional information systems, reporting capabilities and knowledge utilisation. Even though strategic management is a rather new concept in Finnish HE organisations, there is the willingness to have a larger emphasis on strategic development in systematic manner (Juppo, 2011; Ranki, 2016). When it comes to strategic knowledge management and knowledge-based management, it is not common for HE organisations to have a strategic approach to it (Veer Ramjaewon and Rowley, 2017).

Finnish HE organisations, as well as other HE organisations globally, have noticed the need for knowledge-based management. Like organisations from other industries, HE organisations are eager to develop their knowledge-based management practices but at the same time they are facing several challenges concerning knowledge-based management that were not evident or visible beforehand (cf. Ransbotham et al., 2016). In this study we point out these challenges and increase the understanding of knowledge-based management in HE organisations.

3 Research methods and empirical setting

This research was conducted as a qualitative single case study (Yin, 2002). The case organisation was the Tampere University of Technology (TUT). TUT merged with University of Tampere and Tampere University of Applied Science at the beginning of 2019 forming Tampere Universities community. In this study, we focus on time before the merge and solely on TUT organisation. The university was founded in 1965 and at the time of the study it consisted of 8300 members of personnel and students. The upper management included a rector, two vice rectors (for education and research), and five deans. These together formed an executive team of the university. In each faculty, there were two vice deans (for education and for research). Each faculty consisted of different amounts of units which were managed by a head of a unit. In total there were 19 units in the university. To support all university functions there were teaching and research related services and financial services departments.

The study was carried out during 2017 and 2018, with a focus on university's knowledge-based management. Empirical data consists of 19 theme interviews which were conducted in late 2017. Interviewees were members of upper management, middle management and personnel of support services as can be seen from table 1. Interviews covered all members of the steering group. Interviewees of vice deans, members of administrative services and heads of units were chosen so that all faculties would have similar proportions of interviewees.

Table 11. Introduction of the interviewees.

Number of interviewees	Title
1	*Rector*
2	*Vice rectors: head of education and head of research*
5	*Deans (of all faculties in TUT)*
3	*Vice deans*
3	*Members of administrative services: Teaching services, financial services, research services*
3	*Heads of a unit*

The aim of the interviews was to find out different views of organisation's knowledge-based management and to investigate general attitudes and culture towards knowledge-based management. Interviews were thematic interviews which were conducted face-to-face on university premises and lasted for 30 to 60 minutes. Interviews were formed following Choo's (2002) information management process model which includes the following phases: defining information needs, acquiring information, processing and analysing information, sharing information, information use in decision-making and feedback. In addition to Choo's model, we studied governance and organisation, measures, and strategy and vision.

Through the interviews we were able to get a vast empirical material for the analysis. The material was analysed in a qualitative manner. The findings were categorised by interview themes and interviewees' title. Firstly, the state of knowledge-based management was outlined for each interviewee group. After that, an overall view of the organisation's knowledge-based management was outlined. In this paper, we summarize the findings and propositions made during the research.

4 Findings and discussion

Valkokari and Helander (2007) point out that by examining organisations' activities through Choo's model the challenges related to knowledge management could be recognised and hence development proposals can be made. Like said before, we expanded Choo's model to enable broader examination of knowledge-based management. The analysis is summarized above.

Information needs. Information needs of different user groups are mostly undefined. In many cases, the shared information does not fulfil the information needs of upper and middle management personnel. Especially information about finances was most often mentioned being lacking. All interviewee groups recognised the same challenge despite differences in their roles in the organisation. Another major information gap was recognised as lack of predicative information. Most interviewees in a leading position mentioned that they could not get enough data or information to support predictive decision-making. It is vital for HE organisations to better utilise predicative information in order to stay competitive in the future (Pucciareli and Kaplan, 2016).

Information acquisition, organisation and storage. Even though most of the time there was enough information available, finding the needed information in due course caused problems. However, there was a clear difference between members of the executive team and other interviewees. The members of executive team felt that the amount of information provided for them was sufficient while other interviewees felt the opposite. That has to do with their role in the organisation since the information is mostly provided for the members of executive team. Even though this resolves the issue of availability it brings up another dilemma: the members of the executive team were highly dependent on the provided information.

Despite required amount of information being available, many interviewees had experienced challenges with finding or receiving information in a timely manner. Information is scattered to multiple information systems and channels. Inability to access information, lack of know-how of using the different information systems, and even unawareness of existing information systems were the main reasons. In addition to concerns raised before, the channels used for information gathering were mostly internal. Most interviewees used merely the sources available within the organisation. Only a few mentioned that they actively seek outer information sources to collect adequate knowledge to support their decision-making.

Information products/services. Above mentioned challenges affected information providers' workload; most of their time is currently spent on basic level reporting for executive team. Therefore, other interviewees felt that they do not get enough support from specialist providing and analysing information. Also, the commensurability on information perceived to be a challenge. As people gather data from the systems as they wish and maybe even form some reports of it by themselves, the results do not tend to be comparable due to different choices made in the data collection and combination.

The case organisation has a business intelligence system in use. Currently, it is only used for creating monthly reports for the executive team. The reports are sent via email and therefore information is converted to a static form. The system would allow investigating reports from multiple point of views and levels and so on enable more thorough understanding about the issues. According to Peters et al. (2016) the use of information system tools correlates positively with the competitiveness of the organisation due to wider information utilisation potential. However, currently the executive team do not find IS usage to be part of their job. Overall, there has not been a ruling of how the business intelligence system should and could be used to better support decision-making.

Information sharing. Information sharing was mostly mentioned in positive context. The interviewees thought that the amount of information shared is good via information systems. Also, they had good communication with colleagues and mostly the exchange of information was seen to work well. Unscheduled conversations were considered one of the most important sources of information. This causes a problem by since the level of uncertainty of information sharing is quite high.

Currently, information sharing is not very targeted and the strategy seems to focus on pushing all information out there for people to find. A challenge occurring from information system-based information sharing is that finding information is quite dependent on how actively one seeks it. This combined with lack of know-how in information system utilisation can cause problems in the organisation.

The interviewees also recognised prevailing willingness to use information to share information openly in the organisation. Currently, the situation is not quite there yet. The hierarchical structure of the organisation is vertically rather high, and information flows mostly from top to bottom. Personnel found it hard to share information the other way around.

Information use. According to the interviewees, decision-making is mostly knowledge-based. Information is used when it is available in timely matter. However, middle management did not always have enough information to support decision-making. Especially financial information was considered being lacking. On the other hand, upper management rely heavily on the information provided for them. The people preparing reports for management emphasised that they do not get to participate in decision-making situations even though their presence would be beneficial to open up the reports verbally so that the context and all matters effecting on the background will be noticed.

Governance and organisation. Based on the interviews, it is evident that there is willingness to use information to support decision-making. As implied earlier, this willingness does not always translate to action due to a couple of different reasons. The most important barriers are finding the needed information and the knowledge utilisation culture of the university and the attitudes towards it. The lack of transparency in decision-making undermines the culture of knowledge-based management.

The organisation already had a data warehouse in use which is an important step towards better data utilisation. However, not all interviewees knew how to access it nor had rights to access it if necessary. Those who had access thought that searching for relevant data from the warehouse was challenging. Also, some operational data was not yet connected to the warehouse. The IT infrastructure was considered too complex and non-transparent.

According to interviews, one reason for above mentioned challenges is changed organisational structures which have varied multiple times due to many organisational changes made during past years. Current structure allows all faculties to develop their own data and information utilisation practices. Interviewees felt that there are big differences depending on from which previous structure faculties and units originate.

Measures. At the university, the finances guide strongly of what is measured since TUT needs to fill certain targets set by the ministry of education to receive adequate funding. Most interviewees said that measurement is purely quantitative, and it does not support developing teaching and research. Measurements was seen as a guiding factor action instead of a tool for developing operations. Since almost all measuring was

finances based, measurement did not provide extensive enough information for all strategic and operational planning.

Strategy and vision. Currently, systematic knowledge-based management has not been a clear strategical target for TUT which seems to be common in other universities also (Veer Ramjaewon and Rowley, 2017). The interviewees said that the organisation does not have a strategy for knowledge-based management or if there was, they did not know of it. Also, all faculties, units and even personnel seemed to have different views and modes of action of knowledge-based management. However, it would be important to invest in strategical planning from this point of view. To derive value from organisational data and information in HE context it is necessary to have a clear strategy and managers full support to implement it (Pucciareli and Kaplan, 2016; Sharimillah et al., 2013). In addition to lack of strategy and systematic approach interviewees felt that upper management does not lead by example in this matter currently at least at the level the interviewees would hope they would.

The organisation is willing to develop a culture that support knowledge-based management. The organisation could, for example, improve the manner of how they communicate of decisions made. Even though a decision would be made based on a vast set of information, it is not communicated forwards clearly at the moment. Communicating of knowledge-based decision-making would have a positive effect on the knowledge and information culture of the organisation. According to Pucciareli and Kaplan (2016) academic managers should have a central role in guiding the quality and reputation of decision-making culture. It seems that the decision-making is currently more reactive than proactive though organisation vision seems to be towards a more proactive one.

Based on our study we recognised a few main challenges the organisation faces: 1) knowledge-management is not an organisation-wide practice, 2) scattered information systems cause challenges in information finding and sharing and 3) information needs have not been clarified among personnel and information needs are not met at the moment.

5 Conclusions

In this paper, we studied the knowledge-based management of a Finnish higher education organisation. We analysed the level of knowledge-based management by utilising Choo's (2002) model complemented with Jääskeläinen et al. (2019) framework. By combining these models, we were able to expand the analysis beyond using information to support decision-making by investigation and also the organisational strategy, governmental practices and measurement.

As a result, we recognised three main areas which need attention in order to improve knowledge-based management. Firstly, since the organisation has acknowledged the importance of knowledge-based management but there is no organisation wide strategy or common methods yet, it would be important to begin the knowledge driven strategic

development. There is a need for a strong support from upper management in this process to establish a culture and practices for knowledge-based management (Pucciareli and Kaplan, 2016; Sharimillah et al., 2013). The management should communicate more transparently of decisions been made and the data and knowledge on which those decisions are based on.
