Secondly, to resolve challenges in information finding and sharing, information system infrastructure should be revisited to find out ways to uncomplicate it. At least it should be clearer from where different pieces of information are located. Also, it would be beneficial to improve knowledge sharing practices in the university. The stiff structure of the organisation is one cause for challenges at least with information sharing at horizontal level. Overall knowledge sharing practices should be clarified. Lack of knowledge sharing culture is recognised as a barrier to knowledge sharing in HE organisations (Veer Ramjaewon and Rowley, 2017) and therefore this leads back to establishing a culture of knowledge-based management as well.

Finally, there was a challenge of unrecognised information needs which effects negatively on knowledge-based decision-making due to lack of relevant information. The information needs should be identified in order to be able to provide necessary information at the right time for the right people. Also, information sharing could be more targeted to avoid information overflow and so on inability to find the information needed. After all, the development of knowledge practices and processes should be started by focusing on the decision-makers' and the organisations' knowledge needs (cf. Choo, 2002).

The case organisation has challenges related to its knowledge-based management. The challenges are comparable with Myllärniemi et al. (2019) research that studied data-based value creation from a globally operating manufacturing company point of view. Their data was also scattered into multiple information systems, and they had problems with knowledge sharing. Both organisations lacked of understanding of importance of data and information. The results indicate that both organisations need a systematic approach in knowledge-based management. Knowledge-based management is about management and leadership.

This analysis provided a wide understanding about the organisation's knowledge-based management practices and culture and enabled forming proposal for development. In addition, the findings contribute to research in the HE sections where knowledge-based management is not very widely studied. The research material was comprehensive, but it also had some limitations. As the interviewees were mostly members of upper and middle management, and information service personnel, the analysis does not fully cover all organisation, especially research and teaching personnel. It would be beneficial to study the views of other personnel since knowledge-based management is also about a common attitude and culture towards knowledge utilisation in the organisation. After this research was conducted, there has been an organisation merger. Therefore, studying knowledge-

based management in the new organisation and comparing the levels before and after the merger would be an interesting research topic.

Abstract

Banks are nowadays compelled to implement specifically adequate internal procedures and reporting files to be able to identify and manage potential non-performing corporations at a very early stage. This practice has become necessary to monitor performing loans and avoid any deterioration in credit quality. Banks have to fix the set of UTP ("Unlikely-To-Pay") and consider all the situations listed both in the EU CRR ("Capital Requirements Regulation") definition of default and in the IFRS notion of impairment. Different sets of UTP triggers may be defined on a portfolio-by-portfolio basis where the core corresponds to the financial distress prediction, which represents an extensive ongoing research topic. To investigate the influence on different states of financial distress of both micro-economic indicators and firm-specific factors, this paper applies a predictive model, well known in academics, on a unique sample of UTP. In particular, the Z-Score and its revised version were applied to companies included in a special and confidential register of UTP loan positions from a major Italian bank. This allowed the authors to effectively analyze the Z-Score and Z'-Score ability to predict UTP positions. Existing literature on Z-Score, on the contrary, considers the filling of bankruptcy procedures as a criterion for distress, which represents only the final phase of a crisis. In addition, the inclusion of corporate governance variables as control variables is another relevant contribution, since most of past research includes only economic and financial variables.

Results confirm the ability of the Z'-Score model to predict UTP, which is an event far earlier than insolvency

Keywords – Corporate bankruptcy prediction, Financial distress, Z-Score, Statistical learning

Paper type – Academic Research Paper

1 Introduction

Empirical studies have sought to identify a shared notion of crisis. The first attempts in this sense derive mainly from analyses of a discriminating type, namely, Beaver's model (1966) and Altman's model (1968).

According to many recent international studies, a company is in crisis when the market value of its assets falls below a certain threshold (the so-called default boundary - Black and Cox, 1976; Leland, 1994; Longstaff and Schwarts, 1995) while, on the other hand, certain other approaches consider the phenomenon to be a result of financial loans (e.g., the inability of a company to meet its current financial obligations) (Lummer and McConnell, 1989; Gilson et al., 1990; Wruck, 1990. Hotchkiss, 1995; Peterson et al., 1995; Tashijian et al., 1996; Beaver and Engel, 1996, Anderson and Sundaresan, 1996; Andrade and Kaplan, 1998; Boot, 2000).

Such efforts, put in place mainly to promptly identify the very first signs of crisis, allow a company and its consultants to better manage both the strategic and financial levers at their disposal to bring back the company to regularly create value (Blum, 1974, Ohlson, 1980, Zmijewski et al., 1984, Boster et al., 1992, Li and Sun, 2008; Christensen and Li, 2014).

The ability to identify the signals of the crisis as soon as possible, moreover, plays a fundamental role in managerial terms. Indeed, the effectiveness of the adoption of strategic actions in response to the negative dynamics of economic and financial results is strictly correlated to its promptness (Vašíček et al., 2017; Schivardi et al., 2017; Brodi, 2018).

Alert analysis is therefore of particular interest, and this study has been carried out in this perspective. A unique sample is used in this research. Thanks to the support of a major bank operating in Italy, the authors were able to collect confidential information regarding companies included in the sample for the 2006-2016 period, and, specifically, the dates of the inclusion of the companies in the register of UTP positions[1] held by the bank. These data, to be considered as early signs of crisis, are used as reference events for the Z-Score calculations of our analysis. The results confirm that the Z-Score model is a valid tool for alert analysis, as it is able to predict the first signs of financial instability.

[1] *A private register that includes the companies that miss debt repayments (principal or interest). Unlikely to pay (or Utp) are credit exposures for which the bank deems total repayment to be unlikely. Compared to bad loans, they are considered less risky. For this reason UTP is considered an early alert of crisis.*

The paper is organized as follows. The first part provides an overview on the existing literature for the prediction of financial distress, followed by a detailed analysis of the Z-Score model to understand its functioning and applicability. Then, the goal of the research is outlined and the following sections are dedicated to both the construction of the sample and the analysis of the results. Finally, conclusions and managerial implications are stated.

2 Review of the literature on financial distress prediction

Studies on corporate crisis can be grouped according to the following five main strands: the first is related to the causes of corporate crisis (Hedberg et al., 1976; Schendel and Patton, 1976; Hambrick and D'Aveni, 1992; Gales and Kesner, 1994; Slatter and Lovett, 1999; Sheppard and Chowdhury, 2005; Vašíček et al., 2017); the second to the indicators of cororate crisis (Beaver, 1966; Altman, 1968; Blum, 1969; Deakin, 1972; Edminster, 1972, Wilcox, 1976, Taffler and Tishaw, 1977, Dambolena and Khoury, 1980, Ezzamel et al., 1987, Winn, 1993, Bijnen and Wijn, 1994; Hung, 2004; Reisz and Perlich, 2007; Fiordelisi and Mare, 2013; Hernandez Tinoco and Wilson, 2013; Christensen and Li, 2014); the third is the one related to the debt analysis (Diamond, 1991; Ofek, 1993; Asquith et al., 1994; Chemmanur and Fulghieri, 1994; Aggarwal, 1995; Hotchkiss, 1995; Gilson, 1997; Ongena and Smith, 2000; Kahl, 2002; Brunner and Krahnen; 2004; Mooradian and Ryan, 2005; Hotchkiss et al., 2008; Dudley E., Yin Q.E., 2018); the fourth is the one focused on the evaluation of companies in crisis (Gilson et al., 2000; Damodaran, 2009); the last, is the one focused on solutions of judicial and extrajudicial crisis and comparative economic efficiency (Berkovitch and Israel, 1998; Rasmussen, 1998; Blazy et al., 2008).

With reference to the main issues analysed in this research, the strands indicated under points 1, 2 and 3 are the most relevant and, among these, the analysis of the causes represents the starting point for the preparation of an effective intervention plan. Obviously, it is not possible to draw up a definitive list of all the possible causes of crisis, which are often due to competition among several factors (Slatter and Lovett, 1999).

As for the indicators of crisis, since the 1960s, many studies, mainly from the US, have focused on the possibility of combining publicly available data with statistical classification techniques to prevent business failure. Not long before the previously mentioned studies of Beaver and Altman, which gave a strong boost to further investigation on the issue, Tamari (1964) proposed an initial pioneering attempt to statistically analyse failure.

Considerable effort has also been made to replicate and extend these models in other contexts and countries outside the US, finding strong similarities and notwithstanding the specificities of individual countries in the predictive approaches; random studies on bankruptcy are indeed much rarer (Altman and Narayan, 1996). In response to contingent factors, researchers and professionals have developed newer and more sophisticated systems to more quickly identify any signal of crisis with further details (Altman, 1998),

to evaluate the strategic variables and, therefore, to support the decision-making process (Amigoni, 1998; Eccles, 1991). In addition to the traditional predictive indicators and models of a financial nature, new multi-dimensional indicators were considered, implemented by extra-accounting measures and financial and physical techniques.

There are at least four methodological approaches to the development of risk assessment systems (*scoring*): (i) the linear probability model, (ii) the *logit* model (Ohlson, 1980; Zavgren, 1985; Forestieri, 1986; Aziz et al., 1988; Keasey and McGuiness, 1990; Platt and Platt, 1990; Theodossiou, 1991; Salchenberger et al., 1992; Ward, 1994; Back et al., 1996; Laitinen and Laitinen, 1998; McGurr and DeVaney, 1998; Dimitras et al., 1999; Kahya and Theodossiou, 1999; Beyonon and Peel;, 2001; Neophytou et al., 2001; Foreman, 2002; Brockman and Turtle, 2003; Lin and Piesse, 2001; Westgaard and Wijst, 2001), (iii) the *probit* model and (iv) the discriminant analysis model (Altman, 1968, 1993, 2002; Deakin, 1972; Edmister, 1972; Blum, 1974; Alberici, 1975; Libby, 1975; Taffler, 1976-1977; Altman et al., 1977; Deakin, 1977; Moyer, 1977; Taffler and Tisshaw, 1977; Altman, 1983; Booth, 1983; El Hennawy and Morris, 1983; Casey and Bartzack, 1984; Gombola et al., 1987; Mantoan and Mantoan 1987; Aziz et al., 1988; Piesse and Wood, 1992; Coats and Fant, 1993; Altman et al.,1994; Altman et al., 1995; Back et al., 1996; Altman and Narayanan, 1997; Jo et al., 1997; Pompe and Feelders, 1997; McGurr and DeVaney, 1998; Dimitras et al., 1999; Kahya and Theososssiou, 1999; Yang et al., 1999; Altman et al., 2013).

Credit scoring models work quite well in various domestic contexts and at different times and yet have been subject to at least three types of criticism: (i) they are based largely on accounting data, without consideration of other crucial elements (data on market values); (ii) models based on linear discriminants cannot describe the reality of the facts, which are intrinsically non-linear; and (iii) the predictive models shown above are often weakly correlated with the underlying theoretical models (Altman and Saunders, 1998).

Bellovary et al. (2007) have identified approximately 150 predictive models developed since 1965 and, although such analysis reveals that many of the predictive models can show efficacy in the early warnings of insolvencies, the authors also highlighted how researchers are continuously developing new predictive models that try to describe, in an absolute way, the possible insolvency of companies. This has led the authors to conclude that future research should focus on evaluating the effectiveness of using existing models rather than looking for new ones.

It has been demonstrated that existing models tend to have diminished effectiveness in the presence of different samples (e.g., size, sector, type, legal status, area of operational interest, etc.). Part of the generalizability of the model is its applicability in periods of different observations with respect to the "*test case*" originally used (Grice and Dugan, 2001; Grice and Ingram, 2001; Wu et al., 2010). In this sense, in more recent times, numerous empirical studies have been carried out to test the efficacy of the main models by suitably adapting or following the original formulation, with samples selected in

specific domestic contexts, also outside North America or Europe (Taffler, 1984; Peel et al., 1986; Altman et al., 1995; Bottani et al., 2004; Charitou et al., 2004; Alareeni and Branson, 2013; Altman et al., 2013; Cestari, 2013; Celli, 2015; Giacosa, 2016; Kováčová and Kliestikova, 2017). Within these cases it is possible to identify some relevant works focused on the Italian context (Bottani et al., 2004; Altman et al., 2013; Celli, 2015; Giacosa et al., 2015; Giacosa et al., 2016; Madonna and Cestari, 2016).

The model developed by Altman in 1968 (also called *Z-Score*) certainly represents one of the most commonly adopted and easy-to-use tools for assessing default risk, and while the original version of the model was built on a sample of manufacturing companies, it can also be applied to other industries (Al-Sulaiti and Almwajeh, 2007).

As explained by Altman and Le Fleur (1985), this model can be transformed into an active strategic tool aimed at preventing major financial crises. The aim of the *Z-Score* models is to measure the distance – through a score system and with a reasonable error rate – between companies from two groups (healthy and problematic).

The model, which has a descriptive-comparative nature (Altman, 1970), is based on five quantitative variables and aims to identify the tendency that links the trend of the accounting indicators in the years before insolvency for healthy companies and for those in crisis.

Altman's model is based on a formula that assigns a score that can describe the financial soundness of a company and predict its probability of default within a certain time horizon.

In analytical terms, the following linear function represent the *Z-Score* model:

$$\boldsymbol{Z-Score} = \frac{Working\ Capital}{Total\ Assets} x\ 1.2 + \frac{Retained\ Earnings}{Total\ Assets} x\ 1.4 + \frac{EBIT}{Total\ Assets} x\ 3.3 + \frac{Market\ Value\ of\ Equity}{Book\ Value\ of\ Total\ Liabilities} + 0.6\ x \frac{Sales}{Total\ Assets} x\ 0.99 \quad (1)$$

The original *Z-Score* was built on a sample of 33 US manufacturing companies listed on regulated markets. Some authors have criticized the predictive ability of the *Z-score* (and its variants) with reference to non-US companies because the model is closely linked to the characteristics of the US market (Grice and Ingram, 2001; Grice and Dungam, 2001; Ooghe and Balcaen, 2006; Kapadia, 2011). Instead, several studies on the application of the model to samples of US companies (e.g., Timmermans, 2014) have shown a significant predictive ability of the *Z-score* model, up to 95% in the year previous to the insolvency of the companies analysed (year -1), to 83% two years before insolvency (year -2) and 48%, 29% and 36%, respectively, three, four and five years before insolvency (year -3 year; year - 4; year -5).

Assessments carried out over the years outside the US market have shown that the same model is efficient (Charitou et al., 2004; Alareeni and Branson, 2013).

In 1993, Altman introduced the *Z'-Score* (Altman, 1993), which consists of an adaptation of the original model for companies that are not listed in the financial markets.

In analytical terms, the following linear function represent the *Z'-Score* model:

$$\boldsymbol{Z' - Score} = \frac{Current\ Assets - Current\ Liabilities}{Total\ Assets} x0.71 + \frac{Retained\ Earnings}{Total\ Assets} x\ 0.847 + \frac{EBIT}{Total\ Assets} x\ 3.107 + \frac{Book\ Value\ of\ Equity}{Book\ Value\ of\ Total\ Liabilities} x\ 0.420\ x \frac{Sales}{Total\ Assets} x\ 0.998 \quad (2)$$

In 1995 Altman et al. developed the *Z''-Score* model under the name of "*double and prime score"* for non-manufacturing companies and, possibly, those operating in emerging markets (with the insertion of a correction).

In analytical terms, the following linear function represent the *Z''-Score* model:

$$\boldsymbol{Z'' - Score} = 3.25 + \frac{Current\ Assets - Current\ Liabilities}{Total\ Assets} x\ 6.56 + \frac{Retained\ Earnings}{Total\ Assets} x\ 3.26 + \frac{EBIT}{Total\ Assets} x\ 6.72 + \frac{Book\ Value\ of\ Equity}{Book\ Value\ of\ Total\ Liabilities} x\ 1.05 \quad (3)$$

An analysis carried out on extensive databases in international contexts (32 countries including 29 European countries and 3 non-European countries - China, Colombia and the US) has produced very positive results for the *Z-Score* model. Nonetheless, to give greater efficiency and effectiveness to the model in both European and non-European countries, it is appropriate to structure the original analysis through the inclusion of "*country-specific*" estimates that would improve the effectiveness of the results (Altman et al., 2017).

Recent studies have shown the effectiveness of the *Z'-Score* for analyses carried out on samples of Italian companies (Madonna and Cestari, 2016; Paoloni and Celli, 2018).

A recent study on manufacturing enterprises under the Italian bankruptcy procedure (Altman et al., 2013) in the period 2000-2010 showed that the majority of the companies analysed is classified in the area of insolvency according to *Z''-Score*: in particular, in the last four years of the period considered, scores were always lower than 1.23.

Another recent study (Paoloni and Celli, 2018) on a panel of 200 companies (half of which have been subjected to bankruptcy procedures, while the other half consists of "healthy" companies) revealed the *Z'-Score* model's good diagnostic reliability in measuring the health of Italian manufacturing SMEs. In particular, the *Z'-Score* model allowed for detection of companies under default risk.

Our research adopts the Z-Score model as an indicator of the probability of default, in line with the existing literature which suggests going deeper in details in terms of its effectiveness in different contexts. At the same time, however, it aims to address a different research question compared to existing studies. The main gap in the existing

literature is related to the fact that, due to availability of data, the main research question has always been something like "*Is the Z-Score model able to predict the state of crisis defined by the filling of the bankruptcy procedure?"* This was due to the fact that the information related to the state of insolvency is typically recognizable only when it becomes public (i.e., the procedure has been filled). This has a high impact from a managerial perspective: the state of crisis is recognized too far, at a time when corrective actions become more difficult to apply. Our research aims to answer a different question. Specifically, is the Z-Score model able to predict the state of crisis defined by the inability of a company to comply with the deadlines and methods of debt payment in a phase prior to the possible filling of a bankruptcy procedure? In other words: is the Z-Score able to predict UTP classifications? The managerial implication is relevant: the ability to map early warnings allows for earlier intervention, with more effective corrective actions and with fewer limitations. The research gap that this paper aims to fill is therefore related to the timing granted by the analysis of the probability of default through Z-Scoring, which the existing literature demonstrates to be effective but not timely. Here we seek to demonstrate its efficacy as well its ability to be timely.

3 Objective of the study

Since the late 1970s, the number of databases containing historical data relating to companies in crisis has grown considerably, and the use of these elements increasingly allows for the development of new and more appropriate approaches (Altman and Saunders, 1998). It is precisely in the wake of this informative advantage that our study has been able to draw on a considerable amount of information coming from strategically relevant domestic credit institutions.

Due to the characteristics of the unique selected sample, made up of 220 Italian companies, a discriminating element of particular innovation has been used to partly fill the existing research gaps and to add one additional element regarding the applicability of the Z-Score model.

The aim of our study is twofold.

First, we want to verify the accuracy of Altman's model (with particular focus on the *Z'-Score* model).

Second, we want to test its ability to predict early signals of crisis and not just insolvency.

Internal and external stakeholders need to be able to anticipate the warning signs of a crisis before it reaches the point of no return that can lead to very dangerous consequences (Warner, 1977; Charalambous et al., 2000; Charitou et al., 2004).

In line with the importance attributed to stakeholders' interests, the analyses carried out in the present work follow the stakeholder theory approach (Freeman, 1984; Donaldson and Preston, 1995), which considers the company from the point of view of the holders of interest in general.

4 Sample definition and construction

The research begins with the identification of a unique sample, which is one of the main elements of innovation. Historically, the reference literature on corporate crises has faced a limitation in the availability of data relating to *business restructuring* processes. Beyond the complete lack of available data concerning the out-of-court recovery processes (recovery plan), which are naturally private, data on so-called judicial processes (e.g., debt restructuring agreements) and qualitative information on the management of processes are particularly difficult to achieve. Thanks to the support of a leading bank operating in Italy, the authors managed to obtain not only economic and financial data concerning companies in crisis but also the date of their inclusion in the special register of UTP positions, which for us is the event representing the crisis (while for the existing literature the event is represented by the filling of the public bankruptcy procedure).

The very nature of the data obliges the authors to make some further considerations. If from a legal point of view the state of crisis is assumed to begin when the company enters one of the procedures provided by bankruptcy law, from a bank's perspective, this *status* can be determined at a very early moment corresponding to the date on which a debtor experiences problems in the restitution of the interest or principal portion of its debt to the bank. At that time, the bank completes a special register of "unlikely to pay" positions and then takes all possible measures to protect its economic interests.

The concept of "corporate crisis" adopted in this work, therefore, takes its cue from an unfamiliar, perhaps unique definition. This setting can considerably broaden the analytical perspective. The traditional definition adopted in literature refers to a moment of publicity of the state of crisis to conduct analysis, taking as a reference only the moment at which the company gains access to one of the procedures provided by bankruptcy law; in contrast, the definition of crisis adopted in this study allows for identification of crisis even in previous moments and even independently from the access to one of the procedures provided by the law. This perspective allows for the analysis of all cases in which credit management has a private and confidential process, where access to one of the procedures provided by bankruptcy law is only one of the possible outcomes.

The sample was built by adopting the bank's information system. Specifically, we considered a) any case in which a company was unable to repay interest or part of the principal payment and for this reason b) was included in the "special register" of the bank and c) had positively concluded a restructuring process at least two years before this study began. There are two outcomes of the restructuring process. The first is complete rehabilitation of a company in its capacity to repay debts ("*in bonis*" status), and the second is the confirmed inability to repay debts because the state of crisis is too deep ("*workout*" status).

The extraction from the bank's information system allowed the authors to identify 72 companies that successfully completed the process.

Then, for each company, the following information was collected:

a) **Economic and financial data**: the database obtained through the extraction from the information system of the bank was further integrated by extracting relevant financial data on Bureau van Dijk's AIDA and Amadeus databases. Data extraction concerned the three years before and the three years after the "crisis moment" (inclusion in the special register), as reported by the restructuring managers from the bank, through interviews and surveys conducted by the authors.
b) **Governance data:** the database was further integrated with additional data on corporate governance from the CERVED database.

Following the identification of the sample, two additional samples were built for the purpose of our analysis. Therefore, the final sample is composed of three sub-samples:

- **1 (Firms in financial distress that succeeded in restructuring)**: companies that, starting from the year 2014, have shown positive results in terms of capacity to repay their obligations to the bank. No listed company has been included.
- **2 Firms in financially sound position)**: companies that did not show economic and financial problems during the period 2007-2016. A total of 72 companies were identified. No listed company has been included.
- **(Firms which have failed)**: companies that ceased their operations as a consequence of bankruptcy, voluntary liquidation, judicial liquidation or dissolution in the 2014-2016 period. A total of 76 companies were identified. No listed company has been included.

Starting from the identification of the economic and financial data of the companies in sub-sample 1, the maximum, minimum and average values of the turnover were identified and considered as an approximation of the size of the company. The sectors of these companies were also identified. Then, the entire population of Italian companies included in the dimensional limits of sub-sample 1 was identified (minimum and maximum turnover limits of the sub-sample 1). Then, only companies included in the same 2007 ATECO (Nace rev. 2) sectors of sub-sample 1 were considered. This population includes 34,124 units. Starting from the identified population, “deceased” and “healthy” companies were identified. In total, 76 "deceased" companies were identified. For the “healthy” companies, *pairwise* sampling was carried out starting from sub-sample 1. In particular, for each restructured company, another company was identified as having similar characteristics in terms of size (turnover) and reference industry (ATECO 2007). To have a balanced sampling, 72 companies were identified randomly according to these criteria through SPSS. The final sample, including the three sub-samples, is therefore made up of 220 companies.

5 Methodology and definition of variables

After elaborating the descriptive statistics to verify the existence of any *outlier* data, we proceeded to the elaboration of the correlation analysis for the variables included in our analysis. Linear regression is then used to test our hypothesis. The Y variable included in

the models is a dummy assuming values between 0 and 1, depending on whether the company is healthy (0) or recovered or ceased (1). This choice derives from the authors' desire to extend the number of observations in order to arrive at a more significant result through greater granularity in the considered data. Aware of the limits deriving from the attribution of a dummy variable to three different conditions, we also proceeded to verify the model for a sub-sample of companies belonging to two conditions. To run this second test, only companies included in sub-samples 1 and 2 were considered.

With regard to the variables included in our models, Z-Score is the Altman's score already defined; it is used as independent variable to try to explain the Y that is represented by the dummy variable. For the definitions of the other variables included in the model please refer to the Appendix.

6 Results

Correlation analysis provided the authors with significant results. Since the number of variables initially collected and considered is considerable, in Table 1 only those variables that show significant[1] relationships with the dummy variable are reported, with the (positive or negative) signs of their relation as highlighted in the very last column.

Table 1 – Correlations: summary of results

Variable	Variable	Positive or negative relationship
Company status	No. of board members (2007-2011)	-
Company status	No. of CEO (2015-2018)	-
Company status	No. of Sole Directors (2007-2011)	+
Company status	No. of Sole Directors (2015-2018)	+
Company status	No. of Liquidators (2015-2018)	+
Company status	President of BoD (2015-2018)	-
Company status	Sole Directors average term of office	+
Company status	Board of Directors average term of office	+
Company status	Z-score (2007-2011)	-
Company status	Z-score (2012-2014)	-
Company status	Z-score (2015-2016)	-
Company status	Z-score (2007-2011) Revised	-
Company status	Z-score (2012-2014) Revised	-
Company status	Z-score (2015-2016) Revised	-

[1] *Correlation is significant at 0.01 level (two-tails).*

It must be emphasized that the consistency of *Z-Score* configurations varies over the years. It is interesting to note that despite the inclusion of the 2007-2011 financial crisis period in our analysis, the z-score of this period is not actually significantly related to the status of the companies. This allows us to conclude that the financial results of that period do not distort the analyses of subsequent periods (or even that the crisis that the companies went through was not predictable through the z-score observable between 2007 and 2011).

For all the periods under analysis, there seems to be a significant negative relationship between the value of the score and the status of the company. This is consistent with the conceptual approach of the score, which involves the association of scores that are as high as the probability of company insolvency is low. The state of the company is here approximated with a dummy variable (0 = healthy company, 1 = recovered or ceased enterprise), and its relation to the score seems to confirm this hypothesis.

Following the correlation analysis, all the variables with significant correlations have been included in two regression models:

- The first model includes the analysis of the *Z-Score* in its original formulation;
- The second model includes the analysis of the *Z'-Score* in its *revised* version.

The regression analysis aims to create a better understanding of the causal link between the variables.

6.1 Model 1

Among the explanatory variables, *Model 1* accounts for the *Z-score* in its original formulation and the *governance* variables that were significant in the correlation analysis. The main data concerning the model are summarized below in Table 2 R-square value of the model is 0.315.

Table 2 - Regression results: Model 1

Model	R	R-square	R-square adjusted	Standard error
1	,561a	,315	,289	,39664

Model		Non-standard ratios		STANDARD RATIOS		
		Beta	Standard error	Beta	T	Sign.
1	(Steady)	,832	,080		10,466	,000
	Sole Directors (2007-2011)	,092	,052	,108	1,768	,079
	Liquidators (2015-2018)	,112	,061	,110	1,829	,069
	President of BoD (2015-2018)	-,107	,043	-,150	-2,472	,014
	Zscore0711	,060	,032	,157	1,855	,065

	Zscore1214	-,158	,033	-,450	-4,855	,000
	Zscore1516	-,032	,018	-,127	-1,786	,075
	BoD average term of office	,015	,005	,174	2,900	,004

a. Dependent variable: status

The results of the regression analysis, expressed by the level of significance, and the sign of the standardized Beta coefficient confirm the relationship between the *Z-Score* and the status of the company. Indeed, there is a significant negative relationship between the average value of the *Z-Score* in the years 2012-2014 and the *status* of the company. The lower the score, the higher the probability that a UTP emerges.

Therefore, the model confirms the ability of the *Z-Score* tool to predict the status of a company, at least on time horizons that extend to two years earlier than the occurrence of UTP. The results, however, lose significance if extended to wider horizons (Average value of score between 2007 and 2011).

The analysis reveals significant relationships with the corporate governance variables, included here as non-financial control variables. Therefore the model provides suggestions for further research where non-financial variables could be used.

6.2 Model 2

Model 2 arises from the need to include the *Z-Score* in its revised version in the analysis. With respect to model 1, therefore, the only variables which were substituted are those related to the *Z'-Score*. Non-financial control variables remain unchanged (Table 3).

Table 3 – Model 2: Regression results

Model	**R**	**R-square**	**R-square adjusted**	**Standard error**
2	,491a	,241	,213	,41728

Model		**Non-standardized ratios**		**Standardized ratios**		
		B	**Standard error**	**Beta**	**t**	**Sign.**
2	(Steady)	,921	,088		10,488	.000
	Sole Directors (2007-2011)	,115	,054	,136	2,114	.036
	Liquidators (2015-2018)	,101	,064	,099	1,575	.117
	President of BoD (2015-2018)	-,158	,044	-,223	-3,570	.000
	Z-Score 2 0711)	-,061	,029	,114	1,111	.037
	Z-Score 2 1214)	,016	,006	-,356	-3,395	.005
	Z-Score 2 1516)	,020	,018	-,109	-1,541	.268
	BoD average term of office	-,012	,008	,179	2,831	.125

a. Dependent variable: status

The results of *Model 2* largely overlap with those of Model 1 in terms of sign and significance of relationships. Relationships with *corporate governance* variables are maintained. The relationships between the status of the company and the *Z'-Score*, this time in the *revised* version, are maintained as well.

To further test the obtained results, we proceeded to verify the statistics following a double path: Firstly, a verification of the model on a sample represented only by healthy or restructured companies is implemented. This assessment was necessary as the dummy variable used until now (which is dichotomous) actually contains three different possible statuses related to the company (healthy, restructured or ceased). The implemented verification grants a better matching of the conditions under which the company lies (healthy or restructured) with the values associated to the dummy variable (0 and 1). The verification was carried out both for the *Z'-Score* and for the *Z"- Score*. The results, as reported in Table 4 and 5, are confirmed both in terms of significance and signs of the relationship.

Table 4 - Regression results: Z'-score for healthy and restructured companies.

Model		Non-standardized ratios		Standardized ratios		Sign.
		B	Standard error	Beta	t	
1	(Steady)	,646	,109		5,949	,000
	Sole Directors (2007-2011)	,080	,102	,061	,784	,435
	Liquidators (2015-2018)	,084	,467	,014	,180	,857
	President of BoD (2015-2018)	,038	,061	,046	,619	,537
	Z-Score 1 0711	,018	,047	,046	,388	,698
	Z-Score 1 1214	-,157	,047	-,433	-3,321	,001
	Z-Score 1 1516	-,014	,022	-,058	-,623	,534
	BoD average term of office	,017	,007	,210	2,518	,013

a. Dependent variable: status

Table 5 - Regression results: Z"- score for healthy and restructured companies.

Model		Non-standardized ratios		Standardized ratios		Sign.
		B	Standard error	Beta	t	
1	(Steady)	,667	,112		5,983	,000
	Sole Directors (2007-2011)	,069	,107	,053	,648	,518
	Liquidators (2015-2018)	,132	,467	,022	,282	,779
	President of BoD (2015-2018)	,039	,062	,048	,638	,525
	Z-Score 2 0711	,030	,024	,176	1,275	,205
	Z-Score 2 1214	-,083	,023	-,515	-3,569	,000
	Z-Score 2 1516	-,007	,009	-,069	-,749	,455
	BoD average term of office	,017	,007	,208	2,469	,015

a. Dependent variable: status

Then, a second verification considered a control sample extrapolated from the original one in order to verify the permanence of the levels of significance, even for a random sample of observations taken from the original sample. In particular, the control sample considered 51% of the observations of the original sample, selected randomly by the

SPSS software. In this case too, the verification was made both on *Z'-Score* and on *Z"-Score*. The results are reported in Table 6 and 7.

Table 6 - Regression results: Z'- score for the control sample.

Model		Non-standardized ratios		Standardized ratios	t	Sign.
		B	Standard error	Beta		
1	(Steady)	,578	,121		4,794	,000
	Sole Directors (2007-2011)	,082	,108	,067	,754	,452
	Liquidators (2015-2018)	,032	,472	,006	,068	,946
	President of BoD (2015-2018)	,042	,066	,054	,628	,532
	Z-Score 1 0711	,045	,054	,117	,836	,405
	Z-Score 1 1214	-,181	,056	-,475	-3,230	,002
	Z-Score 1 1516	-,014	,023	-,061	-,608	,545
	BoD average term of office	,020	,007	,252	2,668	,009

a. Dependent variable: status

Table 7 - Regression results: Z"- score for the control sample.

Model		Non-standardized ratios		Standardized ratios	t	Sign.
		B	Standard error	Beta		
1	(Steady)	,636	,124		5,112	,000
	Sole Directors (2007-2011)	,047	,113	,039	,416	,678
	Liquidators (2015-2018)	,150	,467	,028	,322	,748
	President of BoD (2015-2018)	,055	,066	,072	,836	,405
	Z-Score 2 0711	,040	,025	,234	1,590	,115
	Z-Score 2 1214	-,099	,026	-,571	-3,750	,000
	Z-Score 2 1516	-,006	,009	-,059	-,601	,549
	BoD average term of office	,017	,007	,220	2,296	,024

a. Dependent variable: status

Also in this case, the results are confirmed both in terms of signs and significance of the considered variables.

7 Conclusions

Despite the low diffusion and use of adequate predictive indicators in managerial and banking practice, this work confirms the predictive ability of one of the existing models, specifically Altman's *Z'-Score*.

Having reached statistically significant results on a unique sample of companies, this paper confirms that the *Z'-Score* can not only predict bankruptcy, but also the inability to make earlier debt repayments, approximated by the occurrence of Unlikely to Pay (UTP), which is the discriminating and innovative criterion used in our study.

Further relevant results that could be useful for the development of future research, emerged from the analysis.

With particular reference to the *corporate governance* variables, included in our study as control variables, we found a number of interesting relationships. The topic has strong relevance given the limited literature on the matter (Baysinger et al., 1985; Denis et al., 1995; Himmelberg et al., 1999; Huson et al., 2004; Fahlenbrach et al., 2007). This is a research gap to be filled by further research that is focused on corporate governance within corporate restructuring processes.

8 Research limitations and future researches

The work suffers from several problems. First, an issue relating to the national context emerges due to the fact that all the companies included in the sample are based in Italy. Further research could analyse different context, with companies and banks of other countries. The size of the sample used is another limitation that can be solved by future research. However, in the absence of publicly available data on UTP, the use of confidential information, both important and limited, becomes necessary. This problem, we believe, is likely to be common to any research that wants to investigate the characteristics of companies that are classified among UTPs within the banking information system. Based on the dataset sample used we will examine in future researches more advanced techniques such as neural networks, support vector machines (SVMs) and "new age" statistical learning models, including generalised boosting and random forests.

Variables definition

- Z-score (2007-2011) refers to the average score in the period before the crisis (2007-2011);
- Z-score (2012-2014) refers to the average score in the period during the crisis (2012-2014);
- Z-score (2015-2016) refers to the average score in the period after the crisis (2015-2016);
- Z-score Revised (2007-2011) refers to the average revised version of the score in the period before the crisis (2007-2011);
- Z-score Revised (2012-2014) refers to the average revised version of the score in the period during the crisis (2012-2014);
- Z-score Revised (2015-2016) refers to the average revised version of the score in the period after the crisis (2015-2016).

Control variables[1] are defined below:

- Number of board members (2007-2011): number of people who took the role of member of the Board of Directors in the period prior to the crisis (from 2007 to 2011);
- Number of CEO (2015-2018): number of people who took the role of CEO Chief Executive Officer in the period following the crisis (from 2015 to 2018);
- Number of Sole Directors (2007-2011): number of people who took the role of Sole Director in the period prior to the crisis (from 2007 to 2011);
- Number of Sole Directors (2015-2018): number of people who took the role of Sole Director in the period following the crisis (from 2015 to 2018);
- Number of Liquidators (2015-2018): number of people who took the role of judicial Liquidator in the period following the crisis (from 2015 to 2018);
- President of BoD (2015-2018): number of people who took the role of President of the Board of Directors in the period following the crisis (from 2015 to 2018);
- Sole Directors average term of office: average duration of the role of Sole Director;
- Board of Directors average term of office: average duration of the role of Board Member.

[1] *Please note that we report only the definitions of the control variables that show a significant correlation with the dummy variable and that are therefore subsequently used in the regression.*

Diversity Potentials or Diversity Challenges? Attitudes towards Refugees under the influence of Intercultural Contact and Acculturation Strategies

Abstract

Because of the development of migration during the last past years, this paper's objective is to identify and/or confirm factors, which predict the development of prejudices. With Germany as a preferred destination of many refugees, the research focuses on German students and their attitudes towards people with migration background. This study examines if the construct of social identity is a possible predictor for prejudices. Thereby, it also examines if there is a moderator effect of contact quality and contact quantity.
The results indicate the importance of contact quality und contact quantity in reduction of prejudices, but the effects were only significant for some of the tested models. Because of the relatively weak manifestation in the study at hand, alternative instruments should be used for investigation.
Based on the obtained results this paper finally tries to give some guidance for the facilitation of diversity and reduction of prejudices at higher education institutions.

Keywords – migration, social identity, acculturation strategies, ethnic identity, prejudices

Paper type – Academic Research Paper

1 Introduction

Since recent years, one topic dominated news headlines: migration. A vast amount of people is escaping from war and conflict and is driven from their home country. In Europe, the numbers of asylum seekers also rose extremely. Especially Germany accepted a high number of involuntary migrants. The number of asylum applications peaked with

745.545 in 2016, but strongly declined since then (BAMF [Bundesagentur für Migration und Flüchtlinge, English: Federal Office for Migration and Refugees] 2018).

Integration of the newly arrived citizens constitutes itself is the greatest challenge. A variety of populations with different cultural background now lives in Germany and is part of the German society. At the same time, research confirms that with increasing social and cultural diversity, prejudices between the groups increase as well (Benz & Widmann 2007). Prejudices in turn, are obstacles for a successful integration. Mostly, those prejudices are unjustified.

It becomes clear that for a successful integration, prejudices need to be removed or at least reduced in European societies. In order to do so, factors that influence the development of prejudices need to be identified. Measures to reduce prejudices can only be taken, if the circumstances are clear, in which such negative beliefs can flourish. Therefore, this undertaking has the endeavor, to identify and/or confirm factors, which ought to play a role in the development of prejudices. While the confirmation of relationships between factors does not bring societal change itself, the paper will advocate for appropriate measures, which can be derived from the findings.

Within the scope of this project, the research group investigated the attitudes of students in Germany towards migration and therefore conceptualized a survey for German students and students with migration background. The researchers scrutinize the construct of *social identity* as well as the influence of *contact* with the group of people with migration background. The highlighted issue and possible connections are extensively investigated in this academic work and recommendations for action concerning integration are derived.

2 Rationale

Dovidio, Hewstone, Glick and Esses (2010) recognized that prejudices should be viewed as a result of processes that happen in every individual. Overall, prejudices are considered hostile attitudes towards members of a group, which are caused solely by their group membership (Aronson, Wilson & Akert 2008). In general, people mention prejudices together with stereotypes, whereby both terms need to be separated. People develop stereotypes in the framework of cognitive processes, which serve simplification and which are necessary, to categorize the multitude of environmental stimuli (Aronson et al. 2008). Hereby, it is a matter of generalizing assumptions about traits of a group and its members, which can be either positive or negative. Prejudices on the other hand are mostly described as negative and rather affective manifestations of attitudes (Duckitt 1992).

Pettigrew and Meertens (1995) developed a theory, which differentiates between covert and overt prejudices. Whereas covert prejudices are direct and can be articulated, covert prejudices are defined as indirect negative attitudes towards the outgroup. Underlining cultural differences and one's own traditional values expresses this.

There is a vast amount of theories regarding the origin of prejudices. However, as a more emotional aspect of prejudice the study takes xenophobia into consideration. While xenophobia is an extended version of prejudice. It is coined mostly by fear against members of the outgroup, regarding a variety of possible issues of threat, and aggression against the outgroup (Bolaffi 2003). Consequently, it is in the scope of this study as a third component next to covert and overt prejudice.

The following paragraph will explain other constructs, which are investigated in connection to the development of prejudices other constructs and therefore are relevant for this work. How people perceive others depends on how people see themselves and how they categorize themselves. In this context, identity plays a major role.

Identity is a multi-layered and partly highly debated concept, which relates to the feeling of who we are and to which groups we belong (Hall 2003). Identity comprises, the personal identity, which separates us from other individuals and the social identity. Social identity influences the self-concept through membership in social groups (Simon & Troetschel 2007).

According to Wenger (1998), people define themselves through familiar and comprehensible things and separate ourselves from unfamiliar and ambiguous things. In this context, the cultural distance is important. With greater cultural differences of sojourners and host country nationals, the line between ingroup and outgroup rises and consequently the *gap* between both groups grows (Schaefer & Simon 2017).

Tajfel (1981) defines the construct social identity in his theory as part of the self-concept, which is derived from the knowledge and belonging to a group. It goes hand in hand with the value and the emotional meaning, the sense of belonging the individual has. Building on this, Schwartz, Montgomery and Briones (2006) describe ethnic identity as subjective meaning of one's own ethnic sense of belonging and feelings one has towards this group. The individual has a say in his/her feeling of belonging, whereas the ethnicity is pre-determined at birth by the origin of the parents (Phinney 1992).

By reviewing the definition of prejudices as intergroup phenomenon, the relationship between people as cause for prejudices becomes apparent. In the scope of social comparison and appreciation processes, which serve the purpose of enhanced self-confidence, self-categorization into groups is an essential motivational factor for prejudices (Turner & Hewstone 2012). Transferring this to group differences between German host country nationals and migrants in Germany, ingroup/outgroup thinking is most likely to occur. This research results show that the construct of social identity is of high relevance. Therefore this study considers social identity as a possible predictor for prejudices.

The construct acculturation describes the change of cultural patterns of groups of individuals, which is caused by the persistent and direct contact with unfamiliar cultures (Berry 1990). Such changes can happen either one-sided or bilateral between both groups. According to Berry (1990), such changes depend on expectations, which respective group members have about the relationship towards the other group (van Dick, Wagner, Adams,

& Petzel 1997). This can be the conviction that cultural differences like the ethnic identity in a community should be kept on the one hand or abandoned on the other hand.

With his work *The Nature of Prejudice* (1954), Allport was one of the first researchers, who saw the contact between different ethnic groups as a chance, to reduce prejudices (Salzborn 2016). He stated four situational premises, which need to be given, so that contact can lead to a reduction of prejudices. Next to the equal status of both distinct groups, according to Allport (1954) the different groups need to focus the same goals or values, without competition between themselves. Finally, the support of authorities is also required. This theory became known under the name of *contact hypothesis*. Today, it is a well-established theory in social psychology (Salzborn 2016). Yet, it was found that not all of Allport's four premises have to be present. Indeed, this premises facilitate the reduction of prejudices.

Brown and Hewstone (2005) added that group salience is essential for the change in perceiving the outgroup. Based on these research results, this study implements the contact hypothesis and transfers it to the contact between migrants and German students.

3 Research Question, Hypotheses & Measurement Instruments

3.1. Research Questions and Hypotheses

Building on the current literature this study aims to identify factors, which influence prejudices towards migrants. In more detail, the research question is: *Which factors predict of prejudices?*

Hereby, *the development* the study wants to investigate the dynamic relationship between variables. Target group are students, since a substantial part of this societal group will be the decision makers of tomorrow. However, the researchers to not exclude participants of other age category.

It is necessary to consider the respective influences of social identity and ethnic identity when investigating the development of prejudices. Thereby, the researcher split prejudices into overt and covert prejudices as well as xenophobia. Moreover, the aim is to receive a comprising picture of the construct *prejudice*.

For the same reason, the researcher measure the constructs of social identity and ethnic identity as two different concepts. Additionally, the study scrutinizes, how far the relationship between the named independent variables and the development of prejudices depends on the extent of contact to migrants. Following this, the current work investigates the meaning of social identity in relationship to the development of prejudices.

Based on this, the researcher build the first hypothesis:

> *H1: There is a relationship between social identity and prejudices towards migrants: the identification with the ingroup predicts overt and covert prejudices towards migrants and the manifestation of xenophobia.*

Research on the contact hypothesis provides evidence that frequent contact and qualitatively high contact (positive experiences) with people of different cultures and ethnicities can reduce prejudices and therefore improve intercultural communication (Allport 1954; Pettigrew 1998; Gómez, Tropp & Fernández 2011; Miles & Crisp 2014). Hence, the researchers expect that contact, moreover contact quantity and contact quality, have a moderating effect on the influence of the independent variables on prejudices. It follows the second hypotheses:

> *H2: Contact to migrants moderates the relationship between the investigated independent variables and the prejudices against migrants. Thereby, contact quality and contact quantity are independent moderators.*

3.2. Measurement Tools

The researcher measured the ethnic identity with the MEIM (Multigroup Ethnic Identity Measure). Phinney (1992) conceptualized this scale to inquire the ethnic identity of participants with different cultural heritage. Consisting out of 20 items, 14 items measure the ethnic identity with subscales for *Affirmation and Belonging* (confirmation and belonging), *Ethnic Identity Achievement* (extent of the ethnic identity) and *Ethnic Behaviours*. This study used all subscales of the MEIM in combination with open questions for ethnic group membership and questions about the ethnicity of the participant In the latter, there were four possible answers: (1) *I see myself as German*; (2) *I see myself as migrant;* (3) *I see myself as ethnic German immigrant to Germany;* (4) *open answer*. Those answers were adjusted for the target group of Germans and for migrants living in Germany. The researcher excluded the two items for ethnicity of the parents of the MEIM in this study.

To assess the identification of the participants with their ingroup, the researchers used the *Social Identity Scale* by Orth, Broszkiewicz & Schütte (1996). The scale consists out of 16 items, which include questions for the subscales of *Polish identity, German identity* and *binational identity*. The questionnaire uses a seven-point Likert scale. The authors emphasize that it is possible to transfer the scales to other ethnic groups as well (Orth et al. 1996).

For assessing impact of contact to refugees, the researcher chose the *General Intergroup Contact Quantity and Contact Quality Scale* by Islam & Hewstone (1993). This scale includes five items for each, *contact quantity* and *contact quality*. The contact quantity measures the frequency of contact in different settings.; the contact quality measures if the encounter was experienced as positive or negative.

In order to measure prejudices towards the group of refugees, the researchers use the *Blatant and Subtle Prejudice Scale* (Pettigrew & Meertens 1995). The scale entails 20 items of which one half measures overt prejudices and the other half measures covert prejudices. Further, the researchers divided overt prejudices into *threat and rejection* and

low familiarity. Covert prejudices differ in terms of the factors *defense of traditional values*, *exaggeration of cultural differences* as well as *denial of positive emotions.*

To assess xenophobia, this study included the short version of the eponymous scale *Xenophobia* was chosen (Wetzels, Gabriel & Pfeiffer 1998). This scale entails nine items, based on a four-point Likert scale. The researchers calculate the internal consistency in form of Cronbach's Alpha for the three different target groups resettler, migrants and native Germans. The values were $\alpha = .62$, $\alpha = .55$ and $\alpha = .83$.

3.2 Sample

In total, 699 people completed the survey. Therefore, the researchers used an online survey. Indeed, they recruit participants via social online networks such as Facebook, Xing and LinkedIn. With 69.8 %, about two thirds of the sample are female, 30.2 % are male. In total, 84.9 % are studying. The average age was 25.68 years (SD = 4.61), whereby the range between the youngest (16 years) and the oldest (50 years) is quite big. 89.9 % were born in Germany and 10.1 % in a foreign country. The distribution of subjective sense of belonging is almost identical, whereby the majority state to be German with 80.9 %. 19.1 % state that they have a migration background.

4 Results

4.1 Hypothesis 1

This hypothesis presumes a relationship between social identity and prejudices. This hypothesis is directed and assumes that prejudices increase with higher manifestation of social identity. The degree of identification with the ingroup strongly predicts the overt prejudices for the group without migration background ($\beta = .70$, $p < .01$). There is no significant relationship for the group of people with migration background.

For people without migration background, identification with the ingroup is a strong predictor for covert prejudices ($\beta = .54$, $p < .01$) as well. The relationship for people with migration background ($\beta = .28$, $p < .05$) is weaker, but exists. These results support the claim that stronger identification with the ingroup increases covert prejudices, regardless of group membership. Nevertheless, H1 can be only fully confirmed for the group of people without migration background.

4.2 Hypothesis 2

Furthermore, this study examines how strongly the impact of group contact to migrants concerning contact quantity and contact quality influences the relationship. Therefore, the researchers use a moderation analysis with respective independent variables as predictors and respective types of contact as moderators. To test for moderated mediation amongst

the independent variables, they use the Macro *PROCESS Version 3.1* by Andrew F. Hayes and Cai (2007). AS mentioned before, this study assumes that the mentioned independent variables influence prejudices. However, they also might have effects on each other, therefore distorting the direct effects on prejudices. Based on this, the researchers produced 36 possible combinations of dependency among the factors.

The analysis shows, that only seven of those 36 tested models are significant.

Five out of six models concerning the combination of the independent variable acculturation strategy, the moderators contact quality and contact quantity as well as the three dependent variables with manifestations of prejudices, overt and covert prejudices and xenophobia were significant with p <.01. An overview of the combinations is provided in table 1.

The results demonstrate that there is an interaction effect between the predictors of acculturation strategy and the contact quantity in relationship to overt prejudices. This model explains 55 % of the total variance (p < .01). The interaction effect with p <.01 is highly significant as well. The same applies to covert prejudices as criterion. The explained variance of this model is at 41% and with p <.01. Therefore, the model is highly significant. The interaction effect with p = .02 is also significant. Finally, the researchers test the combination of contact with manifestation of xenophobia. Again, the model is significant with p <.01 and can explain 45 % of the variance. Surprisingly, contact quantity had no direct effect on xenophobia and is insignificant (p = .10). On the other hand, the interaction effect between contact quantity and acculturation strategy on xenophobia is significant with p < .3. This shows, that contact quantity together with acculturation strategy can predict xenophobia.

Exemplary, figure 1 displays the moderation effect of contact quantity and covert prejudices. For the moderation variable contact quality, the results show significant interaction effects for acculturation strategies. In relationship to overt prejudices the model explains 65 % of the variance and is significant with p <.01. The interaction effect between acculturation strategy and contact quality on overt and covert prejudices is also significant with p <.01. The interaction of contact quality and acculturation strategy on xenophobia, is not significant (p =.11) this was found to be not significant, wherefore no interaction effect is assumed. Regarding the criterion xenophobia, p <.01 and an explained variance of 57 % could be found. The interaction term is also p <.01 and subsequently highly significant. Exemplary, the influence of contact quality on the relationship between acculturation strategy and overt prejudices can be found in figure 2. It seems that the effect of acculturation strategy on different subtypes of prejudice is moderated by contact quality and quantity.

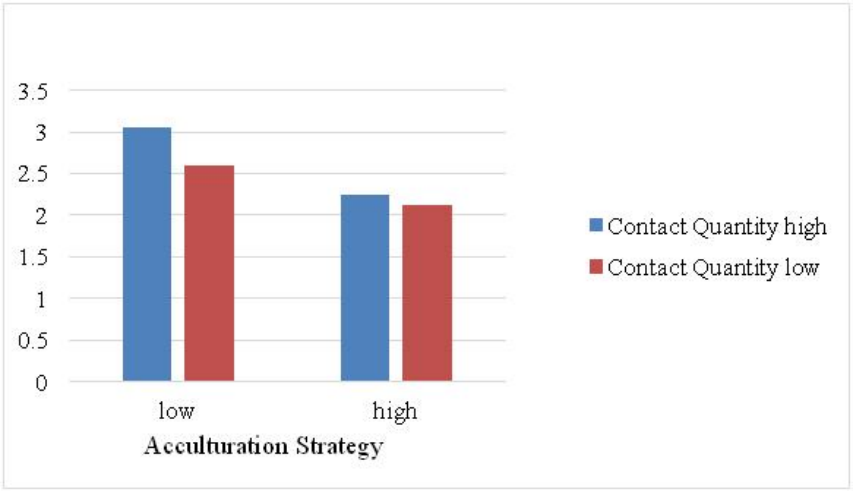

Fig. 1 Influence of contact quantity on the relationship between acculturation strategy and covert prejudices (own depiction)

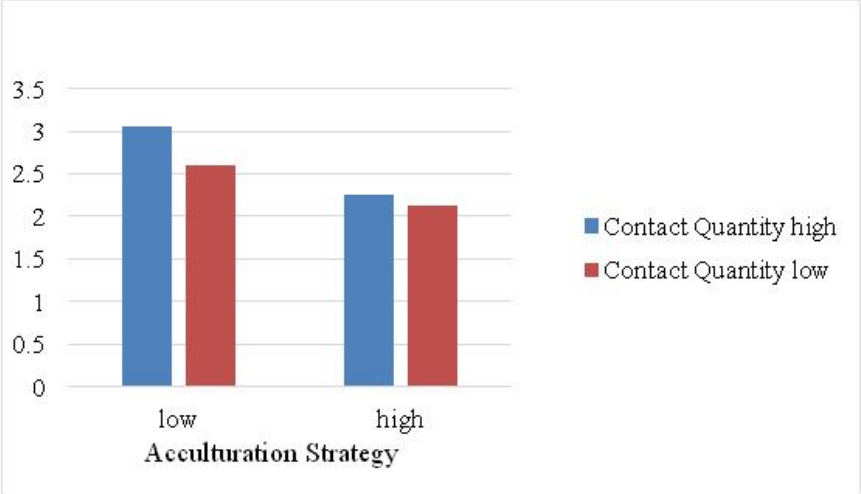

Fig. 2 Influence of contact quality on the relationship between acculturation strategy and overt prejudices (own depiction)

Table 1 Moderation analysis, predictor acculturation strategy

		coefficient			model

	Contact Quantity	-.04	.03	.10			
	Interaction	.07	.03	.03			
	Acculturation	-.25	.04	<.01	.57	60.04	<.01
	Contact Quantity	-.13	.02	<.01			
	Interaction	.08	.02	<.01			

Notion: centralized mean predictors, standard error HC3-corrected

Identification with the ingroup (social identity) of people without migration background (Germans) is another predictor, where the results show a significant effect. For the variables social identity and prejudices the researchers confirm two models with the moderator variable contact quality. Concerning overt prejudices, the explained variance is 62 %. With p <.01 the model is significant. The interaction effect is significant as well (p <.01). In addition, concerning the impact of the manifestation of xenophobia the results show a significant interaction effect with p <.01. Figure 3 displays the influence of contact quality on the relationship between identification of the ingroup for people without migration background (Germans) and overt prejudices as an example. Table 2 provides an overview of the values. Apparently, the effect of social identity on the development of overt prejudice for the German subgroup partially depends on the quality of the contact this group experienced with migrants.

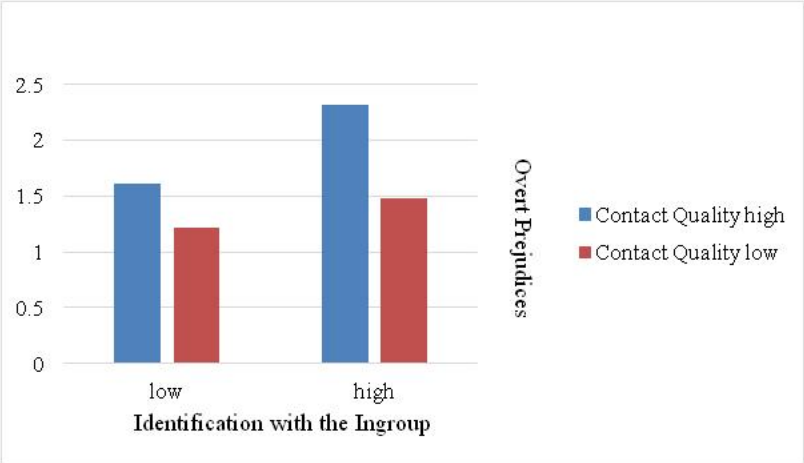

Fig. 3 Influence of contact quality on the relationship between identification with the ingroup (DE) and overt prejudices (own depiction)

The researchers find quite similar results for possible interaction effects between social identity and contact quality and two subcomponents of the prejudice construct. For both, overt prejudices and xenophobia, table 2 presents the statistical output. It is to note, that the explained variance of both models is virtually identical.

Table 2 Moderation analysis – predictor identification with the ingroup of people without migration background

		coefficient			model		
K		**β**	**SE**	**p**	**R^2**	**F**	**p**
Overt	Social Identity (DE)	.17	.02	<.01	.62	77,16	<.01
	Contact Quality	-.24	.03	<.01			
	Interaction	.06	.02	.01			
Xeno	Social Identity (DE)	.14	.02	<.01	.60	61.79	<.01
	Contact Quality	-.19	.03	<.01			
	Interaction	-.05	.01	<.01			

Notion: Centralized mean predictors, standard error HC3-corrected

Unfortunately, the other models are not significant. Therefore they need to be rejected. It was investigated how different independent variables affect the dependent variables while considering moderation variables. The results confirm that contact quantity and quality play a crucial role for several models and that the effects are significant. However, this is only true for distinct combinations with acculturation strategies and identification with the ingroup of people without migration background. Hence, H2 can only be partly confirmed.

5 Interpretation

First, it is to say that although this study obtains significant relationships between prejudices and other factors, the strength of those prejudices seems questionable. Evaluation of the scale shows that the identification of German participants with the German ethnicity is not strong. Despite the current trends, to build borders, many young people seem to have a different self-concept. The often chosen identification with the ethnic group *Human* indicates that they also see other people as human and do not separate them based on culture. Herefore, there is a need of further research, especially in comparison to different age groups and geographical regions.

Concerning the group of people with migrational background, this study obtains no or very weak relationships regarding the manifestation of prejudices. Overt prejudices and xenophobia are not related to the social identity of people with migrational background. In contrast, there is a significant effect on covert prejudices. The study assumed that people with migration background had fewer prejudices towards the other group (Germans), since immigrants more often bear the negative consequences of prejudice and xenophobia (Van Laer & Janssens 2011). The results do not confirm this assumption. Instead, it seems that people with migration background do not openly state their aversion towards other cultures (overt prejudices), but still have them to a small degree. It is to note that the sample of people with migration background is small (38 participants). Further investigations with bigger sample sizes are necessary to draw valuable conclusions.

The researchers expected main effects of the variable social identity on the different types of prejudices. The analysis confirms this. Higher identification with the ingroup predicts higher levels of all prejudice types. According to that it seems valuable to establish interventions that reduce ingroup thinking and facilitate cultural intelligence and more open acculturation strategies to reduce prejudices.

Moreover, this study observes moderation effects about identification with the ingroup (social identity). However the analysis only confirms this for the group of people without migration background (German students) and the moderator variable contact quality. The results demonstrates that positive contact with refugees reduced prejudices – even if identification with the ingroup remains very high and prejudices are rather strong. For the social identity the results show that the contact quality could reduce prejudices. However, there is no moderation effect of contact concerning covert prejudices. This effect is still not present, if the model is tested with regard to people with migrational background.

Next to the testing of the derived hypotheses, the analysis of the data reveals that there is considerably low contact between German students and migrants. This is an insight, which gives need for further research in regard to the questions why there is only low levels of contact to this group. Including refugees and migrants in society related activities like sport clubs and entertainment events could enhance both – the contact quantity and the contact quality. In addition, further studies need to obtain comparable

data to other target groups such as working persons, elderly and parents, to confirm the general relevance of the tested factors.

Overall, the extent of this study has to be critically evaluated. Through the multitude of constructs, this study includes many factors, which cannot be investigated sufficiently enough. This represents the timely limitation of this undertaking. The researchers measured the constructs with several subscales respectively, which enable to get a differentiated view on the relationships. However, this makes the survey quite extensive. Furthermore, scales like the MPQ or the MEIM contain different sub-dimensions, which cannot be highlighted because of the limitation of the work. For this matter, future research could scrutinize less constructs more differentially or investigate them in a scope of a more extensive work that addresses all variables in more detail.

In addition, regarding the content of the questionnaire, some participants gave critical feedback. Participants often stated that the term *ethnicity* was not further defined. Many people did not have a concept of this term, which refers to the answer possibility: *To which ethnic group do you allocate yourself?*

Finally, further research need to review the reciprocities in both directions and influences of the independent variables in more detail. Thereby, it is possible to assume an influence of social identity on acculturation strategy and prejudices, but also in combination with contact (Badea et al. 2018). The significant interaction terms indicate that the effect is also retroactive. For instance, prejudices can also lead to less contact and therefore affect the acculturation strategies. In conclusion, the influence contact, in form of contact quantity and quality, needs to be investigated in detail.

Furthermore, the distribution of the contact quantity could have affected the results. As already mentioned, this dimension was lowly developed for most participants and caused by the rare manifestation of high contact frequencies. Subsequent, it was difficult to make valid assumptions about the relationships.

5.1 Advice for Implication

The high number of refugees, which came to Germany in the past seven years, poses challenges for natives as well as for refugees. Up to this date, integration has proven to be a successful model to bring benefits to the economy (Batsaikhan et al. 2018). The success of integration depends on different factors. Behaviours and attitudes of people towards other cultures and different social identities all are important for the dynamic interplay between the individual and the unfamiliar environment. These dynamic processes are visible at e.g. internationally orientated universities, where contact between students with different cultural backgrounds is part of the concept.

From the results obtained in this work, it is possible to generate several guidance's regarding the facilitation of diversity and the reduction of prejudices at the higher education institutions. Social identity, or the degree of identification with the ingroup act as important variable concerning the manifestation of prejudices. The development of a

shared identity in the sense of identifying with a bigger group that includes people with different heritages has a positive relationship with reduced prejudices. Projects with refugees or projects and partnerships with international universities, which bring people and students from different nations together and let them work for a shared goal, can promote this.

Finally, meetings of this kind can be accompanied by pre- and post-courses with the topic of cultural intelligence and social identity. Knowledge about psychological processes during group formation and meetings with unfamiliar people as well as viewing respective processes on a meta level can enable students to critically reflect about their behaviour and their thoughts in such situations. Additionally, such courses can communicate a positive view on values, traditions and norms of other cultures, which makes the bridge to the acculturation. Shared projects as such do not only have the advantage that they can include many variables, but also facilitate direct contact.

During the analysis of the survey it became eminent that the extent of contact between students and refugees is very low, which gives food for thought. Even if contact can only restrictively compensate negative influences of other variables, contact programs have demonstrated to be one of the most successful approaches for the reduction of prejudices (Brown & Hewstone, 2005; Pettigrew & Tropp 2006). Shared projects with refugees would therefore promote contact and at the same time offer the possibility to exchange information about the universities and their access.

Foresightedly, measures like this indirectly facilitate the integration of migrants at the workplace and at educational institutions. It becomes obvious that for a successful integration and facilitation of all variables, which are in relationship to the reduction of prejudices, overarching projects/programs are necessary. As proven this study, it is necessary to consider influences of individual and interpersonal factors in order to foster cooperation in a multicultural society.

Abstract

Climate change mitigation is the central challenge of the 21st century. An increasing proportion of economic and psychological applied research addresses the question of how to encourage people to adopt more climate-friendly behaviour (Pettman und Zabel 2005; Schmitt 2018; Stoknes 2015; Thaler und Sunstein 2008).
Although many people think it is important to protect the environment and have a stable pro-environmental behavioural intention, this is reflected only to a limited extent in specific environmental behaviour (Bundesministerium für Umwelt und Naturschutz und nukleare Sicherheit (BMU) 2019).
The present explorative study addresses the question of which measures could foster everyday climate-friendly behaviour. The study focuses on an evaluation of the measure "Klimaschutzbürger 2.0" ("Climate Protection Citizens 2.0") undertaken by a local authority in Germany.
The explorative study, in which qualitative and quantitative interviews were conducted to generate hypotheses, took place as a participating observation of the last workshop meeting with subsequent written questioning of the participants. Special attention was paid to the question of whether online services such as climate change mitigation apps have a positive impact on behavioural intentions.
The primary data collected enable hypotheses to be generated, facilitating the further exploration of the predictors of environmentally responsible behaviour in subsequent projects.

Paper type: Academic Research Paper

1 Introduction

Almost two thirds of the German population consider environmental and climate protection to be an elementary prerequisite for coping with future tasks (Bundesministerium für Umwelt und Naturschutz und nukleare Sicherheit (BMU) 2019). In studies by the European Comission it was found out that the protection of the environment is important for around 95% of the EU-citizens (Kopatz, 2018). Although environmental protection is widely accepted as a value, this often does not change everyday behaviour (Hellbrück and Kals 2012, p. 95).

A growing part of ecological and psychological applied research is devoted to the question of how people can be encouraged to adopt more environmentally friendly behaviour (Stoknes 2015; Schmitt 2018; Thaler and Sunstein 2008; Pettman and Zabel 2005; Waskow and Pannenbecker 2013).

2 Theoretical Background

2.1 Environmental awareness

Environmental or climate awareness is a multidimensional construct.

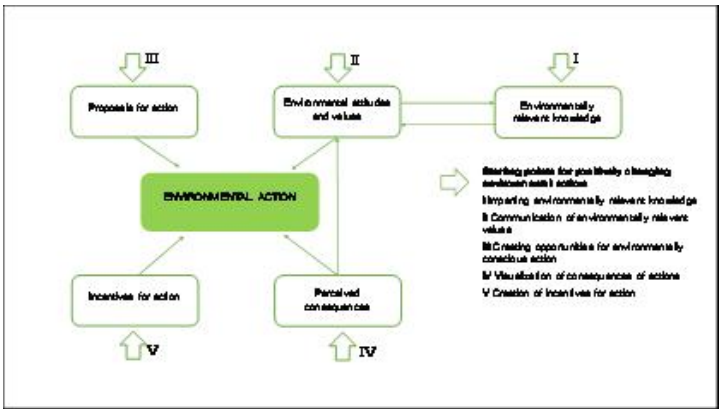

Figure 1: Influence scheme for environmentally conscious action after Fietkau and Kessel (1981)[1]

In the model by Fietkau and Kessel (1981), environmentally conscious action is explained by the interaction of five factors: environmentally relevant knowledge, environmental attitudes and values, offers for action, perceived consequences of one's own behaviour and incentives for action. Knowledge only has an indirect influence on

[1] *With slight changes quoted from Hellbrück and Kals 2012, p. 105*

environmentally relevant actions and is brought to bear via attitudes and values (Waskow and Pannenbecker 2013).

Five basic approaches to changing environmental behaviour are assigned to each of the five influencing factors mentioned: Imparting environmentally relevant knowledge, communicating environmentally relevant values, creating opportunities for environmentally conscious actions, making the consequences of actions visible and creating incentives for action. The five influencing factors are interrelated in many ways (City of Münster, Office for Green Spaces, Environment and Sustainability 2017, S. 47; Hellbrück and Kals 2012).

From the psychological point of view, a great barrier for environmentally friendly behaviour is the conviction of many people that they cannot achieve anything through individual changes in behaviour.

This expectation reflects the conviction of a lack of self-efficacy. The concept of perceived self-efficacy, also called (optimistic) competence expectation, was introduced by Bandura (Bandura 1977, 1997) as an essential aspect of his social-cognitive theory. The General Self-Efficacy Expectation (SWE, German: Allgemeine Selbstwirksamkeitserwartung) refers to the personal assessment of one's own competencies to cope with the difficulties of daily life and to be able to cope with critical situations by one's own efforts (Jerusalem 1990; Schwarzer 1992).

Since a considerable proportion of CO2 emissions is generated in the satisfaction of everyday needs in private households, the individual decisions of citizens are of great importance. This is where the strategy of influencing decisions affecting climate protection in everyday life comes in. These are at the centre of the case study examined. Special attention was paid to positively influencing the self-efficacy expectations of the project participants.

2.2 Theory of Decision

The process that is perceived as a decision requires that a person in a situation has at least two choices (Pfister et al. 2017, p. 4). A decision - like other cognitive functions - always requires knowledge and motivation and is often dependent and accompanied by emotions (Pfister et al. 2017, p. 8).

The cognitive effort required by a decision ranges from largely automated and effortless decisions to those that require detailed information search and processing. Regarding the cognitive effort, one can distinguish between routine, stereotypical, reflected and constructive decisions (Pfister et al. 2017, p. 40). The underlying guiding idea of the case study examined is to "routinise" climate-friendly behaviour in everyday life.

The view prevailing in the early days of decision research, namely that emotions are merely disturbing side issues of the actual decision-making process, has been thoroughly revised by more recent research (Pfister et al. 2017, p. 11). Of great importance for

decision research is the System 1/ System 2 theory of Tversky and Kahnemann (Kahneman and Tversky 2013; Kahneman 2012).

System 1 stands for the cognitive and emotional processes that take place largely automatically, involuntarily and unconsciously. An important characteristic of them is that they function effortlessly. System 2 stands for processes that are controlled, conscious and intentional (Kahneman 2012).

2.3 Decision Heuristics

Decisions are mostly not made rationally, but intuitively with the help of System 1. Thereby, people use certain heuristics and are subject to cognitive distortions or errors of judgement (bias). These include amongst others (Kahnemann, 2012):

- Availability heuristics (the rash connection to already existing experiences and beliefs)
- Recognition heuristics (a known information has a higher credibility per se)
- Framing-effect (the different presentation of the same information causes different emotions and judgements)
- Halo-effect (one characteristic outshines all others in the overall assessment
- Loss-aversion (the tendency to weight losses higher than profits)
- Status-quo bias (the general tendency to stick to the current situation)
- Confirmation bias (the tendency to interpret new information to be consistent with existing beliefs)

A further error of judgement important for environmental behaviour is that the value of a decision is weighted differently against the background of the time dimension. The long-term benefit of climate-friendly behaviour, which is recognised by most people, loses its motivational power in view of the currently perceived increased effort that consumers perceive when using climate-friendly offers. This insight is the starting point for measures that seek to keep the costs of climate-friendly behaviour as low as possible and to make the benefits of such behaviour tangible as soon as possible (Kahneman 2012; Kopatz 2018; OECD 2017; German Advisory Council on Global Change (WBGU)).

2.4 Nudging as a method of Decision-Influencing

The so-called Nudging systematically uses these decision errors for the desired influence on behaviour. "*Nudges (gentle pushes), i.e. impulses for desired changes in behaviour, are at the centre of a current international discussion on strategies of so-called "libertarian paternalism". Among the prominent examples of such nudges are default options which, from a paternalistic perspective, prescribe "good" solutions as standards, but always include the option of choosing an alternative (opt out).*" (Thaler and Sunstein, 2008, quoted by the German Advisory Council on Global Change (WBGU), p. 83).

The electricity bill, which shows that one's own consumption is higher than the average consumption of comparable households, can be described as nudging, because this tends to lead to increased efforts to save electricity (Kopatz 2018).

Although not uncontroversial (Bornemann 2019), nudging is increasingly finding its way into political-administrative processes. The British government, for example, established a "Behavioural Insights Team" in the administration in 2010 to apply nudge theory to improve the effectiveness of government services, including in the areas of health and climate change (Rare and The Behavioural Insight Team 2019).

The following chart provides an overview of nudging strategies that should be applied in environmental protection following a publication by the Behavioural Insight Team (Rare and The Behavioural Insight Team 2019).

Figure 2: Nudging (Rare and The Behavioural Insight Team 2019, p. 21)

2.5 Social Norms and Group-Processes

Research of the limited rationality of human behaviour emphasizes the importance of social norms and group-processes for the establishment of behavioural changes. Just knowing how other people decide influences one's own decision. People act predominantly in the way that is socially desirable, comparing their behaviour with that of others (Kahneman 2012; Stoknes 2015).

> *„Peer behaviour is one of the strongest predictors of green behaviours and attitudes on issues like littering, energy, and water use. Since the imitation effect is strong, asking consumers to go green will fail unless they are convinced that many others will do the same" (Stoknes 2015).*

Social change therefore requires people who set new social standards with their behaviour, which others then imitate. These people are also referred to as "agents of social change" in analogy to "change agents" in the organizational context (Ahaus 2017).

They act as role models and trendsetters. It is known from diffusion and transition research that "change agents" have a convincing idea of change, network with each other and thus find important fellow campaigners.

(Rogers 1983; Grin et al. 2011; Kristof 2010; Engel et al. 2018; Ahaus 2017). In this way they manage to gain the critical mass for change (German Advisory Council on Global Change (WBGU), p. 257).

> *„Since climate change is often described using highly abstract, scientific data, people yearn for personal interaction and face-to-face conversations to help them process and embody the information. […] Face -to-face contact and word of mouth are still king" (Stoknes 2015).*

The conceptual approach of the case study examined was to involve people who have a certain predisposition for social change processes in the project, to encourage them in their role as "change agents" and to support their multiplier role in their respective social networks.

3 Case Study, Method and Sample

In the following, the evaluation of the measure "Klimaschutzbürger 2.0" ("Climate Protection Citizens 2.0") in the district of Steinfurt[1] is presented. The project is part of the so-called "Master Plan 100% Climate Protection"[2], in which the goal was formulated to make the district energy self-sufficient by the year 2050.

The case study from Steinfurt has its conceptual forerunner in the BMBF-funded research project "KlimaAlltag" ("Climate Everyday Life"), which started in spring 2011. In this project, so-called "climate households" from different milieus voluntarily committed themselves to reducing their CO2 emissions in the areas of housing and energy use in the home as well as in the areas of nutrition and mobility. Over a period of half a year, they received specific advice on this issue and were scientifically supported in the implementation of the recommendations (Wilhelm and Schulz 2017; Ernst et al. 2016).

Contrarily to the examined case study of the "Klimaschutzbürger 2.0", the participants of the project "KlimaAlltag" were visited three times at home during the six-month field trial and advised on site (Waskow and Pannenbecker 2013, p. 7).

In the project "Climate Protection Citizens 2.0", 18 households from 12 municipalities were accompanied for one year (from January to December 2019) in testing a climate-

[1] *The district is located in the northwest of Germany. It is rather rural, has 434,000 inhabitants and 24 county municipalities.*

[2] *https://www.kreis-steinfurt.de/kv_steinfurt/Kreisverwaltung/%C3%84mter/Amt%20f%C3%BCr%20Klimaschutz%20und%20Nachhaltigkeit/energieland2050%20e.V./Service/Informationsmaterial/Masterplanbericht_Langfassung%20.pdf , [Accessed 8. April 2019]*

friendly lifestyle. The concept rested on three pillars: firstly, behaviour-oriented climate advice from experts, secondly, active testing of climate protection measures in the areas of nutrition, mobility, energy and consumption by the participants, and thirdly, the exchange of information among the participants at regular meetings.

A positive effect was expected from building a sense of belonging to a community of climate-friendly households. In this way, the meetings were intended to contribute to "community building" in addition to the acquisition of knowledge and exchange of experience. This was to have a positive influence on their self-efficacy expectations and to strengthen the participants in their role as "agents of social change".

3.1 Method of Data Collection

The explorative study, in which qualitative and quantitative interviews were conducted to generate hypotheses, took place as participating observation of the last workshop meeting on 29.11.2019 with subsequent written questioning of the participants (n=16).

For reasons of data protection, only gender (44% female, 56% male) and age (37.5% 31-50 years, 62.5% 51-70 years) could be queried. The standardized questionnaire on general self-efficacy expectations (Hinz et al. 2006) could not be used either. In a period of two weeks after the workshop a follow-up survey in the form of telephone interviews was conducted with four participants.

3.2 Research Questions

Amongst others, the following questions were examined

- Did the participation in the project have a positive effect on climate-friendly decisions of the test persons? Which offers had the greatest influence?
- Based on the self-efficacy hypothesis, do the test persons have the impression that their behaviour can positively influence climate change?
- Do the participants see themselves as "agents of social change" in that they were able to encourage people outside the project to adopt more climate-friendly behaviour?
- If so, how many people in their social environment did they tell about the project?
- Does the exchange within a group of like-minded people have a positive influence on climate-friendly behaviour?
- Do experience-based events have a positive influence on environmentally conscious behaviour?
- Can an app that shows the effects of individual behaviour on CO2 consumption make a positive contribution to changing behaviour? If so, which functions are considered particularly important?

4 Findings and Discussion

4.1 Control and Behavioural Intentions

To examine the basic control conviction in terms of self-efficacy, the following two questions were asked: *"Are you convinced that your individual behaviour makes a difference and can positively influence climate change?"* This question was answered with 86% agreement (43% "fully agree", 43% "agree", n=16).

The question: *"Participation in the project 'Climate protection citizens' has had a positive effect on my climate-friendly behaviour?"* was answered with 87% agreement (62% "agree completely", 25% "agree", n=16). As expected, most of the test persons are convinced that their behaviour can have an influence.

4.2 Model learning and group processes

Next to the technical inputs at one of the workshops on the topic of nutrition, the testing of concrete measures in everyday life and the exchange with other climate protection citizens had the strongest influence on a change in behaviour of the test persons.

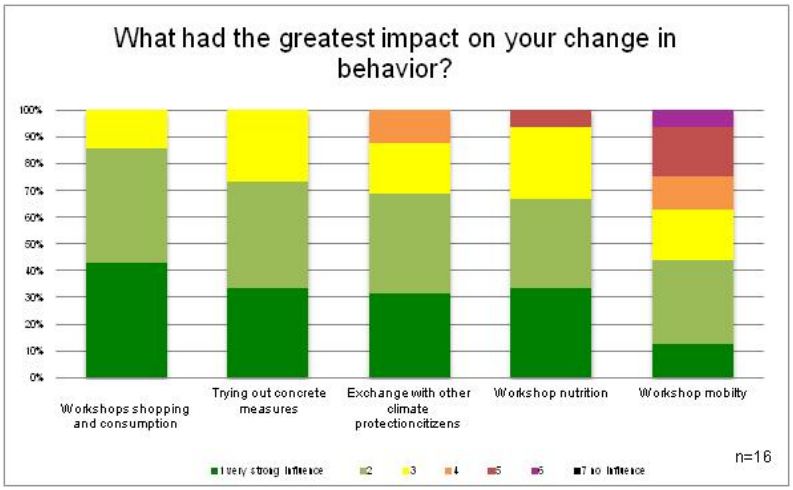

Figure 3: Subjectively perceived percentages of impact on the change in behavior

56% of the climate protection citizens have also exchanged information with each other outside the project meetings. Almost all of them would like to continue this after the end of the project, whereby personal meetings are preferred. The mentioning of WhatsApp as an exchange medium is interesting. This indicates that electronic media are certainly important for establishing contacts. This insight is important because it would be

much easier and cheaper for the circle to stay in contact with climate protection citizens via electronic media in order to ensure the important task of further supporting and stabilizing the network.

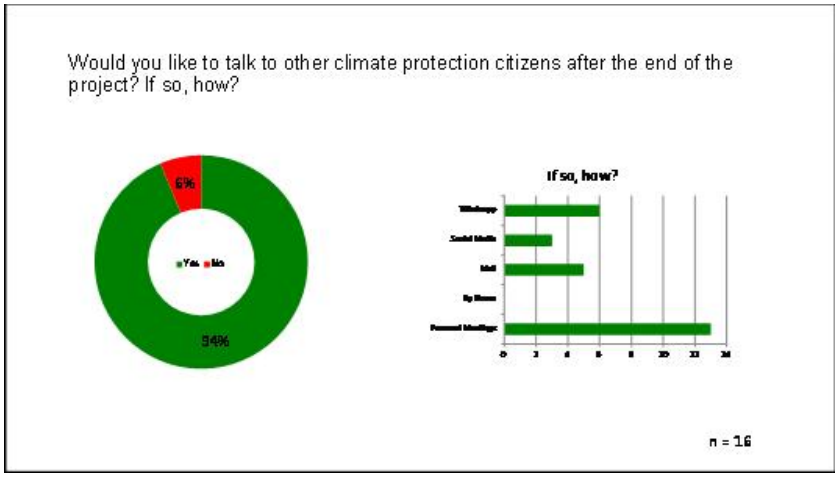

Figure 4: Willingsness to talk to other climate protection citizens after the end of the project

In the following telephone interviews with 4 climate protectors this aspect was deepened. In response to the question "Could you imagine following selected specialist presentations of the project via the Internet in future (so-called webinars) and then exchanging views with other climate protection citizens via chat?", 2 out of 4 respondents answered "yes".

4.3 Multiplier effect of the project

One important assumption was that climate protection citizens have an important multiplier role as "agents of social change". The implicit hope was that the project participants would share their knowledge in their social networks and incite others to adopt similar behaviour.

The statement: *"Do you have the feeling that you were able to motivate people outside the project to adopt more climate-friendly behaviour?* (n=15) 73% of the respondents agreed.

Another question related to how many people the participants told about the project. The results showed a wide spread: According to the participants, a total of about 500 people were reached. Altogether 4 participants reported more than 50 other people about the project, one even more than 80.

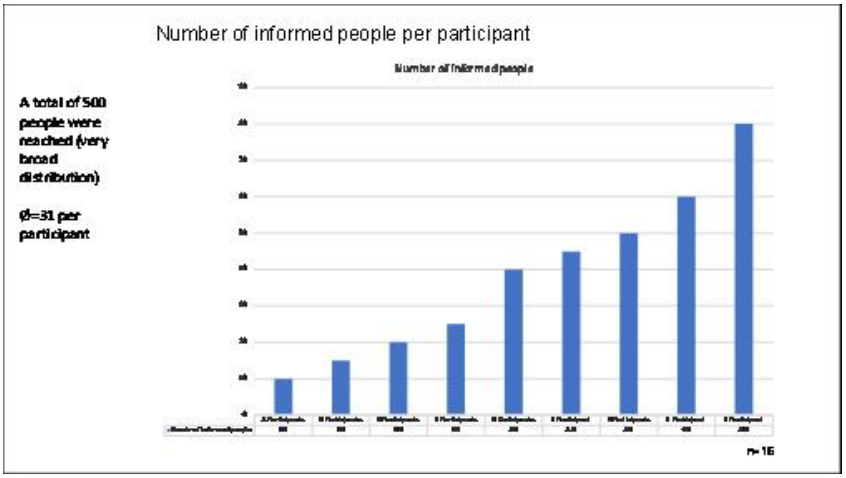

Figure 5: Number of informed people per participant

These main multipliers would have to be addressed and supported separately in future, as they seem to be very willing to disseminate information relevant to climate protection. Another hypothesis is that they serve as role models in social groups and that their influence on other people is particularly high.

In the telephone interviews that followed, this aspect was taken up once again with the following question: *"Could you imagine taking part in a project in which you learn how to organise small workshops in your circle of friends and acquaintances and pass on your learned knowledge about climate protection to others?"* Only 2 of the 4 interviewees could imagine this with restrictions.

4.4 Climate protection app as an incentive to change behaviour

According to the nudging approach, one assumption of the project was that an app that shows the effect of one's own behaviour on CO2 consumption could make a positive contribution to behavioural change. For example, could social group effects be simulated using certain forms of online challenges? Could elements of gamification cause a positive behavioral effect?

These assumptions were operationalized with the following criteria:

- Does the app have a traceable CO2 consumption calculator?
- Is there a simple point or reward system for ecologically sensible action?
- Are there small competitions that encourage participants to act in an ecologically sensible way?
- Can ecological behaviour, tips or little stories be shared with others?
- Can the participants communicate with each other in a simple way?
- Is the app easy to use (usability)?
- What personal data is collected and stored (data protection)?

Based on these criteria, a comparison of 4 already existing climate protection apps was made, which, however, did not produce a satisfactory result.

Until the survey was made, no respondent used an app that documents individual CO2 consumption. The question about the respective functions of an ideal-typical climate protection app resulted in an age-dependent evaluation. Respondents in the age group of 31-50 year-olds rated the relevance of such an app significantly more positively than respondents in the age group of 51-70 year-olds.

A CO2 calculator and the opportunity to post tips and little stories were rated as particularly important. The possibility of holding small competitions and exchanging ideas with others via chat was rated least important.

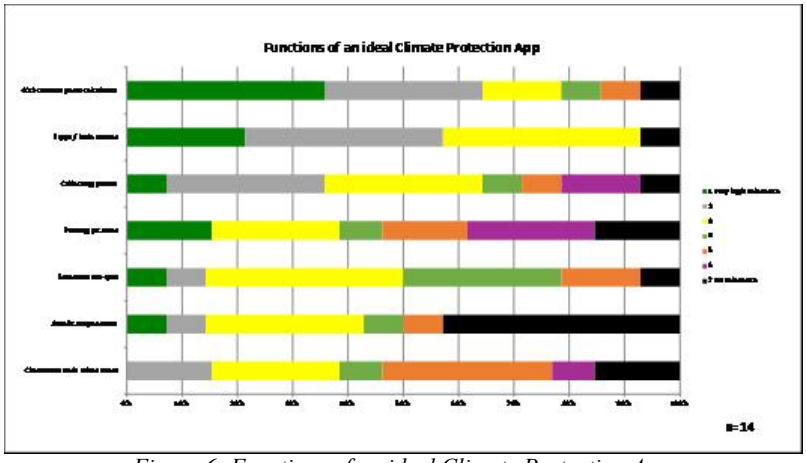

Figure 6: Functions of an ideal Climate Protection App

5 Conclusion

The basic assumptions regarding self-efficacy, group processes and model learning could be supported by the results of the survey. However, it must be noted that the group of the participants of the project was formed through self-selection therefore a higher affinity for climate-friendly behavior could be assumed.

To be able to generalise the statements more strongly, random groupings such as in the project KlimaAlltag (Stieß 2013) would have been desirable. A standardised query on the general self-efficacy expectation (Hinz et al. 2006) would also have strongly increased the significance of the results.

The testing of new forms of climate-friendly behavior (model-learning through experience-based experiences) had a very strong to strong influence (top-2-boxes) on almost 80% of the participants on their change of behaviour. Social group processes such as the exchange with other climate protection citizens also had a high influence (almost

70% top-2-boxes). 56% also exchanged views outside the project meetings, and almost all of them would like to do so after the end of the project.

The intended multiplier effects of the project can only be estimated to a limited extent. A good 70% of the participants felt that they were able to motivate people outside the project to adopt more climate-friendly behaviour. However, these effects - operationalised by the number of people to whom the climate protection citizens had told about the project - were very broadly spread. According to their own statements, there were four participants who told more than 50 people about their experiences. Further research is needed to find out whether these people have special characteristics and how the municipality could support them even better.

If special social processes can be supported by new media such as apps, must be examined separately. The support through a special app was rated very differently by the participants. Younger people rated it as much more positive. Offers of gamification such as small competitions were rated as not important by the majority. The social exchange also seemed to have no benefit for the respondents. One finding of the survey is that the benefit of an app could have been better determined by qualitative studies such as a design thinking workshop. Further research is needed here.

All in all, "social snowball effects" (e.g. train-the-trainer concepts), in which the participants are enabled to pass on the knowledge they have acquired in the projects to their social networks in a self-directed way and thus act as "agents of social change", should be more strongly encouraged.

A further development of the Steinfurt model is the real-world laboratory "Climate-friendly decisions" of the City of Münster[1]. Here, offers and providers who have already done pioneering work regarding climate protection were actively brought together with potential users (City of Münster, Office for Green Spaces, Environment and Sustainability 2017). The focus was on linking up with the user expectations of the citizens. The project focused on non-monetary incentives for environmentally friendly behaviour.

A differentiated target group orientation can significantly increase the scope of climate policy measures. Such differentiation should consider both socio-demographic characteristics and lifestyle orientations to link up with the "realities" of private households and lifestyles. In an (unpublished) pre-study within the Münster Model, clusters of milieus were formed that differ from one another in terms of climate protection.

Stieß et al. (2013) summarise their findings from the "Everyday Climate" research project in the so-called "4-E model". The model distinguishes four dimensions (Stieß 2013, p. 13):

[1] *The city of Münster has about 300,000 inhabitants and is also located in the northwest of Germany. Here, too, twelve households tried out new products, behaviour and services in 2019 to find out how to make their everyday life more climate-friendly (City of Münster, Office for Green Spaces, Environment and Sustainability 2017).*

- **„Enable“** refers to tools that empower people to adopt environmentally-friendly behavior, for example by providing information or trying out measures.
- **„Encourage“** includes all instruments that create monetary or non-monetary incentives for environmentally friendly behaviour.
- **„Engage“** describes instruments and measures that promote individual and collective commitment to environmental protection and thus help to mobilise individuals.
- **„Exemplify“** aims to "incite" other people to environmentally friendly behaviour by making role models visible.

The measures from the case study "Climate Protection Citizens 2.0" can be assigned in particular to the dimensions "Enable" and "Exemplify".

In conclusion, however, it should be noted that as important as the behaviour of individuals is in climate protection, it is necessary to flank this at the political level with laws, taxes and educational programmes (Kopatz 2018).

Abstract

The present paper is aimed at proposing a training evaluation model specific for anti-money laundering in bank. This evaluation model was structured to take into account challenges that today banks and other intermediaries subject to anti-money laundering regulations have to face, and the possible exposition of intermediaries to those risks related to knowledge management. The originality of the proposed model lies in the fact that, to the authors' knowledge, today, a model specific for AML training evaluation in banks still not exist. Among the limitations, there is the fact that, for the moment, it is a purely theoretical model and that needs to be tested.

Keywords – Training Evaluation Model, AML/CTF, Suspicious Transaction Reporting, Customer Due Diligence, knowledge risks.

Paper type – Academic Research Paper

1 Introduction

'Ndrangheta, Camorra, Cosa Nostra, Nasa Stvar, Mara Salvatrucha, Yakuza, Solntsevskaya Brava, Le Mileu, Obtshak, so many ways to name organized crime, an economic sector in all respects, which has never known and still knows crisis. Figures on organized crime's turnover show its unequivocal solidity and dangerousness for the entire world economic system. Moving large volumes of capital, money laundering and terrorism financing occupy a very important position among organized crime's activities. In the last few years, the United Nations Office on Drugs and Crime hypothesized that the amount of money spent by criminals and tax evaders on the planet annually fluctuated

between 800 and 2 million dollars. In other words, from 2 to 5% of global GDP. These figures have almost never been updated. And this is not even the biggest problem, if we consider that with the spread of increasingly sophisticated technologies, crimes such as money laundering have found ways to become increasingly difficult to identify and therefore prevent. Damages caused by these financial offences are there for all to see. Engaging in the fight against them has now become a moral obligation.

Economic crimes affect financial sector in the extent of about 45% of all financial organizations and, in terms of "penetration" of crimes as money laundering, the sub-segment of banking gets the primacy concomitantly with investment management and capital markets segments (PwC, 2015, 2018; Global Initiative against Transnational Organized Crime, 2017). Banks, in fact, carrying out financial intermediation activities, play a crucial role in the payment system and, therefore, are more exposed to situations potentially related to illicit financial transactions. It's not a coincidence that in Italy, for example, Financial Intelligence Unit (FIU), in the first half of 2019, received 51,201 reports of suspicious transactions (SOS), 3.8% more than the corresponding period of the previous year (FIU Official Web Site). However, the large amount of such reports is not the only indication of an effective action to prevent financial crimes. The system of prevention and contrast of money laundering and terrorist financing works properly, above all, thanks to the continuous improvement of the quality, timeliness and completeness of the reports of suspicious transactions. In this context, the role of reporting subjects is crucial. Financial Intelligence Unit has recently found some critical issues related to the lack of diagnostic capacity of reporting subjects, especially in the insufficient focus of suspicion, as well as the incomplete and incorrect compilation of reporting model (FIU Official Web Site). At the same time, in the new provisions on customer due diligence to combat money laundering and terrorist financing, the Bank of Italy provided new tools for Know Your Customer (KYC) procedures based on advanced technological solutions, such as the biometric recognition of customer suspicious elements (Banca d'Italia, 2019). But making these tools available to reporting agents, defined by the competent authorities as doubtful and unprepared, could further aggravate the weakness of their skills profile, as they are required to employ new, more advanced and complex technologies to recognize suspicious situations. A contradictory situation therefore appears to arise: the found weaknesses in the capabilities of the reporting agents are answered by providing complex tools based on advanced technologies.

In this sense, anti-money laundering training could play a fundamental role in correcting the shortcomings in the abilities of the reporting agents. Even more helpful could be the evaluation of anti-money laundering training programs. In almost all cases, banks are obliged by legislation to do anti-money laundering training. The same does not apply to training evaluation. And in fact, this practice is still not very widespread, as shown by a lack of proper scientific production on this topic (La Torre, M., 2015).

The present paper has the main purpose of covering this lack by highlighting the importance of anti-money laundering/combating terrorism financing (AML/CTF) training

evaluation, proposing an original training evaluation model which aims to respond simultaneously to the challenges posed by the Competent Authorities and technological progress, also considering the further threat of so-called knowledge risks, i.e. the risks associated with knowledge management.

For this purpose, the remainder of this paper is organised as follows. In Section 2 below, the regulatory framework is proposed and the role of suspicious transaction reporting and customer due diligence process in preventing and combating ML/TF is highlighted. Section 3 is dedicated to the potential of the AML/CTF training evaluation in supporting the quality of suspicious transactions reporting and customer due diligence process; a digression on the most well-known training evaluation models and on the main knowledge risks is also provided. The paper continues with Section 4, in which the training evaluation model is illustrated in its structure and main characteristics. Conclusions and ideas for future research are contained in Section 5.

2 Suspicious transaction reporting and customer due diligence process in preventing and combating ML/TF. Opportunities and challenges from technological progress

The international anti-money laundering regulatory framework is the result of a complex articulation of sources consisting of international standards, European standards and international conventions. The main objective of the European regulation on the prevention and combating money laundering and terrorist financing has been, from the beginning, to create a harmonized regulatory environment between the Member States, especially implementing, over time, the evolution of the international principles. The five Directives and the various provisions issued since the 1990s are testimony to this commitment.

In particular, with the fourth Directive (EU/2015/849) but, above all, with the fifth Directive (EU/2018/843), currently in force, the prevention system of the Member States is definitively aligned with the Recommendations of the Financial Action Task Force (FATF) of 2012, enhancing the risk-based approach, a fundamental criterion for the gradation of preventive measures and controls. “FATF Recommendations represent an international standard, which countries should implement through measures adapted to their particular circumstances; the measures set out by the FATF Recommendations basically refer to: i) identify the risks, and develop policies and domestic coordination; ii) pursue money laundering, terrorist financing and the financing of proliferation; iii) apply preventive measures for the financial sector and other designated sectors; iv) establish powers and responsibilities for the competent authorities (e.g., investigative, law enforcement and supervisory authorities) and other institutional measures; v) enhance the transparency and availability of beneficial ownership information of legal persons and arrangements; vi) facilitate international cooperation” (FATF, 2019, p. 6).

Fourth Directive also confirmed the central role of the Financial Intelligence Units (FIU). In accordance with international rules and criteria, a Financial Intelligence Unit (FIU) is expected to be present in each Member State, with full operational autonomy, with functions to combat money laundering and terrorist financing. The main task of FIU in the system of prevention of money laundering and terrorist financing is the acquisition of financial information regarding money laundering and terrorist financing hypotheses mainly through reports of suspicious transactions sent by financial intermediaries, professionals and other operators. Of this information, FIU performs financial analysis, using all the sources and powers available to it, and assesses the relevance for the purposes of transmission to investigative bodies and collaboration with the judicial authority, for the possible development of the action of repression: " FIUs, therefore, act as intermediaries between private entities, subject to AML/CFT obligations and law enforcement agencies. The added value of the FIU is the analysis it carries out on all the information received, as well as the wide range of other financial information that it has at its disposal and that it can use to better evaluate the information on the suspects provided" (The role of the Financial Intelligence Unit, available at https://uif.bancaditalia.it/sistema-antiriciclaggio/uif-italia/index.html). From these last statements, the importance of a correct and efficient reporting activity by the interested parties is underlined, especially in consideration of the impressive volume of reports that FIU receives every year. In 2019, Financial Intelligence Unit for Italy received 54,621 reports of suspicious transactions, an increase compared to those received in the corresponding period of the previous year (+12.2 percent). During the year 105,789 reports were acquired, with an increase of 7.9 percent compared to 2018. The growth in the second half of the year was determined by the anti-money laundering reports, which reached 53,773 units (+13.2 percent), in absolute the highest number of reports of the species received in a 6-month period. The reports relating to the financing of terrorism, on the other hand, recorded a further reduction (375 compared to 409 in the second half of the previous year, which already showed a decrease compared to the same period of 2017) (UIF, 2020a, p. 1). As regards the consistency check of the data transmitted with the reports, in January 2020, some evolutionary interventions were released aimed at allowing a more accurate representation of the operations described in the reports of suspicious transactions and improving the quality of the data transmitted. In addition, new data consistency checks will be added to new checks to ensure greater compliance of the data sent with the regulatory provisions. Unlike pre-existing controls, which always involve discarding the report in case of violation, the new verification scheme allows, in the presence of minor inconsistencies, the acceptance of the data sent. In such cases, the reporting parties will receive a special message with the list of identified findings which must be carefully checked; in the event that errors or gaps are actually found in the data transmitted, a replacement report must be sent promptly (UIF, 2020b, p. 1).

The effects of technological progress and the digitalization process have therefore impacted also the reporting of suspicious transactions, as well as customer due diligence:

" […] innovation is not confined to new financial products and services. It also includes the development of new solutions to address specific compliance challenges, such as customer due diligence (CDD), which is central to the AML/CFT regime. Meeting CDD obligations can be challenging for firms, as this process is often associated with significant costs and customer inconvenience" (EBA, 2018, p. 2).

The provisions of the Bank of Italy regarding customer due diligence, issued on 30 July 2019, also support the application of technological innovation. In particular, these provisions: i) regulate the video-identification procedures with security features suitable to mitigate the risks associated with the physical absence of the customer; ii) confirm the possibility of conducting adequate customer verification, even remotely, on the basis of a flexible procedure, according to which financial intermediaries can autonomously identify the most appropriate controls to mitigate these risks, such as feedback based on forms of biometric recognition; iii) allow intermediaries to automate some phases of the AML/CFT processes, providing algorithms for risk profiling and automatic procedures to monitor customer operations and identify anomalous operations (Banca D'Italia, 2019). On 10 November 2019, Legislative Decree 125/2019 also again amended the anti-money laundering legislation: the interventions concern, among other things, the expansion of the categories of obliged parties, certain changes in the subject of adequate verification and some corrections to the sanctioning system.

In such a context, improving the quality, timeliness and completeness of reports of suspicious transactions represents a primary objective of the system for preventing and combating money laundering and terrorist financing; the abilities of the reporting agents both to correctly identify the situation of real danger, and to use new technologies for the detection of suspicious behavior, must be up to the task assigned by the control and supervisory Authorities.: "[…] the European Supervisory Authorities (ESAs), expects that competent authorities ensure that all relevant staff employed by firms, and also staff at the external provider, are provided with regular training which specifically focuses on the practical application of the innovative solution and its technical abilities as well as on the detection and escalation of potentially suspicious transactions arising from the use of the innovative solution. Such training should be provided in addition to ongoing general AML/CFT training" (EBA, 2018, p. 10).

The real situation, however, does not seem exactly in line with the expectations of the Authorities. A survey conducted by the Bank of Italy in the first half of 2019 showed a certain resistance of financial intermediaries to use tools based on new technologies (especially those connected to AI) in the context of AML/CFT processes, with particular reference to profiling customer risk and the identification of suspicious transactions. Based on the evidence that emerged from the survey, in the 2017-2018 two-year period the intermediaries' anti-money laundering function was involved in 33 FinTech initiatives. In the following Table 1, the results of the Bank of Italy survey, with reference to the main innovative solutions adopted in the AML/CFT area, are reported.

Table 1 - FinTech investigation by the Bank of Italy. Main results

FinTech Initiatives	Response from financial intermediaries
New procedures for remote identification	From the answers provided by 64 intermediaries, it emerges that: six intermediaries use certificates for the generation of digital signature, issued by bodies accredited by AGID, for the identification of customers; only 4 intermediaries employ alternative remote recognition procedures, which provide for: i) the initial transmission by the customer of his own photo or video, in which the customer shows himself in possession of the identity document of which he has transmitted copy or, in the case of the video, utters a word suggested by the system; ii) subsequent manual verification of the information transmitted; Finally, no intermediary uses identification methods based on regulated digital identities (for example the SPID) nor does it use automated biometric recognition systems to identify customers for anti-money laundering purposes.
Databases for Customer Due Diligence	Widespread and generalized use and mainly used to identify politically exposed persons, terrorists, subjects subjected to financial sanctions, subjects involved in negative press reports regarding AML/CFT.
Algorithms for risk profiling and transaction monitoring	Progressive refinement of the automatic systems and algorithms used for profiling the ML / FT risk of the customers and monitoring the transactions, through a progressive adaptation of the risk and anomaly indicators with respect to the specific operations of the customers of the individual intermediaries and through the use of Big data and AI (such as Machine Learning and neural networks)
Automation of AML processes	Increasing automation of some phases of the anti-money laundering processes, especially in the identification of high risk subjects, in customer risk profiling and in the collection of data and information through OCR systems for the extraction and conversion of text from scanned documents or images.

Source: our elaboration from Banca D'Italia, (2019), pp. 23-25.

From the results summarized in Table 1, emerged that financial intermediaries, and in particular banks, still look with some prudence to technological innovations in AML/CFT processes. The motivation could concern both the sometimes excessive complexity of the technology at the basis of the proposed instrument or solution, and problems that go beyond technological progress and which date back to the relationship between AML provisions and preparation of the recipient banks' staff.

3 Supporting the quality of suspicious transactions reporting and customer due diligence process. The role of AML/CTF training evaluation

The application of tools and techniques with high technological content in the field of prevention and combating money laundering and terrorist financing is now a consolidated reality. "The benefits of using these tools could be found in the possibility of reducing regulatory arbitrage used by criminal organizations, even if the collaboration between the various countries in this field is still at an early stage. The main criticalities that characterize these tools concern the computational capacity required and the confidentiality constraints on information, the latter particularly relevant if external resources are used in the development of the tools" (Coelho et al., 2019).

In this sense, a valid support certainly comes from the training of human resources - which is also mandatory by law for anti-money laundering - but even training evaluation, as sometimes could occur several lacks ranging, from a weak connection between training and organizational results, to a flawed attention about trainees' needs and changes in work behaviors after training (Bird, Cassel, 2013), and also to the possible exposure of the financial intermediary to the so-called knowledge risks.

Training evaluation models

"Training evaluation is a systematic process of collecting and analyzing information for and about a training programme which can be used for planning and guiding decision making as well as assessing the relevance, effectiveness, and the impact of various training components" (Hashim, 2001, p. 374). Over the years, several scholars have dealt with training evaluation, also proposing models to be applied in organizations of different types and sizes, and with reference to the training programs of the most diverse themes. Among the training evaluation models proposed over time, there are some well known and applied for decades in companies all over the world. Table 2 below presents them in a concise manner, highlighting their structure and main characteristics.

Table 2 - Training Evaluation Models

Training evaluation models	Structure	Main characteristics
Kirkpatrick's Four Level Model (1959)	Four levels: 1. Reaction 2. Learning 3. Behaviours 4. Results	It is the best known, discussed and applied training evaluation model. Level 1 deals with feelings and reactions of trainees towards training activity. Level 2 allows to check the level of learning post-training. At stage 3, work behaviours are evaluated and at fourth organisational results are assessed. Relationship between levels is hierarchical, this means implicitly consider better - for information - every level than its antecedent.
Hamblin's Five Level Model (1974)	Five levels: 1.Reactions 2. Learning 3. Job behaviours 4. Organization 5. Cost-benefit	Hamblin's model points out the difficulty of linking training to organizational performance due to the influence of direct and indirect elements and stresses, at the same time, that training evaluation should focus mainly on level of trainees' learning.
Brinkerhoff's Six Stage Model (1987)	Six levels: 1. Goal setting 2. Program design 3. Program implementation 4. Immediate outcomes 5. Intermediate outcomes 6. Impacts	This model, although similar Kirkpatrick's, adds a level specifically devoted to definition of training objectives, which must be clarified and defined before delineation of training program.

Bushnell's Input-Process-Output Model (1990)	Four levels: 1. Input 2. Process 3. Output 4. Outcomes	It consists of four stages: input, process, output and outcomes. At first level, performance of some elements such as trainers and trainees qualification, training materials and budget is evaluated. At process stage, training action is assessed and, at third level, elements considered are trainees' reactions, knowledge and skills acquired and training's effect on work behaviours. Do not confuse this last stage with output level, which concerns long term training's effects.
Richey's Model (1992)	Four levels: 1. Trainee's characteristics 2. Knowledge 3. Attitude 4. Behaviours	Model that emphasizes influence of some factors, both referred to the context is and to some specific trainee's characteristics, as abilities and attitudes respect to delivery system.
Kaufman, Keller, Watkins' Five Level Model (1994)	Five levels: 1a. Enabling 1b. Reaction 2. Acquisition 3. Application 4.Organisational outputs 5. Societal outcomes	Compared to other contemporary models, it added a level of training evaluation dedicated to societal outcomes, ie the social consequences of organisational actions. Also detailed are the first two levels, considering the role of methodologies, tools and resources and effectiveness of their use in training activity.
Holton's HRD Evaluation Research and Measurement Model (1996)	Three levels: 1. Learning 2. Individual performance 3.Organisational results	This model considers influence of motivational, environmental and ability elements on training outcomes, such as trainees' learning, their individual post-training performance and results at the organizational level.
Phillips' ROI Training Evaluation Model (1996)	Five levels: 1. Reaction and planned action 2. Learning 3. Applied learning on the job 4. Business results 5. Return on Investment	Respect to Kirkpatrick's, this model adds a fourth level dedicated to the ROI of training, a level to wonders if monetary value of training results exceed costs incurred for implementation of training program in the organization.
Kuzmin's Participatory Training Evaluation Method - PATEM- (2004)	Five levels: 1. Introduction and process description 2.Data collection 3.Data analysis 4. Feedback 5. Reflection	PATEM is a very flexible and collaborative training evaluation model. Measuring trainees' reactions to training, this model allows to obtain interesting information about evaluation findings. With this model, evaluation becomes part of training and promotes involvement of participants, which can in this way share their experience both at individual and group level.

Pineda's Integrated Training Evaluation Model (2010)	Six level: 1. Participant satisfaction 2. Learning achieved 3. Pedagogical coherence of training program 4. Transfer of training 5. Training impact on organisational goals 6. Training profitability	This model offers an integrated approach to the analysis of variables that can affect training evaluation. It introduces a new level of evaluation on pedagogical appropriateness, which has the purpose to verify the internal coherence of training process in order to achieve training goals more effectively and efficiently.

Source: La Torre, M., (2015), p. 609.

Each of these models could be useful to increase the accuracy of customer risk profiling and to improve the reporting quality, although they are not specific to AML training, and do not provide attention to knowledge risk prevention.

Knowledge risks

Knowledge risks can be defined as "a measure of the probability and severity of adverse effects of any activities engaging or related somehow to the knowledge that can affect the functioning of an organization on any level (Durst & Henschel, 2020, p. 5).

Any organization, regardless of type and size, can be exposed to several different knowledge risks. Durst and Zieba (2018) first mapped these risks, also distinguishing them according to their nature in human, technological and operational. In the following Table 3, a schematization of the main types of knowledge risks is provided.

Table 3 - Knowledge risks

Knowledge risks	Main features
Risk of knowledge loss	It is both a human and technological knowledge risk. With reference to its human origin, risk of knowledge loss could manifest itself every time in an organization human resource management strategies are implemented. Therefore, this knowledge risk could be really insidious because it could become unavoidable in response to phenomena as employee turnover - voluntary or involuntary – or to accidents as death or illness of employee (Durst & Zieba, 2017).
Risk of knowledge waste	Belonging to the category of operational knowledge risks, risk of knowledge waste could occur in situations where the knowledge in the possession of the organization - and potentially valuable - is not used; it always originates within the organization (employees), and has the character of randomness (Durst & Zieba, 2017).
Risk of knowledge spillover	Organizations could be exposed to the risk of knowledge spillover if valuable knowledge leaves the organization and ends up to competitors that use it to their advantage. The risk of knowledge spillover originates from outside the organization (co-operants, competitors) and relates to the relationships that the latter maintains with the external environment (Durst & Zieba, 2017).
Risk of knowledge hoarding	Risk of knowledge hoarding is defined as "the act of accumulating knowledge which may or may not be shared in the future; that is, it is

	knowledge that has not been requested by another individual" (Webster et al., 2008, p. 6)
Risk of knowledge hiding	Is defined as "an intentional attempt by an individual to withhold or conceal knowledge that has been requested by another person" (Connelly et al., 2012, p.65).
Risk of knowledge unlearning	It is the "process of reducing or eliminating pre-existing knowledge or habits" (Tsang and Zahra, 2008)
Risk of knowledge forgetfulness	It can be considered as the abandonment of practices or entire strategies that were dominant, but which now hinder the acquisition of new knowledge and therefore also organization competitiveness
Risk of knowledge outsourcing	It belongs to the category of operational knowledge risks, originates from the outside of the organization (co-operants), and is a risk attributable to a single potential cause (situation-specific risk) (Durst & Zieba, 2017).
Risk of knowledge digitization	It belongs to the category of technological knowledge risks. It originates within the organization and is connected to the use of digital technologies for the performance of corporate functions, including also knowledge management (Durst & Zieba, 2017).

Source: our elaboration.

In this paper, we propose an AML/CTF training evaluation model specific for banks and other intermediaries subject to the anti-money laundering discipline. A model that takes into account both the expectations of the competent Authorities, and the ability of human resources to correctly apply the knowledge learned during training, and the quality of the knowledge management internal to the organization in terms of prevention of knowledge risks that could influence AML training output. In the following section, the presentation of the aforementioned model is proposed.

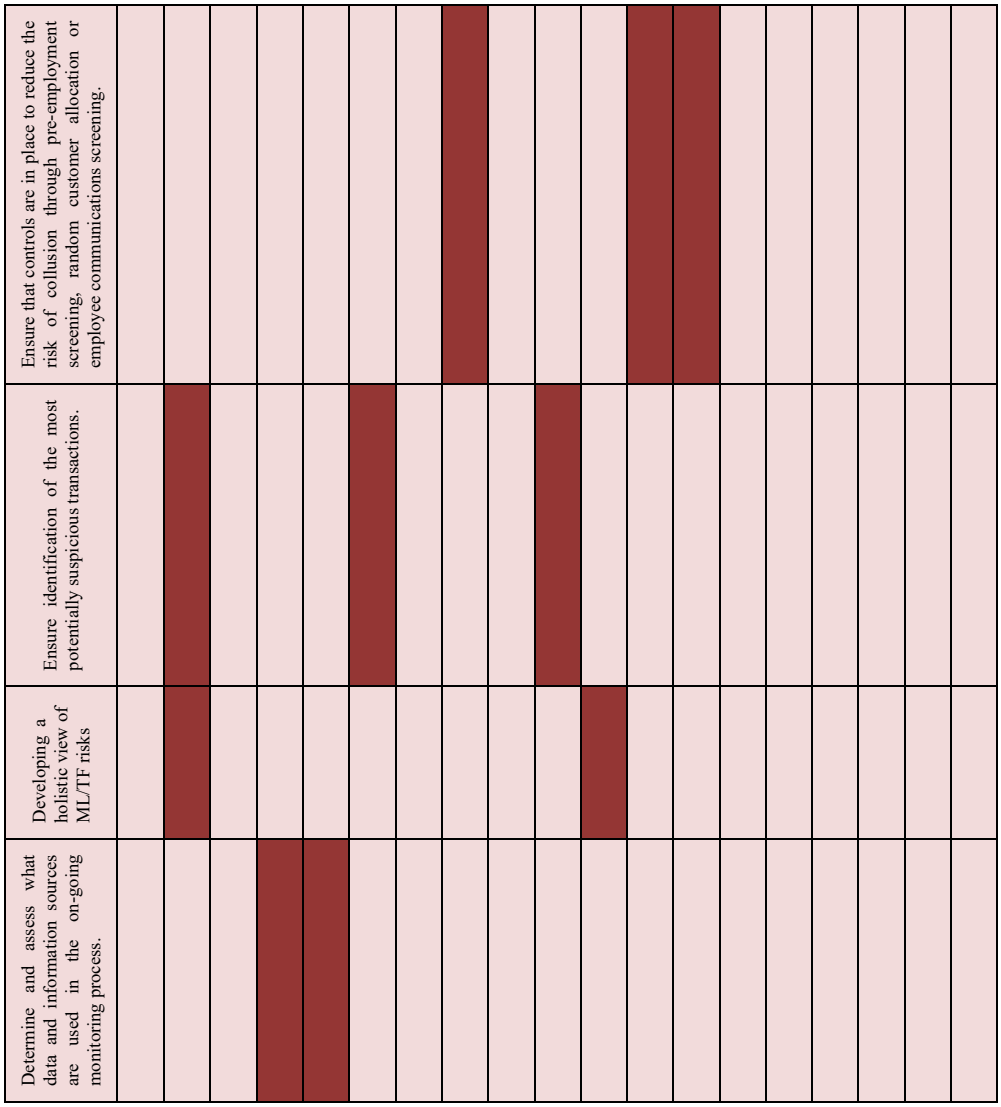
4 Towards a specific training evaluation model for AML/CTF in bank

The model proposed in this study has the dual objective of filling the gap in the training evaluation literature due to the lack of specific assessment models for AML/CTF in banks, and of supporting the recipients of anti-money laundering legislation in the prevention and contrast of financial crimes, responding to the requests and expectations of the competent Authorities. The structure of the proposed model is presented in the following Table 4.

Table 4 - AML/CTF Training Evaluation Model

Authorities Expectations	Knowledge Risks									Knowledge resources needed					Knowledge resources available				
	knowledge loss	knowledge waste	knowledge spillover	knowledge hoarding	knowledge hiding	knowledge unlearning	knowledge forgetfulness	knowledge outsourcing	knowledge digitization	Training activities	Team work	External expert coaching	Incentives	Processes simplification	Training activities	Team work	External expert coaching	Incentives	Processes simplification
Complete evaluation of the technological solution to ensure that it has undergone appropriate tests aimed at establishing whether it is in line with internal AML / CFT policies and procedures and with AML / CFT regulation.									■			■		■					
Drafting of a document that describes in detail the roles and responsibilities regarding the application of the technological solution in AML/CTF processes. If this solution is not in-house, the intermediary's autonomy. must be reiterated with references to any changes to the solution itself					■			■			■								

Ensure that all relevant staff employed by the companies, as well as the staff of the external supplier, receive regular training which focuses in particular on the practical application of the innovative solution and its technical capabilities.	Identification and evaluation of other risks associated with the innovative solution and also with the external supplier (where the solution is not developed internally).	Periodic evaluation of the innovative solution, with identification of possible errors and weaknesses.



Source: our elaboration.

The main features of the proposed training evaluation model are:

- The proposed assessment takes into account the main regulatory requirements with specific reference to the latest forecasts for technological solutions for customer profiling and the reporting of suspicious transactions for AML / CTF purposes.
- Based on these requests, the model the possibility of considering the possible exposure of intermediaries to knowledge risks.

- Based on the type of knowledge risk identified, the model gives the possibility to consider one or more knoweldge resources necessary to face the identified knowledge risks.
- With respect to the knowledge resources identified as necessary to manage knowledge risks, the model offers the possibility of identifying the knowledge resources actually available to the organization.

The output of the assessment is therefore represented by a greater awareness of the knowledge resources available to the organization: this will allow the training activity to be structured so as to satisfy any deficiencies that emerged during the assessment from the difference between the knowledge resources needed and those actually available.

5 Conclusions

The use of innovative technological solutions is now a consolidated reality also with reference to the prevention and contrast of financial crimes. This is demonstrated by the fact that the reference regulations and the control activities of the competent authorities in the field of anti-money laundering and the fight against terrorist financing are also dealing with ever-increasing attention to these issues, especially with reference to the adequate verification of customers and the reporting of suspicious transactions by financial intermediaries.

The thing that still raises some doubts is whether bankers are really ready to use such technologically advanced solutions in anti-money laundering operations. The results of a recent survey conducted by Bank of Italy showed that Italian bankers still show some diffidence and uncertainty in the application of these solutions.

Beyond the frequency of use, however, human resources must be adequately trained, especially with reference to complex issues such as anti-money laundering. Precisely with reference to the complexity of the subject and the particularity of the interests at stake, training should also be accompanied by an adequate training evaluation activity. There are several training evaluation models made available by scholars over the years, from the four-tier model of Kirkpatrick (1994) to the six-tier model proposed by Brinkerhoff (2001). Despite the number of such models, it is surprising that to date, there is still no specific training evaluation model for the banks and other financial intermediaries to whom the AML discipline is addressed. In this regard, in this paper, a specific model for the evaluation of AML training has been proposed. Although in a still theoretical formulation, the model has the objective of specifically supporting the banks engaged in the fight against financial crimes, proposing an evaluation that consider: 1) the expectations of the competent authorities regarding the compliance of the intermediaries with the provisions; 2) the possibility that intermediaries are exposed to risks related to the management of knowledge useful for an effective contrast to financial crimes; 3) the difference between knowledge resources necessary to face the knowledge risks deriving from deficiencies in the AML training activity and the knowledge resources actually

available to the intermediary. With reference to future research, the next step could be to try to test the model on an AML bank training program.

Abstract

Organizations are increasingly considered Complex Adaptive Systems (CAS). This view has outlined the need to adopt a different theoretical and methodological approach in organizational research and design. The present paper copes with this challenge and aims firstly at introducing an agent-based computational laboratory, named CLOD (Computational Laboratory of Organizational Design), to explore the advantages that agent-based approaches could offer to scholars and practitioners in the organization research, particularly in the field of organizational design. Furthermore, some generative simulation experiments are reported and discussed to analyze the impact of the increasing complexity of the external environment on learning performances of organizations of different sizes.

The conceptual architecture of the computational laboratory CLOD is based on the seminal March's model of exploration and exploitation in organizational learning. Some generative experiments have been performed (18 experimental sets), in which organizations of different sizes have to learn by coping with external environments characterized by increasing complexity levels (modeled through the values of the parameter K in the NK landscape), and, eventually, by a certain level of turbulence.
In a stable setting, as expected, the learning performances of the organization decrease significantly, moving from a single peak environment (K=0) to higher levels of environmental complexity (K =5). Furthermore, the increasing size of the organization is related to better performances in stable environments for low or moderate levels of complexity. In turbulent and complex environments, instead, the size of the organization, particularly in the medium-long period, seems to be not influent and other organizational solutions have to be found to reach significant learning performances.
The Clod lab can be considered, at this stage of the research, as a tool supporting theory development or refinement in organizational design disciplines. Further applications can be tested for practical and teaching purposes.

Keywords – Complex Systems, Organizational Learning and Design, Agent-Based Modelling, NK Landscape

Paper type – Academic Research Paper

1 Introduction

The studies on organizational design represent a well-established stream in organization research (Donaldson, 2006). Until the advent ok knowledge-based economy, the primary purpose of organizational design scholars was to define effective and efficient structures to deliver great volumes of standardized products or services toward customers (Yoo at al., 2006). Furthermore, the focus on structure of traditional organizational design studies was also devoted to explicitly reduce the uncertainty of external environments, by providing "stability and predictability" (Yoo et al., 2006, p.215). The Structural Contingency Theory, developed about five decades ago (Lawrence and Lorsch, 1967), states that it is possible to define a priori what kind of organization is required to deal with different environmental conditions. The underlying hypothesis is that the organizational structure has a decisive role in determining organizational performances. Also, technology has been considered pivotal in defining organizational solutions (Thompson, 1967). It is therefore not surprising that, with the development of information and communication technologies, the contingent hypothesis has been extended to design formal systems for coordinating collective action (Raymond, 1990).

During the nineties, the organizations have started to be increasingly considered as Complex Adaptive Systems (CAS), as stated effectively by Morel and Ramanujam: "Organizations are now routinely viewed as dynamic systems of adaptation and evolution that contain multiple parts which interact with one another and the environment. Such a representation is so common that it has acquired the status of a self evident fact" (Morel and Ramanujam, 1999, p. 278). This perspective has outlined the need to adopt a different

theoretical and methodological approach in organizational research and design. It has implied the need to consider the interdependence between the different parts and the processes of the organization, and the co-evolution between the organization and the external environment (Boisot and Child, 1999).

More recently, organizational design & development's scholars highlighted the need for new approaches considering the challenges deriving from the growing environmental complexity and the limits of more traditional approaches (Jelinek et al., 2008, p. 317): "Organization design science is still very early in its development: different, even conflicting theories about organization design and development abound; laboratories for organizational experiments are largely absent; and little knowledge on management and organization is systematically codified — too much remains anecdotal and dependent on context".

The present work aims at contributing in this direction to the emerging research line that try to characterize the organizational research as a "science of design" (Jelinek et al., 2008), by adopting methodological approaches able to support a better understanding of the relationship between the organization, its performances, and the external environment. Particularly, the article intends to present a computational laboratory based on an agent-based model, to support the organizational researchers in organizational design.

As argued by (Boero and Squazzoni, 2005, sec. 1.15), these kinds of tools (like agent-based modelling and simulation) allow "translating, formalizing and testing theoretical hypotheses about empirical reality in a mechanism-based style of analysis". They offer additional possibilities to social sciences' researchers due to their capability of taking into account aspects and methods like "heterogeneity and adaptation at micro level, non linear relations, complicate interaction structures, emergent properties, and micro-macro links". In doing so, they allow to contribute to theory development and testing in the area of organizational research. From the practical point of view, these new methodological approaches offer the possibility of developing support tools for managers, consultants, and policy makers, as well as innovative tools for teaching and learning about organizations and their environments (Gómez-Cruz et al., 2017).

Agent-Based Modeling & Simulation (ABM&S) is the methodological approach that inspires the construction of CLOD.

2 The Agent-based computational laboratory

The CLOD laboratory has been developed starting from the conceptualization of mutual learning between the organization and its members as conceived in the March' s model of 1991. To reframe the original cellular automata model in an agent-based environment we first subdivided it in different blocks (classes of agents, environment, learning mechanisms and organizational structure and procedures) and then we translated each block in specific elements of a pseudo-code. Furthermore, for each building block of the lab some additional features have been created to include potential extensions and to increase the realism of the original model. Table 1 summarizes the characteristics of the

blocks in the actual version of the CLOD lab and reports, for each block, a short description, the extensions of the original model that have been modelled in the actual lab, and future developments. In the next sub-sections, we describe more in depth the characterization of the main building blocks, briefly referring to the possibilities offered by some of the extensions included in the current version.

Table 12: CLOD Lab's building blocks

	Building blocks	Description	CLOD	Future developments
Agents	Organization	Set of internal stakeholders within a business (e.g., employees, managers, the board of directors, investors) that work to achieve the organization's goal and satisfy the external demanding.	Members Subset: Elite Leader	Departments Customers/Market Segmentation
	Environment	The external stakeholders that are not within a business itself but who care about or affect its performance (e.g., consumers, regulators, investors, suppliers).	Customer/Market	
Environment features	Complexity	The number of Customer/Market's requirements	#dimension	Competitive Environment
		Interdependence degree between Customer/Market's requirement.	K	
	Turbulence	Exogenous environmental change affecting customer's request.	Degree Frequency Span	
Organizational structure	Size	The organizational dimension measured as the number of employees and managers employed.	#members	Specialization Network Groups
	Hierarchy	A system that has many grade or ranks from the lowest (members) to the highest (Leader)	3-levels	
Organizational processes	Turnover	The rate at which members leave the organization and are replaced by new ones	– Yes – No – Yes, after equilibrium	Selection criteria Assessment method
	Elite selection	Set of rules enabling members to follow the organization (hierarchical) climbing properly	Best performances	
	Evaluation method	Metrics and parameters set out to assess the organization performances and the performances of single members	Score or Fitness	
Evaluator	Individual agent	Someone that judge the performances according to the defined evaluation method	– Customer – Leader	Different Stakeholders
	Market	The Market evaluates the organization performances based on the level of fitness	Landscape	
Variation	From Leader	Members' beliefs change according to those of the leader and a settled	Conformity	Socialization Other criteria

	From Members	probability. The leader changes his beliefs according to those of Elite members and a settled probability.	Listening	
Cognitive settings	Uncertainty	The beliefs of agents are expressed considering the Ambiguity of Natural Language	Fuzzy (Verbal Judgements Dual-truth Model)	From Creativity From Experiences

2.1 The agents

Any entity of our laboratory is an agent able to make some actions according to a set of rules. The main agents are the environment and the organization. The environment is represented by one agent or by a landscape, while the organization is represented by different classes of agents (breeds in NetLogo language).

2.1.1 Environment

The external environment is fundamentally represented by the customer who expresses her/his needs through a string of #dimension binomial choices (YES/NOT), computationally implemented by 1 and -1. In our proposal, the number of dimensions characterizing the customer's needs is a parameter that can be modified through a slider in the lab interface.

Moreover, the environment could be also characterized by a certain level of turbulence. The turbulence is particularly important as it adds dynamicity to the complexity of the environment and represents the intensity of surprises coming from technology, regulations, and markets.

2.1.2 The organization

The March's model represents an organization that develops on three levels. According to that, in our agent-based interpretation, the first level consists of the members of the organization, agents characterized by individual beliefs and knowledge about the external environment. The second level is made by a subset of members, named Elite, interpreted as an intermediate hierarchical level of most influential members legitimated by their superior performance. On the third level, there is a leader who represents a hierarchically higher level (the top management or the CEO) that is responsible to cope with customers' requirements. This organization is asked to answer the external environment, represented in the baseline version of the CLOD by a customer who expresses his requests through the elements of a vector of requisites.

Both members and the leader represent their beliefs about customer's requisites through a string of #dimension elements that could be represented by crisp or fuzzy

values. In the crisp representation, beliefs of organizational actors could be each equal to 1, -1 or 0. The value 0 in one of the dimensions of the vector of an organizational actor means that she/he is not able to express any belief on the corresponding dimension of the customer's vector. The current version of our laboratory also includes a fuzzy representation of organizational beliefs, but this extension is not analysed in this paper (for details about that, see: Ponsiglione et al., 2019). It is possible to note that in accordance with March's model, our lab can simulate an organizational turnover process in which one or more members leave the organization and are replaced by members 'novices' with random beliefs, according to a probability named "turnover-intensity".

2.2 Evaluator as the customer

In the case in which the evaluator is associated with the customer, the program models his/her needs through a string of #dimension binomial choices (YES/NOT), computationally implemented by 1 and -1. In our proposal, the number of dimensions characterizing the customer's needs can be modified by the modeller or by the experimenter. Increasing the size of customer requirements' vector simulates a more demanding market. Accordingly, the increase in customer dimensions implies a corresponding increase in the number of leader and members' dimensions.

The level of turbulence in the environment is implemented as the probability of changes of customer's requisites, happening according to a probability named "turbulence-degree".

2.3 Evaluator as the market

When the evaluator is the market, the model includes the representation of the environment as a NK fitness landscape as proposed by Kauffman (1993). This means that the needs of the market are modelled in terms of a fitness landscape (Kauffman & Weinberger, 1989). This type of landscape is useful in analysing the complex aspects related to companies' organizational learning and adaptation processes. Based on Kauffman's model (1993), two essential structural variables have been considered in the CLOD lab: N, the number of attributes that characterize the environment (from a computational point of view N is the parameter #dimension), and K, the number of attributes of N with which a given attribute interacts. Each attribute can take two possible values, represented in the agent-based model using 0 and 1. The shape of the landscape is determined by the interactions between the attributes. In the case in which there is no interaction between the attributes (K = 0) the landscape tends to present a single peek configuration, implying, according to Levinthal and Warglien (1999), a situation in which any local improvement leads to a global improvement, also known as the universal "best practice" situation. In all the other situations, as K increases from 1 to N-1, the fitness landscape becomes increasingly rugged, passing from a moderately rugged situation to a

randomly multi-peaked one. This scenario has been modelled in the CLOD by randomly choosing for each attribute a number of K attributes that affect the fitness value associated to that dimension. For each combination between the values of a particular attribute and the values of the attributes upon which it depends, a random fitness value has been generated in the interval [0,1]. The fitness landscape is given by the values of all the possible combinations for all the attributes.

Similar to the case in which the evaluator is the customer, the requirements of the entire market can evolve over time, due to a certain level of turbulence, determined by changes in areas such as technology and regulations. This fact is reflected in the proposed model, using the "turbulence-degree" probability. At each iteration, the attributes in the array of market requirements will change with the probability "turbulence-degree", chosen in the interface of the model. The new fitness values for the attribute will be computed by subtracting their current value from 1. An example is given in Table 2 for the case K = 1 in which the fitness value of any attribute is affected by only one other attribute. The first two columns include the potential combinations of values between the current attribute d_i and the attribute d_j that influences its fitness value w_i. The last column includes the updated fitness values.

Table 13: Updating the fitness value of the attributed

2.4 Learning mechanisms

Two types of mechanisms, which partially resume the learning mechanisms of March's model, contribute to spread the knowledge throughout the organization. On the one hand, there is a top-down learning based upon the principle of conformity: the knowledge of each member of the organization is compared with that of the leader; members' beliefs change according to those of the leader with a probability called "members-conformity-degree%". In the case in which the evaluator is the environment, the knowledge is replaced by the mean fitness value, calculated for each member and for the leader and taking into account the fact that they search and move in a NK fitness landscape.

At the same time, best performing members (the performance of each actor is measured as described later) are selected as belonging to the Elite. The Elite interacts with the leader through an additional learning mechanism: the disagreement between beliefs of Elite's majority and those of the leader leads to a modification of the latter with a different probability named "leader-listening-ability%". Through these two mechanisms, the leaders and the members become more homogenous and converge over time to a stable equilibrium.

2.5 Organizational processes

Central in the original March's model is the organizational process of learning performances evaluation. This evaluation is basically made by the Reality in the March's model and by the customer (or by the market) in the CLOD laboratory. The result of the evaluation process, in fact, depends on the agreement between members or leader beliefs and customer's requisites (market's needs).

All members and the leader are aware of their overall performance represented in term of Score. The Score is given by the number of beliefs that match customer's requisites minus the number of disagreements, normalized on the number of dimensions. A different concept is that of Knowledge. The Knowledge is measured at any time as the proportion of customer's requisites correctly represented in the beliefs of leader and on average in members' beliefs. Neither the members nor the leader has any information of customers' requisites. In this context, both leader and the members can reproduce false beliefs in their processes of exploration and exploitation.

Another fundamental process in March as in the CLOD lab is the Elite selection. At each time step, all members with higher scores than the leader could interact with him influencing his beliefs. In fact, each Elite's member expresses its own answer to the customer for any dimension. The output of the 'voting' process ends with an array of proposals calculated as the majority of the sub-groups 1 or –1.

When the evaluator is the market, the mean fitness (that is the measure of performances, replacing) is computed for all the members and for the leader. Similar to the case in which the evaluator is the customer, a fundamental step is represented by the selection of the Elite, which will include the members of the organization having a mean fitness greater than the one of the leader. Given the fact that each member of the Elite has its own individual points of view regarding the requirements of the market, an overall point of view of the entire Elite is determined by computing for each dimension the majority belief.

The laboratory has been implemented using NetLogo agent-based modelling platform (version 6.1.1).

3 Experimental design

In this section, we describe the two experiments that have been performed to explore some utilities offered by this computational laboratory as a tool for organizational research and design. The first experiment lets to internally validate the NK extension of CLOD laboratory by comparing the results obtained through simulations with the results showed in Bocanet and Ponsiglione (2012). Concerning the validation of the CLOD laboratory reproducing March's model, results are reported in Ponsiglione et al., 2019.

The second experiment aims at analysing the effect of environmental complexity and of different organizational sizes on performances measured in terms of fitness.

Both experiments were conducted in a stable (Experiment 1.1 and 2.1) and in a turbulent environment (Experiment 1.2 and 2.2); related parameters of the behavioural spaces are reported in Table 3 and 4. For each experimental configuration, 100 simulation's iterations were performed to make results more robust.

For the internal validation of the model, we simulated 81 configurations in a stable environment. In the turbulent environment, leader-listening ability% and members-conformity-degree% were both fixed to 50, while the K values were 1, 5, and 10 (Table 3).

Table 14: Experimental Design for NK model validation

Experiment 1.1 Effect of learning rates in **Stable Environment**	#dimensions	30
	#members	50
	Eq-stop	True
	leader-listening-ability%	10;50;90
	members-conformity-degree%	10; 20; 30; 40; 50; 60; 70; 80; 90
	Turbulence?	False
	Turnover?	NO
	K	1-5-10
Experiment 1.2 Effect of learning rates in **Turbulence Environment**	#dimensions	30
	#members	50
	Eq-stop	False
	leader-listening-ability%	50
	members-conformity-degree%	50
	Turbulence?	True
	Turbulence Degree	2
	Turnover?	NO
	K	1-5-10

In Table 4, both Experiments simulate organizations of different sizes (50, 100, 200) coping with an increasing environmental complexity. According to prior March's results, we settled the leader-listening ability% and members-conformity-degree% equal to respectively 90% and 10% as this configuration represents the combination that achieves the best organizational performances.

Table 15: Experimental Design

Experiment 2.1 Effect of environmental complexity and organizational size in **Stable Environment**	#dimensions	30
	#members	50;100;200
	Eq-stop	True
	leader-listening-ability%	90
	members-conformity-degree%	10
	Turbulence?	False
	Turnover?	False
	K	1-3-5
Experiment 2.2	#dimensions	30

Effect of environmental complexity and organizational size in **Turbulence Environment**	#members	50;100;200
	Eq-stop	False
	leader-listening-ability%	90
	members-conformity-degree%	10
	Turbulence?	True
	Turbulence Degree	2
	Turnover?	False
	K	1-3-5

4 Results and discussion

This section briefly reports and discusses the experiments performed through the CLOD laboratory. For each Experiment, we report some graphs to visualize the outputs of simulations and the One-way ANOVA tests with the relative post-hoc. The latter allow us to appreciate the existence of statically significant differences among different obtained outputs. More details will be provided in the following sections.

4.1. Results of Experiment 1.1

With this Experiment, we intend to internally verify the code of the agent-based NK extension, on which the CLOD laboratory is based. We compare our results with those reached through other different models, that have been already verified by the comparison with some stylized facts reported in the relevant and related literature (in particular, we take into account Bocanet and Ponsiglione's study, 2012).

Figure 2 shows the main results of Experiment 1.1. On the y-axis of Figure 2 the organizational performance is reported (average-leader-score); and on the x-axis there are the levels of member-conformity-degree%. The different values of leader-listening-ability% are represented by different colours (blue=10%, red=50%, green=90%). It is possible to note that the higher the K value, the lower the organizational performances. Moreover, for high levels of complexity (K > 5), organizational performances are strongly affected by randomness (Bocanet and Ponsiglione, 2012). Finally, in a stable environment, greater environmental complexity makes the learning rates less impactful in determining organizational performances. These results are also proved also by the ANOVA tests, given that as K increases, the number of statistically significant differences among organizational performances, determined by diverse learning rates, decreases very fast (ANOVA tests are available upon request).

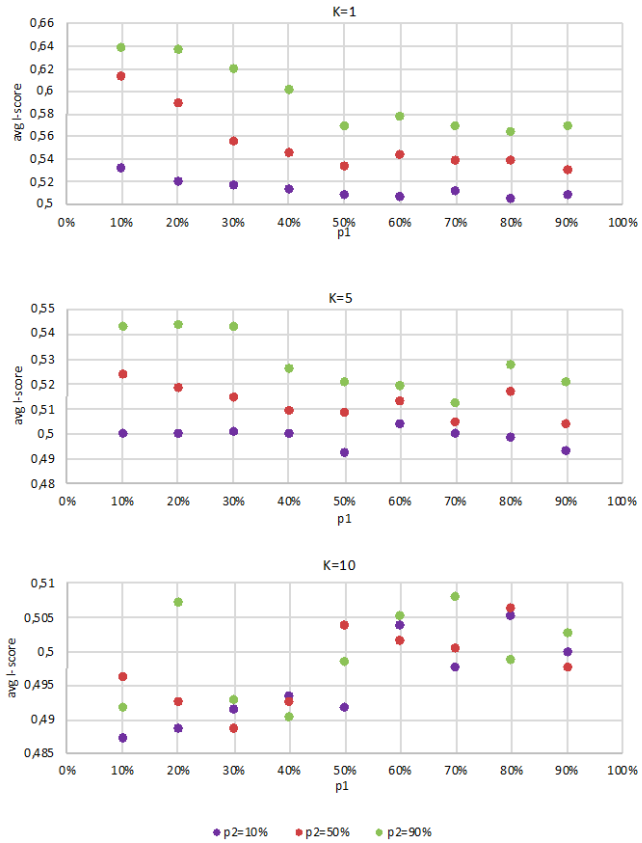

Figure 3: Results of Experiment 1.1

These results appear to be in line with those obtained by Bocanet and Ponsiglione (2012). Moreover, the trends of organization's performance as reported in Figure 1 for the Experiment 1.1 are substantially similar to those obtained and published by March (March, 1991, p. 76). In fact, we can notice that the peak of knowledge accumulated in the organization is obtained when the leader-listening-ability% is high (90) and the member-conformity-degree% is low (10). The convergence of results is not confined to some specific points, but is verified for the whole trend, thus giving further support to the internal validation.

4.2. Results of Experiment 1.2

The Experiment 1.2 aims at analysing the impact of different learning rates on organizational performances in turbulent environments. In Figure 3, we can observe that in the case of K = 1 the trend of average leader knowledge is consistent with the trend identified by March (1991, p. 80). In fact, the average leader knowledge (for each

considered period of time, the value of leader knowledge is averaged on 100 simulation runs), after an initial increase, decreases dramatically as simulation evolves, because the system is not able to preserve a certain degree of internal diversity.

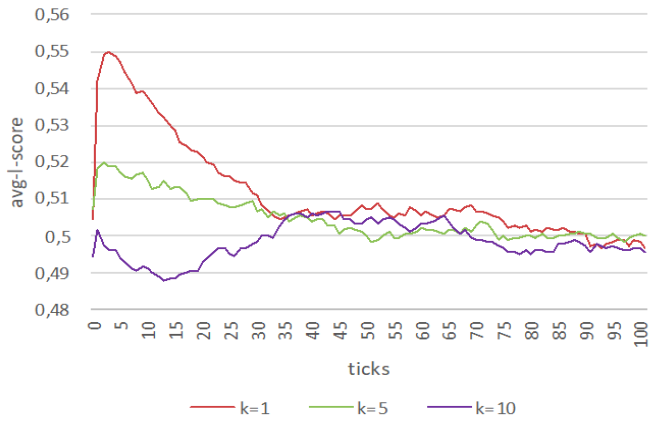

Figure 4:Results of Experiment 1.2

Over the simulation, the organizational performances progressively deteriorate, until the achievement of completely random results, represented by the average score around 0,5. This value represents a sort of attractor on which the performances converge for all the K values. These results are confirmed by the ANOVA tests shown in Table 5. Indeed, while at the beginning of the simulation, some statistically significant differences exist in terms of organizational performances related to different levels of environmental complexity, after this temporary phase, such statistical differences disappear.

Table 16: Model Validation Experiment 1.2 - Comparison among different K values 1; 5; 10

P1=50% P2=50%	**K**			**Test**	
Number of Step	**1**	**5**	**10**	**p-value**	**post-hoc**
Step_4	0,5488	0,5188	0,4961	0,0000	2-1*;3-1*;3-2*
Step_14	0,5298	0,51301	0,4887	0,0000	2-1*;3-1*;3-2*
Step_34	0,5048	0,5058	0,5028	0,8322	2-1;3-1;3-2

*.05 and **.01

In other words, with customer's requisites that change over time, the lack of internal diversity, due to the achievement in the short period of an equilibrium stage, determines a progressive deterioration of organizational performances, until the achievement of completely random results. Finally, results of Experiment 1.2 can be assumed as a further sort of internal validation of the agent-based model, able to reproduce qualitatively the same behaviour of the original cellular-automata model of March (1991), also with different levels environmental complexity.

4.3. Results of Experiment 2.1

Results of Experiment 2 are reported in Figure 4. Results are presented using box-plots. Each graph in Figure 4 compares the distributions of the leader's knowledge values for different organizational sizes with respect to a specific value of K.

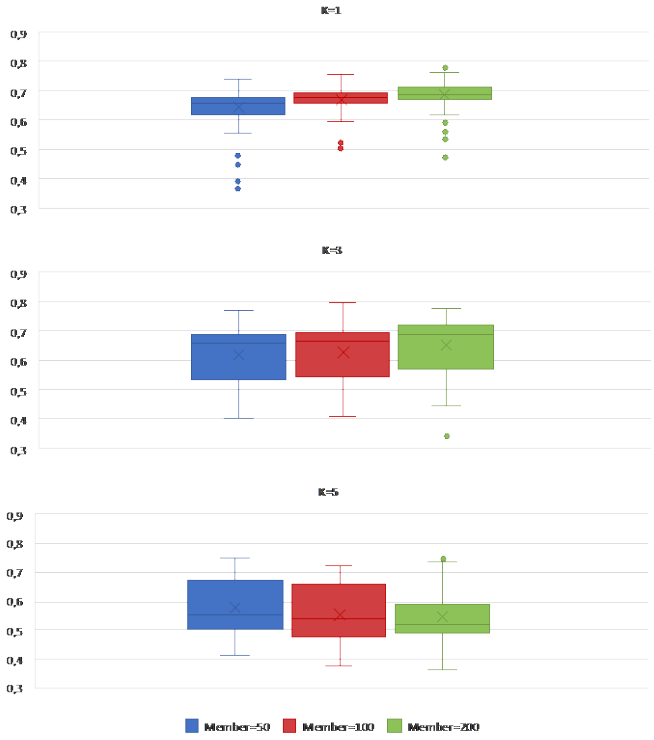

Figure 5:Results of Experiments 2.1

As shown in the upper part of Figure 4, in stable environments the organizational size plays a role in determining organizational performances, although the increasing environmental complexity has a negative influence on the level of knowledge achieved. In order to verify the impact of organizational size on performances, some ANOVA tests have been performed (Table 6).

Table 17: Results of ANOVA test Experiment 2.1

P1=90% P2=10%	**Organizational Size**			**Test**	
K	**50**	**100**	**200**	**p-value**	**post-hoc**
1	0,6454	0,6729	0,6873	0,000	2-1*;3-1*;3-2*
3	0,6212	0,6292	0,6529	0,044	2-1;3-1*;3-2**
5	0,5769	0,5536	0,5451	0,046	2-1**;3-1*;3-2

In particular, there are statistically significant differences among considered groups (small, medium and large organizations) in terms of organizational performances with reference to K equals to 1. On the contrary, as K increases, the number of significant differences is reduced; specifically, for K=3 there are statistically significant difference between small and large (p-values=0,05), as well as between medium and large (p-values=0,1). For K = 1 and 3, the Anova tests confirm that better performances are achieved by larger organizations. While for K=5, there are statistically significant differences between small and medium (p-values=0,1), as well as between small and large organizations (p-values=0,05); in these latter cases, best performances are achieved by smaller organizations. It seems that, in stable environments and for low-moderate levels of complexity, the increasing size of firms is able to sustain learning performances over the random value. In the case of K= 5, performances are very close to the average level of knowledge (0,5) and only small firms can reach performances level significantly different from the random value. Table 7 shows that different levels of environmental complexity affect the organizational performances for any organizational size. According to the literature, large organizations respond better than the smallest ones to increasing environmental complexity, excepting the case of K = 5

Table 18: Results of ANOVA test Experiment 2.1

P1=90% P2=10%	K			Test	
Organizational Size	1	3	5	p-value	post-hoc
50	0,6454	0,6212	0,5769	0,000	2-1*;3-1*;3-2*
100	0,6729	0,6292	0,5536	0,000	2-1*;3-1*;3-2*
200	0,6873	0,6529	0,5451	0,000	2-1*;3-1*;3-2*

4.4. Results of Experiment 2.2

The Experiment 2.2 aims at analysing the effect of environmental complexity and organizational size in a turbulent environment. As expected, increasing K implies an organizational performances decrease. Moreover, for higher K values, the organization with 100 employees appears to perform better than the other ones, although not all the statistical differences are significant (Tables 9-10).

Step_34	0,5759	0,5546	0,5148	0,0000	2-1*; 3-2*; 3-1*

Table 10 shows that, as expected, different levels of environmental complexity affect the organizational performances. While, Table 9 shows that in turbulent environments and for increasing levels of complexity, the role of size is not clearly defined and, as suggested also by March in is seminal work, the process of learning seems to be a "random walk" (March, 1991, p: 80).

This evidence suggests that the additional complexity of the external environment determined by turbulence requires other organizational solutions over the increasing of size (e.g. the personnel turnover) to generate an internal diversity in the firm to cope with the external dynamicity. The size of the organization in terms of members seems to be not significant to address learning challenges determined by increasing turbulence of external reality.

5 Conclusions

The goal of this work was to analyze the potential of an agent computational laboratory as a support tool for organizational design. The paper describes the blocks of the laboratory, which is based on an agent model, and proposes two types of experiments. A first group of experiments is aimed at verifying the model internally; the second group of experiments intends to explore the organization's behavior in environments characterized

by different levels of complexity and dynamism and analyses the role played by the organizational size in these contexts.

Organizations activate their learning capacity for answering to uncertainty and changing environments (Lei et al., 1999; McGill and Slocum, 1994; Wu and Shanley, 2009) and the role of organizational size in this response is not clearly assessed in the literature. Our results confirm that larger organizations, in general, reach better performances with respect to smaller ones in stable environments, also when the complexity of external environment increases. Instead, in the presence of moderate levels of turbulence, the organizational size seems to be not crucial in developing better learning capacity and organizational performances, and in the presence of moderate to high levels of complexity the organizational response seems to be "a random walk". This finding prompts us to investigate on more appropriate solutions to make organizations able to preserve or develop a specific level of diversity adequate to a certain degree of environmental complexity and dynamicity. Next developments of the research will be devoted to activate additional features of the lab to assess the impact of other organizational variables and solutions to organizational performances in complex and turbulent worlds.

Abstract

The main objective of the study is to investigate how firms can improve their performance. In particular, the impact of the creation of knowledge by firms (closed innovation) or the share of knowledge among firms (open innovation) on the firms' performance is investigated. Both economic and innovation performance are considered. The economic performance is evaluated using the turnover of firms, whereas the innovation performance is evaluated using not only the number of patents but also other patents features that are relevant in predicting the forward citations that are considered as a proxy of the innovation performance and capability. The results show that firms' innovation performance increases in the share of knowledge case, whereas the economic performance has a better result in the case of no share of knowledge.

Keywords – Agent-based models, Knowledge, Innovation, Performance.

Paper type – Academic Research Paper

1 Introduction

In their efforts to progress and produce new technologies and perform superiorly in complex and uncertain innovation and competitive environments, firms increasingly must rely on external knowledge (Chesbrough, 2003). In this way, firms shift toward the so called "model of open innovation". The main element of "open innovation" is "the use of purposive inflows and outflows of knowledge to accelerate internal innovation" (Chesbrough, 2006). It implies the collaborative production and exchange of knowledge across organizational boundaries (Enkel et al., 2009) confirming that knowledge sharing is the main driver of successful collaborative innovation (Bogers, 2011).

The global tendency, i.e. the shift toward open innovation and the need to exchange knowledge, has been supported by several studies (e.g., Bader and Enkel, 2014; Terjesen and Patel, 2017; Zobel et al., 2017; Lazzarotti ed al. 2017). Thus, firms search and cooperate with external knowledge sources and actors in order to complement and upgrade their internal knowledge bases and competencies, thereby accelerating their own innovation process effectively and efficiently.

The mentioned studies demonstrate the correlation between open innovation and performance. However, despite often significant correlations have been confirmed, the link between open innovation and innovation and economic performance is pivotal. Few authors found that this relationship may take for example an inverted U-shape (Greco et al., 2016). Moreover, to understand which kind of innovation performance are really enhanced by open innovation and share of knowledge is very difficult.

This lack of agreement is probably due to methodological choices and lack of data rather than to the real proprieties of the phenomenon. Indeed, for example, often U-shaped relationships have not been hypothesized in previous studies (Greco et al., 2016; Cheng et al., 2019).

In order to fill this gap, the present study proposes an agent-based model to simulate different relationships and overcome the difficulties in acquiring large-scale data about firms' openness and performance. The main objective of the study is to investigate how firms can improve their performance. In particular, the impact of the creation of knowledge alone by firms (closed innovation) or the share of knowledge among firms (open innovation) on the firms' performance is investigated.

The study specifically investigates firms' performance when they adopt an open or a closed innovation strategy, i.e. sharing or not knowledge Among the different open innovation strategies, co-patenting is one peculiar and strong possibility very useful to investigate this openness paradox. Co-patenting implies the share of knowledge between the partners and the joint ownership of collaborative outcomes and often it has been seen as a not efficient strategy because of its complexity, challenges and managerial costs (Belderbors et al., 2010; Belderbors et al, 2014). With the agent-based model, how the development of joined patents may impact on both economic and innovation performance can be simulated. The economic performance is evaluated using the turnover of firms, whereas the innovation performance is evaluated using not only the number of

patents but also other patents features that are relevant in predicting the forward citations that are considered as a proxy of the innovation performance and capability (Ponta, 2019). In Ponta (2019), using machine learning algorithms, the following patents features have been identified: the number of backward citations, the number of International Patent Classification (IPC) classes, the number of extensions, the number of months between the publication date of the youngest and the oldest patent of the family. In particular, the number of IPC classes may represent the diversification of the company and in how many different technological domains the company can operate for a new innovation, the number of backward citations may be a proxy of the knowledge owned by the company and consequently the quality of the innovation, the number of extensions may represent the level of internationalization acquired (Petruzzelli et al., 2015) by the company and the number of months between the publication date of the youngest and the oldest patent of the family characterized the ability of the company to refine an innovation (Dechezlepretre et al., 2017).

Results show that firms that share knowledge have better innovation performance, evaluated not only with the number of patents but also with the other patents features described in Ponta et al. (2019).. Differently, in terms of economic performance the no share of knowledge shows better performance and a U-shaped relationship occurs. In conclusion, the developed agent-based model provides a very suitable tool to make classical what-if analysis. In particular, it is a sort of computational laboratory where to perform experiments and find the more convenient policy to improve the firms' performance (Pyka et al., 2009; Raberto et al., 2019; Iandoli et al., 2012).

The paper is organized as follows: Section 2 presents the model, Section 3 shows the results and Section 4 provides the discussions and conclusion of the study.

2 The model

To investigate the main objective of the study outlined above, an agent-based model and simulator (PABIM) has been developed.

The model includes heterogeneous agents that represent firms organized as a directed random graph, i.e. the interactions are unidirectional and characterized by a weight w_{ji}, assumed a positive real number.

The graphical representation of the present PABIM model in terms of firms (circles) and interactions (lines) is shown in Figure 1.

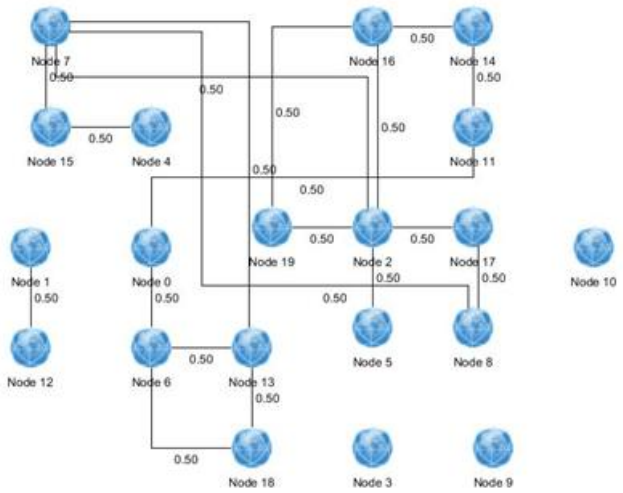

Figure 7 – Graphical representation of PABIM model in terms of firms (circles) and interactions (lines) at time step 0.

At the beginning of the simulation, all the firms have the same output node degree, defined as the number of outgoing arrows, and are endowed with the same quantity of cash and the same number of employees. During the simulation, the output node degree of each firm is directly proportional to the firm's size, i.e., it increases if the firm's size increases and decreases if the firm's size decreases, thus the number of employees, proportional to the firms' size, varies during the simulation.

In the model, a firm i is characterized by an identifier id_i, a number of employees N_i, a list of its filed patents P_i, an amount of cash C_i, the turnover Tu_i, the percentage of turnover invested in R&D α_i, an industrial sector IS_i and a probability to patent ρ_i.

The percentage of turnover invested in R&D research is different for each firm and proportional to the firms' dimension. At each iteration step, each firm invests a fraction of the turnover in R&D research, necessary to file patents. All the R&D expenses are finalized to patent.

The probability ρ_i of firm i to file for a patent is set to depend on the cumulated R&D research investment Mc_i employed by the firm i since the latest patent filed, as follows:

$$\rho_i^t = 1 - \frac{1}{1 + \eta\, Mci\,{}_i^t} \qquad (1)$$

where η is a shape parameter, homogenous across all firms, setting the patent research speed, i.e., the higher is η, the higher is the probability to file for a patent, for any level of cumulated R&D research investment Mc_i employed.

The probability to make a patent using shared knowledge between firm i and j (co-patent between firm i and j) is given by Eq. 2

$$\rho_{ij}^{t} = 1 - \frac{1}{1 + \eta\,(Mci_{i}^{t} + Mci_{j}^{t})} \quad (2)$$

If firm *j* cannot patent alone, it chooses from among all the firms' requests, to make a patent using shared knowledge with the firm with the greatest connection strength.

If a patent is not possible at time *t*, the firm can extend a patent issued at time step *t-1*. If firm *i* did not file for a patent at time step *t-1* no patent is extended.

The patent is characterized by an identifier, an IP class, one or more countries in which the patent is extended, the number of forward and backward citations. It is worth remembering that the backward citations are the patents cited when the new patent is issued, whereas the forward citations are the ones received by the patent. Moreover, a patent is characterized by a cost composed of a part that represents the cumulated (discounted) cost of filing and maintaining a patent and another part that depends on the R&D investment done until the year of filing. Moreover, a patent is also characterized by an extensions cost which represents the cumulated (discounted) cost of extending and maintaining the extensions of a patent. Management costs have also been considered.

The value of the patent, intended as the cumulated (discounted) turnover generated by the patent is defined by firms proportional to costs, through a multiplier $\mu_{p,i}$ defined at the beginning of simulation and constant during the simulation. $\mu_{p,i}$ is a positive real number to consider both the case of success and failure of a patent. In particular, $0 < \mu_{p,i} \leq 1$ represents the failure case, whereas $\mu_{p,i} > 1$ represents the success case.

The revenues for firm *i* of a patent *p* filed at time *t* is:

$$R_{p,i}{}^{t} = \begin{cases} V_{p,i}^{t} & \text{if firm } i \text{ files a patent alone at time step } t \\ V_{p,i}^{t}\ \nu \dfrac{Mc_{i}^{t-2}}{Mc_{i}^{t-2} + Mc_{j}^{t-2}} & \text{if firm } i \text{ files a patent at time step t using shared knowledge with firm } j\ (copatent) \end{cases} \quad (3)$$

where ν is a coefficient positive and less than 1, which simulates the management costs between firm *i* and *j*. Furthermore, the turnover of firms is updated. and firms determine the number of employees to hire or fire at each iteration step, according to their revenues. In particular, if the variation of turnover, ΔTu_i, is larger than zero firm *i* will hire a number of employees directly proportional to ΔTu_i, whereas if ΔTu_i is smaller than zero firm *i* will fire. Furthermore, if ΔTu_i is equal to zero no hiring or layoffs are implemented.

Finally, at each time step, the economic and innovative performances are evaluated. It is worth remarking that at each time step t, each firm checks if it can make a patent alone, and if not, the firm can try to share knowledge with the connected firms.

It is worth remarking that at each time step *t*, each firm checks if it can make a patent alone, and if not, the firm can try to share knowledge with the connected firms.

2.1. Firms Performance

At each iteration step, the economic performance Pe_i^t of firm i is evaluated as its turnover Tu_i^t. As said in the introduction, in literature many measures have been proposed to evaluate the firms' innovation performance. Among the performance measure based on secondary data, i.e. the patent database, in this paper, not only the traditional measure of number of patent is considered, but also the following patents features have been considered: the normalized number of patent, the number of backward citations, the number of IPC classes, the number of extensions, the number of months between the publication date of the youngest and the oldest patent of the family, each of them defined using machine learning algorithms, i.e., Regularized Least Squares, Deep Neural Network and Decision Trees, as described in Ponta et al. (2019).

3 Computational Experiment

3.1 Design of experiments

In order to investigate the research question described above two scenarios have been considered. In the scenario (i) each firm can only create knowledge, whereas in the scenario (ii) the knowledge's share strategy is allowed. Simulations have been performed ceteris paribus, meaning that all the parameters are identical with the exception of the strategy. In particular, twenty firms, working in eight different sectors have been simulated. It is worth noting that each firm can file one patent maximum per year. The two cases previously described are explored with six different values of η, the parameter which controls the probability to translate the R&D investment into patents, see Eq. 1; in this way twelve different scenarios are obtained. The methodology used is based on Monte Carlo computational experiments: each scenario is simulated with fifty different seeds of the pseudorandom number generator. So, a total of 600 simulations were considered in order to conduct the investigation. The computational results are presented in the form of boxplots. In particular, each boxplot shows the distribution of the time averages of relevant variables over a twenty-years time interval, concerning the fifty simulations characterized by different seeds. Boxes enclose the values from the first to the third quartile; they also include whiskers that extend up to the minimum and maximum data points that are not considered outliers; the horizontal segments inside boxes represent the median of the distribution. The analysis aims to investigate the impact of sharing knowledge on firm performance, considering both economic and innovation performance. Table 1 summarizes the simulations initialization data. The data used in the simulations were estimated from the Orbit Intelligence database provided by Questel[1], collecting patents that are published by firms with a registered office in Italy, or by an inventor with

[1] *www.questel.com*

a residence in Italy from 2000 to 2018. It is worth noting that each firm can file only one patent per year maximum.

Table 21 - Simulation Parameters

Symbol	Description	Value
T	Years	20
I	Number firms	20
ES	number economic sector	8
do	number of initial output connection	0, 2
T_u	Turnover init	20000
η	patent research speed	0.00001 to 0.001
α	% of turnover invested in R&D	[2 - 17]
μ	Multiplicator	[0.5 - 2]
ν	coeff management cost	0.9
C_e	patent extension cost	350
C_f	patent filed fixed cost	500

3.2. Results

Figure 2 shows the economic and innovation performance in scenario (i) (blue) and in scenario (ii) (red). The scenario (i) is characterized by a no share of knowledge strategy. As in the real world, firms patent only alone and do not cooperate to achieve technological improvement more quickly. Scenario (ii) is characterized by the possibility to share knowledge, that is, firms cooperate to reach the issue of a patent. In particular, Figure 2 (a) shows the economic performance approximated with the turnover. It can be noted that for all the values of η, the turnover in scenario (i) is larger than in scenario (ii), meaning that firms can convert R&D investment into patents without sharing knowledge, and making patents alone saves the management costs. For a firm, it is more remunerative to reach enough knowledge to patent rather than to use shared knowledge. Moreover, for very large η the two scenarios are similar because, even in the case of shared knowledge, firms file for patents alone. Furthermore, it is worth noting that in both scenarios the maximum value of economic performance is reached for an intermediate value of η meaning that too less or too large number of patents does not permit to reach the optimal value of economic performance. Figure 2 (b) shows the innovation performance evaluated with the number of patents. For all η the innovation performance is larger in scenario (ii), i.e. when firms share knowledge. Moreover, it is worth noting that, both in Figure 2 (a) and (b), the increase of the capacity of firms to translate R&D expenditures into patents is not proportional to the increase in economic and innovation performance. In fact, for larger η the economic and innovation performance behaviour is very similar. In order to investigate innovation performance deeply, Figure 3 shows the five patent features mentioned in Section 2. In each subfigure, both scenario (i) in blue and scenario (ii) in red are plotted for easy comparison. Figure 3(a) shows the normalized number of patents with

respect the firm size. It is possible to observe that for all η it is larger in scenario (ii), i.e., when firms share knowledge are able to file for a larger number of patents compared to the no share case. Thus, independently of the ability of firms to transform R&D research into patents, the possibility to use sharing knowledge increases the innovation performance of firms. The number of backward citations, the number of IPC classes, Figure 3 (b) and (c) show the number of IPC classes and the number of backward citations patent features, respectively. It is possible to observe that for all η in scenario (ii) the two features are larger than in scenario (i). Finally, Figure 3 (d) and (e) show the number of extensions, the number of months between the publication date of the youngest and the oldest patent of the family, patents features. It can be observed that for all η in scenario (i) and in scenario (ii) these patents features are larger than in scenario (ii). It is worth noting that in both scenarios the maximum number of these features is for η not very small nor very large. Summarizing the results of the innovation performance, in scenario (ii), i.e. when firms can share knowledge, firms reach better performance compared to scenario (i).

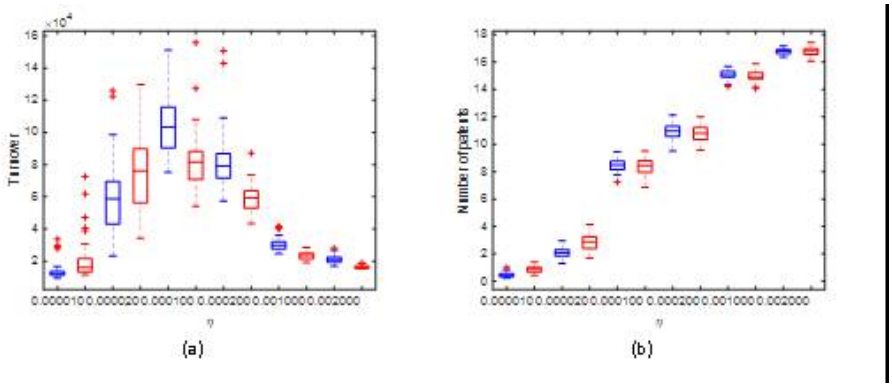

Figure 8 – Distribution of: the economic (a) and innovation (b) performance of firms for scenario(i) (no share of knowledge) in blue and scenario (ii) (share of knowledge) in red

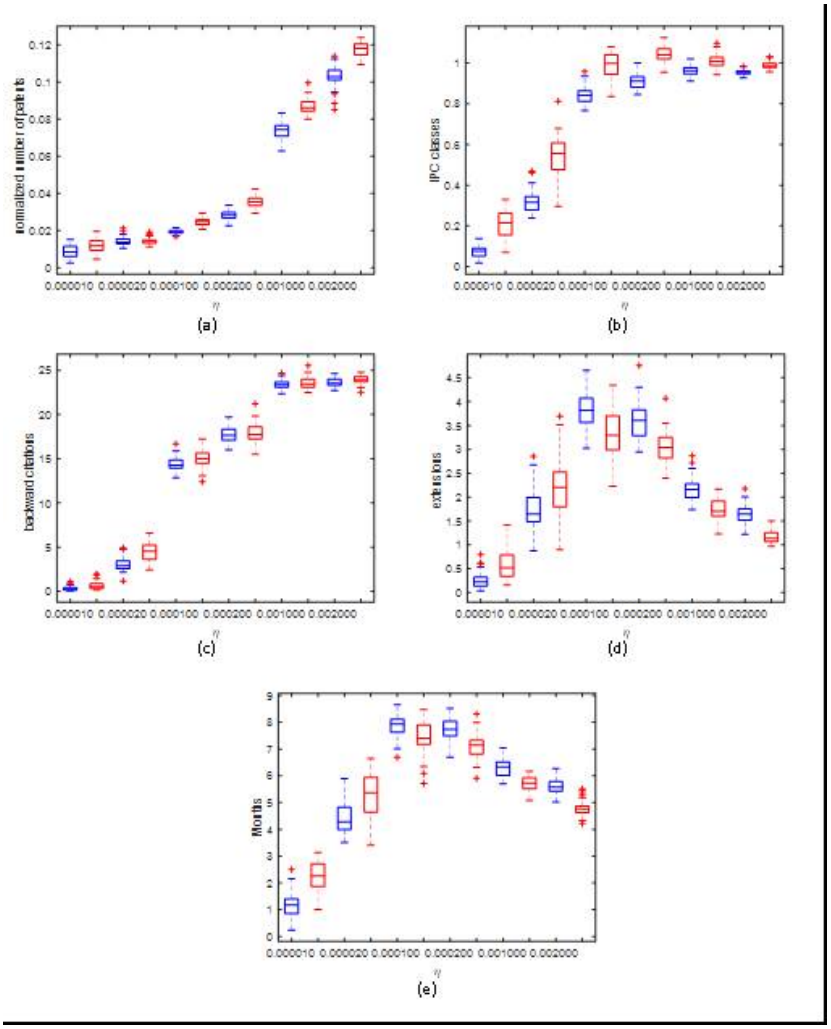

Figure 9 - Distribution of the following patents features: the normalized number of patents (a), the number of extensions (b), the number of IPC classes (c), the number of backward citations (d) and the number of months between the publication date of the youngest and the oldest patent of the family (e) for scenario(i) in blue and scenario (ii) in red.

4 Discussion and Conclusions

The computational results presented in the paper are able to capture the impact of the creation of knowledge by firms or the share of knowledge among firms on firms' performance. The paper has proposed a new methodological approach, i.e. an agent-based model, that provides a more complete understanding of the phenomenon, of the pivotal link between open innovation and innovation and economic performance (Greco et al.,

2016) and of which kind of innovation performance proxy are really enhanced by open innovation.

Furthermore, the firm performance dynamics that emerged from the simulations show important results, both at the economic and innovation levels. The possibility of a co-patenting strategy points out very interesting aspects. In particular, the economic performance is greater in the case of a no co-patenting strategy and there is also a U-shaped form. This result confirms that filing for a joint patent is more expensive, because, for example, managerial costs between the firms are also necessary. Moreover, the inverted U-shaped demonstrated that when increasing the patent research speed, there is a sort of maximum for both shared or not knowledge. High R&D velocity could lead to lower economic benefit probably because of difficulties in capturing the innovation value and high R&D expenses cannot generate higher sales. In the case of co-patenting, this is even more true, probably because co-patenting could lead also to higher complexity and managerial costs, confirming also more recent studies about the not linearity of the relationship (Greco et al., 2016). Instead, innovation performance is more effective in the case of a co-patenting strategy. In particular, in terms of number of patents developed, the open innovation strategy of sharing knowledge and developing a co-patenting shows better performance. The use of external knowledge permits to fill internal lack of competencies and develop a larger amount of innovations. Also in terms of diversification, the share of knowledge permits to increase the performance. However, at a certain point, there is a sort of plateaux where the share or not of knowledge reach similar performance. This suggests that when the research speed of a company is particularly high, probably the company cannot reach other technological domains and the share or not of knowledge will not lead to higher diversification. Differently, for lower research speeds, the use of a co-patenting strategy permits to reach more technological domains and increase the diversification. This suggests that the other partner help to open toward more sectors and technological domains (Petruzzelli et al., 2015).

In terms of backward citations and consequently of quality of the innovation, companies with lower R&D speed increase their knowledge base and their innovation quality when sharing knowledge. When companies own a higher research speed, the possibility of sharing knowledge leads to lower expansions in terms of knowledge base, probably because they internally own already a wide knowledge base and innovation competencies (Petruzzelli et al., 2015).

In terms of patent extensions and consequently internationalization of the innovation in other countries, the sharing of knowledge is positive for lower levels of R&D speed. After a certain point, the sharing of knowledge lead to lower benefits. That could be due to the fact that companies with high R&D speed already market and protect their innovation at an international level and in multiple countries (Petruzzelli et al., 2015).

Results in terms of the number of months between the publication date of the youngest and the oldest patent of the family that represent the ability of the company to refine an

innovation show that probably the sharing of knowledge for lower R&D speeds allows to better refine the innovation. Differently, companies with higher levels of R&D speed are already capable by themselves to internally refine the innovation and propose incremental changes to the original one (Dechezlepretre et al., 2017).

In conclusion, the agent-based model here developed provides a tool that is very suitable for making a classic what-if analysis. In particular, it is a sort of computational laboratory where to perform experiments and find the most cost-efficient policy to improve the performance of firms. In fact, it allows for understanding what happens in terms of performance if a firm decides to adopt an open innovation strategy and specifically adopt a joint-patents or not. This allows for taking a further step towards understanding the outcomes tied to applying a possible joint patent strategy that has not yet been widely analyzed, due to a lack of data. This simulator will be a very useful tool for managers because they will be able to simulate a chosen strategy before applying it in the real world. Nevertheless, this study is not without limitations. Although patents are widely used to measure innovation performance, they represent only a limited set of company innovation assets. Furthermore, in some sectors, patents are not widely adopted as mechanisms to protect innovations because other innovation assets that are more difficult to measure, such as R&D expenditures, intellectual assets, human resources skills, and aesthetic design, also provide information to measure innovation performance (Grazzi et al., 2020). For this reason, other sources of information and data (for example expenditure in R&D) will be used to strengthen the simulator. Moreover, in the model, firms can choose only one strategy from among the possible ones, i.e., to patent alone, to co-patent and to extend an older patent, but in the real world, firms can patent and extend an older patent at the same time. Thus, the possibility to adopt a mixed strategy will be allowed in future research. Other next steps, to overcome some limitations, are to differentiate the R&D expenditure, which in the current model is only used to patent. Finally, it is worth remembering that this is a first step to verify if and how a patent's features influence a firm's performance based on a modeling assumption that needs to be further investigated.

Abstract

Collaborative innovation networks represent adequate structures within which to foster members' abilities to interact and cooperate in order to increase the level of knowledge and facilitate access to innovation. In this paper we consider two collaborative innovation network models, called orchestration and choreography and we compare them in terms of knowledge flow by means of a network centrality measure called Neighbours' Information Patrimony, recently introduced to study the influence of the pattern of connections around a network member. We present empirical results on a wide set of simulations and we discuss outcomes and results to explain some behaviour in such innovation networks.

Keywords – Collaborative innovation networks, Network orchestration, Network choreography, Neighbours' Information Patrimony.

Paper type – Academic Research Paper

1 Introduction

In recent years, innovation has evolved beyond the boundaries of single firms towards a more network-based approach (Ferraro and Iovanella, 2017; Grange et al. 2020). Firms investing in innovation outside their internal and business borders increase indeed their opportunities to innovate. Thus, firms have undergone a fundamental change in the way they undertake innovation activities. In particular, in the framework of a knowledge-based economy, firms join innovation networks that allow them to share knowledge with partners, enabling access to new technologies and resources (Hurmelinna-Laukkanen and Nätti, 2018).

Collaborative innovation networks, which emerged in recent years as a result of the evolving challenges faced by businesses, represent adequate structures within which to foster members' abilities to interact and cooperate in order to enhance the level of knowledge and facilitate access to innovation (Galati et al, 2019). They allow the creation of new value by combining ideas and practices and sharing resources, skills and technologies, thus fostering relevant synergies. Innovation networks can be seen as the consequence of combining existing and novel knowledge from various firms and their business boundaries in order to create unique products, services, and processes depending on the current needs of the market.

Although the scientific literature has explored how the relationships among network members help achieve the innovation outcome (Ferraro and Iovanella, 2015), little has been said regarding how single members act to exploit and manage the network. As a matter of fact, the processes that a network member must perform in order to control, coordinate, influence and monitor its own activities within the network remain poorly understood.

Generally, interactions are considered by means of operational processes (Kuura and Lundin, 2019) that are operationalised concepts in the form of a process construct of developmental events; thus, processes are meant as sequences of activities, that are assessed over time in order to explain causal relationships between variables. In a networked environment, a process is intended as a sequence of deliberate and purposeful cause-and-effect actions that are instrumental in the evolution of the system. Such actions comply with the network's rules and purposes and allow value to be created from the system.

As in Slotte-Kock and Coviello (2010), we notice that network processes are different according to the structure of the underlying network. For this reason, we identify two different models: the orchestration model (Dharanaj and Parkhe, 2006; Faccin et al. 2020) and the choreography model (Ferraro and Iovanella, 2015).

The structure of the network influences the spreading of knowledge among its members., Information availability stemming from the network connection patterns varies indeed starting from the observation that a single member is not only affected by its alters (i.e. its neighbours), but also by the alters of its alters. Under this perspective, different patterns of knowledge diffusion correspond to different network structures.

In the light of the above, the aim of the present paper is to look into how information mechanisms are managed within the orchestration and the choreography models. In doing this, we initially contribute by providing a formal representation through a network science approach (Barabási, 2016).

Under the proposed approach, it appears as relevant to observe how the neighbourhood of a network's member, as well as the patterns featuring alters of alters, influence knowledge exchanges. Starting from recent developments concerning the assessment of the neighbours' information patrimony relating to a network's member (Arpetti and Iovanella, 2019), we hereby analyse how different patterns of relationship influence the network and how members can benefit from such patterns.

The outcomes of the proposed reflection allow to distinguish network's members based on their neighbour's information patrimony and provide supporting empirical evidence with a view to implementing sustainable development and assisting in assimilating, utilising and reconfiguring the knowledge flow.

2 Organizational models: orchestration and choreography

2.1 The orchestration model

Traditionally, the literature considers planned networks as interactions represented in a hierarchical structure, with a prominent member or participant performing a leadership role in managing the system. The operation of such networks is well described by the *orchestration* model, which considers the fundamental role of the orchestrator or hub as the one holding particular importance and exercising influence, due to its individual qualities and prominent position within the network (Dharanaj and Parkhe, 2006).

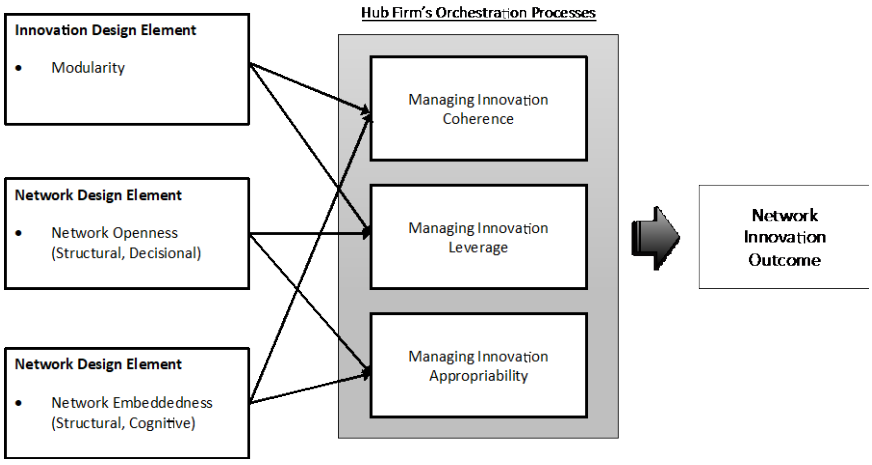

Figure 1: Orchestration processes, innovation design and network design (source: Nambisan and Sawhney, 2011).

Due to its central position, the orchestrator monitors and controls the knowledge flow and keeps a huge number of connections that, in turns, are willing and able to provide it with important opportunities and resources. The orchestrator has the qualities necessary to pull together and leverage on the dispersed resources and skills of network members, via facilitating and coordinating the interactions needed to achieve the outcome of the system. Furthermore, the orchestrator influences the network design and how processes are established (Laukkanen and Nätti, 2012).

The centrality of the hub implies its higher position within the members' hierarchy and therefore constitutes a significant source of power. Usually, network members perceive the central firm as holding a higher status and being more trustworthy than peripherals, since it can access knowledge and resources more easily. Indeed, it is generally the orchestrator who recruits network members and shapes their connections. By consolidating the legitimacy of the network's activities, it is able to attract further partners and to put increased efforts and resources into encouraging fruitful links among members (Paquin and Howard-Grenville, 2013).

In orchestrated networks, activities are implemented according to the members' role and are constrained by the corresponding patterns of network composition. Such activities are undertaken through instances of the orchestration processes undertaken by the hub. The orchestrator acts as a controller and executer in the network and functions as a leader with the possibility of invoking process execution by network members.

Figure 1 shows the orchestration model as reported in Nambisan and Sawhney (2011).

2.2 The choreography model

Recently, more complex and heterarchical organisations have emerged featuring more than one hub, where the decision-making power is spread among all partners. In such cases, the orchestration model is no longer suitable to describe the networked environment. Indeed, network members participate in a self-organising process, in which order emerges on the background of the interactions among partners. Although such networks must deal with issues similar to those featuring the orchestrated systems, such as relations, processes and value creation, they require a leadership type that is more likely to be spread throughout all partners.

The *choreography* model (Ferraro and Iovanella, 2015) takes all members of the network into consideration, without relying on one single core actor. We argue that choreography governs behaviours by shaping the level of connectivity and cohesion among network members. It represents a valid organizational system in order to support the execution of certain activities and to achieve effects resulting into innovation outcomes.

The choreographic shape of a system results in coordinated activities among all members which consequently produces heightened innovation. Interactions in choreography are concrete instances of activities carried out by members, which comply

with the network's rules and purposes (Cinelli et al, 2019). Activities can take place between members – for example, in the case of the knowledge flow when two or more agents share information – or they can be within agents.

In the choreography model (see Figure 2), network's members share certain assets, capabilities and production capacities while maintaining their individuality. The network's leadership and control are peer distributed among partners and collaboration patterns are more relevant than individual roles.

The choreography requires that potential members interested in the benefits of joining the network demonstrate certain membership characteristics, which are mainly expressed in terms of ontology, which extends the concept of embeddedness introduced by Nambisan and Sawhney (2011). The ontology allows members to conceptualise what exists within the network. The conceptualisation is completed within the domain of knowledge, formally characterised by the set of objects that can be represented and referred to as the universe of discourse. The set of objects and their relationships are reflected using a specific vocabulary that represents knowledge. In this context, ontology is described by defining the names of the entities in the universe of discourse, i.e., members, processes, resources, etc. with a semantic description of each term.

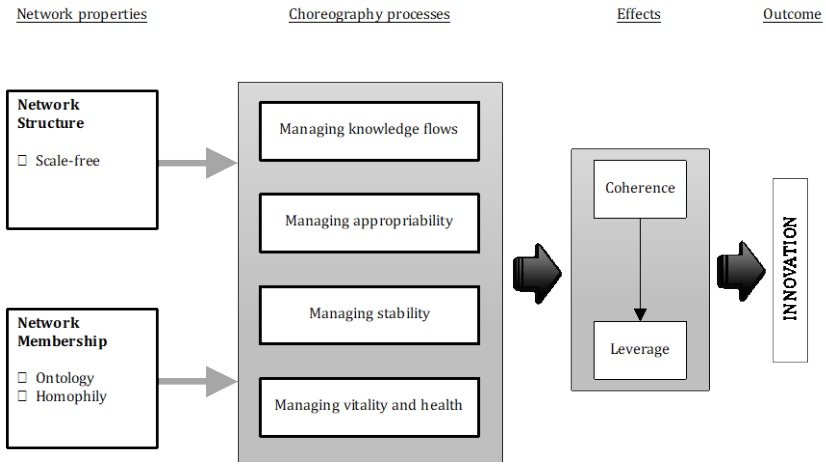

Figure 2: The choreography model (source Ferraro and Iovanella, 2015).

2.3 Comparing the management of knowledge flow between the two models

In orchestration, the hub leverages on the embeddedness to facilitate information dissemination, interpretation and persuasion. On the other hand, in choreography, members recognise a certain degree of consensus to the knowledge domain of ontology and are committed to it, as long as their actions are consistent with its set of definitions. Members act in accordance with the ontology and behave rationally in order to achieve the final outcome of the network.

Network members should join orchestration or choreography models to exchange, spread and use knowledge in order to stay competitive. Such efforts require collaboration in ever more open and distributed configurations in increasingly complex situations, characterized by a growing number of heterogeneous actors.

Table 1. Knowledge flow management in orchestration and choreography models.

Orchestration	***Choreography***
Knowledge is defined	Knowledge is not defined *a priori*
The hub integrates partners knowledge assets and capabilities	Enhances access to knowledge sources
The hub coordinates knowledge sharing among partners	Envisions exchange, share and use of information among members
Knowledge is defined to meet market requirements	Enhances how information mechanisms are located
Knowledge flow is monitored and controlled by the hub	Creates an environment of trust and commitment in which to share information among members
The hub, due to its status, can access knowledge easily	Facilitates assimilation of information among partners
Knowledge is shared, acquired and deployed within the network	Provides for sharing good practices and business experience within and outside the network
The hub assesses the value of knowledge in the network and organizes its transfer where it is required	Enhances trust among members so that they are more willing to share assets
The hub manages the knowledge leverage	Enhances learning from the network

Throughout the two observed configurations, the knowledge flow among members runs in different ways. Table 1 summarises the main differences between the orchestration and choreography models in terms of knowledge management. In particular, the orchestrator manages the knowledge leverage by offering a common set of technologies, tools and other assets that all network members can use with the aim of ensuring a coherent quality, minimising redundancies and enabling product improvement. The hub manages also knowledge coherence in order to preserve external knowledge coherence and ensures that network members adapt their activities accordingly and coordinate interactions among them with a view to guaranteeing internal coherence. The orchestrator therefore defines policies for intellectual property rights distribution and allocates rewards stemming from product commercialisation. The details of the relevant strategies and practices are resumed in Table 2.

Table 2: Network processes, strategies and practices (source, extract from Nambisan and Sawhney, 2011)

Orchestration Process	***Strategies and Practices***
Managing Innovation Leverage	• Identify opportunities for asset leverage by analysing common innovation activities among partners • Modularise leverageable assets by redefining innovation architecture • Establish centralised infrastructure to host and to facilitate asset leverage • Group leverageable assets based on their usage context and offer guidance • Establish forums to involve partners in the design and development of leverageable assets • Define multiple levels of partner involvement in asset design based on intensity of asset leverage • Implement systems that monitor partners' asset usage
Managing Innovation Coherence	• Utilise ties among partners to disseminate information on the changes in the innovation platform • Utilise common vocabulary/frameworks to shape partners' perspectives on the innovation platform • Offer tools based on common vocabulary and frameworks to facilitate transition to revised platform • Group partners based on innovation architecture to redefine member interactions and task coordination • Organised workshops, etc., to rapidly redefine partner ties based on revised innovation architecture

In the choreography model, knowledge coherence and leverage are considered as internal effects of the network since they represent the added value to the system for the members (see Table 3). The model ensures the impartial distribution of value within the system, thus reducing the threat of members' opportunism, whilst strengthening equitable allocations.

Innovation coherence deals with the consistency of the network's activities regarding the coordination and alignment of processes and outcomes. Within choreography, we can distinguish between internal and external coherence. The former concerns the alignment of innovation processes with the interactions of members within the network, whilst the latter is related to the technological environment and the market structure where the network operates. Innovation coherence permits a shared alignment with the technological environment, complying with the network's goals and fulfilling outcomes with respect to market needs.

The innovation leverage has to do with the control, reuse and sharing of technologies, processes, and other innovation assets with a view to supporting and enhancing innovation, thus creating additional value for assets' owners and for the actors controlling the assets. Such leverage allows members to include and integrate new technologies in their internal innovation processes, thus contributing to generating additional profits for network members through attracting new potential partners.

Table 3. Network choreography effects

Choreography Effects	***Activities***
Coherence	• Use common and shared tools based on network ontology • Align with the technological environment • Ensure that network members attend organised workshops and training actions • Align with the processes and outcomes • Align with the network's goals • Align the network's outcomes with the marketplace
Leverage	• Enhance the network identity • Identify opportunities for asset leveraging among network members • Involve partners in the design and development of leverageable assets • Control, reuse, and share innovation assets • Incorporate innovation into other members' innovations • Generate additional profits for members • Attract new members

The network is able to manage and strengthen the value-creation opportunities through choreography by including leverage among members and generating surplus value, whilst taking into consideration the structure of the assets that can be shared and deployed. This effect can be improved by allowing new members to join the network, thereby increasing the degree to which current innovation assets can be leveraged. Furthermore, members are expected to be more willing to leverage on other members' innovation assets if they recognise similar characteristics.

In Table 4 we resume the main characteristics of the two models under analysis. We focused mainly on the knowledge flow and the consequent leverage and coherence required in order to provide the innovation outcome.

For further details, we refer to the above mentioned literature and the references therein.

Table 4. Main characteristics between orchestration vs. choreography models (source Cinelli et al, 2019).

Orchestration	***Choreography***
Individual leadership	Diffused leadership
Hierarchical organisation	Heterarchical organisation
Centralised executer	Peer-to peer
Clearly defined outcome	Broad innovation outcome
Tacit and explicit knowledge	Explicit knowledge
Bilateral relationships	Multi-lateral relationships
Essential information	Redundant information
Managing innovation leverage	Ontology-driven leverage
Managing innovation coherence	Network membership-driven coherence
Clearly defined market opportunities	Less-defined market opportunities
Hub controls assets	Broad sharing of assets
Asymmetry of benefits for hub and members in creating and adding value	Benefits for all members in creating and adding value

3 Inter-organisational network modelling and evaluation of the network information patrimony

For our purposes, we consider the definition of Neighbours' Information Patrimony (*NIP*) introduced in Arpetti and Iovanella (2020).

The *NIP* is a measure which exploits networks properties in order to understand how a node may take advantage of the set of its connections as a whole. In this respect, the information patrimony of an individual can benefit from the network configuration, via capturing information stemming from its connections' patterns.

To this end, the proposed measure considers the quality of nodes' connections and consequently, how nodes might enjoy benefits deriving from a good neighbourhood – meaning a superior connections set – thus obtaining better information.

Let us consider a network $G = (V, E)$ representing an inter-organisational network where the V set contains the n organisations in the system, while the E set contains all m collaborations among such organisations. Members of the V set are indicated by an index i while the E set can be conceptualised through the adjacency matrix A, whose generic element a_{ij} is equal to 1 if the link between i and j exists or, otherwise, to 0. In the present paper, we consider undirected and unweighted networks, i.e., the relationships at stake are mutual and considered as being continuous over time.

Among the different network measures used in Social Network Analysis, we consider the *centralization degree* of a node i, called d_i, which measures the number of nodes that are present in its neighbourhood and the *average degree of the neighbourhood* of a node i, called $k_{nn,i}$ and defined as (Pastor-Satorras et al, 2001):

$$k_{nn,i} = \frac{1}{d_i} \sum_j d_j a_{ij}$$

It is now possible to introduce the collective effects of a neighbourhood on a node i and we therefore define the Neighbours' Information Patrimony NIP_i of node i as (please refer to Arpetti and Iovanella 2020 for the full description):

$$NIP_i = \frac{d_i}{2m}\left(1 + k_{nn,i}\right)$$

In this setting, all the information available to the organisation consists of the amounts of connections set present in a network (i.e. $2m$), thus the Information Patrimony IP of a node i is equal to its market share $d_i/2m$ (i.e. its portion of market due by its degree). The above formula introduces a further component, the effect on the information patrimony induced by the network, thus the NIP of a node i is equal to the sum of its information patrimony with the information patrimonies of all its connections, i.e. the nodes j in its

neighbourhood. Some simple algebraic manipulations bring to the above outlined formula.

By means of the present contribution, we intend to analyse the different behaviour of the NIP in the two introduced models, namely orchestration and choreography, and, to this purpose, we consider the following hypothesis:

> *HP1. The orchestrated network is modelled with a central node, called hub, connected to each of the other members; no other connections are allowed; the choreographed network is modelled as a scale-free network.*

Scale-free networks are a well-known network model introduced in Barabási and Albert (1999). Such networks are open and dynamically formed by the continuous addition of new nodes that represent members, while the links between members mimic collaborative agreements. Scale-free networks emerge in real situations characterized by inhomogeneity in degree distribution, with a few nodes having many links and the majority having only a few connections. In general, degree distribution in scale-free networks follows a power law distribution with exponential rate conventionally indicated with γ.

Scale-free networks offer a theoretical framework for the choreography model that permits a suitable abstract representation of inter-relations, where the network characterization indicates the mapping of connections among elements. Although networks may appear very different from each other with respect to their functions and attributes, the analysis of their structure denotes the ubiquity of several asymptotic features and reveals the emergence of general and common self- organizing rules (Ferraro and Iovanella, 2015; Cinelli et al., 2019).

In Figure 3 an example of orchestration network model – where the orchestrator is reported as the central node in dark green – and an example of choreography network model where nodes are coloured in a gradient of green proportionally to their degree are represented. Both networks feature 50 members and it can be easily noted how the hub holds a central position in the orchestration model, while the choreography is characterised by a degree distribution admitting a few nodes having high degree, and a majority of them having a low degree.

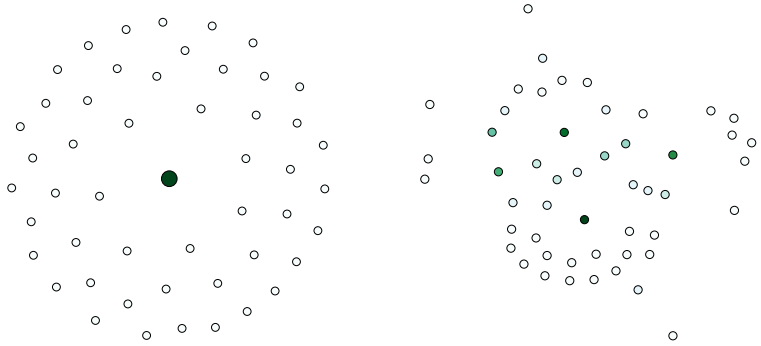

Figure 3: An orchestration network (left figure) and a choreography network (right figure).

Under the perspective of HP1, in this paper we aim at studying the two different network representations considering the *NIP* in order to draw empirically observable outcomes as well as insights for explaining real-world network behaviours.

4 Empirical analysis

The analysis was conducted by simulating the two different models by means of synthetic networks generated considering, for both cases – orchestration and choreography – the number of members as $N = \{10, 20, 30, 40, 50, 100, 150, 200, 250, 300, 350, 400, 450, 500, 550, 600, 650, 700, 750, 800, 850, 900, 950, 1000\}$.

In order to simulate the orchestration networks, we created for each value of N a star network where the central node – which has degree equal to N - 1 – acts as the orchestrator, while the other orchestrated nodes have degree equal to 1. The choreography organisation was simulated by generating scale-free networks. For each value of N we generated 100 different networks; the results, in the following, are averaged over such a set. For the sake of completeness, please note that, for a fixed N, only one star can exist, while a scale-free network can assume different configurations, each of them respecting the same power law degree distribution; in our setting, we considered the classical value of $\gamma = 2$ (Barabási, 2016).

The left diagram in Figure 3 shows the values of *NIP* for each value of admissible degree. Red spikes indicate that, in the orchestration, only two types of members are allowed: the orchestrator and the orchestrated members. For the orchestrator, the value of *NIP* is 1 since it owns all the information patrimony in the network, while the orchestrated members benefit of a large value of *NIP* since they are all connected to a single, huge, node.

When we consider the choreography case, we note a different distribution of the values, the highest related to the low value of degree. It means that small nodes benefit more from the connection patterns than hubs, since they are more prone to be connected to nodes with highest degrees.

As a result, the *NIP* is a measure capturing a well-known effect, i.e. the network impact on the information patrimony of a node: the higher the quality of the neighbourhood, the more the benefit for the relevant node.

Clearly, in the case of orchestration, the absolute values are higher but it is worth noting that, should the hub in the orchestration disrupt, all the values of *NIP* would crash to 0, while in the case of choreography, a hub disruption would have a moderate effect on the *NIP* values of the remaining nodes (Ferraro and Iovanella, 2018).

The right panel in Figure 3 shows the value of *NIP* for the nodes with higher degree. In the case of orchestration, it is always equal to 1 since the hub controls all the information patrimony in the networks. In the case of choreography, the value of *NIP* is slightly increasing with N, but it never reaches the value of 1. It means that, even if a hub reaches high degree values, it never controls all the information patrimony in the network.

We can therefore conclude that the two organisations show opposite behaviours that we can expect but that are not easy to empirically explain. The orchestrator has a full control of the information patrimony, but the network is poorly resilient; on the other side, in the choreography context, as a result of a smaller degree, hubs still maintain high values of information patrimony, and the system is more resilient.

We performed an additional analysis of the two organisation types by looking into the distribution of *NIP* between members by means of the Gini index (Gini, 1912).

The Gini index is widely used in order to measure the inequality among the values of a vector of numbers (e.g., the income of a nation, etc.). A value of 0 expresses a perfect equality (all the values are the same) while a value of 1 expresses a perfect inequality.

For instance, in the left panel of Figure 4, the Gini index for the vector of degrees in the orchestration case is trivially equal to 1, since the hub has degree $N - 1$ while all the other members show a degree 1. In the case of choreography, as it can be anticipated, we can recognise a certain level of heterogeneity in the degree.

When we analyse the *NIP*, the orchestration case shows an almost perfect equality since N - 1 members own a value of *NIP* equal to 0.5, except for the single case of the hub having *NIP* equal to 1. In the case of choreography, the Gini index shows instead a more heterogeneous behaviour, since the information patrimony is more spread among the members of the network. This aspect is again expected, but the *NIP* measure is able to confirm and capture it empirically.

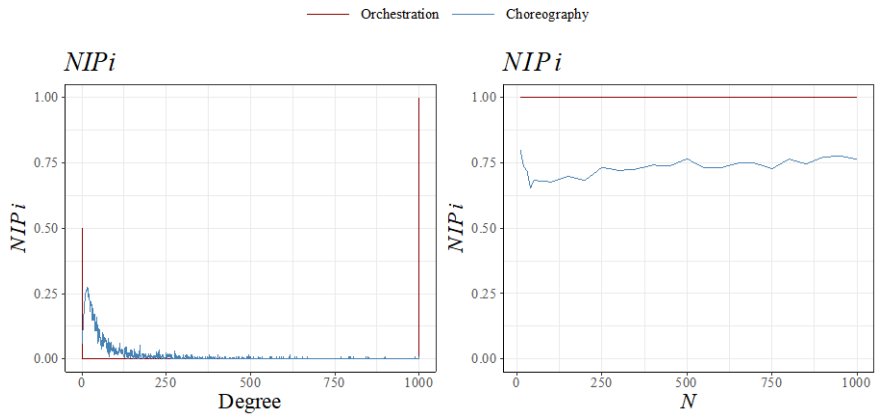

Figure 3: Values of NIP for each degree (left figure) and for hubs for each value of N (right figure); values averaged on 100 runs in the choreography case.

The relationship in terms of information patrimony between the orchestration and the choreography models unveils a trade-off between the two models that can be expressed in terms of information patrimony versus reconfiguration costs. In the case of orchestration, the system exists because of the presence of an orchestrator who, in a centralised manner, rules the other members giving rise to a fault-intolerant system where any mistake by the

orchestrator would imply the loss of all the connections and essentially the impossibility to timely reconfigure the system. The choreography model show instead an opposite layout, meaning a fault-tolerant system where the loss of the most prominent node has relatively severe consequences on the whole system and in which members affected by the loss can still benefit from their remaining connections in order to pursue their activity.

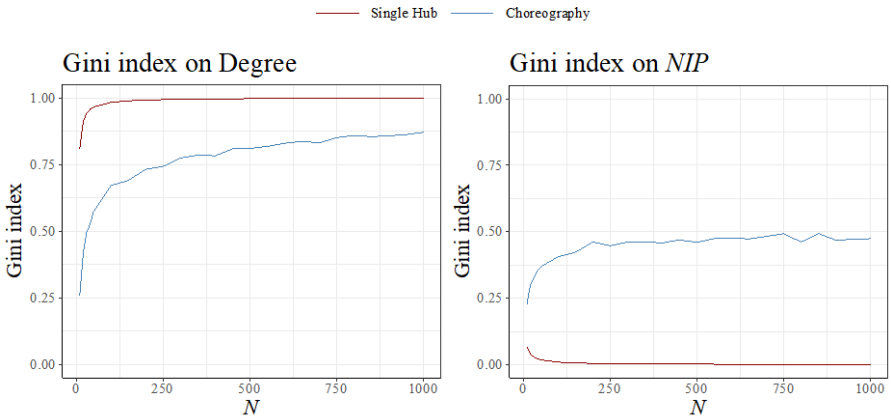

Figure 4: The Gini index for the degree values (left figure) and for the NIPs (right figure); values averaged on 100 runs in the choreography case.

5 Conclusions

This study considers two different network organisations, hierarchical and heterarchical, and describes two models able to characterize their behaviour, namely orchestration and choreography.

By means of a new measure, called *NIP,* we discussed how knowledge flows among the members in both models. The simulations carried out on synthetic networks provide empirical evidence of the differences between the two models in terms of heterogeneity and resilience.

These preliminary results pave the way for future investigations, mainly in the field of defining how knowledge flows within the two models and how leverage and coherence can be expressed within them.

Abstract

This paper deals with the main meta-choices problems that arise in the multidimensional benchmarking of knowledge-based organizations. The first is the metachoice problem related to the choice of the algorithm used to compute the ranking (Iazzolino et al., 2012; Laise et al., 2015; Daraio, 2017a). The second is the metachoice problem related to the choice of the variables to be included in the model (Daraio, 2017a). Lastly, a third metachoice problem is related to the choice of the data on which the analyses are carried out (Daraio, 2017a).
The authors focus on multidimensional benchmarking analysis applied to KPIs related on one side to the IC (divided in the three dimensions of Human Capital, Structural Capital and Relational Capital) and on the other side to performances, evaluated in both financial and non-financial terms.
In particular, this paper analyzes the problem of ranking a sample of 65 Italian Universities based on performance-related criteria. The methods used to carry out the comparative analysis are (i) Data Envelopment Analysis (DEA) and (ii) Analytic Hierarchy Process (AHP).

The paper demonstrates the difficulties of the "implementation problem" in performance measurement, related to the subjectivity of results of the evaluation process when there are many evaluation criteria, as in a benchmark context.

Keywords – Ranking, Multicriteria, Efficiency analysis, DEA, Metachoice, Universities, Performance, Intellectual Capital

Paper type – Academic Research Paper

1 Introduction and contribution of the paper

The article deals with the problem of evaluating business performances in knowledge-based organizations. In particular, the problem of ranking a set of Universities based on performance-related criteria is analyzed.

In this work, we propose a theoretical contribution that brings together two lines of research in which the authors have worked in recent years. The first strand concerns the complexity of evaluating the activities of knowledge organizations, which include universities (Daraio, 2017a, b, 2019, 2020). The second refers to the measurement of the performance of companies with multicriteria methods and the so-called *metachoice* problem that always arises in a benchmark multicriteria analysis that can be synthesized as follows: "*how to choose an algorithm to choose*?" (Iazzolino et al., 2012; Laise et al., 2015). By putting these two contributions together, we propose a new model for evaluating the performance of knowledge organizations that considers the different components of knowledge capital as inputs, and includes the Value Added produced by the institutions among the outputs. By applying this model to the case study of Italian universities, we highlight how the evaluation of the business performance of knowledge organizations is affected by three different *metachoice* problems that interact with each other, influencing the obtained results.

The main result we show is that behind rankings there is not a perfect measurement, or in economic terms, a maximization of performance is not feasible (or reachable), due to the existence of three *metachoice* problems. The first is the metachoice problem recalled above and investigated by Iazzolino et al. (2012) and Laise et al. (2015) which relates the *methodology* dimension in Daraio (2017a), and underlies the choice of the algorithm used to compute the ranking. A second metachoice problem underlies the theoretical dimension of the modeling, called *theory* in Daraio (2017a), that relates to the following choice: which variables to include in the model, or better "*how to choose the theory to identify the variables to consider in the model and in the empirical analysis*? A third metachoice problem that arises relates the *data* dimension in the framework of Daraio (2017a), and consists in the choice and main limitations of the *data* on which the analyzes are carried out, in other words, *what data have to be used in the analysis, and how data problems and limitations affect the empirical analysis*?

As we will see in the empirical illustration on Italian universities, these three metachoice problems are relevant and are able to affect the rankings of the considered knowledge institutions; furthermore, they interact with each other witnessing the complexity of the evaluation related to its implementation (Daraio, 2017b).

When studying Universities and in general knowledge-based organizations an important element has to be considered. The main characteristic that drives performance is *knowledge*, and in particular the so-called Intellectual Capital (IC). The inclusion of knowledge and IC in the assessment of performance is not immediate also for the *data* problems related to its measurement.

In this paper, the authors focus on multidimensional benchmarking analysis applied to Key Performance Indicators (KPIs). KPIs are related, on one side to the IC (divided in the three dimensions of Human Capital, Structural Capital and Relational Capital) and on the other side to performances, evaluated in both financial (Revenues, Value added, Ebitda) and non-financial (number of publications, number of patents) terms.

The paper provides several practical implications in all cases in which a ranking has to be assigned to a group of organizations based on performances.

The adoption of a set of criteria is certainly an advantage to avoid uni-criterial or mono-dimensional myopic evaluation. However, this also creates some methodological problems. The paper demonstrates the difficulties of the so called "implementation problem" in performance measurement, related to the "relativity" (subjectivity) of results of the evaluation process when there are many evaluation dimensions, as in a benchmark context.

2 Complexity of the assessment: the metachoice problems of knowledge organizations

In this paper, we want to highlight the *metachoice* problems that always arise in a multidimensional benchmarking analysis.

The authors of this paper argue that any multidimensional benchmarking evaluation implies the development of a *model* that concerns the choices made from a theoretical, methodological and empirical point of view (data). See Figure 1 that shows the main dimensions of an assessment which coincide with the metachoice problems.

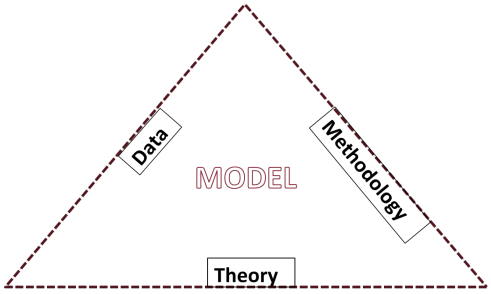

Figure 1. Main dimensions of the metachoice problems of knowledge organizations

From a *methodological* point of view, a metachoice problem arises because multicriteria (or multidimensional) ranking algorithms cannot be selected using a multicriteria algorithm; the choice of an algorithm ultimately depends on the *subjective* preference of the policymaker; and the metachoice solution to the benchmarking problem is, in accordance with Simon's satisficing solution, describing a non-maximizing performance measurement methodology.

In order to perform a benchmark analysis, a set of dimensions in addition to criteria must be chosen. The choice of the variables that proxy the main conceptual dimensions considered in a multidimensional benchmark highlights the *theoretical* metachoice problem. To decide what are the main conceptual references of the model of the benchmark we pursue we cannot use a theoretical justification, we need to explicit the *subjective* preference of the policymaker and/or the analyst that carry out the analysis.

A third metachoice problem arises when an empirical analysis has to be carried out. A third dimension to consider is *data*, and the problems of choosing the data, their availability and their quality interact with the two previously described metachoice problems, showing the complexity of the benchmarking exercises particularly when the focus is on multicriteria benchmark analysis applied to a set of knowledge organizations.

3 The case study: analysis of efficiency of the Italian universities

In this section the case study is illustrated. The empirical analysis is based on the analysis of the efficiency of a set of Italian Universities.

3.1 Sample and data collected

The attention was focused on a sample of 65 University scattered throughout Italy. Universities of different types and sizes were considered: 11 mega-universities, 15 large universities, 16 medium universities, 13 small universities, 5 polytechnics, 2 doctoral institutes, 3 high schools. Data collection takes three years, from 2016 to 2018, in order to use the most recent data available.

A series of indicators have been identified, divided into inputs and outputs, to evaluate the performance of Italian universities. The indicators will be illustrated in detail in the next section.

3.2 The selected indicators: intellectual capital and performance

This paper proposes a set of indicators especially designed for universities and related to the intellectual capital dimension.

The term intellectual capital (IC) was first introduced by John Kenneth Galbraith: the concept of the term incorporated a degree of 'intellectual action' rather than 'intellect as pure intellect' (Edvinsson & Sullivan, 1996). The intangible assets and IC constitute the largest proportion of universities' assets (Ramírez Córcoles, Peñalver, & Ponce, 2011;

Secundo, Margherita, Elia, & Passiante, 2010; Secundo, Margherita, Elia, & Passiante, 2010). When related to a university, IC is a term used to cover all the institution's non tangible or nonphysical assets, including processes, innovation, patents, the tacit knowledge of its members and their capacities, talents and skills, the recognition of society, its network of collaborators and contacts, etc. (Ramírez Corcólez, Tejada, & Gordillo, 2013).

At an international level, it is generally accepted that there are three basic components of IC: (i) Human capital, (ii) Structural capital and (iii) Relational capital (Ramezan, 2011; Steward, 1994; Johnson, 1999; Smith & Parr, 2000; Edvinsson & Malone, Intellectual Capital, 1997). The components of university's IC have been categorised in various ways, although undoubtedly it is the tripartite classification that is most widely accepted in specialised literature (Secundo, Margherita, Elia, & Passiante, 2010; Leitner, 2004; Bezhani, 2010; Paloma Sánchez, Elena, & Castrillo, 2009). Specifically, it is possible to read the three components as follows (Ramírez Córcoles, Peñalver, & Ponce, 2011):

1 *Human capital*: The sum of the explicit and tacit knowledge of the university staff (teachers, researchers, managers, administration and service staff) acquired through formal and not formal education and refresher processes included in their activities.
2 *Structural capital*: The explicit knowledge related to the internal process of dissemination, communication and management of the scientific and technical knowledge at the university.
3 *Relational capital*: The extensive collection of economic, political and institutional relations developed and upheld between the university and its non-academic partners, i.e. enterprises, non-profit organisations, local government and society in general.

According to literature, the input indicators are defined starting from the three components of the IC.

Input indicators*:*

Human Capital

- No. Academic Staff
- No. Technical and administrative staff
- Academic Staff costs
- Technical and administrative staff costs

Structural Capital

- No. Departments
- Patents and similar intellectual property rights
- Concessions, licenses, trademarks and similar rights
- Scientific equipment

Relational Capital

- Contributions from others (private)

- Contributions from others (public)
- Contributions from commissioned research and technology transfer

The main goals for universities are generally accepted to be the production, diffusion, transfer and preservation of knowledge (Young Chu, Ling Lin, Hwa Hsiung, & Yar Liu, 2006); for this reason, university performance assessments are defined by the output indicators listed below.

Output indicators*:*

- Total Revenues
- Value Added
- EBITDA
- No. Patents
- No. Spin-offs
- No. Journal papers

The indicators were selected with the criteria of the feasibility of data gathering and of consistency between universities: most of the indicators can be valued through the items of the university's income statement and balance sheet, the others through online portals.

Some important theories (Kaplan & Norton, 1996; Sveiby, 1989) suggest that non-financial measures provide a means of complementing financial measures and should also be present at the strategic level of the firm; therefore we consider both financial indicators on the amount of resources devoted to a given activity, and non-financial indicators, as number of academic staff or number of spin-offs.

4 Results

4.1 Descriptive statistics and preliminary correlation analysis

On the base of the discussion and literature described in the previous section, we identified the variables reported in Table 1 to be considered respectively as inputs and outputs to assess the performance of the Italian universities.

Table 1. Inputs and outputs selected according to the literature.

INPUT	**Label**
Cost Of Technical And Managerial Staff	X1
Personal Cost Dedicated To Research And Didactics	X2
Contributions From Other (Private) Entities	X3
Contributions From Other (Public) Entities	X4
Proceeds Research Commissioned	X5
N Management And Administrative Staff	X6
N Teaching Staff And Researchers	X7
Scientific Equipment	X8

Concessions, Licenses And Trademarks	X9
Patent Rights	X10
N Departments	X11
OUTPUT	**Label**
Total Income	Y1
Number Of Patents	Y2
Number Of Articles In Magazines	Y3
Added Value	Y4
Ebitda	Y5
Active Spin Off	Y6

The tables reported in Appendix show some descriptive statistics on the data available for 65 Italian universities over the years 2016-2018. As emerges by inspecting the values reported in the tables, there is an high heterogeneity among the Italian universities considered (high standard deviation values and high interquartile ranges) and most of the considered dimensions of inputs and outputs show skewed distributions (average and median values differ for almost all variables over the whole period). For the variables X11 and Y6 the data are available only for the 2018.

The following Tables 2 and 3 show the correlations among inputs and respectively outputs. The analysis of the correlation is particularly useful to carry out a preliminary assessment of the relationships among the variables because for the methods that will be used to compute the rankings of the Italian universities, and in particular, for the Data Envelopment Analysis, the so-called "*curse of dimensionality*" is really a plague. This means that the algorithms involved in the DEA efficiency score computation require many (even thousands!) data when the number of variables used is quite high, as is the case here (for further details, see e.g. Daraio and Simar, 2007).

In the further analysis we keep into account the correlations that are most significant (values higher than 0.9) for the final selections and inclusions of variables in the analysis. In this step of the analysis, then, we see that our final dimensions of performance selected to calculate the ranking of the performance is influenced by a methodological problem (the curse of dimensionality).

Table 2. Input correlation matrix

INPUT CORR MATRIX	**X1**	**X2**	**X3**	**X4**	**X5**	**X6**	**X7**	**X8**	**X9**	**X10**	**X11**

Y6	0.531	0.599	0.516	0.525	0.461	1.000

The following Table 4 shows the variables that will be used to calculate the rankings of Italian universities.

Table 4. Inputs and outputs finally chosen for the empirical analysis

Input variable	**Output variable**
total personnel cost	added value (VA)
human capital	number of patents
structural capital	number of articles in magazines
relational capital	spin-off active
scientific equipment	
concessions, licenses, and trademarks	
contributions from other (private) +(public) entities	
commissioned research proceeds	

4.2 Methods applied to compute the rankings of knowledge organizations

The methods used in the analysis to carry out the comparative analysis on the rankings of the Italian universities are Data Envelopment Analysis (DEA) and Analytic Hierarchy Process (AHP). DEA is a method based on linear programming to estimate an efficiency score that measures the distance of a set of decision making units from an efficient or best practice frontier. The variant of the AHP used for the analysis, called AHP Benefit-Cost Ratio (BCR), considers the distinction of the considered dimensions in benefits (considered as outputs) and costs (considered inputs).

Here below we report the specific algorithms implemented:

1) DEA Input oriented assuming Constant Returns to Scale (Charnes, Cooper, and Rhodes, 1978), labelled as DEA INP CRS

2) Dea Input oriented assuming Variable Returns to Scale (Banker et al. 1984), labelled as DEA INP VRS

3) Dea Output oriented assuming Constant Returns to Scale (Charnes, Cooper, and Rhodes, 1978), labelled as DEA OUT CRS

4) Dea Output oriented assuming Variable Returns to Scale (Banker et al. 1984), labelled as DEA OUT VRS.

5) AHP BCR: analytic hierarchy process (AHP) with the variant called AHP Benefit-Cost Ratio (BCR), implemented according to Robert (2020).

All the scores have been normalized to have comparable values comprised between 0 and 1.

4.3 Comparative analysis on the results obtained

We have computed the rankings of the Italian universities using the methods outlined in the previous section.

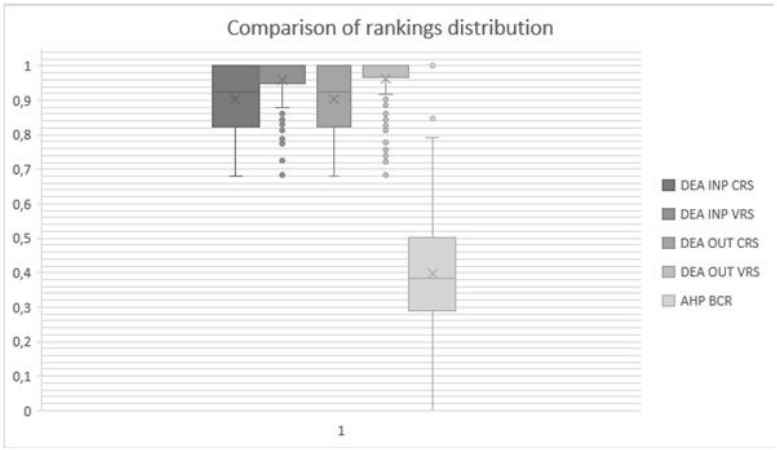

Figure 1. Boxplots of the distribution of the efficiency scores calculated on the sample of Italian universities with the 5 methods applied.

Figure 1 shows the comparison of the distributions of the rankings obtained by applying the 5 methods outlined in the previous section. We note that the DEA input and output Constant Returns to scale efficiency scores coincide, as they should by definition, while the distributions of DEA variable returns to scale are more skewed and show the presence of many outliers. This is an additional warning we have to keep into account. DEA estimators of efficiency are determinist in their nature. This means that all the deviations observed from the efficient frontier is attributed to inefficiency, so no noise is

allowed. As a consequence, the efficiency scores calculated by DEA suffer from the influence of outliers and/or errors in the data. About the AHP BCR method, we observe that the scores are much more spread than the efficiency scores calculated with the DEA approach.

But a question may arise now to reader and it is the following. Of course, by applying different methods we obtain different results and so different values for the efficiency scores of the Italian universities, but are those that are on the top of one ranking also on the top of the other rankings? In other words, is the rank correlations among the efficiency scores high or low?

The answer to this question is reported in the following Table 5.

Table 5. Spearman Rank correlation among the efficiency scores calculated with the 5 methods: DEA INP CRS, DEA INP VRS, DEA OUT CRS, DEA OUT VRS, AHP **BCR .**

	DEA INP CRS	**DEA INP VRS**	**DEA OUT CRS**	**DEA OUT VRS**	**AHP BCR**
DEA INP CRS	1				
DEA INP VRS	0.6069	1			
DEA OUT CRS	1	0.6070	1		
DEA OUT VRS	0.6003	0.9989	0.6004	1	
AHP BCR	**0.5494**	0.3217	**0.5494**	0.3202	1

A rank correlation value close to 1 means that the two efficiency scores calculated on the base of two methods, although they show different values, correspond to the same ranking of the universities analysed. A rank correlation close to -1 indicates that the efficiency scores calculated with a method are almost the invers in the order of those calculated with another method, meaning that those universities that are on the top of a method are on the bottom of the other and *vice versa*. Intermediary values of the rank correlation show varying level of correlations among the rankings obtained by the different methods.

The results reported in Table 5 show that the rank correlations calculated on the efficiency scores of all the 5 methods are positive and very high for the DEA VRS input and output model. We note that the rank correlations between AHP BCR and DEA CRS Input and output model is quite high, with a value of 0.549, and this could signal a certain similarity/agreement between the hypothesis underlying the two methods. Of course, the rank correlations are not equal to 1 and this means that universities on the top of a given method are not on the top of the other methods consistently, and this create a problem of choice of the algorithm that has to be done by the researcher.

A final metachoice problem that arises in the evaluation of the rankings of knowledge organization, relates to the choice of the *theory*. At this purpose, an interesting extension of this work could be to analyse what happens if we include in the model only the Human capital as input, while the outputs are the same as the previously described overall model. Then we could investigate also what happens if we include only structural capital or

relational capital as inputs. These further analyses are left for further developments of this paper.

5 Discussion and conclusion

The main conclusions of this paper are the following:

(i) In the evaluation of knowledge organization (as universities are), when is based on different genuine criteria and on a set of different dimensions including IC, three metachoice problems arise and interact among each other. Multicriteria ranking algorithms cannot be selected using a multi-criteria algorithm (methodological choice); so they rely on the subjective choice of the analyst/policy maker that has to choose also the conceptual background of the benchmarking (theoretical choice) addressing the empirical issues that arise (data choice).

(ii) the choice of an algorithm, of the conceptual reference and of the data ultimately depends on the subjective preference of the analyst/policy maker that should be explicitly described highlighting the "fitness for purpose" strategy (satisficing principle) followed, inevitably based on the compromise choices done to address the existing metachoice problems.

Our proposal or solution to the benchmarking problem is in accordance with Simon's satisfacing solution, describing a non-maximizing performance measurement methodology (Simon 1955; 1978; 1997). It may be worthwhile to emphasize that Simon's point of view is adopted by the Managerial Acconting multicriteria approach: "we believe however that achieving satisfactory profit is a better way of stating corporation goals" (Anthony, 1966). As is well known, such a perspective has a long tradition in managerial and accounting literature (Anthony, 1966; Cyert and March, 1963; Drucker, 1966; March and Simon, 1958; March, 1966; March, 1996).

Our suggestion to the analyst who conducts performance assessments is therefore to be transparent with stakeholders (including policy-makers and managers of universities that use rankings), describing all the crucial meta-choices that underlie their analyzes and highlighting the role that they have on the results. This behavior defined "technologies of humility" by Jasanoff (2007) could be achieved through a checklist as proposed by Daraio (2019), according to which, the analyst describe all the choices done in the analysis and the impact that these choices have on the obtained results, possibly identifying lines for further improving the analyses. This approach corresponds to the awareness of having achieved a "satisficing" result in terms of rankings of the institutions, à la Simon, which considers the hypotheses and compromises done, rather than an objective measure of the institutions that may fit all the purposes.

Abstract

Research in the areas of management and strategy commonly considers the issue of networks as a really broad issue in the organizational phenomenon but little addressed by its complexity (Moliterno & Mahony, 2011). However, recent studies have invited to different methodological approaches to distinguish different types of variables among networks issues (Chen, Chang, & Chang, 2015; Ofem, 2015; Oyedokun Akintunde, Adele Ademola, Ogunkunle Oluwatobi, & Adegbile Aderibigbe, 2016; Peltier & Naidu, 2012; Toledano, Urbano, & Bernadich, 2010). Despite the development of these studies, especially in Anglo-Saxon contexts, in Latin American countries have been less addressed, despite being described as an important area in the research agenda for management (Ferreira, Reis, & Miranda, 2015). For some authors, the absence of an integrated theory of networks in management has led them to design theoretical proposals, such as Moliterno & Mahony (2011) who suggested the multilevel capacity in organization's networks, explained by different actors and interactions between them.

In this paper we focus in to measure and analyze the relationship between Collaborative Managers Networks (CMN) and Performance of Small and Medium-sized Enterprises (SMEs) in an emergent economy like Mexico, to provide recommendations to managers to integrate collaboration with different actors in management practices into their business strategies. The designed theoretical model was contrasted through a system of partial least squares (PLS-SEM) of structural equations modeling, using the SmartPLS® software (Ringle, Wende, & Becker, 2015) obtaining information from 170 SMEs operating in the Bajio Region (México) in the leather-footwear sector.

The results provide evidence that companies with CMN have a positive effect on its firm performance. However, the majority of networks are oriented just on building links with business actors. Financial and political actors are less involved in managerial practices of collaboration. These findings have strategic implications for the entrepreneurs, mainly in getting advantage in new strategies of collaboration among new actors.

This paper provides evidence of four main CMN insights. Firstly, derived from literature research, a CMN conceptual approach. Secondly, the research findings support understanding on the relationship between CMN and Mexican SMEs Performance and propose a multiple dimension CMN model using PLS-SEM as statistical tool. Thirdly, a Spanish adapted test of CMN that use measuring scales in a Latin-American country. Finally, this research attempts to recommend innovative networking strategies in managerial practices and entrepreneurial dynamics on SME companies.

Keywords – Networks, SMEs, Performance, Collaboration, Entrepreneurship.

Paper type – Academic Research Paper

1 Introduction

Research in the areas of management and strategy commonly considers the issue of networks as a really broad issue in the organizational phenomenon but little addressed by its complexity (Moliterno & Mahony, 2011). However, recent studies have invited to different methodological approaches to distinguish different types of variables among networks issues (Chen, Chang, & Chang, 2015; Ofem, 2015; Oyedokun Akintunde, Adele Ademola, Ogunkunle Oluwatobi, & Adegbile Aderibigbe, 2016; Peltier & Naidu, 2012; Toledano, Urbano, & Bernadich, 2010).

Despite the development of these studies, especially in Anglo-Saxon contexts, in Latin American countries have been less addressed, despite being described as an important area in the research agenda for management (Ferreira, Reis, & Miranda, 2015). For some authors, the absence of an integrated theory of networks in management has led them to design theoretical proposals, such as Moliterno & Mahony (2011) who suggested the multilevel capacity in organization's networks, explained by different actors and interactions between them.

In order to discuss about network theory, it is necessary to describe how social interactions provide the ability to connect with different actors (individuals, companies, public institutions, groups, etc.) for both scenarios: individuals and organizations. Hence, mainly management research has used this approach to describe organizational phenomena, but not how the organization is structured through these networks (Salancik, 1995), connections and dynamics. This scenario provides a theoretical and empirical gap in the exploration of new approaches to the treatment of networks; especially those formed by key players in the strategy and improve of performance of the organizations, such as the function of manager. New interests and personal interactions are manifested in complex networks, especially when needs and environmental changes are dynamic, this scenario disrupts the formation of new patterns (Ibarra, 1996; Salancik, 1995) and even dynamics between actors.

Networks involve the movement of *power*, *information* and *knowledge* that allow access to resources (Acquaah, 2007), opportunities for economic promotion and social support. For Small and Medium Enterprises (SMEs) access to different kind of resources is the key for survival and log-term consolidation processes. In that sense, studying the impact of networks on performance becomes a strategic issue that give insights about how a SME's manager should connect with different actors in order to get benefits from the commonly named 'networking'.

2 Collaboration Networks: a complex ocean of relationships and a key driver for performance

Collaboration Networks are links constructed by the orientations and capacities of individuals (Ibarra, 1996) in order to interact with key organizations or people. Even though, each organization has a series of fundamental actors that depending on the level and intensity of the interactions could create a 'central node' in the case of organizations or a 'connectivity node' in the case of individuals (Robinnet, 2016; Salancik, 1995). This interpretation becomes fundamental when studying companies' clusters, because the main task is to detect such patterns of behavior and discover principal links, intensity and why these are established.

As we mentioned, the analysis of networks in organizational theory is focusing on the assessment of how the networks are structured in actor's number. Although recent literature has focused on the effect of networks on entrepreneurship, mainly through

internal networks (Martins, 2016) but not over external ones. This last is a central gap in the management research agenda (Edmond & Wiklund, 2010; Ferreira et al., 2015) that could provide a path to a 'theory of networks'. Similarly, less common is the study of how networks and their flows, with external actors, affect performance of organizations. Determine the actors that mostly contribute to the improvement of organizational performance or how they describe the contribution of each categorical network (Political, Business or Financial), become a main trend in strategy and management studies, especially to elaborate practical recommendations to a SME's manager.

In the network approach analysis there is a risk: "Not seeing and distinguished forest from the tree" (Salancik, 1995, p. 346). For that reason, and avoiding this risk, studying networks involve getting information about blocks of interactions and detecting, at individual level, the actor that will diffuse resources to other social members or organizations. However, from this point of view (Greve & Salaff, 2003; Ibarra, 1996; Salancik, 1995) the study of interactions is the starting point of a network analysis that allows to consider two steps: Firstly, how a particular network block affects the organization or not. And secondly, how a particular actor affects the organization or not. Both approaches give us some hints about the importance of the creation or the absence of links with particular actors. Especially in industrial clusters where a collaboration behavior becomes essential to cope deficiencies or a lack of resources, mainly in SMEs startups.

According to Salancik (1995), this phenomenon of enterprises with not interaction with certain external actors is mainly caused by the following two reasons: First, the absence of advantages in the interaction, meant that the link does not generate any useful resource or relevant information. And second, the existence of institutional barriers that could inhibit or prohibit interaction. Both elements reveal a lack of closeness or a belief that there is not a possible benefit from the interaction with certain groups, actors, hidden costs, etc.

In this process, when an interaction between two actors takes place, it is likely to readjust the structure of this relationship and therefore new networks are created. For example, if an SME entrepreneur approaches to a federal agency for the granting of support, the federal agency will undoubtedly refer the case to a state agency, creating a new link to strengthen the SME. These new relationships could generate certain tension with different actors. According to the last example, a SME entrepreneur can attend to a federal office, because there is a belief in the local sector that state office has not any resource to provide support to local businesses. This could create a tension between government levels and therefore the fields of action of each one.

This complexity of dynamics of collaboration and its effects through networks create a series of conflicts and 'Network Resources Opportunity Gaps (NSOP)', especially for SMEs and in the design of managerial networking strategies. As Salancik (1995) mentioned, an effective network approach should be oriented to understand the effect of this theoretical variable (Collaboration Networks) and describe how this helps to explain

a detected research problem; in this case the lack of consolidation of SMEs, opening opportunities to search new markets or collaborative associations among SMEs, and of course, the improvement of performance in a long-term view.

Considering that the SMEs flourishing in the economy is a fundamental way to enhance social development and to improve a country's quality of life (OCDE, 2015b) particularly for an underdevelopment country as Mexico (INEGI, 2014). For that reason, understanding how certain individual links or networks blocks can increase or decrease the SME's performance level, becomes fundamental.

3 The Collaborative Manager Network: SME Manager as a networking strategist

The managerial figure in the organizations is commonly visualized (and idealized, most of the times) as the leader of the organization but this is only partially true. Even though management and leadership are related, management exercised is an art, a science and a share-trade that converge in organizational frameworks of great turbulence and immediate results (Mintzberg, 2009). Manager position, according to the definition, is the "person who is responsible for an entire organization or for an identifiable part of the organization" (Mintzberg, 2009, p. 16).

In that sense, performing as manager entails a coexistence with pressures and activities that most are defragmented. These activities involve the manager to change and decide on many occasions quickly and with a lot of stress. In this context, the manager must decide strategies counseling different actors and possible outcomes. For that reason, "be a manager is more like to be at the center of the hurricane, they have a lot of action, mobile, fluid, tangible, ongoing and non-routine activities" (Mintzberg, 2009, p. 31).

In that context, the manager becomes a strategic organizational axis and strategic center of a company (Mintzberg, 2009). Moreover, a double role is conceived (interior and exterior) and in both of them the manager must communicate around an environment and control inside the corporative team. This could create tensions and struggles inside the organization, for that reason, a manager should be connected with strategic actors outside the organizational borders, especially not only to access resources, but also to receive advices and feedback.

Working as networks for managers means to be part of a complex structure of trust relationships between companies, managers or units (Borgatti & Halgin, 2011). For the members of each network, the nature of communication and support may be unilateral or bilateral but mainly linked to the achievement of products, services, resources and actions. Networks are distinguished by shared activities and control between the actors and that end up being conducted through processes, events and sometimes particular rituals of cooperation (Milovanović, Primorac, & Kozina, 2016). Relationships of cooperation within organizations can be derived between multiple levels commonly established by hierarchical management figures towards external characters (Geletkanycz

& Hambrick, 2006; Lee, Lee, & Pennings, 2001). These connections are a pivot of limit expansion in the search of resources, opportunities or advices that could facilitate a performance improving (Li, 2005). These connections provide some added values for managers, for example the ability to share and disseminate information, not only unilaterally, but multilaterally in the context in which they operate (Xin & Pearce, 1996). For example, for SMEs in contexts as Mexico and most of Latin America, the lack of confidence in institutions formally constituted by government (OCDE, 2015b, 2015a) allow an alternative search for resources or access to market information by other means, as informal contact networks or by collaboration with customers or key suppliers (Peng & Luo, 2000).

In that context, understanding and analyzing the design, maintenance and development of managerial networks managers and external actors assume it as a systemic and cooperative activity between them. That allows to analyze the construction and management of personal relationships with others and how these connections impact on performance (Coulthard & Loos, 2007). This represents a shift in the management, because the focus is now on the manager and its dynamics of collaboration, being a 'central actor in a networking strategy'. Commonly, networks entail certain strategic goals, for example: socio-affective links to face risk-taking (Kaplan, 1984), access to capital for investment, growth, loans, among other purposes, and encouragement to persistence in business (Hoang & Antoncic, 2003). However, especially on SMEs performance, recent investigations demonstrate the impacts of these in the business context (Doloreux, 2004; George, Wood, & Khan, 2001; Kusumawardhani, Mccarthy, & Perera, 2009; Tendai, 2013).

The empirical evidence mentions that the alliances and links that organizations establish with those distinguished by an entrepreneurial style, gain access to new technologies, gain technical and operational talent, remain as industry benchmarks and in general obtain a creative capacity (Lee et al., 2001; Peng & Luo, 2000; Xin & Pearce, 1996). Then, collaboration networks are then related to be as 'escape valves' of companies that are looking for a competitive advantage over those organizations that do not establish links with entrepreneurial organizations (Alvarez & Barney, 2001). Organizations that are assumed as connected entities (both internally and externally) are fertile crops for the creation of new social networks (mostly external) and are highly attractive spaces for entrepreneurs who use their interpersonal relationships to achieve resources that would not be affordable only by using their internal networks. In other words, a managerial decision to connect a company with different actors around a business ecosystem could strengthens the organizational capacities to access to privileged industrial information, new resources and talents for innovation, risk taking and proactivity, learning and the discovery of opportunities (Martins, 2016).

Undoubtedly, this context offers an opportunity, especially for SMEs that are looking for new networking strategies that strengthen certain competitive advantages over other competitors in the market. This search for SMEs managers begins with possible links

with government offices and financial institutions. However, a lack of trust with these actors, especially in underdevelopment economies create 'connection barriers'. Nonetheless, the economies should be oriented by the construction of links between these actors, because they facilitate new approaches, resources and opportunities for local SMEs and hence their growth and survival (Su, Xie, & Wang, 2015).

Su et al. (2015) classify these connection-actors, in three main categories: First, as 'political networks' corresponding to established relationships with government officials, government agencies, state and local government agencies, professors and research centers. Secondly, a different type of networks, as 'financial networks' that emphasize relations with bankers, private financing officers, investors, potential partners, shareholders and banking agencies. And third, as 'business networks' corresponds to the relationships that the organization established with customers, suppliers and competitors.

4 A backbone in networking strategy for SMEs managers: Collaborative Manager Network (CMN) and its effects on performance

Even though some studies have been conducted to understand the influence of collaborative networks in organizations and new ventures (Cisi, Devicienti, Manello, & Vannoni, 2016; Ripollés, Blesa, & Ripollés, 2006; Su et al., 2015; Walter, Auer, & Ritter, 2006; Zhao & Aram, 1995)there is still a theoretical and empirical gap in describing and understanding the effect that collaboration networks have on the performance of organizations (Ferreira et al., 2015; Martens, Lacerda, Henrique, & Rodrigues de Freitas, 2016).

However, this is a complex issue and materializing the study of networks is multifactorial. The social fabric that managers possess is derived from scenarios of numerous contacts both at a formal and informal level and these can have (or not) a strategic purpose for the resources of the companies. In that sense, it is important to point out that the literature in strategic management indicates that the presence of these relationships and contacts has a positive effect on the company. The strongest argument in this sense is that a company that does not relate to actors in its environment will have a worse performance than those that do so (Cisi et al., 2016). Understanding the structure of the formal and informal relationships of the organization with key actors means possible important allies, especially in the search for resources in their business environment (Díaz García & Carter, 2008).

However, there are findings pointing to the virtue of collaboration networks in a significant way, as well not. In the literature research, findings have been obtained in two senses: the first one indicates that density of the network and familiar connections have a positive effect on the performance of the organization, but it may not be statistically significant (Surin & Wahab, 2013). And in the second sense, the possibility of negative effects between collaborative networks and performance (Ricciardi, 2014). These results

open a debate between the relationship between collaboration networks and performance, being a main issue in the research management agenda.

Hence, the effects of collaboration manager networks on performance's company become an area of research opportunity for strategy and management fields, especially in Latin America economies (Ferreira et al., 2015; Robinnet, 2016; Širec & Bradač, 2009; Tendai, 2013) is fundamental to make an operational research with a network approach. For that reason, firstly it is necessary to describe the actors and resources that are attracted and detached from the network (Stamm, 2004). According to this and even if the networks performance positive effect is still in debate, to set an operational concept of manager's network becomes important in order to design a possible measure scale and a future assessment with performance as planned in this research. In that sense, the concept of 'Collaborative Manager Network (CMN)' is defined for this research as a *microstructure of relationships trust-based between SME's manager and other actors in a business environment, these links are mainly established with some strategic purposes as to share knowledge, information or resources. To have an easy and operational pattern to study these networks, actors are separated in three networks categories: a) political networks, b) financial networks and c) business networks*. This operational approach for CMN includes three elements that allow adapted design items and measure them from a SME's manager perspective in a survey: 1) extension (Adapted from Peng & Luo, 2000), 2) uses (Adapted from Acquaah, 2007) and 3) intensity (Adapted from Ibarra, 1996; Kumar Panda, 2014; Panda, 2014). The next paragraphs describe these operational elements:

Extension of the CMN. Undoubtedly, the issue of measuring extension of a network is a complex issue, open questions, such as: how many contacts does the government have? Or how much do you invest in gifts for the 'x' network contacts? It broadens the spectrum of the non-response bias and hinders the collection of information; however, Peng and Luo (2000) structured items that facilitate measuring process. The items were adapted to a Mexican cultural context and a Likert scale that allows evaluating if a certain type of network is considered from the range of "very small" to "very extensive" by the respondent manager.

Uses of the CMN. Connections with strategic actors through these networks facilitate the acquisition of resources more easily and quickly than if they were not present; for managers, creating, developing and extending their networks depends on a series of factors (Ibarra, 1996), some of them are: personality, background life-history and experience gained in the industry. As well as, of course, developing the skill to establish those connections with true socio-affective perspectives with clients, suppliers, competitors, research centers, government agents, bankers, shareholders and staff that are in contact with the company's processes. For these reasons, when an organization is exposed to a series of external networks (Granovetter, 1983) it is exposed to high quality information (and other resources) for its products. Under this context, it is possible to determine that there are three main uses of collaboration networks (Acquaah, 2007): 1)

Access to *valuable information* for the industry (INFO), 2) Access to *resources* that promote a competitive advantage (RES) and 3) Acquisition or exploitation of *knowledge* (KNOW). In order to adapt these items a Likert scale of 1 to 7 is included, from "very little" to "a lot" and the uses are established in columns and in the rows the actors of each of the networks, this survey design makes easier the information gathering process with managers. This design was originated from the recommendations of the managers visited in the previous pilot study and this element saved considerably time in the collection of information and possible bias among managers' answers.

Intensity of the CMN. Intensity assessment was established through the time that the manager invests on the development and maintenance of their networks. As mentioned in previous lines, the importance of the network is established by a socio-affective link established and one of the ways to promote it is continuity and familiarity in the human contact process (Ibarra, 1996; Kumar Panda, 2014). For this reason, a categorical and ordinal scale of five items was established which measures manager time-investment from none to more than 10 hours per month.

Even though, the analysis of CMN-performance relationship is considered relevant in relation to improve business performance, in particular, because networking is considered as a strategic key of SMEs. Performance is a complex issue, especially to be measured. In the last decades it has been the focus of a number of studies, however there is not a homogeneous and universal definition (Davidsson, Achtenhagen, & Naldi, 2010; Davidsson & Honig, 2003). Mintzberg (2009) mentioned that the continuous search of a performance's improvement must be accompanied by series of management tactics that support even capacity and expansion mind-sets. In our economic scenario, even though survival becomes important, growing and improving performance for the company meaning confidence, power and independence in its environment (particularly for SMEs). So, growth and improvement of performance are two sides of the same coin.

For that reason and derived from a literature review that allows to describe a homogeneous performance definition that joining organizational performance and growth aspects, it was considered appropriate to use Quinn and Rohrbaugh's model (1983), which is based on fourteen elements to assess business performance. Quinn-Rohrbaugh's methodology (1983) has been widely used at the international level, correlating it to variables, such as, innovation (Van-Auken, Madrid-Guijarro, & García-Pérez-De-Lema, 2008), the transfer of knowledge (Rodríguez Orejuela, 2007) and the organizational culture (Hartnell, Ou, & Kinicki, 2011). This one-dimensional performance approach analyses the components of the organization and establishes the criterion of efficiency towards internal-external relationships, organization's structure, flexibility and the attention on goals and procedures. This model enables the assessment not just financial or operative performance, but also includes a notion of an organizational performance (Venkatraman & Ramanujam, 1986). One-dimension approach and fourteen items characterize this organizational performance concept, which includes conditions related

to: human relations, open system, internal processes and finally sales and personnel indicators.

In our next section, we describe a framework to explore the relationships between two elements: 1) The Collaborative Manager Network (CMN) with three networks categories (Political, Financial and Business) in a reflective model and 2) One dimensional Quinn and Rohrbaugh's performance model.

This main conceptual model represents the relationships that were empirically investigated in Mexican SMEs in footwear and leather industry in Guanajuato state.

5 Exploring the relationships between CMN and performance in Mexican SMEs

Figure 1 presents the framework proposed to investigate how CMN affect company performance. The effects between the CMN construct and organization's performance have been studied previously in different industrial and manufacturing sectors (Baum, Calabrese, & Silverman, 2000; Cisi et al., 2016; Havnes & Senneseth, 2001; Kusumawardhani et al., 2009; Li, 2005; Naudé, Zaefarian, Najafi Tavani, Neghabi, & Zaefarian, 2014; Ofem, 2015; Ricciardi, 2014; Širec & Bradač, 2009; Tendai, 2013).

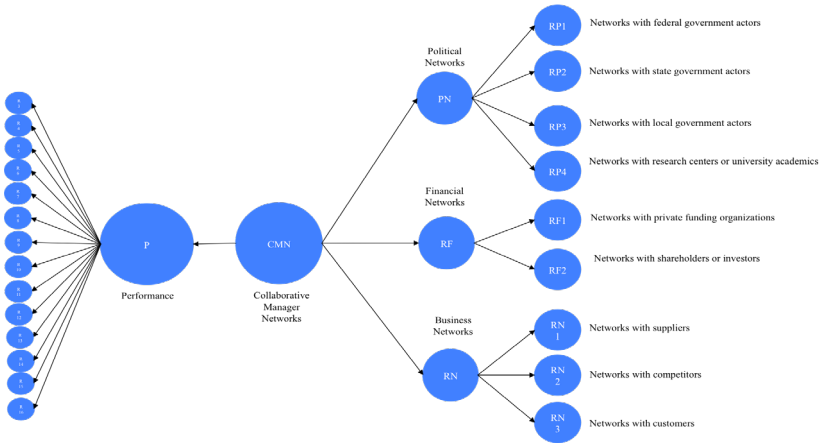

Figure 1. Research theoretical model

The results of previous research show that the relations between CMN and performance have a diversified effect, depending on the characteristics of the sectors, networks type and the way in which it is measured. In this context, this study proposes an exploratory investigation of the relationships between CMN and Performance of Mexican SMEs in the Bajio region, which is one of the most important economic sectors in the country. For this reason, the following working hypothesis is proposed:

Hypothesis 1. *Collaborative Manager Networks (CMN) has a positive effect on Performance of SMEs in the leather-footwear sector, in the Mexican Bajio Region,.*

5.1 Research Methodology

In order to verify the existence of a relationship between CMN and SMEs performance the Structural Equations Model (SEM) approach has been deployed (Hair, Hult, Ringle, & Sarstedt, 2014). This statistical model belongs to multivariate analysis tools of second generation that allow simultaneously measure the associations (Hair et al., 2014). The variables building the model are Performance as one-dimensional concept and CMN with three types of networks: a) Political, b) Financial and c) Business measured with items related with: extension, intensity and use.

The theoretical model to be tested contains a latent variable of second order: CMN; detaching from it, three categories according with Su, et al. (2015). The organization's performance is a dependent variable of first order, which is an unobservable variable and therefore measured by fourteen items adapted from Quinn-Rohrbaugh's model (1983).

Data about these variables were collected through a survey, which was applied to SMEs managers in the cities of Bajio region with the highest density of enterprises in leather footwear sector (CONACYT, 2014; INEGI, 2014). In total 170 valid instruments were obtained during fieldwork (See table 1). For the exploratory objective of this research, the sample size obtained (170 observations) and data distribution (not-normal), the use of the PLS-SEM technique was used (Sarstedt, Ringle, Smith, Reams, & Hair, 2014).

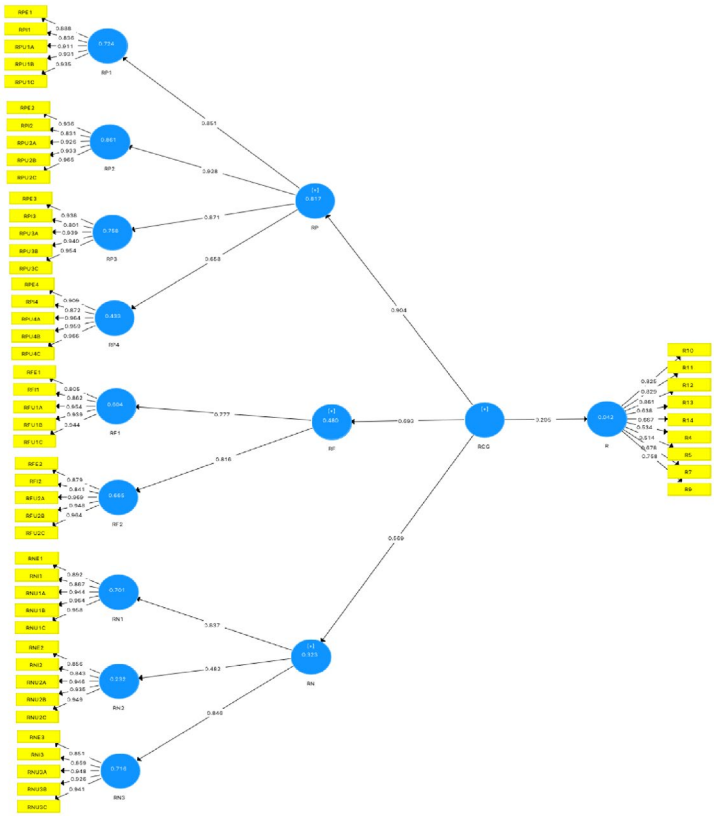
Table 1. Frequency by firm size

Firm Size	Frequency	Percentage	Valid percentage	Accumulated percentage
Medium	9	5.3	5.3	5.3
Small	161	94.7	94.7	100.0
Total	170	100.0	100.0	

Source: Obtained using IBM SPSS® software.

5.2 Findings

Derived from the literature a research model type I reflective was designed (Becker, Klein, & Wetzels, 2012) and PLS-SEM algorithm was analyzed by the SmartPLS® 3.2.7 software for the 170 observations (see Figure 2).



Source: Obtained using SmartPLS® software (Ringle et al., 2015).

Figure 2. Path model in SmartPLS®

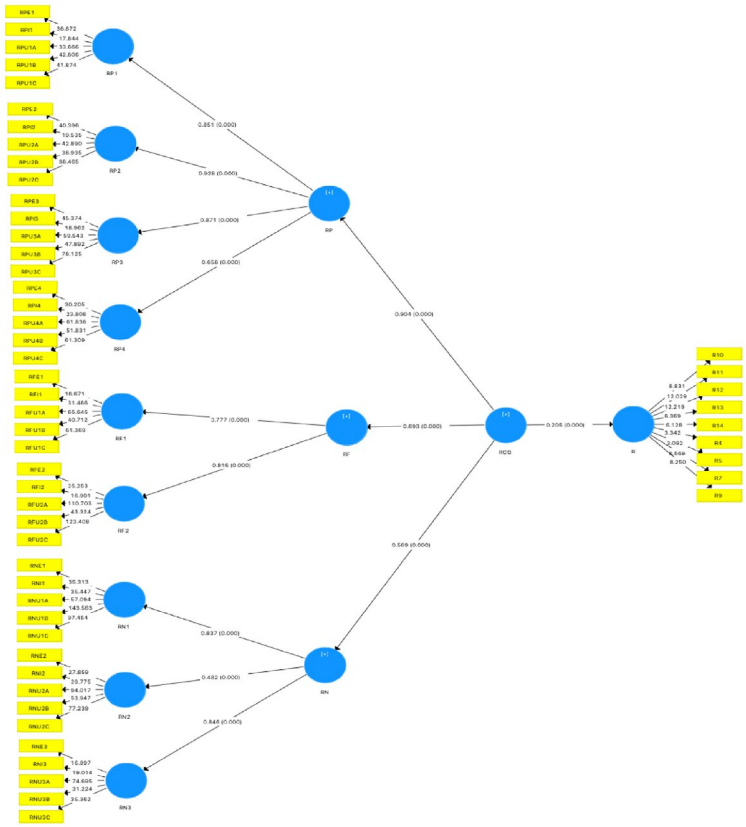
In reflective models, evaluation starts with the loading's assessment obtained by checking each indicator of each network. Loadings greater than 0.700 indicate that the construct explains at least 50% of the indicator variance, if they not get that loading, remove indicators is a recommend path in order to improve the model fit. In this case, indicators get the minimum score to pass the first step of test.

According to the results, approximately 20% of the SME performance is influenced by CMN. This scenario provides a scheme about the importance of the CMN in the performance development in the leather-footwear SME. This factor determines to enhance and guide strategic efforts to strengthen activities of linkage between diverse actors of the economic ecosystem and SME managers that allow them to improve their performance as well as increasing their survival rate.

A significant discovery in the model was a low orientation to connections on Financial and Political Networks (see Figure 3) in Mexican SMEs of leather-footwear sector. A low orientation to build networks with federal political actors was detected. As well, a low orientation to create networks with University professors and Research Centers was

detected. These are main discoveries among managerial practices because of a short-oriented strategy with this kind of actors that provides a disconnection between fundamental knowledge, resources and information around the environment. If this connection happens, the SME could get some resources or information to survive an economic crisis. This is a main practical recommendation derived from this research. Moreover, it is considered as a gap to attend an opportunity area to develop a networking strategy oriented to improve the performance in a short-term.

For the performance construct, a Hair's criterion (2014) was adopted where the researcher can examine the effects on the composite reliability and the validity of the construct before eliminating indicators that loadings are below from 0.700 (Hair et al., 2014). It is necessary to mention that after the analysis, indicators below this standard continued to respect the general parameters of the corresponding model and therefore continued to be part of the dimension (see Figure 3).



Source: Obtained using SmartPLS® software (Ringle et al., 2015)

Figure 3. Adjusted path model in SmartPLS®

The next validation step is to analyze Internal Consistency Reliability of the model, when using SEM-PLS it is determined through composite reliability. The parameters for this in exploratory studies indicate that the margins of 0.60 to 0.70 are acceptable, parameters between 0.70 and 0.95 are considered satisfactory, higher or equal values to 0.95 can produce problems with redundancy, however, in the scenario that items measure different aspects of theconsidered constructs and are highly correlated, it means that there is a good measurement model (Becker, 2015). In this case, this happens with CMN scores for this reason. Performance dimensions obtained scores greater than 0.85 but less than 0.95 (see Table 2). The next step is the evaluation of the convergent validity of reflexive constructs. Convergent validity is determined by the average variance extracted (AVE) of all items associated with each construct (Sarstedt et al., 2014). The AVE value is computed by the mean square of the loads of all indicators associated to the construct (Sarstedt et al., 2014). An acceptable AVE corresponds to 0.50 or greater; the construct explains at least 50% of the variance of its items. In this sense, the elements of the CMN and Performance constructs have an AVE higher than 0.50, thus manifesting convergent validity (see Table 2).

Table 2. Results of Reflective Model

Construct / Dimension		Index	Loading	Composite Reliability	AVE
Collaborative Management Network	Political Networks	RP1	0.851 0.928	0.956 0.965	0.812

Subsequent to the reliability and convergent validity of the reflective constructs, it is necessary to determine the discriminant validity of the constructs. The discriminant validity determines how different a construct from others is in the model. The most

conservative way to do it is using the Fornell-Larcker criterion (Hair et al., 2014; Sarstedt et al., 2014) by comparing the square root of the AVE of each construct, if it is greater than the correlations with the other constructs, according to the Table 3, it can be defined that there is discriminant validity.

Table 3. Fornell-Larcker criterion to discriminant validity of the model

	R	RF1	RF2	RN1	RN2	RN3	RP1	RP2	RP3	RP4
R	0.711									
RF1	0.047	0.903

Subsequently, an evaluation of the structural model was performed. For this, it is necessary to consider the following criteria: a) the coefficient of determination (R^2), b) the crossvalidated redundancy (Q^2) and c) the path coefficients (Sarstedt et al., 2014). The indicator R^2 is a measurement relative to the variance explained on each dependent construct, so it is assumed to be a predictive measure of the model. The interpretation ranges considered are: greater than 0.67 it has substantial value, moderate explanatory value with 0.66-0.33 and a weak value with a range of 0.32-0.19 (Chin, 1998).

The results indicate that CMN networks corresponding to RP2, RP3 (state and local government) and RN3 (connections with customers) have values that allow a substantial explanation of the construct. This constitutes a discovery with practical implications, since it provides interesting insights about the possible networking strategies and a main gap to build relationships that Mexican SMEs in the leather-footwear sector can adopt in short-term (see Table 4).

Table 4. R^2 and adjusted R^2 of the structural model

		R^2	Adjusted R^2	Q^2	
CMN	RF	0.480	0.477 0.602	0.468	
	RF1	0.604	0.663 0.319	0.458

Another way to evaluate the predictive relevance of the model is Q^2, which is described as a predictive measurement, where values greater than zero indicate an acceptable predictive value (see Table 4). The cross-validated redundancy is used to obtain the Q^2 value (Hair et al., 2014; Sarstedt et al., 2014). The results indicated model's predictive value.

Afterwards, the strength and significance of the path coefficients were evaluated by the relations established in the model and its hypotheses constructed from it. Using SmartPLS® there were four relationships obtained of the variables (see Table 5). From the results obtained, it can be highlighted that CMN has a positive and significant relationship, with performance (0.205). In addition to these discovers, and in order to comply with the objective and hypothesis of this research, it can be highlighted a significant and positive relationship the three network categories with CMN in the Mexican SMEs of leather footwear sector of the Mexican Bajio region (see table 5).

Table 5. Coefficient path and significance of the structural model

Relation	Coefficient Path	t value	
RCG -> R (Hyphotesis)	0.205	3.774	***
RCG -> RF	0.693	13.287	***
RCG -> RN	0.569	13.646	***
RCG -> RP	0.904	47.647	***

6 Discussion and Conclusions

Based on the results obtained and presented on Table 5, it can be inferred that CMN as a variable has a positive and significant effect on the performance of Guanajuato companies in the leather-footwear sector. The model has explanatory capacity and predictive relevance, which indicates that it has the quality characteristics to be, highlighted in decisions and discussions by academics, managers, industrial chamber leaders and authorities at its various government levels. This discovery is in accordance to (Cisneros-Reyes, Lira & Arredondo Hidalgo, 2019) who proposed that a leather footwear SMEs transformation should start with the willingness, not only of the businessmen and businessmen's guild, but, especially, of the government and of the academic institutions that count on the knowledge and resources to stimulate it.

These empirical observations obtained show that the CMN has approximately 20% influence on the performance of SMEs in the leather-footwear sector on Guanajuato State. Similarly, it can be inferred that according to the value of R^2 (≥ 0.02) it has a weak explanatory capacity (Cohen, 1988) however, despite the above, the model has predictive relevance. This scenario gives an acceptance of the main hypothesis of this research study.

This finding has valuable implications in the formulation of commercial and strategic scenarios in cooperation between competing companies, especially in the leather-footwear sector. Like Havnes and Senneseth (2001) who also find that the CMN has a positive effect on the performance of companies. For these researchers, companies that showed greater intensity in their collaboration showed a considerable growth in the extension of their market than those companies that consistently showed a low intensity of collaboration. This finding could support the assumption that collaboration through networks precedes growth in market expansion.

It is important to note that the model analyzes a causal relationship between the CMN and the level of performance described by the SME manager. In this collective construction, CMN is manifested by three types of networks and the particular analysis of each network-actor corresponds to a possible second level of analysis, which is undoubtedly interesting for both industry and decision makers, because the level of performance according to the collaboration will be based on what type of actors the manager is related to obtain the maximum benefit from their performance.

In that sense, Su et al. (2015) in a study of new ventures in China about collaboration with various external actors and how they moderated the entrepreneurial effect with their performance, detected that the collaboration networks established by the actors (managerial networking) measured through political, financial and business networks, impact in a differentiated way. Their results confirm, like those presented in this study,

that political networks manifest a negative effect on the relationship with performance (See Figure 7) and that the majority of the connections have concentrated with low indicators of use, extension and intensity (See Figure 4).

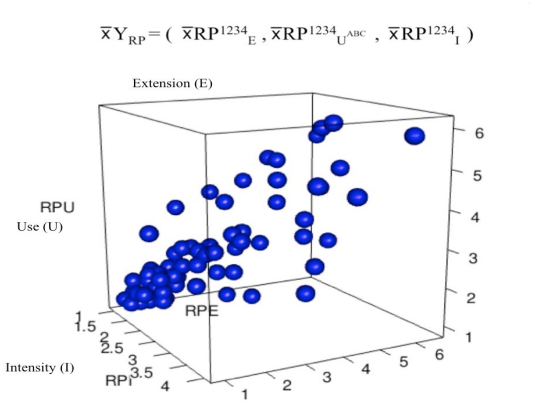

Figure 4. Model of Political Networks and its dynamics on Use, Extension and Intensity Dimensions. Using Open Source Software R.

In addition, financial networks and business networks have a positive effect. Political networks designated with the initials RP maintain a negative causal relation of -0.015 with the performance. Financial networks with the acronym RF with a relatively small positive effect of 0.052 and they have a particular dynamic in model, more SMEs' managers have connections with banks or financial actors (See Figure 5). In the case of Business networks identified with the acronym RN with a considerable positive effect with a value of 0.300 (p=0.000) and they have a dynamic of higher scores of use, extension and intensity dimensions (See Figures 6 and 7).

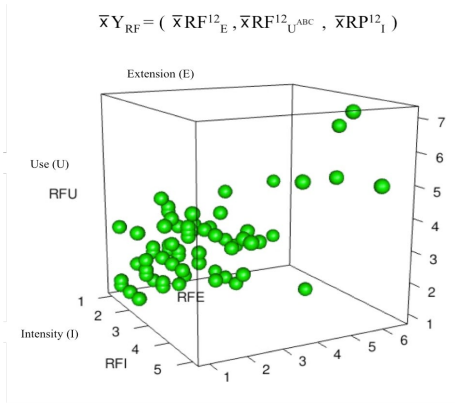

Figure 5. Model of Financial Networks and its dynamics on Use, Extension and Intensity Dimensions. Using Open Source Software R.

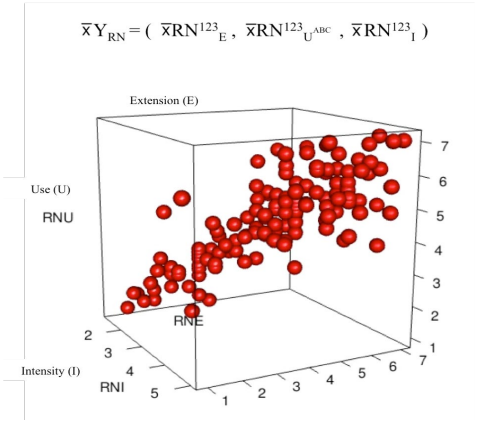

Figure 6. Model of Business Networks and its dynamics on Use, Extension and Intensity Dimensions. Using Open Source Software R.

Derived from the results it can be inferred that the CMN is a construct that its manifestation behaves differently in a causal relationship with performance. In this case, like the findings of Su et al. (2015) the political networks show a negative relationship with the performance and the financial and business networks maintaining a positive effect, this last with a 30% impact on the SME performance. It is possible to conclude that although the CMN has a positive effect, however with the negative effect of RP the total performance is an opportunity area of improvement. In the case of the RN these are positive, significant and with the highest index of the three types of analyzed networks.

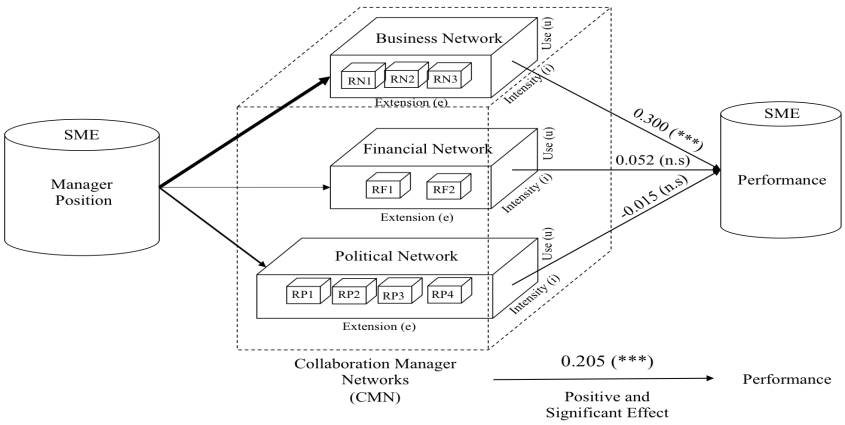

Figure 7. CMN and the differentiated effects on SME performance

The study contributes to advance the conceptual understanding of the relationships between different actors and business performance as well as provides interesting

implications for practice. From conceptual point of view, findings provide evidence of CMNs settings in an emerging and Latin-American economy in a specific SMEs sector. In the field of performance, this research illustrates a behavioral model and determines dynamics and indicators with most significance on the studied sector.

Additionally, findings provide evidence that CMN emerge as an innovative and creative contribution for the design of the link between strategy and networking of the managers. This opportunity gap is an element that has been called 'crossing into the unknown area' of unusual links (the unknown area, the gray area in Figure 8). Relations with key actors, which for 'average manager of the SMEs' are 'unknown'.

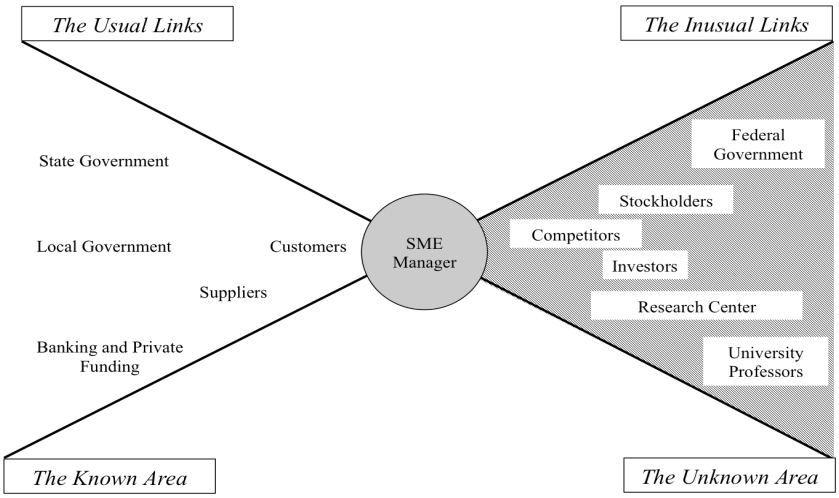

Figure 8. The 'unknown area' for SME Managers as an opportunity gap for networking and enhance performance

As can be seen in Figure 8, relationships established by the manager are mostly around business networks (specifically managers of client and suppliers' companies and just few actors in the political and financial areas). Hence, there is a range of unexplored possibilities from links with other actors. Especially, in a society oriented by knowledge and innovation, for SME manager enhance connections with professors and research centers of the universities of the region of the state of Guanajuato to develop new strategies to improve performance.

And finally, this research provides a methodological option and uses in the analysis of relationships between network analysis and performance by carrying out Structural Equations Modeling (SEM) and Partial Least Squares (PLS), using the software SmartPLS® (Ringle et al., 2015).

Abstract

This paper aims at analysing how the development of digital smart technologies and the Web affected the business model of a particular field of copyright-based companies: the collecting societies. The impact of the Internet and digitalization on the cultural enterprises will be investigated, focusing the analysis of the new business models established. It is necessary to clarify how the operators of the cultural enterprises have transformed their business model into an online business model and who the new players in this market are that have led to the change in the use of copyrighted works. Following an analysis of the literature on the subject, a vertical analysis of a specific sector of the creative enterprises will be carried out. Our research demonstrates the relevance of the analysis of the business models of cultural enterprises and how innovative business models can represent a tool to contrast the phenomenon of piracy. The findings of the research allow to assert that there is a close connection between innovation, intellectual property and business model: the high costs necessary for the creation of innovative products, also related to the protection of intellectual property, can be contained if the management of intellectual property is integrated into the within an innovative business model. Business model innovation can allow managers of this type of firms copyright-intensive to resolve the trade-off between costs and benefits of innovation, reviewing their business models for creating value.

Keywords – Copyright, Digital Technologies, Sustainable Business Model, Collecting Society

Paper type – Academic Research Paper

1 Introduction

In the context of new economy, increased interest in creativity and creative enterprises has emerged; the creativity is considered as the ability to produce new ideas, represents an essential resource in a knowledge-based economy, as well as necessary for the development of scientific, technological and cultural knowledge (Simonton, 2012).

Meanwhile, creative enterprises mainly deal with the production and sale of artistic works and, through the management of intellectual property rights, base their activity on creativity. These companies are also referred to as creative industries or copyright-based companies, emphasizing the importance of copyright protection for their sustainability (Trequattrini, Lardo, 2020).

Given its economic importance, the cultural industry may represent the challenge of the Italian competitiveness in the World, since it is composed by companies with high cognitive intensity, that is characterized by a high rate of creative innovation and specialized human capital, which helps to promote the new generations for the challenges of digital and new business models.

Some cultural industries are global players that have modified their organization in the last few years. The digital transformation and the new Information and Communication Technologies (ICTs) have given rise to a deep change in the business models adopted by companies, in order to exploit the potential of Web 2.0. ICTs allow to process, extract, copy and transfer creative content at a very low cost; this has significant effects on the publication, promotion and distribution of artistic works.

The digitalization process reduces distribution and storage costs and makes it possible to reach significantly more potential consumers. The development of information and communication technologies has historically played an important role in modifying the traditional ways in which culture is produced and distributed.

Technological innovation generates opportunities for the development of new business models or forces the transformation in order to achieve sustainable businesses. Evidence shows that some companies (for example, Amazon, Apple, AirBnB, Facebook) have been successful through the innovation of the business model, in turn made possible by new digital technologies, while others (for example, Japan, Kodak and Atari) have missed these opportunities and experienced performance declines.

Therefore, the aim of this research is to understand how the development of digital smart technologies and the Web affect the business model of a particular group of copyright-based companies: the collecting societies (CSs) (Riccio, 2012; Riis, 2012; Rochelandet, 2003).

In particular, this research presents a qualitative research (Hair et al., 2013) based on the comparison of two case studies of CSs operating in Italy: SIAE and Soundreef. To compare the business model of these societies we used the VUCA framework (Bennett, Lemoine 2014).

The need for strategic management of copyright derives from the presence of clearly identified intangible assets capable of ensuring a competitive advantage if they are integrated within the business model of the company. The impact of the Internet and digitalization on the cultural enterprises will be investigated, focusing the analysis of the new business models established able to integrate copyright into the business model of the societies to ensure a competitive advantage.

The remaining paper is organized as follows. Section 2 provides a literature review about the CSs, a specific category of copyright-based industries, and about the main studies on business model innovation. Section 3 exposes the methodology. Section 4 explains the case study analysed and Section 5 provides conclusions and main implications.

2 Literature review

2.1. The collecting societies

Economic copyright theory examines the financial incentives and/or contributions linked to copyrights by explaining the related positive and negative features (Watt, 2014). In this context, a copyright is a right recognized in law and represents the authors' original creative work (Hartley, 2005).

Copyright protection has many implications in the current landscape, one of which lies in its economic value on the market. Copyright industries contribute to the gross domestic product of every nation in the world, despite there being different national laws (Smith, 1996).

According to the World Intellectual Property Organization (WIPO) (2005), the copyright-based industries defined as wholly engaged in the creation, production, performance, exhibition, communication or distribution and sales of copyright protected subject matter. These include literature, music, theatre, film, the media, photography, software, visual arts, advertising services and collective management societies. It, annually, classifies copyright-based industries, distinguishing four categories: Core Copyright Industrys; Interdependent Copyright Industrys; Partial Copyright Industry; Non-dedicated Support Industry.

A particular group of copyright-based companies: the CSs (Riccio, 2012; Riis, 2012; Rochelandet, 2003). Particularly, CCSs born as a corporative structure aimed to defend authors' economic interests towards users of protected intellectual, cultural and artistic works. Thus, the corporative model of CSs is based on the remunerations' establishment with users and the remunerations' collection and distribution with their authors and

creators' affiliated. Additionally, they are directed to protect the interests of their members through the suppression of abusive utilizations and assuming solidarity and charitable task fostering members (Di Genova, 2000). CSs are networks composed of authors and creators directed to take collegially advantage of copyright (Besen and Kirby 1989; Hollander 1984; Watt 2014).

They have the following principal functions: license the use of the rights they manage, monitor the usage of works by licensee to enforce the conditions upon which the licence has been granted, collect and distribute the royalties payable as a result of the licensed use (Hollander, 1984). As CSs are constituted somewhat differently in different countries, it is difficult to generalise about some of their characteristics and activities (Handke, Towse, 2007).

The collective rights management (CRM) has received most attention in the economics literature. Economists typically see CS as an efficient way of overcoming the problem of high transaction costs for administering copyright in some markets (Coase, 1960; Williamson, 1979). In addition to the transaction cost theory, the economic function of copyright management companies can be explained through the information's economy (Sandler 2004; Stiglitz 2002). A not symmetric distribution exists in terms of information among contractual partners and connected risks. The existence of asymmetric information might generate adverse contractual conditions assumed by less informed individuals. In the absence of solutions from the market, broker intervention becomes essential. CSs devoted to acquiring licences are inclined to take actions based on their transaction experience.

Additionally, CSs are better able to detect violation of intellectual, cultural and artistic works allowing for the litigations activation and income increasing from the copyright (Tétrel 2008). Thus, CSs have a strong position to assume contractual risks. They can easily collect information on the market to fix a price maximizing the profit connected to cultural and artistic works. They can offer general licences as an incentive to their users. In a related manner, an issue related to optimal dimensions of CSs is posed. CSs represent the natural monopoly (Watt 2014, 167).

2.2. Business Model Innovation

Business model innovation (BMI) has attracted extensive attention from scholars and practitioners. BMI can be considered both the main instrument for enterprises to adapt to environmental changes and continuously create value (Karimi and Walter 2016), and also the key driving force for enterprises to create competitive advantages and achieve excellent performance (Martins, Rindova, and Greenbaum 2015).

Nowadays, the digital era and the Industry 4.0 paradigm, combining different technologies, open unforeseen possibilities to create radically new products, services, to share knowledge between different actors of the technology ecosystem (Lombardi, 2019)

and to generate innovative business models (Caputo, Marzi and Pellegrini, 2016; Spieth et al., 2016).

Many scholars have shown how companies can substantially enhance their value creation process by developing innovative business models (Abdelkafi et al., 2013). BMI refers to a new activity system of the firm (Foss and Saebi, 2016) and innovative structures for value creation and value capture (Chesbrough, 2010) involving a single firm and its alliance partners and customers (Bouncken and Fredrich, 2016).

The emerging smart technologies allow companies to show and create knowledge and to increase their competitiveness (Lombardi, 2019). To improve the possibilities to compete in new contexts, digital technologies (Loebbecke and Picot, 2015; Roden et al., 2017) are powerful forces pushing firms toward new business models (Cohen and Kietzmann, 2014; Fjeldstad and Snow, 2018; Holweg and Helo, 2014), making the capability to innovate increasingly relevant (Chesbrough, 2010; Foss and Saebi, 2018; Zott and Amit, 2007).

Therefore, the digital technologies have changed the way of doing business also creating new competitive contexts. In fact, there are industries in which competition have started through the introduction of new technologies able to overcome structural obstacles and monopoles developed during years. An important example is the one of the sector of collecting societies where also regulatory action has brought the development of competition through the creation of new companies based on innovative business models but also the BMI of companies previously operating in the market. In this perspective, in the next section, we are going to analyse how the development of digital smart technologies and the Web affected the business model of the (two collecting societies operating in the Italian scenario: SIAE (Società Italiana degli Autori ed Editori) and Soundreef Ltd.

3 Methodology

This study presents a qualitative research (Hair et al., 2013) based on the comparison of two case studies. According to Massaro et al. (2019), qualitative methods allow researchers to illustrate the influence of the social context. Within qualitative research methods, case studies support researchers when "a how or why question is being asked about a contemporary set of events over which the investigator has little or no control'' (Yin, 2014). Additionally, case study research allows gathering a profound understanding of a "real-world case" (Ridder et al., 2014). We claim that the case study methodology is an appropriate research method that will enable us to test the existing theory on a specific research context, gathering a deep understanding of a complex social phenomenon (Yin, 2014).

Particularly, the research method consists of a set of specific procedures, tools and techniques to gather and to elaborate data on the changes that characterized the change in their business model. Data were collected in the form of primary and secondary data. Data triangulation (Patton, 2002) assists our aims both in collecting more comprehensive

relevant information and crosschecking the consistency of the source to enhance the robustness of our findings. The first step of the study is to identify the profile and the business model of the main copyright collecting societies operating in Italy: SIAE (Società Italiana degli Autori ed Editori) and Soundreef Ltd. Thus, the primary sources are the following: Website of SIAE and Soundreef Ltd. ; the statute of SIAE and Soundreef Ltd.; the financial statements of SIAE and Soundreef Ltd. In the second step the research, to compare the business model of these societies we used the VUCA framework (Bennett, Lemoine 2014).

3.1. The VUCA framework

VUCA model (Bennett, Lemoine 2014) is taken root in emerging ideas in strategic leadership that apply in the organizations identifies the variables that affect the context in which organizations view their current and future state. They present boundaries for planning and policy management. The particular meaning and relevance of VUCA often relates to how people view the conditions under which they make decisions, plan forward, manage risks, foster change and solve problems.

VUCA is an acronym to describe or to reflect on the volatility, uncertainty, complexity and ambiguity of general conditions and situations. Volatility represents the nature and dynamics of change; Uncertainty reflects the lack of predictability; Complexity represents the confusion that surrounds organization; Ambiguity represents the potential for misreads.

4 Results and discussion

In this section, we explain the functions and the business models of SIAE and Soundreef Ltd in order to identify the main characteristics of these type of societies.

SIAE is a society established for the collective management of authors' rights; from a technical point of view, it is a Public Body with economic interests based on membership. The authors and publishers holding economic rights on their works can entrust SIAE with their protection, SIAE collects the rights due to them and then distributes them to each relevant rightholder. Every year, SIAE issues over 1.2 million licences for the use of protected works, thus making the recognition of the right easy for all those wanting to use those works and guaranteeing authors and publishers with the payment of a just remuneration for their work.

SIAE's business model is based on an extenisve collection to be administered, a widespread presence in the area (in Italy there are 10 offices, 28 branches and 435 agents), a multiplicity of services to be provided in agreement with other entities. Over the years there has been a large recovery in efficiency in the control activity through the introduction of innovative IT tools.

Soundreef Ltd is an Independent Management Entity (Directive 2014/26/EU) registered with the Intellectual Property Office of the United Kingdom. Soundreef Ltd

manages the rights of over 39,000 songwriters and music publishers worldwide, 22,000 of whom are Italian, and operates in over 90 countries either directly or via representation agreements. Soundreef Ltd is owned by Soundreef S.p.A., a company that develops the appropriate technology for monitoring, collecting and maximizing the earnings of songwriters and music publishers. The company regularly deals with millions of transactions and analyzes a vast amount of data, with the aim of improving data security and efficiency in the music industry.

The Company uses a SaaS (Software as a Service) developed to track reproductions analytically and to calculate the fees, making payment to the rightholders faster than compared to traditional methods. Soundreef's activity focuses on two areas: in-store, that is when music is played in shops, commercial activities or restaurants; live, for live performances, with online compilation of the digital borderò and direct payment of the organization of the concert without any type of intermediary.

The business model is based on a widespread use of digital tools, which allow Soundreef to have a remarkably short cycle of reporting and royalty payments. Another aspect of differentiation concerns the transparency of information, in the sense that every author or publisher who subscribes to Soundreef has an online profile where he can view exactly where his music is played, also territorially, how much he has earned and when it will be paid.

From the analysis of the characteristics of the two societies, it is possible to asserts that the main differences in Soundreef's business model compared to that of SIAE are intrinsically linked to the different legal form and organizational structure that the two economic entities strategically adopt.

Soundreef Ltd is an Independent Management Entity while SIAE is a Public Body

The digital transformation and the new Information and Communication Technologies (ICTs) have given rise to a deep change in the business models adopted by companies, in order to exploit the potential of Web 2.0. ICTs allow to process, extract, copy and transfer creative content at a very low cost; this has significant effects on the publication, promotion and distribution of artistic works. The digitalization process reduces distribution and storage costs and makes it possible to reach significantly more potential consumers. Technological innovation generates opportunities for the development of new business models or forces the transformation in order to achieve sustainable businesses.

The current challenge that involves all collective societies is linked to the need to adapt their business model to the international and national regulations that enable access for new players in the market with multi-territorial licenses and new digital technologies (Haunss, 2013).

In the Italian context, on the one hand, there are traditional collecting societies that have tried to answer to the growing relevance of the Internet and ICT, trying to transform previous business models in a digital model (SIAE). On the other, there are the new players, established in recent years, who have tried to impose a new interpretation of how

to do business in this market, promoting their own model based on fully digital organization management, to obtain greater value (Soundreef).

The main difference, as well as in the legal form, is in the geographical location. SIAE has its headquarters in Rome, but has 10 regional and interregional offices and 28 branches distributed throughout the Italian territory, which is accompanied by a large number of agents. SIAE also operates in the international context through representation contracts signed with over 150 authors' companies in 145 countries. Soundreef, on the other hand, is based in London and has managed to operate on the national territory by relying on the LEA, the newly formed non-profit company that collects the rights of Soundreef members in Italy. This was possible following a sentence of 12 September 2014 by the Court of Milan, which established the legitimacy of Soundreef's activity in Italy.

In addition, SIAE and Soundreef stand out in the way in which copyright protection is exercised.

Soundreef was born properly as an innovative digital platform; therefore, it operates entirely through technological and IT tools. The creation of Soundreef, in 2011, and the promulgation of the Barnier Directive, in 2014, are simultaneous with the implementation by SIAE of an innovation process focused on digitization, which achieves the maximum level of investments in 2015. In fact, the creation of Soundreef in the market has marked the beginning of substantial digital investments by SIAE, in order to adapt to the technological evolution and services required by copyright holders in parallel both with Soundreef and The entire market, now made up of collecting companies, which operate mainly through digital and innovative tools.

Although SIAE has evolved in a digital sense, the competitors and, above all Soundreef in Italy, would seem to be able to use more advanced digital instruments. One of these, for example, allows Soundreef to monitor, analyze and account for every single radio passage, allowing the author directly to recover the royalties on his song.

Digital tools allow Soundreef to have a remarkably short reporting and royalty payment cycle. Through the Soundreef live, for example, it is possible to report to the author and publisher after only 7 days from the date of the concert, while a traditional collecting can arrive to report even after 12 months. In addition, for payment, Soundreef pays its authors within 90 days of the concert while a traditional collection can pay up to 18 months after the concert.

Another aspect of differentiation with respect to a traditional management model concerns the transparency of information, in the sense that each author or publisher who signs up for Soundreef has an online profile where he can view exactly the place where his music is played, how much he earned and when he will be paid.

SIAE has also innovated through the digitization processes, trying to adapt to new business models. The digitalization process of SIAE is in line with the global panorama and is also linked to the need to contrast the competition from other emerging collecting companies following the liberalization of the market.

In particular, SIAE has redefined the service model, the offer and the rates, developing an innovative technological architecture through various digital touch points and new processes, with the aim of making the user experience as fast as possible and effective.

Unlike Soundreef, SIAE maintains its presence at the base of its business model through branches throughout the national territory, maintaining in the direct relationship with its authors and editors, as well as with the event organizers themselves, the strength of the own creation of value. The latter feature constitutes an important advantage in possession of SIAE built over the years.

The comparison between the business model applied by SIAE and by Soundreef can be made by applying the VUCA framework (Bennett, Lemoine 2014). SIAE, operating in a context of great uncertainty, adopts traditional strategies aimed at defending the rights it possesses, limiting external transfers, that is, through the dynamic management of the portfolio of rights geared towards closure, taking into account the limited degree programmability of business also for the regulatory context characterized by continuous evolution and the high level of cognitive self-sufficiency. Despite recent efforts to innovate its business model with the activation of digital-based services, SIAE still has as its objective the implementation and dynamic exploitation of the copyright rights held based on full exclusion, in order to exploit a monopoly position in relation to the rights held, excluding third parties from their use and using them as a defense or attack tool against competing companies.

Considering the collecting companies that recently entered the copyright management market, Soundreef bases its business model on the digital management of copyright and on agreements with non-profit companies for the collection of rights and with software houses for the software that allow monitoring and recognition of the rights of its customers on the various channels, especially digital. Being a private company and not a public economic entity such as SIAE, Soundreef's objective is to maximize the utility deriving from the exploitation of the intellectual property rights held; in a highly volatile context, Soundreef has a very clear idea of the future of the business (high rate of business programmability and a limited level of cognitive self-sufficiency), keeping the strategy of open innovation more adequate.

Soundreef, in fact, has a limited repertoire to administer and a limited knowledge of the sector, being a start up; however, it is clear that the sector will evolve towards digital technologies. It follows that, in recent years, it has gradually expanded the library of rights to be administered through important acquisitions of rights from the outside and, at the same time, has exploited, through agreements with technologically advanced suppliers, knowledge in the field of digital. The agreement concluded with SIAE has the objective, on the other hand, of consolidating its position also in the traditional services sector.

5 Conclusions and main implications

The findings of the research allow to assert that there is a close connection between innovation, intellectual property and business model: the high costs necessary for the creation of innovative products, also related to the protection of intellectual property, can be contained if the management of intellectual property is integrated into the within an innovative business model. It follows that business model innovation can allow managers of cognitive-intensive enterprises to resolve the trade-off between costs and benefits of innovation, reviewing the characteristics of their business and involving partners in new models for creating value.

Our research demonstrates the relevance of the analysis of the business models of cultural enterprises and how innovative business models can represent a tool to contrast the phenomenon of piracy.

The future of copyright management is evolving and will continue to change due to the evolution of digital and Internet technologies, which transform the way in which creative works protected by copyright are made available, used, consumed. and redistributed. All this will necessarily entail a redefinition of the concept of territory, material copying and broadcasting, which the collecting societies will have to face, transforming and innovating the business model (Hilty, Nérisson, 2013; Lyubareva et al., 2014).

Abstract

According to several authors (Kane et al., 2015; Yeow et al., 2018), strategy is a crucial element regarding firms' digitalization and technology is not the only key factor. On the other hand, SMEs face specific challenges to seize digitalization opportunities and take advantage of them, mainly due to their lack of resources and capabilities (Cenamora et al., 2019). Therefore, the purpose of this research is to deepen the study of digitalization in SMEs, focusing on the analysis of the strategic dimension. In particular, the aim is to better understand the factors that condition digital strategy in SMEs, considering this as a kind of strategy supporting firm's digitally-enabled growth (i.e. digitally-enabled growth strategy). The conditioning factors taken into account are digital leadership and digital organizational culture.

A maturity model approach is applied. In particular, a self-assessment questionnaire based on the "DIGROW" digital maturity framework (North et al., 2019) was addressed to 7,040 SMEs from the Basque region (Spain) between July and November 2018, and was answered by the CEO or the IT manager in each firm. The number of firms that responded to the survey amounted to 540 (response rate 7.67%). After eliminating only partially completed or invalid questionnaires, the final sample consisted of 427 companies. The present study only focuses on SMEs (380 in total), leaving out micro-enterprises.

The results of the regression model tested show that the relationship between each independent variable (i.e. digital leadership; digital mindset; empowered employees) and the dependent one (i.e. digitally-enabled growth strategy) is significant in all cases at a significance level of 95% ($p<0.05$) Therefore, it can be concluded that digital leadership, digital mindset, and the fact of having empowered employees who experiment with digital initiatives have a positive and significant influence on digitally-enabled growth strategy.

This research sheds light on the factors that can support a digitally-enabled growth strategy, thus providing a better understanding of the aspects that need to be reinforced in order to sustain strategies guiding digital transformation and growth.

The findings of this research are helpful for managers who want to foster the development of strategies than can support their firms' growth based on digitalization. Moreover, policy making can be improved by prioritizing the key drivers of business digital transition.

Keywords: digital strategy; digitally-enabled growth strategy; digital leadership; digital organizational culture; SMEs.

Paper type: Academic Research Paper

1 Introduction

Sustainable competitiveness and growth of SMEs are increasingly determined by their capability to make use of digital technologies (EU, 2017), which are creating opportunities for developing new growth routes based on digitalization. A literature analysis by Tarutėa and Gatautis (2014) shows that the adoption of information and communication technology impacts on SMEs performance dimensions such as profitability, growth, market value, social and environmental performance and satisfaction. Many SMEs, however, are lagging behind in digital transition (OECD, 2017). They lack resources and capabilities or suffer from inertia, which hampers opportunities (Cenamora et al., 2019). Moreover, although many SMEs are able to launch specific digitalization initiatives they lack a digital strategy that guides their progress in their digitalization journey and support their growth based on digitalization (i.e. digitally-enabled growth) (North et al., 2019). Kane et al. (2015) posit that strategy and not technology is the key driver of the success in digital arena. Yeow et al (2018) conclude that it is paramount for top management to communicate a clear, albeit broad, strategy to all levels of the organization. Therefore, strategy arises as a key aspect to foster SMEs digital transformation.

Along these lines, this research deepens the study of digital strategy as a lever of growth, by analyzing the conditioning factors or antecedents of said strategy. In particular, the influence on digitally-enabled growth strategy of three antecedent factors is examined by means of regression analysis: digital leadership, digital mindset, and employees' empowerment.

2 Theoretical background

2.1 Digital strategy and digitally-enabled growth strategy

According to recently developed conceptual approaches digitalization goes further and transcends technology (Bharadwaj et al., 2013; Yeow et al., 2018), considering that digital transformation involves the embeddedness of IT throughout organization. IT strategy becomes integrated with business strategy, giving rise to a concept of "digital strategy". In words of Bharadwaj et al. (2013:472) "the time is right to rethink the role of

IT strategy, from that of a functional-level strategy—aligned but essentially always subordinate to business strategy—to one that reflects a fusion between IT strategy and business strategy. This fusion is herein termed digital business strategy". Other authors (Kahre et al., 2017; Yeow et al., 2018) also agree with this approach. In this line, Kahre et al. (2017:4707) posit that "digital business strategy reflects a new logic of competitive strategy where boundaries between business and IT strategy become blurred. Dynamically synchronized, business and IT are mutual drivers of strategic change, business value and ultimately competitive advantage".

On the other hand, based on the exploration of possible futures (Moore and Manring, 2009), firms will have to develop an understanding of how digital solutions will help to deliver the firm's objectives and to review their strategy regarding digitalization. Regarding SMEs, the question of how SMEs can succeed in the digital environment requires understanding what strategic orientation best equips SMEs to compete in that environment. Quinton et al. (2017) advocate a digital orientation which they define as "the deliberate strategic positioning of an SME to take advantage of the opportunities presented by digital technologies. This positioning includes the attitudes and behaviours that support the generation and use of market insight, proactive innovation, and openness to new ideas" (p. 4). Depending on the competitive landscape and opportunities present, digitally enabled value propositions may be defensive, focusing on protecting current revenue or offensive with the possibility of completely develop new business models that yield both revenue increases and cost reductions (Johnson, no year).

Pelletier and Cloutier (2019) argue that SMEs have to understand that a successful and consistent digital transformation requires investing not only in IT artefacts and infrastructure (e.g. hardware, software, networks, etc.) but also in strategic, intellectual, structural, formal and informal, social and cultural dimensions (Chan and Reich, 2007). The challenge, therefore, is to align technological, organisational and human resources (Peillona and Dubruc, 2019). This is supported by Cataldo and McQueen (2015) who highlight the importance of IT in a strategic context in SMEs. Similarly Johnson (2018) states that digital growth depends more on business models than technology. Yeow et al. (2018) found that as an organization shifts towards a digital strategy, misalignments between the emergent strategy and resources give rise to tension and require alignment actions, which iteratively reconfigure organizational resources and refine strategy in order to respond to both changes in the environment and internal tensions. Sunday and Vera (2018) argue that using the concept of dynamic capabilities to examine the process of ICT adoption helps to unveil the recursive nature of the process. This idea is also supported by other authors (Galliers, 2011; Yeow et al. 2018), who consider that digital strategy relies on organizational capabilities: "The dynamism and complexity of the business and technology environment suggest that digital strategy is emergent, iterative, and influenced by evolving organizational capabilities" (Yeow et al., 2018:44).

Based on the above arguments, this study is focused on digital strategy which is . supported by organizational capabilities and addresses ways and means to sustain

competitiveness. Therefore, we introduce the concept of digitally-enabled growth strategy, defined as a process to purposefully align technological, organisational, and human resources to create unique value making use of digital resources including data, information and technologies, in order to support firm's future growth (North et al., 2019).

To implement digitally-enabled growth strategies SME leaders have to empower employees and develop the required skills for transformation in a learning process that requires integrating technology, business and learning strategies in an entrepreneurial-oriented organization. To understand such technology driven transformation processes Fountain's (2004) technology enactment framework differentiates between objective and enacted technologies. Objective technology incorporates innovations such as analytics or the Internet, whereas enacted technology entails the use, design and perception of those technologies by individuals within the organization. The role of technology, therefore, is dependent on the organization and what individuals within the organization make out of it. This observation is particularly relevant for SMEs where technology decisions depend on few people, their level of digital competencies and attitudes.

This sheds light on the importance of leadership practices and the development of a digital mindset or culture in the firm.

2.2 Digital leadership

According to DeLone et al. (2018) governance represents one of the success factors in digital transformation. Therefore, it is crucial that leaders (e.g. owners and/or managers of SMEs) recognize the potential of digitally enabled growth (BCG, 2013).

Digital leadership emerges as a crucial aspect regarding digitalization and the implementation of a digital strategy. El Sawy et al. (2016:141) define digital leadership as "doing the right things for the strategic success of digitalization for the enterprise and its business ecosystem. Digital leadership means thinking differently about business strategy, business models, the IT function, enterprise platforms, mindsets and skill sets, and the workplace". According to Li et al. (2016) leadership is a key aspect for the improvement of SMEs success and "one of the main challenges that SME leaders face today is how to optimally integrate business and information technology systems within their organisations to fully leverage the potential of digital technologies" (Li et al., 2016:186). They also understand that "SME leaders capable of effectively aligning business and digital strategy are more likely to succeed". Therefore effective implementation of digital strategy depends to a great extent on the leaders' capabilities. In this line, digital leaders play the roles of both "strategy formulator" and "strategy implementer" assuring the alignment between strategy design and execution (Li et al., 2016).

Regarding the alignment between strategy formulation and strategy implementation, new digital leadership roles are emerging, such as Chief Digital Officer "who would be in charge of leading the digital units and aligning digital strategies from the top of the

company with the requirements of the local units" (DeLone et al., 2018:217). The importance of leaders' role in the implementation of digital strategy is also emphasized by other authors such as Sow and Aborbie (2018) who study digital transformation in health organizations of USA concluding that "a digital transformation strategy necessitated the collaboration of leaders, resources, and teams to ensure that an implementation was successful and did not significantly disrupt operations" (Sow and Aborbie, 2018:145).

Moreover, digital leaders need to have other capabilities other than the capacity to align strategy formulation and implementation. According to Böck and Lange (2018), digital leaders' main skills and capabilities are the following: adaptability; motivation; the capacity of involving employees in the change process digitalization implies; empathy; communication capacity; technological understanding; trying out new ideas and concepts (i.e. creativity). In this line, other authors also highlight creativity as a characteristic of digital leaders as well as the ability to empower employees (Sow and Aborbie, 2018).

Employee empowerment is specially emphasized by these authors who understand that "leaders must be flexible and support their employees who can make a difference during and after a digital transformation, along with recognizing what they have to offer and how they can make a difference at the organization in the long term" (Sow and Aborbie, 2018:146). Moreover, El Sawy et al. (2016) share this approach stating that "top management and all employees will need to be more adaptive and willing to experiment and innovate while occasionally failing" (El Sawy, 2016:142-143). This is supported by Chan et al.(2019) who argue that in a digitally oriented organization, employees are empowered and encouraged to experiment with digital initiatives. Therefore, digital leaders have to empower people in order to promote experimentation at all organizational levels.

Moreover, digital empowerment allows for increased rationality with stakeholders (customers, suppliers and partners), and employees (DeLone et al., 2018). Empowerment also enables building an organizational meaning inwards and also outwards (Deuze, 2006). Finally, empowered participation of employees involves awareness, motivation, cooperation, technical competence, as well as attitude towards problems, attitude towards participation, learning relationship, and valuation of knowledge (Mäkinen, 2006).

Considering the aforementioned, the following research hypotheses can be formulated:

H1: there is a positive and significant relationship between digital leadership and digitally-enabled growth strategy.

H2: there is a positive and significant relationship between employee empowerment and digitally-enabled growth strategy.

2.3 Digital organizational culture

According to DeLone (2018), digitally-driven organizations are characterized by horizontal communication, democratic culture, and a unified understanding between IT and business. In their opinion, "The hierarchical models that have historically envisaged a

top-down line of command are now being perceived as ineffective as they preclude employees at the bottom of the hierarchy to make fast and informed decisions" (DeLone, 2018:214). Therefore, digitalization needs the implementation of less hierarchical organizational structures and the development of a democratic culture. Culture emerges then as a critical issue.

Moreover, El Sawy et al. (2016) consider that a successful digitalization strategy requires a different kind of people mindset and skill set. People mindset takes part of the organizational culture, since it has to do with the set of beliefs and values people have. Along these lines, Schein (1985) defines organizational culture as "the deeper level of basic assumptions and beliefs that are shared by members of an organization, that operate unconsciously, and that define in a basic 'taken-for-granted' fashion an organization's view of itself and the environment" (Schein, 1985:6). To this regard, the question arises about the kind of mindset or the particular set of beliefs and values that are needed for supporting digitalization. Thus, about the characteristics of a digital organizational culture.

Digital organizational culture can be defined as "the set of behaviours and habits, developed and applied by managers and employees, to take full advantage of new technological advances through the use and diffusion of them and with the objective of transforming business models or organizational models to create value for customers, employees and shareholders" (Lorenzo, 2016:71).

Among the characteristics of an organizational digital culture Duerr et al. (2018) highlight the following: start-up mentality (i.e. idea generation is supported); acceptance of failures; embracing digital skills; power equality among employees and across the hierarchy; dual decision-making (i.e. decisions being made at lower levels and more distributed in the firm); IT as a business creator (i.e. no boundaries between business and IT). Some of these features are similar to those proposed by other authors such as Lorenzo (2016) who emphasizes experimentation, aimed at discovering new business opportunities and the development of new business models enacted by new technologies. The mentioned characteristics are aligned with the idea of a democratic culture and employee empowerment that digital leaders should promote.

On the other hand, there is a strong tradition in the field of Strategic Management regarding strategy implementation, rooted in the assumption that the implementation of a new strategy requires the alignment of both leadership style and organizational culture (Thompson et al., 2019). This is also supported by the 7-S framework developed by McKinsey in the late 1970's, that has become widely accepted and applied (see McKinsey, 2008). In coherence with this classic approach to strategy implementation, we assume that both digital leadership and digital organizational culture are important elements conditioning a successful digital strategy implementation.

Therefore, and according to this approach, we propose the following hypothesis:

H3: digital organizational culture (i.e. digital mindset) has a positive and significant relationship with digitally-enabled growth strategy.

3 Research Method

3.1 Digitalization capabilities assessment questionnaire

A questionnaire has been developed based on the "DIGROW" framework of digital maturity (North et al. 2019) that allows to assess the digitalization capabilities of SMEs. The theoretical foundation of the framework is Teece's (2007) model of dynamic capability development, including "sensing", "seizing", and "transforming" capacities. For the building of a practice oriented self-assessment framework a capacity of strategy definition and communication was inserted between Teece´s "sensing" and "seizing" capacities. As a result, the framework encompasses four building blocks, where each block includes four capacities. Each of these capacities can be evaluated at five levels described by an anchor statement. In a pre-test conducted on firms (North et al., 2019), it was found that these five levels would allow a sufficient degree of differentiation. The building blocks of the "DIGROW" framework, and their corresponding capacities, are the following:

- *Sensing digitally-enabled growth potentials:* searching for digitally-enabled growth opportunities, understanding and developing digital customer needs, sensing technology-driven opportunities, and use of external sources for digital innovation.
- *Developing a digitally-enabled growth strategy:* digitally-enabled growth strategy, digital leadership, digital mindset, and empowered employees.
- *Seizing digitally-enabled growth potentials:* digitally-enabled business models, digital market presence, digital customer experience, and agile implementation/deployment of digitalization initiatives.
- *Managing resources for digital transformation:* digital skills and learning, digital processes, digital technology and security, and digital investments.

3.2 Survey and sample

The companies subject to study are small and medium-sized enterprises (SMEs) from the Basque region in Northern Spain. The definition of SME proposed by the European Union has been applied in order to categorise firms.

SMEs comprise three different categories of enterprises, namely micro-enterprises, small enterprises and medium-sized enterprises (see Table 1). To classify firms, the official European definition of SMEs takes into account three different factors: level of employment, level of turnover, and size of balance sheet.

Table 1: Definition of SMEs

Company Category	Employees	Turnover	Balance sheet total
Micro	< 10	< €2 million	< €2 million
Small	< 50	< €10 million	< €10 million
Medium-sized	<250	< €50 million	< €43 million

Source: Commission Recommendation dated 6 May 2003 regarding the definition of micro, small, and medium-sized enterprises (2003/361/EC) - Official Journal of the European Union, L 124/36, 20 May 2003).

Keeping with this definition, SMEs are characterised by having between 10 and 249 employees. This study focuses only on SMEs, leaving aside micro-enterprises.

The questionnaire explained above was sent to 7,040 SMEs in cooperation with regional business associations between July and November 2018 and was addressed to the CEO or the IT manager in each firm. The number of SMEs that responded to the survey amounted to 540 (response rate 7.67%). After eliminating only partially completed or invalid questionnaires, the final sample consisted of 427 companies. As for company size , 47 firms were micro-enterprises (i.e. less than 10 employees), 220 were small firms (i.e. between 10 and 49 employees) and 160 were medium-sized firms (i.e. between 50 and 249 employees).

3.3 Data analysis

In terms of statistical data analysis carried out, regression analysis was applied with the aim of testing relationships between different sets of variables in depth. The software used was IBM SPSS (version 26.0), and the main results obtained from these analysis are provided in the following section.

4 Findings

Our regression model explores the relationships between the capacities that make up the second dimension or building block of the "DIGROW" framework (i.e. developing a digitally-enabled growth), with digitally-enabled growth strategy being considered as the dependent variable, and digital mindset, digital leadership and empowered employees as the independent variables.

The results of the regression model test show that the relationship between each independent variable and the dependent one is significant in all cases at a significance level of 95% ($p<0.05$) (digital leadership, $t=10.522$ ($p=0.000$); digital mindset, $t=4.343$ ($p=0.000$); empowered employees, $t=3.107$ ($p=0.002$)) [see Table 2]. Therefore, it can be concluded that digital leadership, digital mindset, and the fact of having empowered employees who experiment with digital initiatives have a positive and significant influence on digitally-enabled growth strategy. Thus, all research hypotheses (H1, H2, and H3) are confirmed.

On the other hand, as also shown in Table 2, the relative importance of each independent variable regarding the dependent one is not the same. Digital leadership is the most relevant capacity influencing digitally-enabled growth strategy (β=0.533), followed by digital mindset (β=0.287), and empowered employees (β=0.151).

Table 2: Regression model (coefficients and significance)

Model	Non-standardized coefficients		Standardized coefficients	t	Sig.
	B	Standard error	Beta		
(Constant)	.418	.183		2.288	.023
Your company has a digital leadership	.533	.051	.522	10.522	.000
Your company has developed a digital mindset	.287	.066	.201	4.343	.000
Your company empowers employees to experiment with digital initiatives	.151	.049	.144	3.107	.002

Dependent variable: Your company has a digitally-enabled growth strategy.

Finally, the explained variance of digitally-enabled growth strategy is 0.609 (see Table 3). This means that the three independent variables considered – i.e. digital leadership, digital mindset and empowered employees - overall explain the dependent variable at 60.9%. In other words, these three factors condition digitally-enabled growth strategy to a great extent.

Table 3: Regression model (variance explained)

R	Square R	Adjusted squared R	Standard error of the estimation
.780	.609	.606	1.126

Dependent variable: Your company has a digitally enabled growth strategy.

5 Discussion and conclusions

The findings obtained in this study confirm that digitalization is not only about technology but goes further (Bharadwaj et al., 2013; Yeow et al., 2018). Setting a digital strategy that guides the identification of digitally-enabled growth opportunities, and the use of technology as a leverage to transform the organization and develop new business models and new ways of generating value, is crucial. Also this study shows that digital leadership, digital organizational culture (i.e. digital mindset), and employee empowerment support a digitally-enabled growth strategy.

Moreover, the results are also in line with the classic approach regarding strategy implementation which considers that a coherent alignment between leadership style,

organizational culture, and strategy is key in order to assure a successful implementation of the strategy. This study demonstrates that this logic is not only applicable to the implementation of business strategy but also to the successful implementation of digital strategy.

On the other hand, and as far as practical implications of this study is concerned, this asks SMEs leaders (i.e. owners and/or managers) to provide a clearer picture about the main pillars of the digitally-enabled growth strategy, create a shared understanding, and support digitalization initiatives of the employees. Research demonstrates that proactive companies show strong leadership, develop a digital mindset, have well-developed sensors in terms of technology and market developments, learn from many sources, integrate into business ecosystems and actively promote their presence in the digital market (Conference Board of Canada, 2014; IDC-SAP, 2017; Sinkkilä, 2017; Müller et al., 2018).

Finally, this research has some limitations that open the way to further research. First, the study is cross-sectional, that allows to analyse the conditioning factors of a digitally-enabled growth strategy at a particular moment of time, but it doesn't allow to understand the evolution of the relationship between such factors and strategy over time. In this line, future longitudinal studies might be carried out. On the other hand, this study focuses on SMEs of a particular region. Future comparative studies between SMEs of different geographical settings might be undertaken in order to check if the different elements conditioning digital strategy are equally important or not everywhere.

Abstract

Digital technologies enable firms to streamline, accelerate, and automate the process of procurement, manufacturing, and distribution. Digital technologies allow seamless integration of upstream suppliers and downstream customers into the firm's activities. As a result, a significant shift in supply chain practices and performance is experienced. Substantial research has been undertaken to measure digitalized supply chain performance and its effects on firms. This paper presents a systematic literature review on performance measurement for the digital supply chain to apprehend current practices, recognize gaps and advocate future research itineraries. We used the *Balance Score Card* (BSC) model to categorize 243 identified metrics into four BSC perspectives. Internal and financial perspectives received the most attention while "growth and learning" perspective received the least attention. External partners, such as distributors and suppliers, were virtually ignored in the identified literature.

Keywords – Digital supply chain, Digital transformation, Digitalization, Performance measurement, Balance Score Card.

Paper type – Academic Research Paper

1 Introduction

In a rapidly changing world, businesses are competing against each other to serve customers with a faster, cheaper, and higher quality product. For many firms, quicker and

better supply-chain related activities with respect to competitors are critical to achieve competitive advantage (Ramish & Aslam, 2016). In the current turbulent environment, the competition has shifted from firm vs firm to supply chain vs supply chain (Bi et al., 2010; Büyüközkan & Göçer, 2018). Making it vital for a firm to continuously improve, upgrade, and invest in its Supply Chain. Poirier (1999) predicted that digital technologies would act as "tsunami of change" that will "wash away" traditional supply chain models and transform business activities entirely. True to its prediction in the past decade, digital technologies have penetrated and improved every aspect of the supply chain, including procurement, manufacturing, distribution, and customer/supplier relations (Lu et al., 2012). This adoption and reliance on digital technologies to perform business activities is referred to as "digital transformation" or "digitalization". These terms describe the integration of digital technology into all business areas to create new or modify existing business processes, culture, and customer experiences; fundamentally changing how firms operate and deliver value to customers (Nahrkhalaji et al., 2018; Wei et al., 2019). In other words, digital transformation is the use of digital technologies to enable business improvements (Reis et al., 2018). Therefore, the digital transformation of the supply chain is defined as the use of digital technologies to connect, integrate, and improve the business activities also involving suppliers and customers (Büyüközkan & Göçer, 2018).

Recent studies have reported several benefits of the DSC over the traditional supply chain, including, improved financial performance (Haoud & Hasnaoui, 2019; Youssef & El-Nakib, 2015), operational efficiency (Lu et al., 2012; Zhao & Jiang, 2013), customer satisfaction (Jiang & Zhao, 2014; Jonsson & Gunnarsson, 2005; Zhao & Jiang, 2013), employee skills (Llach & Alonso-Almeida, 2015; Srinivas, 2007), supplier relations (Ranganathan et al., 2011; Zhao & Jiang, 2013) along with a reduction in operational and manufacturing cost (Di Vaio & Varriale, 2020; Haoud & Hasnaoui, 2019; Korpela et al., 2017), cycle time (Haoud & Hasnaoui, 2019), and errors (Youn et al., 2014). Realizing the significant advantages offered by the Digitalized (digital) Supply Chain (DSC) on firm competitiveness, many firms have started the process of full or partial digitalization of their supply chain (Wu et al., 2016). Previous studies have provided guidelines on how to adopt these technologies successfully. Including studying antecedents for DSC (Brandon-Jones & Kauppi, 2018; Ranganathan et al., 2011), frameworks to assist in the process of digital transformation (Kittipanya-ngam & Tan, 2020; Pant et al., 2003; Srinivasan, 2010), assessing firm digitalization level (Gilbert et al., 2017; Makris et al., 2019), and application of emerging technologies (e.g. Big Data, 3D printing, Internet of Things) in the supply chain (Mohr & Khan, 2015; Shah & Ververi, 2018; Wang et al., 2016).

Though DSC has several advantages over the traditional supply chain, the adoption of digital technologies is not easy or cheap. It has both short-term and long-term effect on firm performance and competitiveness. To control/monitor the process and quantify benefits obtained from DSC, effective Supply Chain Performance Measurement systems are needed. Performance Measurement Systems can reveal the gap between planning and

execution that can help firms in identifying problems and areas of improvement (Chae, 2009). As a result, a plethora of studies are available on the topic. For example, Gopal & Thakkar (2012) reviewed 28 articles focusing on supply chain metrics to measure its performance published between 2000-2011. Recently, Guersola et al. (2018) examined 276 articles and reported on the importance and depth of the available literature. Although there are some review papers on Supply Chain Performance Measurement systems, none of them focuses on the analysis of performance measurement of the DSC. Several studies in recent years have measured the performance of DSC systems using self-developed criteria and metrics. These metrics vary in nature and have focused on different aspects of DSC. This study will summarize and synthesize these metrics using the Balance Score Card (BSC), developed by Kaplan and Norton (1992). One key advantage of using BSC lies in its flexibility and ability to be implemented in different types of supply chain systems and organizations (Yongvanich & Guthrie, 2009). BSC adopts a holistic approach in measuring performance, assuring that the system performs well as a unit, not just individual links. Therefore, the objective of this paper is to review the scientific studies measuring the performance of DSC to answer the following research questions.

1. What is the current state of research in DSC performance literature?
2. What are the most used metrics for performance measurement?
3. Which aspects of the DSC performance measurement literature requires further attention?

2 Theoretical background

Supply chain management is the process of managing suppliers, manufacturers, warehouses, and stores to produce and distribute goods in the right quantity, at the right location, on the right time, to minimize system-wide costs while satisfying the service-level requirements (Simchi-Levi et al., 2000). Traditionally, these integrations are discrete and take place in a series of soiled steps (Büyüközkan & Göçer, 2018). With the increase in global uncertainty and ever-changing customer demands, this discrete method of managing a supply chain is no more valid. It lacks the speed, transparency, flexibility, and timely actionable information needed to remain competitive in the current business environment (Büyüközkan & Göçer, 2018). Digital technologies can provide solutions to some of the most pressing challenges in supply chain management by reducing complexity, cost, and increasing volume and flexibility, leading to higher service levels (Agrawal & Narain, 2018), by directly linking suppliers and customers and vice-versa. Unlike traditional supply chain, DSC heavily relies on systems (e.g. software, hardware, communication networks) that support activities performed by globally distributed partners to buy, make, store, move, and sell a product (Bhargava et al., 2013). Büyüközkan & Göçer (2018, p. 165) defined DSC as "*an intelligent best-fit technological system that is based on the capability of massive data disposal and excellent cooperation and communication for digital hardware, software, and networks to support and*

synchronize interaction between organizations by making services more valuable, accessible and affordable with consistent, agile and effective outcomes".

To take advantage of the benefits offered by digital technologies, an increasing number of firms are investing and adopting digital technologies in their supply chains (Büyüközkan & Göçer, 2018). This adoption of digital technologies acts as a double-edged sword. On the one hand, they make supply chains faster, efficient, and reliable. On the other hand, they introduce a higher level of complexity and variables into the system that require more sophisticated metrics to measure its performance (Cho et al., 2012; Mondragon et al., 2006; Ralston et al., 2015). These metrics are used for "*assessing and controlling progress, highlighting achievements, enhancing understanding of key processes, identifying potential problems (e.g., bottlenecks), and providing insight into possible future actions, among others*" (Ahi & Searcy, 2015, p. 361). They enable top management to convey firm objectives in measurable and straightforward terms that allow firms to standardize the processes and define goals clearly (Magretta & Stone, 2002). In the absence of appropriate measures, firms are unable to implement strategy, manage operations and track performance over time (Bremser & Chung, 2005). Both financial and non-financial measures are used for assessing the performance of a supply chain. These measures should be embedded in the system at the time of planning and selected depending upon the goals and type of supply chain (Dweekat et al., 2017). Over the years, different supply chain performance measurement models were developed to standardize and robust the system. These models put forward different methods and processes to measure the performance effectively. Citing the lack of tools to grasp a holistic view of firm performance, Kaplan and Norton (Kaplan & Norton, 1992) proposed the BSC. They argued that BSC would provide a quick and comprehensive view of the business to the top management. Today, BSC is among the most widely used performance measurement model (Saleheen et al., 2018a). Ever since its introduction, BSC has been widely used for measuring firm performance, particularly the performance of the supply chain (Bigliardi & Bottani, 2010; Dweekat et al., 2017; Marimin et al., 2017) including the performance of DSC (Bremser & Chung, 2005; Dweekat et al., 2017; Liang, 2015). Unlike the majority of the models available at that time, BSC included both financial and non-financial measures (Duarte et al., 2011) that monitor the overall firm performance over time (Saleheen et al., 2018b). BSC measures firm performance in the following four perspectives (Kaplan & Norton, 1992): Customer perspective (value-adding view)**,** by focusing on delivering value to customers; Financial perspective (shareholders' view), by focusing on delivering value to shareholders; Internal perspective (process-based view)**,** by focusing on promoting efficiency and effectiveness in processes; Growth and learning perspective (future view)**,** by focusing on sustaining innovation and change capabilities, through continuous improvement and preparation for future challenges.

We advance the notion that the overall performance of the DSC can be measured using these four perspectives.

3 Methodology

To answer the research question, a systematic literature review following the guidelines by Okoli (2015), was conducted. Systematic literature reviews are transparent, evidence-based activities (Tranfield et al., 2003) that report the decisions, procedures, and conclusions made by those conducting the study (Cook et al., 1997). The articles included in the review were retrieved from several queries submitted to the database *Scopus* without specifying the time frame in January 2020. We searched for the multiple combinations of keywords presented in Table 1. The keywords were selected based on a preliminary review of the literature and using a form of brainstorming. The search resulted in 248 articles that were examined for further study. Figure 1 summarizes the methodology of this study. After removing the duplicates and inaccessible articles, remaining 200 articles were subjected to further exclusion criteria. The exclusion criteria included, (i) articles not published in English, and (ii) articles with no mention of the DSC and its performance in their title or abstract. After rigorously analyzing and reviewing the remaining 46 articles, an additional exclusion of 29 articles was made. These additional exclusion criteria focused on the objective of the article: an article was excluded if it did not discuss the metrics to measure the performance of DSC. As a result, 17 articles were identified as relevant to the study.

The references of all relevant articles were also investigated to expand the literature. A total of 6 articles were identified from the bibliography, making the final number of articles used in this study to be 23. Table 2 presents the list of articles along with type and year of publication. The metrics used for measuring DSC performance in the identified scientific studies were recorded. A total of 243 different metrics were mentioned in these studies that were further analyzed and are reported in the following section.In order to explore how the assessment and management of knowledge assets can support NPD process performance improvements, I have carried out an empirical research based on multiple case studies (Eisenhardt, 1989; Mintzberg, 1979; Mintzberg and Waters, 1982; Yin, 1984).

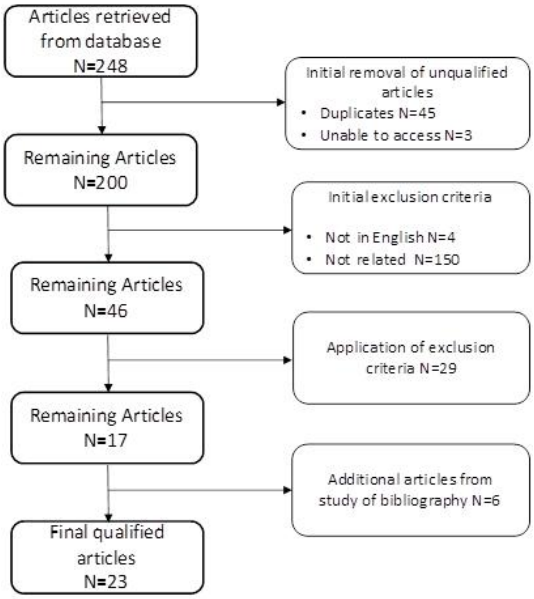

Figure 1. Flow chart of the literature search process

4 Results

The recorded 243 metrics were classified into the four BSC perspectives categories. Different metrics used with a similar focus were merged into one KPI. For example, "supply chain management cost", "transaction cost ", "system cost", and others were merged into the "Operational Cost" KPI. Similarly, "system response time", "data transmission speed", "number of steps in procurement cycle", and others were merged into "Operational Speed" KPI. To measure the performance in one KPI, the data from several metrics will be needed, and the sum of performances of individual metrics will dictate the performance in related KPI. As a result, a total of 37 KPIs were identified. The result of the analysis is presented in Table 3. The analysis results show that the internal perspective received the most attention, with seventeen KPIs (128 metrics). In comparison, growth and learning received the least consideration with only three KPIs (11 metrics), highlighting the fact that not an equal amount of attention is paid towards different performance perspectives.

Table 3: Identified KPIs in the digital supply chain

KPI	BSC Perspective	Metric Frequency	Source
Employee Skills	Growth and Learning	5	(Llach & Alonso-Almeida, 2015; Valverde & Saadé, 2015)
	It measures gain in employee skills through training, changes in responsibility and on-job		

	learning.		
On-time Delivery	Customer Perspective	9	(Dweekat et al., 2017; Marimin et al., 2017; Mezouar et al., 2016; Mukhtar et al., 2009; Valverde & Saadé, 2015; Youn et al., 2014)
	It measures on-time delivery to customers along with delivery cycle time and lead time.		
Operational efficiency	Internal Perspective	23	(Bayraktar et al., 2009; Futschik, 2018; Hafeez et al., 2010; Haoud & Hasnaoui, 2019; Kayikci, 2018; Lu et al., 2012; Marimin et al., 2017; Petrović & Mimović, 2019; Sambasivan et al., 2009; Sammon & Hanley, 2007; Schmidt et al., 2019; Valverde & Saadé, 2015) Sambasivan et al., 2009
	It measures efficiency in operations, internal communication, productivity, and job completion.		
Operational Speed	Internal Perspective	17	(Futschik, 2018; Jiang & Zhao, 2014; Kayikci, 2018; Sambasivan et al., 2009; Sammon & Hanley, 2007; Schmidt et al., 2019)
	It measures time taken to perform activities, process information, data transmission rate, and response time to sudden changes.		
System Reliability	Internal Perspective	17	(Bayraktar et al., 2009; Gilbert et al., 2017; Haoud & Hasnaoui, 2019; Kayikci, 2018; Marimin et al., 2017; Schmidt et al., 2019; Valverde & Saadé, 2015; Wiedenmann & Größler, 2019)
	It measures forecasting accuracy for production, maintenance, and inventory.		
Error Rate	Internal Perspective	14	(Futschik, 2018; Gilbert et al., 2017; Marimin et al., 2017; Petrović & Mimović, 2019; Sambasivan et al., 2009; Sammon & Hanley, 2007; Valverde & Saadé, 2015)
	It measures system, human, and production error rate.		
System Flexibility	Internal Perspective	12	(Dweekat et al., 2017; Futschik, 2018; Kayikci, 2018; Mezouar et al., 2016; Sammon & Hanley, 2007; Schmidt et al., 2019; Youn et al., 2014)
	It Measures flexibility levels in production volume, cycle time, product variety, including flexibility of suppliers and distributors.		
Information availability	Internal Perspective	9	(Futschik, 2018; Sambasivan et al., 2009; Sammon & Hanley, 2007; Valverde & Saadé, 2015; Wiedenmann & Größler, 2019)
	It measures level of access to real-time information and data availability points.		
Inventory Level	Internal Perspective	9	(Bayraktar et al., 2009; Haoud & Hasnaoui, 2019; Jiang & Zhao, 2014; Kayikci, 2018; Mukhtar et al., 2009; Ranganathan et al., 2011; Schmidt et al., 2019)
	It measures inventory level, cycle time and performance of inventory control measures.		
Communication with supplier	Internal Perspective	8	(Hafeez et al., 2010; Llach & Alonso-Almeida, 2015; Sammon & Hanley, 2007; Valverde & Saadé, 2015)
	It measures communication quality and frequency with suppliers.		
Resource Utilization	Internal Perspective	7	(Bayraktar et al., 2009; Haoud & Hasnaoui, 2019; Kayikci, 2018; Sambasivan et al., 2009; Schmidt et al., 2019)
	It measures utilization level of equipment, personal and other resources.		
Responsiveness to Supplier	Internal Perspective	6	(Sambasivan et al., 2009; Sammon & Hanley, 2007; Valverde & Saadé, 2015)

	It measures response time to suppliers' queries, complaints and time needed to process orders and make payments.		
Employee Satisfaction	Internal Perspective	6	(Marimin et al., 2017; Valverde & Saadé, 2015)
	It measures employee satisfaction with the work environment and the system.		
Supplier Relation	Internal Perspective	5	(Gilbert et al., 2017; Llach & Alonso-Almeida, 2015; Ranganathan et al., 2011; Sambasivan et al., 2009)
	It measures level of integration of suppliers in the system and their responsiveness.		
Operational Cost	Financial Perspective	11	(Bayraktar et al., 2009; Dweekat et al., 2017; Futschik, 2018; Lu et al., 2012; Mezouar et al., 2016; Ranganathan et al., 2011; Sambasivan et al., 2009; Valverde & Saadé, 2015)
	It measures costs associated with operations (management, transaction, system, data collections and storage).		
Return on Investment	Financial Perspective	10	(Dweekat et al., 2017; Lu et al., 2012; Mezouar et al., 2016; Valverde & Saadé, 2015; Youssef & El-Nakib, 2015)
	It measures return on investment related to both fixed and variable expenses.		
Labor Cost	Financial Perspective	6	(Futschik, 2018; Haoud & Hasnaoui, 2019; Marimin et al., 2017; Sammon & Hanley, 2007)
	It measures cost associated with human capital (salaries, training cost, and other benefits).		
Production Cost	Financial Perspective	6	(Dweekat et al., 2017; Mezouar et al., 2016; Shibin et al., 2017; Youn et al., 2014)
	It measures cost associated with production (energy, material cost).		
Inventory Cost	Financial Perspective	5	(Futschik, 2018; Schmidt et al., 2019; Valverde & Saadé, 2015)
	It measures cost incurred in managing and storing inventory (raw material, WIP, finished goods).		
Logistics Cost	Financial Perspective	5	(Kayikci, 2018; Petrović & Mimović, 2019; Schmidt et al., 2019; Valverde & Saadé, 2015)
	It measures internal and external logistics cost for both raw material and finished goods.		

*Only KPIs associated metrics having frequency rate of 5 or more are provided. The full list can be accessed at https://doi.org/10.6084/m9.figshare.12250205.v2

5 Discussion

A total of 243 metrics to measure DSC performance were collected during the literature review and were categorized into four BSC perspectives. Performance related to firms internal working; particularly in areas related to operations, product quality and financial returns were most widely measured, indicating these three areas of significant interest to adopting firms. The use of these collected metrics to measure the DSC performance into four BSC perspectives is discussed in the following subsections.

5.1 Financial perspective

Profitability, growth and shareholder value are common financial goals that measure the bottom-line improvements of firms' activities. BSC emphasizes on using financial measures for assessing firm performance by arguing that, contrary to the prevailing belief, firm operational performance has a minimal effect on its financial performance. Kaplan & Norton (1992) emphasized that well designed financial control measures can improve overall firm performance. Our review identified several studies that have measured and reported the positive impact of digitalization of the supply chain on the financial performance of firms (Di Vaio & Varriale, 2020; Haoud & Hasnaoui, 2019; Lu et al., 2012; Youssef & El-Nakib, 2015; Zhao & Jiang, 2013). Such studies argued that digital tools not only reduce the costs associated with supply chain activities, including inventory, warehouse, and logistics activities. But also increase the overall firm profit by increasing sales and profit margins. For example, Youssef and El-Nakib (2015) measured the impact of digitalization in three dimensions Return on Assets, Return on Sales, and Return of Equity. The authors reported that the introduction of digital technologies in the supply chain has a positive impact on all three dimensions. Also Lu et al. (2012) and Zhao and Jiang (2013) measured the effect of supply chain digitalization. They reported a positive impact on process performance, which in turn leads to the better financial performance of the firm. While measuring the performance of the DSC, Haoud and Hasnaoui (2019) concluded that the digitalization of the supply chain results in better resource utilization and quicker inventory turnover that contribute towards significant financial gains for the firm. They also reported that, with the introduction of digital technologies, less training is required by new employees to perform activities resulting in significant financial savings.

5.2 Customer perspective

Every business aims to fulfil customer demands at the right time, at the right price, and with the right product and supply chain is a crucial ingredient in serving those demands. BSC demands that these mission statements are converted into specific measures of measurable goals (Kaplan & Norton, 1992). The introduction of digital technologies has helped firms in achieving these goals. On the one hand, they have decreased firms' response time to customer demands by streamlining the process (Lu et al., 2012). On the other hand, they have also improved the overall firm performance that leads to increased customer satisfaction (Jiang & Zhao, 2014; Zhao & Jiang, 2013). However, performance management systems often fail to measure the impact of supply chain activities on customer satisfaction. Dweekat et al. (2017) authored a literature review about Supply Chain Performance Measurement systems. They argued that the majority of the models available are too inward-looking and ignore the importance of external parts of the supply chain, including customers, and focus should be paid to measure their satisfaction to thoroughly asses the performance of the supply chain. Some recent studies have measured

the benefits of digitalization on customer satisfaction and engagement and have reported positive results. With the help of a case study, Haoud and Hasnaoui (2019) confirmed that the processing time and the number of errors were reduced with the introduction of digital tools in the supply chain, leading to quicker and error-free deliveries to the customers resulting in higher customer satisfaction.

5.3 Growth and Learning perspective

Growth and learning measures focus on assessing the firms' learning curve to meet customers' current and future expectations. It concentrates on evaluating firms' ability to innovate, improve, and learn to meet emerging customer needs (Kaplan & Norton, 1992). Employee training is essential in this regard, as reported by Hafeez et al., (2010), after measuring the DSC performance in dimensions of coordination, efficiency, and finance. An attempt to measure employee learning curve was made by Haoud & Hasnaoui (2019), where they reported that not only worker productivity is increased with the adoption of digital technologies in supply chain practices but also a reduction in time needed to train the new employees is recorded for completing the routine tasks. Their findings were in line with Llach & Alonso-Almeida (2015), where they also reported an increase in employee skills with the adoption of digital technologies including reduction in time needed to train the new employees for completing the task, resulting in significant savings for the firm.

5.4 Internal Perspective

Internal performance measures are critical for assessing the performance and effectiveness of actions towards achieving firm goals. Factors related to cycle time, quality, employee skills, and productivity have a significant impact on firm performance and should be measured to assess the firm internal performance (Kaplan & Norton, 1992). One crucial action firms can take to improve its performance and flexibility in operations is by integrating customers and suppliers into their supply chain (Ranganathan et al., 2011; Youn et al., 2014; Zhao & Jiang, 2013). As a result, the quality of information (Youn et al., 2014) and the product quality (Pearsall et al., 2011) also significantly improves. The operational benefits of DSC measures include increased productivity (Hafeez et al., 2010; Haoud & Hasnaoui, 2019), overall supply chain performance (Lu et al., 2012; Ranganathan et al., 2011), better scheduling and resource utilization (Di Vaio & Varriale, 2020), and flexibility (Youn et al., 2014). In their literature review, Wiedenmann & Größler (2019) deduced that digital technologies could reduce the bullwhip effect of sudden changes in the value chain, hence, increasing the operational efficiency and reliability of the firm. Similarly, Hafeez et al. (2010) confirmed that the firms' operational efficiency is improved with the adoption of digital tools. Zhao & Jiang (2013), while measuring the effectiveness of the DSC, confirmed that it has a positive

impact on firms' overall performance. Llach & Alonso-Almeida (2015) reported that the introduction of digital tools not only improves supply chain performance but also increases firms' operational efficiency in micro firms. Haoud & Hasnaoui (2019) reported a positive impact on resource utilization, time reduction, and worker productivity that all lead to the operational efficiency of the firm after measuring the performance of four case study firms. Contrary to other researchers, while measuring the impact of digital tools, Valverde & Saadé (Valverde & Saadé, 2015) reported a significant positive effect on measures of operations, information and communication but limited impact on quality.

6 Conclusions and Limitations

Based on the methodology by Okoli (2015) to conduct a systematic literature review, this research reviewed 23 scientific publications to provide state of the art on metrics for digital supply chain literature and answer proposed the RQs. The first RQ "*What is the current state of research in DSC performance literature?*" is reported in details in the discussion section in the context of four BSC perspectives. The subsections reported on different studies that have measured and reported the performance of DSC. Several studies present metrics to measure DSC performance; however, still a gap exists. As reported in Table 2, the number of studies per year is somewhat limited, despite calls for more studies.

The second RQ, "*What are the most used metrics for performance measurement?,* was answered in the results section. In general, metrics related to Internal and financial perspective receive greater attention. The metrics focused on measuring performance in dimensions related to "operational efficiency", "operational speed", "error rate", "system reliability", "system flexibility", "operational cost", "return on investment", were used 10 times or more. The complete list of KPI and related metrics frequency has been presented in Table 3.

In response to the third and final RQ, "*Which aspects of the DSC performance measurement literature requires further attention*?", further studies should focus on developing specific metrics for measuring DSC performance. The only study that was identified during our literature review, focusing on developing metrics for DSC performance was by Sambasivan et al. (Sambasivan et al., 2009). This lack of metrics has resulted in a relatively small number of studies focusing on measuring the performance of the DSC. Particularly the call for quantitative measures (Lima-Junior & Carpinetti, 2017) and empirical studies (Ranganathan et al., 2011) is still not satisfied. Additionally, the reviewed studies do not pay equal attention to measure performance in all four perspectives suggested by BSC. For example, "internal perspective" received the overwhelming amount of consideration (61% metrics focus on it), and "growth and learning perspective" received the least attention (5% of metrics focus on it). Another fact that highlighted the need for further research was the inability of metrics to reflect the adoption and advantages of digital technologies used by firms. The majority of the studies

we reviewed used perception-based traditional measures to assess the performance of DSC.

Supplier performance is crucial for meeting a firm's flexibility, cycle time, and quality goals that are essential to achieve higher DSC performance. Surprisingly no or very little attention was paid towards measuring supplier's performance as a result of target firm adoption of digital tools, leaving a significant gap in this crucial area of research. Another shortcoming of the existing literature was noted in its inability to incorporate external factors, such as government (trade policies, environmental regulations), competitors (new units, price changes), and newer technologies. No efforts were made towards incorporating these factors into the supply chain to receive early feedback or warnings. In conclusion, we argue that there still exists not only a need for empirical studies to test available metrics but also a need for theoretical studies to develop appropriate metrics.

We recognized that there are some limitations to the study. First, although *Scopus* covers a wide range of peer-reviewed publications, it does not include all reputable peer-reviewed publications. Therefore, using different search terms and additional databases beyond *Scopus* may have resulted in the identification of other metrics. Additionally, the inclusion of technical reports might have been useful as well. Second, the use of BSC to categorize all available metrics may have wrongfully categorized them into one of the available four perspectives. We recognize here that the original study may have used the metric in a different context.

Abstract

This paper attempts to unravel the research works on challenges corporate universities are experiencing to date. Bibliometric method was used to analyses 21 journal articles on the challenges faced by new-age corporate university for the timeframe 2000-2018. These articles were selected from the Scopus database. For the timeframe 2000-2018 authors critically discuss the results on the lines of most influential authors, countries, institutions, overlay of research works. This study also provides co-word analysis to unearth the major challenges faced by new-age corporate university like Strategic integration of Technology in corporate university, Bottleneck in sustaining Innovation as a catalyst to the competitive advantage of corporate university, and Dysfunctional knowledge management of Corporate University. The findings of this study can help HRD managers to devise measures to address the challenges and provides new lines of inquiry for future research. This study makes a unique attempt to move ahead of the descriptive and procedural aspect of corporate university to critically discuss the challenges aspect.

Keywords – Corporate University, challenges, bibliometric, Scopus

Paper type: Academic Research Paper

1 Introduction

Over time, organizations began to perceive the corporate university concept not only as a tool to transmit internal knowledge but also as a process to ensure a company's survival in the long term (Singh et al., 2020; Alonso-Gonzalez et al. 2018). Since the 1990's there has been an exponential increase in the number of corporate universities (Abel & Li, 2012), this increase is grounded in the assumption that employees with requisite skills, which are aligned to the organization's objectives facilitate overall goal attainment.

Walton (1999) categorized corporate universities into three generations. The first-generation corporate university was repackaging of traditional training and development interventions requiring classroom presence. The second-generation corporate universities focused broader strategy to attain organizational learning whereas the third -generation dealt with virtual aspects of the learning process and possess a large spectrum of strategies of intellectual capital development.

However, corporate universities have a very high failure rate (Singh et al.,2020). It is believed that given today's difficult economic situation and limited support and resources for developmental initiatives, the effectiveness of the corporate university is under scrutiny from senior management. CUs need to be smart about how they spend their time, energy, and resources by aligning all learning activities with organizational goals (Abel and Li, 2011). Also, Corporate university made a paradigm shift from Walton's third generation to the New-age corporate university, which focuses on integrating innovation, technology, and knowledge management. Therefore, it is important to understand the trajectory of challenges that the new-age corporate universities are facing. The objective of this study is to understand the diverse challenges that corporate universities are facing while attaining and sustaining a competitive advantage.

The present study adopts bibliometric approach. Bibliometric analysis a systematic, transparent, and reproducible review process and, thus, improve the quality of the review (Bellis, 2009). It permits assessment of the scientific quality and effect of progress in knowledge in a specific subject (van Leeuwen, 2006; van Raan, 2005). Hence, the present study attempts to tie the fragmented research works on the challenges surrounding new-age corporate universities. The research includes a bibliometric analysis based on 21 research works on challenges faced by corporate universities from 2000-2018, retrieved from SCOPUS. This study adopted co-word analysis as a bibliometric technique to understand the challenges of the corporate university. The following section briefly discusses the methodology and findings.

2 Theoretical Background

It is assumed that organizations that consistently strive to leverage their human capital attain success. Therefore, the relevance of strategic human resource development has risen to improve performance with profitability (Alagaraja, 2013). In order to reorient human resource development to strategic human resource development, organizations in present times are establishing new-age corporate universities. The first corporate university was established by GE at Crotonville in 1955 (El-Tannir, 2002). Corporate universities are a paradigmatic shift from traditional training programs as they are more proactive with being 'purpose- driven' organizations (Rotatori et al., 2020). This dynamic environment wherein companies are rampantly establishing new-age corporate universities to address the complexity arisen due to environmental pressures and expectations can be understood through the integration of complexity theory and institutional theory. Complexity theory questions the conventional tenets of management

by adopting nonlinear and behaviors of systems. Therefore, there is a need for a shift in the traditional mindset of managers, wherein they can leverage complexities (Anderson, 1999). Institution becomes complex due to environmental pressures, norms, values impacting both the individual and institution. Hence, this complexity can better be understood from the lens of institutional theory, which argues that the key focus of the theory is on the institutional environment (Alagaraja and Li, 2015). Hence, the institutional environment influences both people and institutions. In order to acclimatize and address the external pressures, companies adopt legitimacy by devising patterns of responses and action routines that mature over time and become grounded in industry tradition (Peter, 2016). Rapid changes like innovation, technology, and faster transfer of information have compelled companies to discover measures towards human capital development at an exponential scale (Allen, 2007). Therefore, to address these institutional forces, companies started to establish corporate universities to attain shared purpose and meaning for workers and other stakeholders (Singh et al., 2020). Besides, through corporate universities companies were able to transfer their vision and mission across spaces. To summarize, corporate universities have shaped into institutional mechanisms to facilitate learning and performance, enable commitment to share best practices on varied aspects like technology, innovation, and knowledge management (Allen, 2007). Therefore, by adopting an integrative lens of complexity and institutional theory, we attempt to identify and understand the challenges that corporate universities are facing while transforming themselves from traditional training and development initiatives.

3 Methodology

The bibliometric analysis techniques are quantitative methods to analyze increasing literature in different research fields. More specifically, a bibliometric study focuses on investigating and understanding the pattern of the studies (Bhattacharyya and Verma, 2019). Although traditional systematic review of literature can offer in-depth understandings in the topic, bibliometric analysis can provide research breadth by comprehensively handling all the existing studies. Co-word analysis under the umbrella of the bibliometric analysis method utilizes keywords of articles to abstract scientific maps of an area (Singh et al., 2020). This study utilized VOSviewer tool to generate a vivid network diagram through co-word analysis. VOSviewer is an influential user graphic-interface technique that allows researchers to create network maps suitably (Eck and Waltman, 2009). The bibliographic records in the Scopus is searched using following keywords as proposed by Singh et al. (2020): (‘‘corporate university’’ or ‘‘corporate universities’’) AND (‘‘challenge’’ or ‘‘risk’’ or ‘‘barrier’’). Only peer reviewed articles published in journals were retained and a total of 21 articles were obtained in the final data set. This study analyzed the 21 articles using VOSviewer 1.6.8 (bibliometric tool). The dataset comprised of bibliographic information explaining varied aspects of the 21 Scopus indexed journal articles. This meta-data retrieved contained information like the

names of authors and affiliations, article titles, publication timeline and citation information. Descriptive analysis is conducted to comprehend trends associated with the development of the CU literature.

4 Results

In this section results of bibliometric analysis is inferred, the general results indicate the holistic assessment the number of documents published on the area along with its growth trajectory; highly cited publications, influential authors, influential countries and influential institutions. Furthermore, the overlay of documents depicts co-word analysis of challenges faced by the corporate universities on a temporal dimension. Lastly, the co-word analysis indicates what the major themes that have been investigates as challenges to the corporate universities.

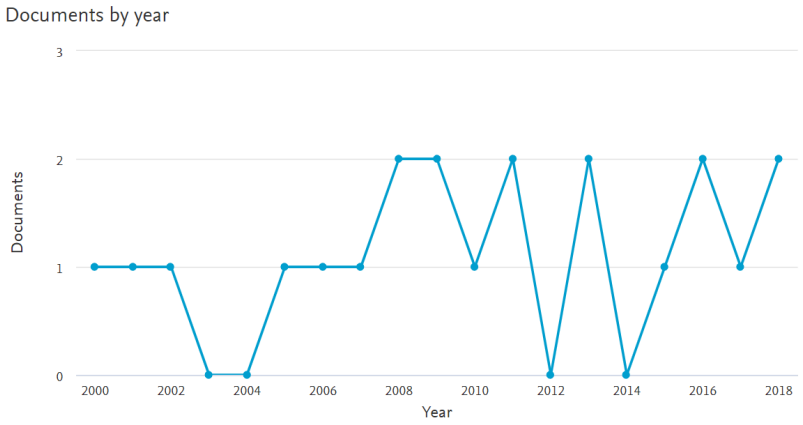

Figure 1 Distribution of publications per year on CU challenges during 2000-2018

Figure 1 indicates that documents in the area of corporate universities that are addressing the concern, challenges, and barriers have increased from 2004 onwards. In total, the field produced more than 21 articles. Post 2004 it is seen that there have been spikes in publications, indicating that output on the given topic has been inconsistent with sudden increase or decrease. For instance, in 2013 having 2 publications whereas 2014 having 0 publications.

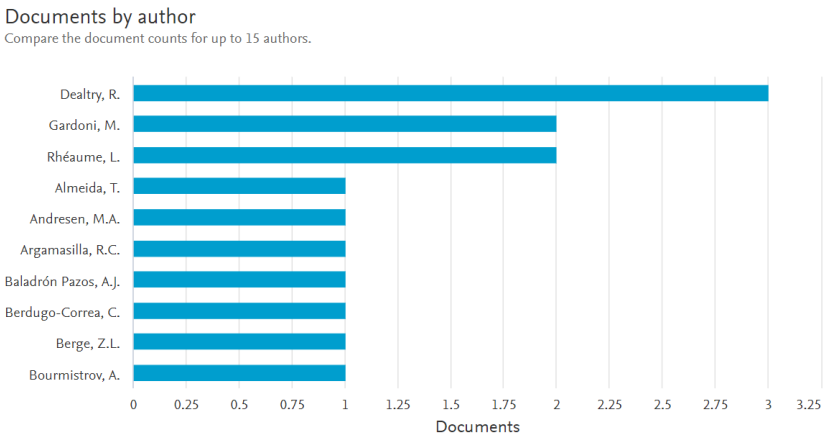

Figure 2 Highly cited authors on CU challenges during 2000-2018

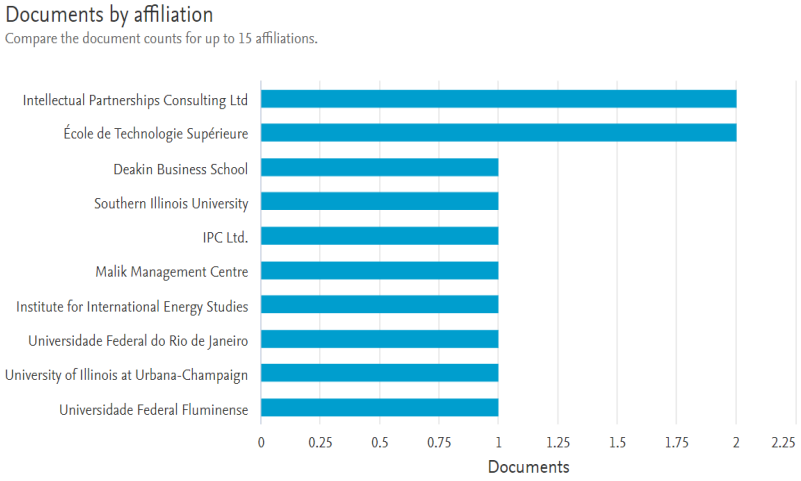

Figure 3 Highly influential institutions- CU challenges during 2000-2018

The leading authors who have widely discussed the challenges faced by corporate are Dealtry, Gardoni, and Rheaume with 3 and 2 documents respectively (See Figure 2). The leading institutions who have addressed this topic are Intellectual Partnership consulting Ltd, and Ecole de Technologie Superiure with 2 documents and Deakin Business school and Southern Illions university with 1 document (See Figure 3). Countries with the highest number of documents in this area Canada, United Kingdom, the United States with 3 documents (See Figure 4). 76.2% of documents are journal articles whereas 23.8% of documents are conference papers (See Figure 5).

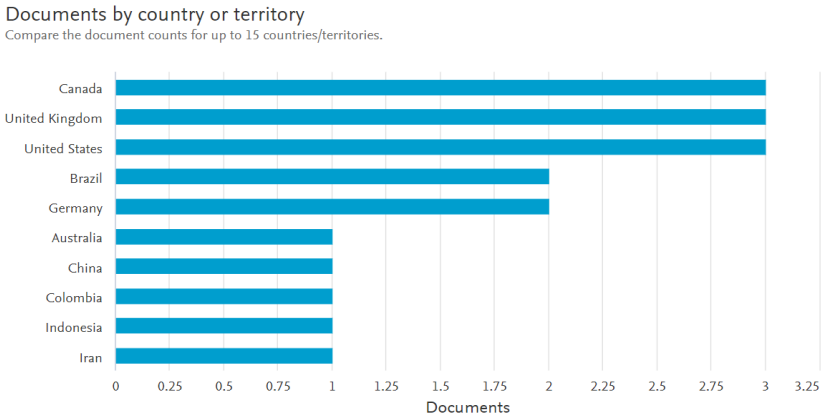

Figure 4 Top countries - CU challenges during 2000-2018

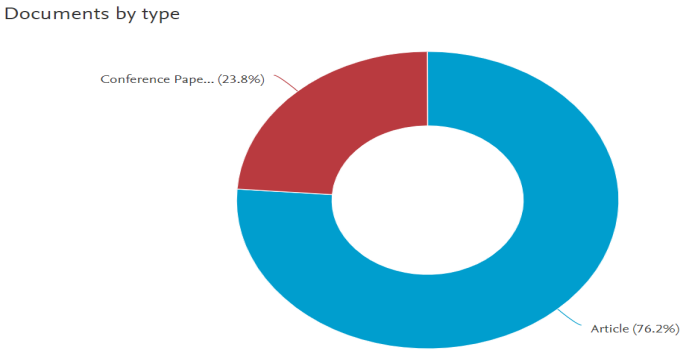

Figure 5 Distribution of documents type from 2000-2018

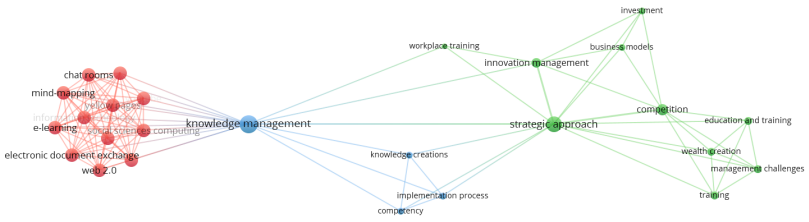

Figure 6 Visualized co-word network of CU challenges from 2000–2018.

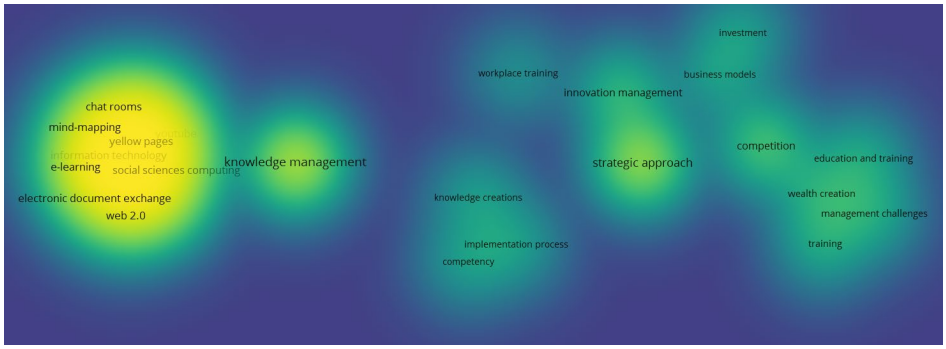

Figure 7 density diagram of CU challenges from 2000–2018.

Figure 8 Overlay of keywords of CU Challenges (2000-2018)

Figure 6 and 7 demonstrate that the co-word analysis aggregate keywords in three cluster including, (a) Strategic integration of Technology in CU (red) (b) Bottleneck in sustaining Innovation as a catalyst to competitive advantage of CU (Green) (c) Dysfunctional knowledge management of Corporate University (Blue). Figure 8 shows the co-word analysis of challenges faced by the corporate universities on a temporal dimension. It is evident from Fig. 8 that keywords like chat rooms, mind-mapping, e-learning, web 2.0, electronic document exchange appeared around 2010 and 2011 (Violet). Much of the focus of the challenges of corporate university research was on the integration of technology. Keywords that were used towards 2012 and 2013 (Green) included knowledge creation, implementation process, competency, strategic approach, training. Most research around this period focused on knowledge management in the corporate universities. Around 2014 and 2015 (Yellow) focused on leveraging innovation in a disruptive business environment. The most prevalent keywords included business models, innovation management, knowledge management, investment, workplace training.

5 Discussion

The present study attempted to investigate the challenges new-age corporate universities are facing through a bibliometric analysis of two decades (2000-2018). Co-word analysis identified three predominant challenges faced by new-age corporate universities (a) Strategic integration of Technology in CU (b) Bottleneck in sustaining Innovation as a catalyst to the competitive advantage of CU (c) Dysfunctional knowledge management of Corporate University. These emergent themes can be understood through the integration of complexity and institutional theories.

5.1 Strategic integration of Technology in Corporate University.

While the integration of technology in functioning corporate university has potential but the effectiveness of it is considerably restricted by the context which impacts the extent of sophistication and incorporation of technology and its capability to facilitate the learning process and output of corporate university (Homan and Macpherson, 2005). E-learning has several advantages for instance it gives required flexibility but this flexibility requires higher responsibility from the individual and higher learning expectancy in non-working time (Homan and Macpherson 2005). Another challenge in the incorporation of technology is learner style (Masie 2001, Homan and Macpherson,2005), if it remains unaddressed it questions the dependency on self-instruction and self-motivation is apt for a broader organizational structure. Dringus (2000) and Homan and Macpherson (2005) cautioned that e-learners may be inept to withstand their momentum without being self-driven, and unless they are ready for isolation. Masie (2001) corroborates with this argument and stressed that "learner acceptance" cannot be assumed to be present, therefore organizations need to address concern of marketing (to motivate participation), support (to facilitate retention), incentives (to give validation of completion of training), and technology (to aid collaboration and give integrated solutions).

5.2 Bottleneck in sustaining Innovation as a catalyst to competitive advantage

Despite the notable advantages attached to the corporate universities, they face certain bottlenecks to their road to attain a competitive advantage (Dealtry, 2001). The way forward is the acumen of the company to replenish their knowledge, which is knowledge innovation. It is believed that knowledge innovation is key to achieve a competitive advantage with excellence (Dealtry and Rademakers, 2005). Organizations in present times cannot afford to sideline the relevance of knowledge innovation as this ignore may make them corporate dinosaurs (Dealtry and Rademakers, 2005) Innovation is not merely technology adoption rather than focusing on market-driven and business-oriented innovation. In recent times, market-driven and business-oriented innovation comes under the ambit of the corporate university. The corporate university needs to reorient itself from reactive to proactive position to meet the expectation of market-driven knowledge

innovation. Furthermore, the challenge of taking strategic options in innovation in corporate university is accruing assets by reducing the risk of replica and imitation. Corporate universities that aim to become open innovation center come across challenges like loss of knowledge, rise in coordination costs, diminished control, and deeper complexity (Rhéaume and Gardoni, 2015).

5.3 Dysfunctional knowledge management of Corporate University

In strategic management literature, widely it is believed knowledge is considered to be an important ingredient to a company's pursuit of excellence and therefore provides a competitive advantage. Organizations trying to attain and contain a higher degree of knowledge and also capitalizing on it requires considerable effort on their end (Dealtry and Rademakers, 2005). Studies have reported corporate universities to be corporate knowledge management institutions (Shaw, 2005; Scarso, 2017). They are bracketed as institutions that are involved in continuing, structural, and strategic steered knowledge transfer, exchange, and development of processes within companies. However, knowledge management in these institutions is still an issue. The issues that corporate universities face is vacuumed thinking, hanging on to ideas, and ignorance. Furthermore, some studies have argued that knowledge innovation cannot be termed as prosperity of technocrats, human capital manager, or scientist (Dealtry and Rademakers, 2005).

It is believed that key emphases of knowledge transfer are restricted to the knowledge dissemination avenues, cross-border communication, and knowledge construction in the context of individual knowledge internationalization and externalization and knowledge triangulation (Crocetti, 2001; Clinton et al., 2009; Baporikar, 2015). Given the corporate universities functions being dynamic has made its knowledge network more complex (Chen et al., 2019). Therefore, corporate universities focusing on technical knowledge adopt basic repositories whereas those focusing on non-technical knowledge utilize more interactive tools (Scarso, 2017).

6 Implications for Researchers and Managers

Scholars need to investigate complex knowledge networks in the context of corporate university's functions. As extant literature as the connected corporate university with knowledge management in a generic manner, studies need to perform an in-depth investigation on knowledge management aspects of corporate university to unearth its pertinent characteristics and processes. Furthermore, researchers need to understand which of the available corporate university models are facilitators of innovation. HR managers need to decipher whether the adoption of e-learning through corporate university is a strategic call or a cost-based decision intertwined with other HR objectives. Managers need to a build learning culture, which is deemed to be a key input for the success of a corporate university to address the issue of pedagogy, locus of control, and quality control. Also, the organizations need to decipher the knowledge management

goals, process and contents that typifies organizational context. Organizations need to identify knowledge management issues and varied corporate university designs to churn out valuable inputs for managers who are keen to capitalize in this organizational solution.

7 Conclusion

Corporate university in academics is a popular but lesser empirically researched topic in HR in comparison to other established HR concepts. Several of CU failure at the time when it is deemed to be providing a competitive advantage to organizations. It is important to ascertain and understand what are potential challenges that are derailing the journey of CU. To address this objective, the present study used VOSviwer to ascertain the research epochs, influential topics, seminal documents, and researcher. On the basis of this input, we further analyzed different challenges faced by CU. Furthermore, we present future research avenues grounded in the current state of the field. Therefore, this study presents researchers with structural and thematic understand of the challenges that the new-age corporate universities are facing.

8 Limitations

The present study makes valuable contribution to the extant body of literature but it also has certain limitations. Firstly, the database of the study was limited to journal articles in the field of business and accounting. Therefore, themes and findings of the study may not be generalized to puritan higher education discipline. For instance, certain higher education journals have theoretical and empirical articles on corporate university. Corporate university as a research area is at a nascent and developing stage, therefore there is a need to replicate longitudinal review of literature to ascertain new themes engulfing the research area.

The Role of Social Capital in the Cluster Evolution in Theory and Practice

Małgorzata Runiewicz-Wardyn

Department of Economics
Kozminski University in Warsaw
Jagiellonska 59, Warsaw 03-301

Abstract

In the last decades, the concept of cluster has gone through the vast conceptual development, resulting in its various definitions and categories - 'cognitive clusters', 'learning clusters', 'creative clusters', 'working cluster', 'effective cluster' (Capello & Nijkamp, 2019; Martin & Sunley, 2003; Lagnevic et al., 2004). Despite of their different approaches all above definitions share one common 'relational' context. Starting from the Porterian concept of 'industry cluster' as spatial networks of industries, which enjoy positive externalities from co-location and frequent interactions, to the more recent concept of a 'working cluster', where firms and other organizations maximize benefits from the synergetic effects coming from integration, cooperation, and competition (Porter 2008). Furthermore, Bochniarz-Faoro refer to 'effective cluster', which is characterized by the rich social networks that enables all participants to efficiently cooperate with one another (2016). Social networks have been also recognized as underlying factor for cluster development in other studies, including Phillips (2006), Ostergaard (2009). Nevertheless, the inherent complex configuration of every cluster, and its divergent patterns of evolution make it difficult to determine the mechanism of Social Capital formation and its impact on cluster growth. To identify this dependency a more case by case analysis maybe useful.

The study aims to explore and evaluate the role of social capital in the evolution of a cluster, using the example of the life sciences industry. Social Capital is defined here as a capital that results from investments in building relations, institutions and networks that produce collaborative attitudes, shared values, mutual understanding and trust. The notion evolution refers here to gradual transition from an emerging cluster to a functioning and growing cluster during the growth phase of markets. More specifically, the study takes an example of five life sciences clusters - San Francisco Bay Area (US), Cambridge (UK), Copenhagen-Lund (Denmark/Sweden), Seattle (US) and Poland, to answer: How does notion of Social Capital and its different dimensions operate within clusters' evolution? What is the contribution of Social Capital within different stages of clusters' evolution? Does Social Capital and social networks can exert a distinct influence on the performance of different clusters? What types of social networks induce cluster related positive externalities?

Keywords – Social capital, Networks, Cluster, Life sciences.

Paper type: Academic Research Paper

1 Introduction

There is a substantial amount of the high-tech-cluster-related literature considering the following success factors of the clusters: strong science and industry base, strong networks between industry and science, that facilitate the growth of both academic and industrial spin-offs, finance availability for new biotech companies (including venture capital and government funds), as well as traditions of local entrepreneurship (Maskell and Malmberg 1999; Su and Hung 2009). Relatively fewer sources mention the role of social networks between faculty, investors, students, intermediary agents, and local authorities in sharing knowledge, information and thus stimulating inventions and innovations (Broekel and Boschma 2016; Ponds, Oort, and Frenken 2009; Audretsch and Feldman 2004; Golejewska 2018; Adams 2002).

The following study focuses on a relatively less discussed factor – social capital and social networks or larger social structures as a key determinant of the success of the life sciences ecosystem. The study aims to deliver new insights in the discussion on the role of social capital, social networks and collaborative social environments in the leading life science clusters in Europe and the US.

The paper consists of the fourth main sections, followed by Introduction and Conclusions and Implications. The first one discusses the concept of social capital and its role in research collaboration, innovation networks in the high-tech clusters and innovation ecosystem contexts. Second one points out the evolution of the Triple Helix networks along the technology dynamics and the role of social capital in the latter process. The third one focuses on the role of social capital in the university-industry collaboration context. Finally, the fourth one, discusses the empirical study results based on the case study of life sciences clusters.

2 Social Capital – conceptual background

Various authors provide similar and slightly distinctive definitions of social capital. Social capital is broadly understood formal and informal relations between at least two people. Positive social capital creates relationships based on trust, cooperation, openness, while negative capital refers to the social relations that are characterized by the suspicion, hypocrisy and secretiveness (Walukiewicz 2007). In his comprehensive study, Pierre Bourdieu (1986), defines social capital as a private investment in social networks that brings the owner expected benefits, such as wealth, and "symbolic capital" (social position). James Coleman (1988), in turn, regarded social capital as an individual good that could be, however, traded through social networks for the advancement of broader human capital. Finally, the last two decades witnessed many new studies extending social capital from the individual or private good to more of a collective or even public good. This group of researchers include Fukuyama (2001), Putnam (2000), Rosenfeld (2007), Lin (2001), Landabaso et al. 2007, Woolcock and Narayan (2000) and others. According to Francis Fukuyama (2002), social capital is a set of informal norms and rules as well as

ethical values shared by individuals and social groups that enable them to cooperate effectively. For Robert Putnam, social capital does not belong to anybody, but is a public good representing a set of social norms and civic attitudes supporting common actions and trust for both interpersonal and in public institutions (Bochniarz and Faoro 2016). Social capital is defined by experts from the European Commission (2005) in a similar manner – "Social capital refers to those stocks of social trust, norms and networks that people can draw upon to solve common problems". The institutional and relational context is present in Roberto Camagni's definition of social capital, which is "the set of norms and values which govern interactions between people, and "(…) glue that holds societies together" (Camagni and Capello, 2012). The role of networks in the society was further extended in the study by Franz Huber who defines social capital as "…resources embedded in social networks which can be potentially accessed or are actually used by individuals for action…" (Huber 2008:19). Furthermore, he distinguishes "internal social capital" – resources mobilized through relationships between members of the collectivity – from "external social capital" – resources mobilized through relationships between members of the collectivity and actors outside of the collectivity. As an example of this dual character of social capital, Huber uses economic clusters, where the distinction depends on access to knowledge within the cluster and access to other clusters and outside individuals (Bochniarz and Faoro 2016).

Stuart Rosenfeld interlinks the notion of social capital in clusters that gives opportunities to "know-who" to the notion of "know-how". He also classifies social capital from the point of view of openness as positive and negative one (Rosenfeld 2007). Positive social capital creates economic advantages that are major forces for clustering. Negative social capital can develop when there are efforts to limit membership in clusters and "lock-in". Mark Granovetter (1973) distinguishes between "strong" and "weak" ties and states that the strength of a social tie is defined by a combination of the time invested, the emotional intensity between the actors. In other words, ties with a higher degree of emotional involvement are more important in the discovery of a business opportunity, and weak ties become more important when exploiting such opportunities. In the context of cluster interlinkages, strong ties describe strong relationships, based on trust and are characterized by frequent interaction (both formal and informal one) which lead to a greater exchange of knowledge (Burt 2009; Rowley et al. 2000). At the same time, weak ties could potentially add heterogeneity to the knowledge base of cluster actors. Table 1 presents the classification of the characteristics of bonding and bridging social capital.

Table 1. Bonding vs. bridging social capital

Bonding social capital	**Bridging social capital**
Within	Between
Closed	Open

Inward looking	Outward looking
Horizontal	Vertical
Strong ties	Weak ties
Thick trust	Thin trust
Network closure	Structural holes

Source: Ramos-Pinto (2012).

The classification made above may lead to an overly simplified and even contradictory image of the social capital networks. In practice, social relationships are far more complicated and usually accompanied by multiple overlapping relationships that individuals have with each other. Thus, a typical relationship would have some characteristics of both bonding and bridging social networks. Last but not least, bonding and bridging are not completely mutually exclusive and the final structure of the network configuration depends on the type of knowledge interlinkages present in a particular cluster, its technological dynamics, as well as the importance of other dimensions of social capital.

3 Social Capital, Proximity and Technology Dynamics

3.1 Social Capital, Proximity and Effective Cluster

According to Sztompka (2016), a cooperation, trust, and a fair exchange make up the so called "moral space" which is at the core of every community. In this sense, effective clusters and innovation ecosystem approach the same issue – the connections between the entrepreneurship process, localized economic and social contexts and knowledge spillovers (the importance of entrepreneurs drawing on knowledge outside of the firm to increase their competitiveness). As stated by Bochniarz and Faoro (2016), the 'effective cluster' is characterized by "rich social capital that enables all participants to efficiently cooperate with one another, which leads to the increased generation of positive externalities coming from co-location and building collaborative synergy within the cluster, as well as openness for cooperation with other clusters, which leads to knowledge spillovers among them and increasing innovations". This loosely-coupled structure helps to create a culture of innovation within the cluster ecosystem, allowing innovative ideas to not only be formed, but also to thrive and grow. In the effective cluster, groups involved in innovative projects will reach out to each other directly to solve problems rather than require a central office to mediate all communications.

The relation between innovation and social capital was also empirically examined by Hauser et al. (2007) on a sample of European regions. The authors` empirical results

suggest that social capital does have a considerable impact on the production of knowledge. Furthermore, different dimensions of social capital have different effects on the innovation rate, i.e. the positive relationship between the weak ties in social interaction and innovation. Similar study by Laursen et al. (2007) focuses on the structural dimension of social capital and combines the data on social capital at the level of 21 regions with data on innovative activities from a sample of 2,464 manufacturing firms in Italy. The authors argue that, after controlling the firms' characteristics and regional ones, co-location in regions characterized by high levels of social interaction leads to a higher propensity to innovate as well as a higher influence of externally acquired R&D on innovation. Similarly, Ostergaard (2009) analyzed knowledge flows through social networks in a communication cluster in North Jutland, Denmark. The author aimed to answer to what extent social networks contribute to channelling knowledge flows between firms and the local university among engineers and computer scientists. Ostergaard's study proves that there are differences between extent and frequencies for the two types of informal contacts (between the firms and between the firms and the university). Mainly, both in case of the university-industry and industry-university informal contacts are less frequent. These findings contradict the belief that knowledge sharing between firms is more likely to endanger their competitiveness, compared to university-industry knowledge sharing.

Finally, Feldman (1999) in her studies demonstrated that physical proximity is not the main condition for social proximity. In fact, she concluded that "pioneering faculty members to start a company lead other faculty members to found companies as well", suggesting that physical proximity might not be enough to create the 'contagion effect' for the local university-based ecosystem players and the occasions for learning and knowledge exchange seem to be facilitated by a high level of the embeddedness of their social relations with other actors.

3.2 Triple Helix Networks and Technology Dynamics

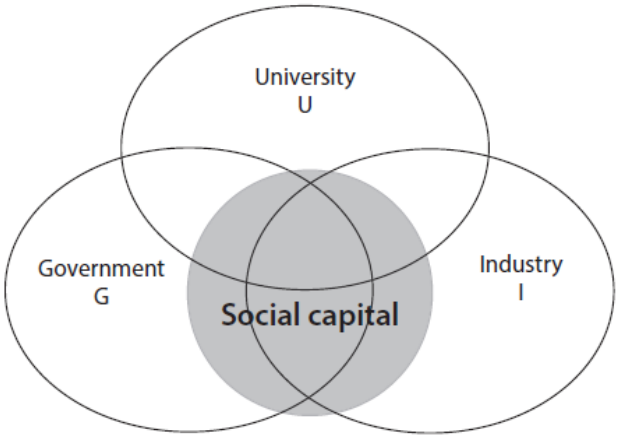
The interaction between individuals or various institutional entities (groups, organizations) plays a critical role in articulating and amplifying knowledge (Nonaka 1995). Yet, as Jensen and Tragardh (2004) put it, the institutional and social interactions architecture of particular Triple Helix relationships model may differ by sector and its technological maturity, e.g. in the case of aerospace, successful research and innovation strategies cannot be effectively formulated and implemented without the government support, whereas in the life science, successful innovation depends on the basic and preclinical research in the life science, the bulk of which is done at the universities. Thus, it is possible to assume that certain types of dynamic externalities and social interactions assist the industry along its life cycle – from a young to a more mature stage. The latter could be explained based on a stylized description of the typical life cycle model, which follows the logistic S curve, starting with the introduction of new products, followed by a

period of strong expansion of production, which then levels off and eventually leads to a decline. A new industry or industries at the introductory stage of their development benefit mostly from diverse knowledge infrastructure and inter-industry knowledge spillovers. Innovation intensity is high, as there are many unexplored technological opportunities (Neffke et al. 2009). At the growth stage of industry development, production becomes more standardized, which opens up possibilities for firms to exploit their divisions of labor and economies of scale. At the stage of maturity, firms typically face vigorous price competition. Profit margins are reduced and technological opportunities are exhausted. In terms of innovation, longer jumps in technology are less likely and so are radical innovations, as the industry has already invested heavily in technology and skill development. The R&D efforts require very specialized, fresh knowledge and skills. Such expertise is best acquired through processes of local tailor education, training systems and access to the university R&D labs and research output. The content of the social ties (both formal and informal ones) between the above actors is different, depending on the types of information and knowledge exchanged between them. In this context of social networking and co-location, next to the leading universities create positive externalities and are especially important for the industries that are undergoing rapid technological change or are in the growing stage of their economic life cycle.

In sum, the evolutionary cluster related literature goes beyond the institutional interlinkages of university, industry, government and society, by going deeper into the specific actors within each sphere, their identities, objectives and social interaction dynamics.

4 The Social Capital in the University-Industry Collaboration

In order to access new talent and technologies, significant investment is being made by high-tech companies in building relationships with research labs and academia. Companies offer doctoral and post-doctoral research funds at leading universities worldwide in order to take steps in the active recruitment of talents. This diversity, interdisciplinarity and connectivity make some high-technology clusters natural environments for the technological convergence. These clusters that created social and institutional mechanisms allowing new ideas to move from one domain to another (Figure 1).



Source: own elaboration.

Figure 1. The role of social capital in Triple Helix networks

For example, the research done by Steinfield and Scupola (2008) concludes that ICT use appears to strengthen the life sciences cluster in Denmark and Sweden (Medicon Valley), and that firms located within the cluster appear to gain some unique advantages from their ICT usage that are not necessarily available to firms outside the cluster. Moreover, the authors concluded that small firms would not gain as much from the use of the ICT infrastructure if not located in a cluster with a strong reputation. Their study emphasized the key role of clusters in creating innovation-friendly ecosystems in the life sciences sector. Yet, strong trust-based relationships are not easily built in the case of such different stakeholders as industry and academia. In fact, researchers from the industry and researchers from the academia work in a different culture and cognitive norms. One example may include the fact that the academic reward for scientific discovery consisting of quality publications or grant/research council funding is highly rank-conscious and individualized. In contrast, pharma industry researchers are salaried as contributors to a team effort aimed at helping invent marketable drugs. Thus, academic science researchers do not routinely operate with levels of collaborative interaction and cross-disciplinary teamwork environment, which is essential to drug discovery and the challenges of applying basic research to address therapeutic/medical needs (Janero 2015). The academic scientists are not equally trained in such matters as decision theory, collaborator relations, or risk and project management. Thus, preclinical university-industry discovery alliances can have discord over the fundamental laboratory findings, i.e. the overvaluation of procuring knowledge by university scientists and undervaluation of new knowledge by industry professionals whose expertise and vision are down the critical path toward market. Such organizational, social and cultural distinctions pose a challenge to discovery research collaborations between university and industry sectors. Establishing common ground for the university-industry discovery collaboration depends

critically on the individuals involved, who can break institutional barriers and inculcate focus, cooperation, inclusion, and trust among its participants. Even though social capital should not be considered a panacea for increasing the levels of innovative activity, yet, there is there is sufficient evidence that the positive influence of social networks reveals a strong contextual and environmental influence on this activity.

5 The Social Capital in the University-Industry Collaboration: Case Study of Life Sciences Clusters

In terms of methodology, most social science researchers acknowledge that the "social capital" and "social networks" are complex issues and therefore, they would benefit most from the integration of qualitative and quantitative approaches. In practice, however, effective quantitative research requires a larger sample size, which was not possible in the case of the following research study, due to the limited time and resources. The team of researchers conducted five qualitative case-studies research within the selected sample of the European and US life science clusters. The qualitative sample includes five case studies – life science ecosystems in San Francisco Bay Area (24 interviews), Cambridge (14 interviews), Medicon Valley (12 interviews), Seattle (10 interviews) and Poland (12) (see the full study in Runiewicz-Wardyn, 2020). The questionnaire contained mixed questions (open and closed ones) and was composed of four parts: (1) the mission, structure and types of social networks; (2) the methods of networking and the intensity of interactions; (3) the role of different types of proximities in social networking; (4) the impact of social networks on R&D collaboration and innovative performance. The authors conducted interviews with the heads and deans of departments, the technology transfer offices (TTO), related educational institutions and companies in the following life science cluster ecosystems.

5.1 Cambridge life sciences cluster

The Cambridge life sciences cluster ecosystem is rooted in the mature world-class cluster in life sciences. It is featured by more closed social networks with hierarchical structures and strong ties in the sense of Granovetter (1973). The intensity of networks is somewhat circulates around more powerful individuals (Deans and Heads of Departments) interconnecting the other actors in the ecosystem, as well as holding control over information that originates from other networking groups. In this sense, their closed hierarchical network structure is in line with the spirit of Coleman (1988), it provides the ecosystem actors with greater trust which might be very important when deciding whether to exploit a research/business idea or not. The role of "triadic closures" was significant, as many of these actors formed collaboration links with partners' partners. The physical proximity among Cambridge ecosystem actors allows them to engage in more informal interactions and serves as a precondition to strengthen social ties and trust. On the other hand, the geographic dimension can really matter when strong social networks already

exist, so one could state that physical proximity enhances and strengthens personal relationships within the existing networks.

5.2 Medicon Valley life sciences cluster

Medicon Valley is considered to be one of the strongest mature life sciences clusters in Europe. Its development and cooperation in life sciences was given a major boost in 2000 thanks to the European development funds, which resulted in the opening of the Øresund Bridge, joining Denmark and Swedish life sciences clusters in one dense innovative cluster. This provides benefits both from the learning perspective and exploitation of innovation perspective. In the last decade, many new partnerships have been formed by a mix of Danish-Swedish, public-private, academic-industrial representatives, as both countries share quite similar culture and institutions. Nevertheless, the existing differences in culture and language between Denmark and Sweden affect their differences in social set-ups. The relationships between the researchers and colleagues at the cross-border firm and university levels are based on educational and professional backgrounds rather than personal friendships and territorially contained trust and understanding. As in the view of Granovetter (1973), one could say that social networks in the Medicon Valley are characterized by the weaker ties, but greater openness, as in the sense of Coleman (1988). For this life sciences ecosystem, physical proximity remains a necessary condition for the social proximity to evolve and sustain.

5.3 Bay Area life-sciences cluster

The social networks within the Bay Area actors are characterized by the strength of the weak ties in the sense of Granovetter (1973), which are expanded via both vertical and horizontal interlinkages within the cluster and promote firms' specialization in the life sciences, while enriching them with new emerging (i.e. interdisciplinary) research and commercialization opportunities. The environment of dense networks and bonding social capital, driven by the geographical, interorganizational and cultural proximities also resembles social networks with closure in the sense of Coleman (1988). The research study demonstrated that when the technological dynamics-bridging type of social capital takes an active role (especially via intermediary organizations and personal contacts from one's previous jobs), the role of indirect ties to external collaborators ("triadic closure" that occurs through the shared collaborator inside and outside the cluster ecosystem) becomes active, too.

5.4 Seattle life sciences cluster

In the Seattle life sciences cluster rich academic culture shape a custom not only to collaborate across other disciplines and practice entrepreneurship (Bochniarz 2020). All these lead to a high level of invention and innovation. Following the major social capital

theories initiated by the studies of Coleman (1988, 1990) and Burt (1992), applied in the context of the Seattle region, by types of social capital – "bonding" and "bridging" – they are present in the Seattle life sciences cluster ecosystem, where the University of Washington's faculty and alumni, along with many local non-government organizations representatives, act as partners and intermediaries among the Triple Helices.

5.5 Poland`s life sciences cluster

The study shows that the Polish life sciences clusters stakeholders appreciate the role of social networks and collaboration within the Triple Helix in the development of the life sciences sector in Poland. Nevertheless, the role of social capital and network capital is rather low. There are numerous challenges and barriers to the social networks and social capital formation in the life sciences clusters` ecosystems in Poland (Kozierkiewicz 2020). The most prominent ones are: the low level of trust and the low level of organizational, social and cultural proximity between the scientists and business, little motivation and no mechanisms stimulating research co-operation, patenting and commercialization, legislative gaps and excessive bureaucracy in the scope of clinical trials, the lack of intermediary institutions, brokering university-industry collaboration, low interdisciplinary cooperation, a high level of individualism and little competition over the European research funds. The development of networks differs in various environments related to the development of life sciences technology in Poland. Scientists from the academic environment participate in scientific associations relevant to their specialization. The need for cooperation with business and the need to commercialize their scientific ideas 'is not obvious,' especially for scientists coming from universities.

In sum, the results confirmed that all the analysed university ecosystems have their own internal technological and social dynamics. Considering the intensity and scale of their interlinkages, the Cambridge and Medicon Valley clusters conform with Porter's concept of the 'functional clusters,' with the close synergy between the three Triple Helix components, namely university-industry-government. These ecosystems demonstrate close links between research and faculty staff in medical and related departments of the universities and local bioscience companies, either in the form of collaboration, funding or the employment of graduates as the commercialization channels of university-based research. In reality, both clusters could qualify as Quadruple Helix models (Runiewicz-Wardyn, 2020).

Furthermore, in the case of the two US-based ecosystems – in the Bay Area and Seattle – the clusters involve the mutually reinforcing interaction between several components in Porter's terms, which are characterized by "rich social capital" that leads to the positive externalities that contribute to building collaborative synergy, knowledge spillovers and increase of innovations within, in the sense of Bochniarz and Faoro's concept of an "effective cluster" (2016). Both offer high skilled talents and a very entrepreneurial and innovative culture. Both provide a multinational and diverse environment, facilitating

exchange of best practices and beliefs, in which universities take the lead in the establishment of university industry collaborations, result in cutting-edge developments and inventions which, in turn, attract more talent, firms, and investments. Furthermore, the key differences between the two Western European and US clusters are grounded in their entrepreneurship, social capital and network patterns which develop interdependently in the evolution of their cluster ecosystems. In the Bay Area, a strong entrepreneurship culture, history and social capital promote tight and dynamic networking. In contrast, social capital formation, entrepreneurship and network dynamics in the Medicon Valley and the Cambridge clusters ecosystems have been initiated to the significant extent by the intermediary organizations and "star" scientists. Finally, the research study demonstrates the different configuration of clustering and networking in the evolutionary processes of the European and US clusters ecosystems.

6 Conclusions and Implications

In the past two decades, social capital has emerged as one of the most widely discussed concepts in social sciences. There are many research studies providing evidence that social capital and its various forms play a significant role in the process of knowledge sharing and innovation capability building in the cluster ecosystems. Yet, this process does not always occur spontaneously. The overview of the above literature reveals several controversies around the role of the different types and strength of social ties in the social capital formation around the cluster ecosystems. One of them relates to the discussion whether the open or closed social networks promote social capital of high-tech clusters. Another controversy is related to the argument about the role of strong or weak ties in facilitating knowledge exchange and social capital formation. Finally, the last controversy is related to the role of brokerage and bridges in networks and social capital formation. Nevertheless, the research findings show that even though all life sciences clusters` ecosystems evolve from different origins and follow different evolutionary paths, their success factors lie not only in human and financial assets, but also in the dynamic forces generating and sharing these resources, which depend on the social networks and social capital.

Abstract

In the recent decades, the digital revolution has transformed contemporary societies. New ways of carrying out work activities have spread across in organizations to respond to changes in the peoples' behaviours and aspirations, who ask for a new way of organizing work, more flexible and results oriented and the effective use of new technologies.
Starting from these premises, Smart Working has spread in organizations. This work model represents an opportunity to redesign work in public and private organizations given greater hourly and spatial flexibility, sustainability, effectiveness, and improvement of the organizational well-being of employees in the workplace and the sphere of private life.
This paper aims to understand the perception that public managers have of smart working as a model of cultural and organizational change in public organizations in order to the following aspects: the redesign of the workplace, the redefinition of organizational processes, the consolidation of the trust-relationship between public management and public employees.

In detail, a series of semi-structured interviews were conducted with Italian public managers of local administrations to understand how they manage ICT technologies as a tool to implement the Smart Working model.
Furthermore, this paper aims to contribute to the recent debate on Smart Working in the public sector.

Keywords – Smart Working, ICT, Digital Transformation, Public Management, Organizational Change

Paper type –Practical Paper

1 Introduction

In recent decades globalization and the technological revolution have conditioned and enormously influence the functioning of public organizations.

In detail, Information and Communication technologies have changed not only how work's activities are performed in organizations, but also how people live, work, communicate, and cooperate in organizations (Orlikowski & Barley, 2001; Orlikowski, 1996; Todisco et al., 2020). Moreover, ICT tools have changed, the role of public management in supporting a greater focus on results, relationships with employees, evaluating workloads, and monitoring performance.

Organizations that respond to modern social and economic challenges have been engaged in constant research to define effective, efficient, and innovative models for carrying out work activities (Lee & Kwak, 2012).

One of these models is Smart Working, whose implementation in the organization aims to improve the efficiency and effectiveness of work activities and work-life balance (Torre & Sarti, 2018, Chiaro et al. 2015, Gastaldi et al., 2014).

A focus on management is crucial to understanding the development of a Smart Working model in organizations.

According to many researchers (El Gamry & Heselwood 2018; Sarti & Torre, 2017), managers have a key role in leading organizations in the preliminary phase of the Smart Working introduction.

Starting from these premises, the paper aims to understand the perception that public managers have of technologies in the implementation of Smart Working and how they influence their role.

The remainder of the paper is structured as follows. The next section assesses previous literature on the relevance of digital transformation in the public sector. The third section describes the constitutive features of Smart Working, while the fourth analyses the research context and methodology. The fifth section presents and discusses the findings. The last section provides the concluding remarks and reports relevant theoretical and practical implications emerging from the study.

2 Information & Communication Technology in public sector

In organizational studies, a particular interest is placed on the role that technology has on many aspects of public organizations' life. On the one hand, digital transformation has accelerated new ways of exercising the self-determination of relevant State functions. Citizen communities were able to become acquainted with the so-called direct democracy's methods (Hilgers & Ihl, 2010, Michels, & De Graaf, 2010, Coleman, 2005, Bovens & Zouridis, 2002). Another significant impact of the technological revolution is on the provision of services. Citizens require the provision of increasingly efficient and quality public services that effectively produce visible improvements in the territories (Cordella & Bonina, 2012, King & Cotterill, 2007, West, 2004, Gascò, 2003, Guthrie & Dutton, 1992). Finally, the ongoing digital transformation has changed how organizations interact with the stakeholders and the standard modalities of carrying out work activities. According to many researchers (Dery et al. 2017; Ravenscroft et al. 2012; Benson et al. 2002), the digital transformation and the increasingly extensive technologies devices' application in organizations have allowed managers to redefine processes and organizational boundaries. This development of redefining the organizational processes takes place thanks to the enabling of new technologies that support and integrate the changes in the physical spaces in which the work activities are carried out. The use of ICT to redesign the workplaces and to adapt them to the work activities improves employees' collaboration and communication and puts public employees in better conditions to carry out their activities. Additionally, ICT solutions support the making of environments more efficient with a consequent reduction in fixed managerial costs for the organizations.

3 Smart Working: a revolutionary change for public organizations?

Since the beginning of the 1990s, significant projects for digitizing public administrations have been developed, often acknowledged under the label 'e-government'. The aim of e-government projects is to modernize public administration through greater efficiency, transparency, and administrative simplification, improving the quality of public administration – citizens relationships (Welch et al. 2005, Layne, & Lee 2001, West, 2004). The role of technologies in the transformation of public administration can be framed as the design of new organizational models. One of the first models to implement temporal and space flexibility was teleworking. The first definition of telework was crafted by Nilles, who coined the term 'teleworking' in 1975 to describe the first form of a work configuration in which employees have more opportunities to use different technological tools to improve the family-work balance. In addition to the potential for individual improvement, this company's organizational model was implemented to achieve greater competitiveness in response to the global market challenges. Teleworking helps organizations and management to reduce costs and to ensure greater efficiency and transparency in the organizational process (Baruch 2000; Bailey & Kurland, 2002). Nilles has argued that telework is a concept that covers a

different range of possibilities for working activities, including workers who work at home part-time or full-time. Due to the economic crisis of the early 2000s, public organizations realize the importance of preserving their full organizational potential, looking for increased competitiveness, productivity, and social cohesion. For this reason, many organizations have tried to simplify the teleworking system and make it more flexible, reconsidering employees' role with a new organizational model and approach defined as Smart Working.

3.1 Smart Working: constitutive features

According to many researchers (Ales et al. 2018, Sarti & Torre 2017, McEwan, 2016) Smart Working is a new managerial approach to carrying out work activities in organizations. It is based on the redefinition of people's social boundaries with the introduction of greater flexibility and autonomy in the choice of spaces, times, and technological tools (the so-called BYOD - Bring Your Own Device) to be used.

This definition highlights the essential role of management in guiding organizations towards new conditions of working flexibility and cultural change in Human Resource Management practices.

According to Torre & Sarti, (2018) and Riccò & Porta (2007), it is possible to identify three factors characterizing the Smart Working model: i) the effective use of ICT tools; ii) the workplace redesign; iii) a new Human Resources Management approach.

i) ***The effective use of ICT tools***: Developing an organizational model focused on Smart Working requires critical attention to the use of new technologies and a series of investments related to staff training on the use of the new digital solution. Smart Working is based on the use of ICT solutions to reconfigure and innovate organizational processes and make a flexible way of carrying out work performance. According to Hartog et al. (2015), the change in employee behavior in organizations. is an essential aspect of the development of a Smart Working model, especially in terms of training activities to perfect the use of ICT tools. Furthermore, new digital technologies also play an essential role in simplifying the sharing of information and files, facilitating better real-time interactions between employees and managers, and improving the flexibility of employee work overtime and space (Riccò & Porta, 2017; Alessandrini & Piglialberi 2016, Olsen & Dahl, 2010). Moreover, a Smart Working model operates on the logic of "Bring Your Own Device" (BYOD), which concerns workers' ability to use their digital devices during the execution of the work activities.

ii) ***The workplace redesign***: The implementation of Smart Working involves a redesign of the organizational model and the offices' physical spaces. These factors are fundamental to rethink the strategic processes of an organization

and allow more effective and efficient use of the most modern technological solutions (Tagliaro & Ciaramella, 2016). Coworking spaces, open space offices spread in organizations. The physical redesign of the workplace is an approach that also requires a profound cultural change in the organizational model and the rethinking of the ways that characterize work performance.

iii) ***A new Human Resources Management approach***: the digital transformation has had a significant impact on organizational processes, transforming the way that the management organizes, train, and motivate employees (Stone et al. 2015). Smart working revolutionizes the concept of classic work. Thanks to spatial and temporal flexibility, public employees can affect the autonomous and responsible organization of their work activities. From public management, this represents a significant challenge in increasing the employee empowerment (Zappalà 2017; Riccò and Porta 2017; Tiraboschi, 2017, Stone et al. 2015).

4 Smart Working in the Italian Public Administration

4.1 Research context

In the Italian public administration, the regulatory framework on Smart Working is defined by the following normative and regulations:

- Law n. 124/2015 (art. 14) "Delegations to the Government concerning the reorganization of the public administrations";
- Law n. 81/2017 (art. 18-24) "Measures for the protection of nonentrepreneurial self-employment and measures aimed at favouring flexible articulation in the times and places of subordinate work";
- Directive of the Council of Ministers (DPCM) n. 3/2017: "Directive of the President of the Council of Ministers containing guidelines for the implementation of paragraphs 1 and 2 of Article 14 of the Law of 7 August 2015, n. 124 and guidelines are containing rules concerning the organization of work aimed at promoting the work-life balance of employees".

The Italian Directive n. 3/2017 defines the Smart Working guidelines in the public context and clarifies the objectives imagined with its introduction.

Firstly, the introduction of a more innovative way of organizing work, based on the use of work flexibility and technological tools capable of making it applicable; secondly, a new cultural model of the public organization based on the evaluation of job performance on the objectives; thirdly the recognition of the needs of public employees to work-life balance.

The Italian normative framework assigns relevant emphasis on the role of public management.

Article 14 of Law no. 124/15 defines that all Italian public administrations must adopt Smart Working guidelines to reach at least 10% of public employees in Smart Working for over three years.

Furthermore, the adoption of these organizational measures is considered an objective of public management and is subject to an evaluation of the work of public managers. This part is relevant in the context of performance measurement criteria, both organizational and individual.

Another aspect that highlights the role of public management is that of the technological improvement of public organizations. The directive n.3/2017 recognizes the individual public organization's opportunity to guarantee at the public employees an adequate technological equipment for operating in Smart Working.

Directive n.3/2017 identifies the process that a public organization must follow to begin a Smart Working pilot project.

Initially, it must identify the objectives that the organization aims to pursue with the introduction of Smart Working. An analysis of potential costs and benefits must be recognized, and the organization's technological equipment must then be checked. The public employees must be equipped with tools that secure access to the organization's IT applications and the availability of adequate software and collaboration tools.

Once these elements have been defined, the pilot project can be started. The offices involved in the experimental phase and the number of civil servants who can access individual agreements must be identified.

The final step concerns the Smart Working pilot project monitoring, which highlights the critical issues and benefits encountered in order to redefine the organizational processes and develop it throughout the organizational context.

Source: own elaboration

Italian Government Directive n.3/2017 – Adopting process of Smart Working

4.2 Methodology

In order to examine the perception that public management has on Smart Working and the role of support that they have to improve this working modality in the public sector, a qualitative methodology was chosen.

We have carried out empirical research based on semi-structured interviews, and the research activity was organized in two closely related phases:

- A selection and a context background analysis were conducted with the selection of documents, conference presentations, reports, and regulations to define and to understand how the Italian public administrations began to define the Smart Working trial phase.
- The empirical investigation was conducted with semi-structured interviews with public employees of local and decentralized Italian public administrations.

The semi-structured interviews were conducted by telephone to public employees of Italian local and decentralized administrations who carried out advanced training courses aimed at public employees held at the Federico II University of Naples.

For this research work, it was decided to follow the concept of "elite interviews."

According to Dexter (1970) and Richards (1996), the interviews with managers who hold relevant roles in organizations allow us to understand the relevant decisions more effectively, explain the outcome of the events, and understand the organizational context.

Twenty-seven public managers of Italian local and decentralized public administrations were selected where Smart Working pilot projects had already started or are ready to start.

The semi-structured interviews were part of a larger study on Smart Working in the public sector and included specific questions on how public managers perceive Smart Working as a tool for changing organizational processes and how they were proceeding to implement Smart Working pilot projects in their offices. The time of each interview was approximately 40 minutes.

It was transcribed and coded by hand for each of the questions asked to the interviewees. The analysis of qualitative interview data started immediately after each interview. Additional concepts that were not mentioned in previous interviews were transcript and used for future studies.

It was transcribed and coded by hand for each of the questions asked to the interviewees. The analysis of qualitative interview data started immediately after each interview. Additional concepts that were not mentioned in previous interviews were transcript and used for future investigations.

5 Findings

The interviews carried out highlighted how public managers are performing a significant attempt to adapt the organization to technological changes. From a managerial point of view, they highlight how the use of technologies must be defined within a

perimeter not only of normative regulation or individual agreement but also from a cultural point of view.

> *In detail, one of the public managers of a local administration declared how: "Technologies have entirely changed the way work is organized in the administration. I am happy with this and the administration promoting changes that are essential and exciting compared to other organizational entities in the public sector".*

Another one of the public managers interviewed said:

> *"Operating in Smart Working is undoubtedly an effective way to manage the information flow we have and to achieve the objectives set by the administration effectively. This result is also possible thanks to the use of technology devices that the administration has already provided us".*

The interviewees highlighted how public managers have accepted the technological challenge, placing themselves in a positive perspective. In particular, this interview is intriguing in which a public manager said:

> *"Initially, there were some doubts about this additional burden. It is also due to the technological aspect, to the very complex information systems, to the presence of many applications that cannot always be replicated remotely regarding organizational standards".*

The interviewees also highlighted another positive aspect that they have encountered since implementing Smart Working. It is highlighted how, for a public manager, the effective use of technological devices represents a method of consolidating a work style that has already implicitly spread in public administrations.

Technologies represent an essential cultural consolidation tool of a trust-based organizational model. Indeed, the majority of participants highlighted how the use of technologies can effectively consolidate the already existing relationships in the office.

One of the interviewees said that:

> *"In managing relationships, Smart Working can hardly lead to a decline of relationships, but rather facilitate them, focusing on achieving the objectives."*

Another interesting aspect that emerged from the interviews is that concerning the sharing and transparency of information on the organization's strategy, values, objectives, and performance at all organizational levels. This expectation is strongly linked to the role that the public manager has to assume, based on multiple approaches oriented towards delegation and empowerment, defining the objectives to be achieved collaboratively, identifying the indicators necessary to measure the performance and results of the work, obtained both individually and at the level of the area or of the workgroup.

However, the majority of the public managers interviewed, regarding the employees-technologies relationship, highlighted main perplexities on the digital limits.

A first, concern was related to the different interactions that arise from digital relationships. Some public managers highlighted how communication can be less effective and more complicated due to possible connection problems.

In response to this critical point, the interviews highlighted how public managers spend remarkable consideration on the technical training of public employees and the need to identify ICT employees qualified to intervene in an emergency.

The second perplexity concerns the use of personal devices. As one of the primary elements for developing a useful Smart Working model, public managers pay particular attention to digital security. Indeed, accessing information about professional activities from anywhere and from any device needs developing internal infrastructures capable of protecting the privacy and private documents.

Finally, the last critical aspect concerns the issue of the right to disconnect. Smart Working introduces enormous temporal flexibility, and the risk is that of being permanently connected. The public managers interviewed highlighted how, even before the diffusion of Smart Working, their working activities were endless, through emails, virtual meetings, and instant messaging.

Table1 Public managers' perception of ICT advantages and weaknesses in Smart Working

ADVANTAGES	WEAKNESSES
Improving of work activities' performance	*Privacy and data security problems*
Workplaces' cost reduction	*IT skills*
Cultural change in organization	*Right to disconnect from digital devices*
More well-organized citizen services	*Risk of overlap between personal and professional life*
Internal communication improvement	*Mismatch between goals and effective employees' performance*
More collaboration between public managers and public employees	

6 Discussion and conclusions

In recent years, the academic and managerial debate on the public sector has underlined the relevance of the diffusion of new organizational models in response to contemporary digital and social changes to have public organizations more efficient and effective, more result-oriented, and nearest to the needs of public employees.

Smart Working represents a relevant cultural and organizational change for public organizations more closely linked to organizational models stratified over time and complex to be changed.

Our findings have shown that public managers confirm that digital technologies play a determining role in aiding and making possible new ways of carrying out work performance in an organization.

In detail, public managers perceive technologies as the fundamental driver of Smart Working.

As highlighted in the interviews, digital allows, on the one hand, to develop and virtualize the workspace (e.g., digital workplace) and on the other to improve communication and collaboration processes. Furthermore, the technologies allow the achievement of that hourly autonomy and choice of workplaces, which increases the empowerment of public employees and amplifies a trust-based organizational model.

Our paper contributes to the literature on the use of ICT in the public sector and also provides many interesting theoretical and practical implications.

In more detail, we contribute to the extant literature on the public sector on how technologies have allowed organizations to respond to requests from contemporary society, to define new organizational boundaries and to support public sector reforms.

Furthermore, the following paper confirms the recent literature on the role of ICT in the application of Smart Working. The organizational modality of Smart Working is consistent with the organizational ways of the last decades in which technologies have expanded the characteristics of flexibility and empowerment of public employees.

From a managerial point of view, this paper highlights how public managers' role is relevant for the effective implementation of Smart Working in public administration and how relevant their ability to use technologies to serve organizational change. Smart working represents a significant organizational and cultural innovation for public organizations that require a managerial vision capable of defining new organizational boundaries.

From the interviews carried out, it is relevant to highlight how the use of new technologies is a factor that must go hand in hand with that of cultural change for the effective implementation of Smart Working in the public sector. The majority of the public managers interviewed have the awareness that widespread adoption of Smart Working in all public administrations requires a substantial speedup of the digitization processes of the organization's services and operational processes. This aspect is particularly relevant in this period. During the coronavirus pandemic crisis, in Italian public administrations, with the Directive of Ministry of Public Administration n.2 and n.3/2020 Smart Working has become the primary way of carrying out work activities.

In this, public managers have the relevant task of supporting the development of suitable solutions to guarantee full public employee operations and providing services to citizens in safe, reliable technological environments and with trained employees.

This pressure on the diffusion of Smart Working in the public sector puts greater emphasis on the requests presented by the public managers interviewed on the critical issues of the use of technology in Smart Working. The analysis presented leads to support the need for a secure connection with employees' training, as highlighted in the interviews, and to guarantee high-security standards regarding privacy.

Abstract

The paper proposes the testing of mathematical models of multi-criteria analysis to support the organizational control functions in the automotive sector. One of the most critical aspects of the organizational control functions for automotive companies is the definition and prioritization of problems emerging from the implementation of production cycles. This issue is relevant for the purpose of defining organizational actions that can be used alternatively to solve a problem in the most efficient way possible.
The World Class Manufactring (WCM) methodology offers the automotive sector a series of tools to identify a problem, establish priorities among the criteria to be adopted for its resolution, find the root causes and possible remedies.
This paper describes the results of the first phase of the research project "Multi-critical analysis in support of organizational control systems in the automotive sector" and focuses on the theme of "priorization of errors and analysis of critical processes with the use of tools of multicriterial analysis".
The aim of the research work carried out in this phase of the project is to compare the priority definition tools provided by the WCM used in the automotive sector with the methods for selecting and defining multi-criteria priorities (MCDA). The research, in particular, starting from the study of the tools used in FCA plants for the definition of priorities and the classification of problems in order of importance, intends to develop an innovative theoretical and methodological approach focused on the use of multi-criteria methods such as AHP Sort . The use of multi-criteria methods offers, in fact, the possibility of simultaneously considering a varied set of criteria and of involving the Decision Maker and experts in the sector in the construction and definition of the multi-criteria model to support the decision. The empirical research work aims to verify the hypothesis that innovative multi-criteria analysis methodologies, inserted in the pre-existing control modules

adopted in the WCM methodological paradigm, can generate the possibility for management, not only to measure and govern organizational actions with different perspectives analysis, but also to evaluate the corrective action options with respect to the strategic objectives declared prevalent.

Keywords – Organizational control, Automotive sector, MCDM, Decision analysis.

Paper type: Academic Research Paper

1 Introduction

The work proposes the experimentation of mathematical models of multicriteria analysis to support the organizational control functions in the automotive sector. The domain of research is the automotive industry sector; one of the most important production sectors in the world, both in terms of volumes and turnover. The automotive sector is a sector driven by a continuous process of knowledge exchange that takes place both within companies and with the networks linked to them. The sector is constantly invested by a series of pressures to change, often conflicting, which require: organizational models able to minimize any waste of resources; methods and tools for continuously redesigning production and managerial processes; a strong orientation towards the development of human resources; a holistic approach to accounting information disclosure and organizational control, for the governance of every aspect of the company's operations. Often, however, the most consolidated managerial practices in the sector, although evolved (Global Powertrain Development Process, World Class Manufacturing, etc.), show critical points precisely in the ability of the control systems to incorporate different organizational logics and evaluation dimensions, slowing down in this way the driving forces for change for which the same managerial methods have been conceived. The case of study regards Fiat Chrysler Automobiles (FCA) that is one of the main industrial groups in the world operating in the motor vehicle production chain; a virtuous example, recognized internationally, of change management and lean journey. The directional systems for the control and management of quality adopted by the Italian giant, maturing, have given life in the various plants of the group engaged in research and development to new methods (such as, for example, Workplace Integration) that aim to combine the need for standardization with that of flexibility, especially for families of sensitive organizational processes, such as the launching of new car models in production. Within these management systems, research proposes the use of multi-criteria methods that enhance managers' ability to measure and evaluate the effects of specific organizational actions, balancing the technical and socio-economic dimensions of the same performance, stability needs and incentives to change. In fact, the research aims to build an experimental model for measuring the results of a multi-criteria approach, starting from the operating conditions of managerial tools whose use is now consolidated in the partner company. With multicriteria methods, large amounts of data emerging from the control performed in different areas (Pillar) can be processed in such a way as to

assign weights relative to the different dimensions investigated and in order to arrive at ranking of possible intervention decisions with different repercussions with respect to a purpose more binding identified by the management (cost savings, safety at work, environmental impact, quality, development of skills, motivation of people). In other words, we intend to test the hypothesis that innovative methodologies of multicriterial analysis, grafted into the pre-existing control modules adopted in the methodological paradigm of the World Class Manufactring, can generate the possibility for the management, not only to measure and govern the organizational actions with different perspectives of analysis, but also to evaluate corrective intervention options with respect to strategic objectives declared prevalent. One of the most critical aspects within the company is the definition and prioritization of the problems to be addressed in order to define the organizational actions that can alternatively be used to solve a problem as efficiently as possible. In this sense, the main focus of this work is to compare the WCM prioritization tools used within FCA plants with multi-criteria sorting and prioritization methods. Our research, in particular, starting from the study of the QA matrix which prioritizes and summarizes the problems in order of importance, taking into account of a series of criteria (frequency, severity, costs, intervention time, etc.), proposes a new way of prioritize problems through the use of sophisticated multi-criteria methods such as AHP Sort (Ishizaka, 2013). This study would allow to improve the genesis of knowledge from a network point of view, in fact the identification of problems and the subsequent decision-making on improvement actions take place with the full collaboration between the production line and all external actors such as suppliers. Furthermore, the proposed prioritization work to define a set of actions to deal with the analysis of human errors (Konstandinidou et al, 2006) that occur in the company with greater awareness.

2 Decision support systems and evolution of organizational control

Organizational theory has for some time investigated the evolution of business models inspired by lean thinking, understood as a modern orientation to design and business management, aimed at pursuing efficiency and effectiveness. At an operational level, increasingly sophisticated organizational methods and performance management methodologies (Ferreira and Otley, 2009) are continuously tested in the most advanced organizations, which aim to integrate the principles and techniques of different and consolidated work organization models, such as Total Productive Maintenance, Total Quality Management, Just in Time. In these approaches, a significant space is assigned to the standardization of activities, the measurement of results and the evaluation of the professional contributions of human resources. In them also great emphasis is given to the theme of decentralization and to the hypothesis that the organizational actors responsibly feed the circuits of control and reporting. Thanks also to the implementation of these managerial practices in organizational theory, the concept of control has evolved (Malmi and Brown, 2008) and has integrated components previously kept distinct or defined context variables. The integration of the different types of controls (Planning, Cybernetic,

Reward and Compensation, Administrative and Cultural controls) aims at the joint evaluation of each dimension of the organizational action. This raises stimulating questions about the design of managerial control systems and their requirements in terms of accessibility and involvement of human resources, the ability to activate learning processes, motivation, knowledge integration, and therefore innovation.

Multi-criteria methods can be used to support organizational control functions to manage complexity and stimulate participation, facilitating communication between the subjects involved, allowing decision-making problems to be faced even when the information framework is insufficient, the number of decision-makers is high, their interests vary and vary over time, the number of action alternatives is also high.

Multi Criteria Decision Aid (MCDA) is a multiple criteria comparison procedure that aims to contribute to the development of a learning process that feeds the decision-making process itself.

One of the most critical aspects within companies is certainly the definition and prioritization of the problems to be addressed in order to define the organizational actions that can alternatively be used to solve a problem in the most efficient way possible.

Defects generated in the production system and prevent defective products from entering the market. The improvement proceeds by looking back in the production process, identifying the main cause of a defect and taking countermeasures to avoid its generation and therefore not only find a way to intercept it. This goes through constant monitoring and improvement of the processes to strengthen their capacity and repeatability.

To this end, WCM offers quality control a series of tools to identify, prioritize, find the root causes and the relative solution for every quality problem of the plant.

3 Methodology proposal

The multi-criteria approach to decision problems arises from the need to consider, at the same time, points of view, objectives and criteria of a different and often conflicting nature; it renounces the paradigm of optimality, poorly operational, replacing it with that of the "justified" choice. We are not looking for a single result, but we try to identify the elements useful to clarify the priorities on which to base the choices (Ishizaka & Nemery, 2013). The multi-criteria analysis therefore aims to provide support to the decision maker to achieve an acceptable compromise between the various objectives pursued. The multi-criteria analysis represents today one of the major study areas of the analysis of complex organizations and as such has developed by inheriting the characteristics and principles of this matter in fact, does not attempt to analyze different disciplines in a single general theory, but analyzes the objectives through the structuring of a complex problem; the criteria for selecting the alternatives are expressed in terms of specific objectives and not in terms of basic rules; and the structure and model underlying the articulation of objectives plays an important role; in addition, the approach is closely linked to the analysis of decision-makers' preferences. The analysis of decision-making contexts, the

definition of resources, criteria, alternatives allows you to define a better knowledge of the situations to be analyzed and with it greater possibilities to find solutions more quickly.

When faced with a decision problem, a decision maker's first task is to identify the type of problem. Roy (1981) described four problematic formulations in the multi-criteria context: choice problem (P · α) in which the objective is to select a single best action or to reduce the group of actions into a subset of equivalent or incomparable actions; sorting problem (P · β): the actions are ordered in predefined categories ordered; classification problem (P · γ) in which the shares are ordered in a decreasing preference; problem description (P · δ): the aim is to help describe the actions and their consequences.

In literature there are a considerable number of multi-criteria methods, this on the one hand represents an element of strength, being able to choose from a very varied plurality of tools to support decisions; but, at the same time, the high number of available MCDA methods places the decision maker in the condition of having to make a selection, of the decision support tool that he deems most appropriate. None of the methods are perfect nor can they be applied to all problems. Each method has its limits, particularities, hypotheses, premises and perspectives (Ishizaka & Nemery, 2013). One way to choose the multi-criteria method to be applied is to examine the information requested in input. In this sense, it is possible to organize the methods taking into account the effort to be made in terms of data and initial parameters to be provided. The starting data and parameters range from the need to have only objective elements (for the methods that lead to choice and ordering) and to indifference and preference thresholds (for methods that lead to sorting) up to the maximum effort to specify a utility function. The use of the right multi-criteria method lies in a careful and timely analysis of the theoretical and application context where they want to be applied. Among the most used multicriteria methods in the literature is the Analytic Hierarchy Process (AHP) (Saaty, 1980). The AHP method has been very successful over time and has found space in different fields of application. The elements that have allowed its diffusion in decision-making analyzes are manifold and can be traced back to the type of data, both quantitative and qualitative, used in the construction of the model. The AHP provides a modeling of the decision problem through the use of a hierarchy that allows to break down a complex decision problem into the elementary units that compose it. Structuring a problem is part of the nature of man, that is, he always tries to identify the alternatives, objectives and compromises that exist in a choice he must make. Over the years, various variants of the AHP have been developed, including the AHP Sort (Ishizaka et al, 2012) used for sorting and ranking problems. In particular, the AHP Sort assigns the alternatives of the decision problem to predefined groups (or classes) in an ordinary way according to the preferences of the decision maker, this means that the classes are ordered from most to least preferred. The construction of the AHP Sort is characterized by three specific steps:

- *Definition of the decision problem.* This step represents the starting point for the construction of the model and in the first place provides for the determination of

the objective, criteria and alternatives of the problem; secondly, we proceed with the definition of the classes (the classes can be ordered and can have a label, for example: excellent, good, medium, bad); finally we proceed to the definition of the profiles of each class.[1] This can be done in two different ways: definition of the local limiting profiles, which indicate the minimum performance required for each criterion j to belong to a class C_i; o definition of local central profiles, as an element belonging to the class C_i respect the criterion j.

- *Valutation.* The assessments are defined with respect to the limiting or central criteria, alternatives and profiles. The evaluation of the importance of the criteria in pairs is first carried out g_j in order to derive its weight w_j with the AHP eigenvalue method [2]. Then a single alternative is compared in a pairwise comparison matrix a_k with each of the limiting profiles lp_{ij} or central profiles cp_{ij} for every criterion j. Finally, local priority is obtained p_{kj} from the comparison matrices for the alternative a_k.
- *Class assignment:* Class assignment involves the aggregation of weighted local priorities, which provide a global priority for the alternative k and a global priority lp_i for the limiting profile[3] or cp_i for central profile[4]. The comparison of p_k whit lp_i or cp_i is used to assign the alternative a_k to a class C_i (fig. 1) .

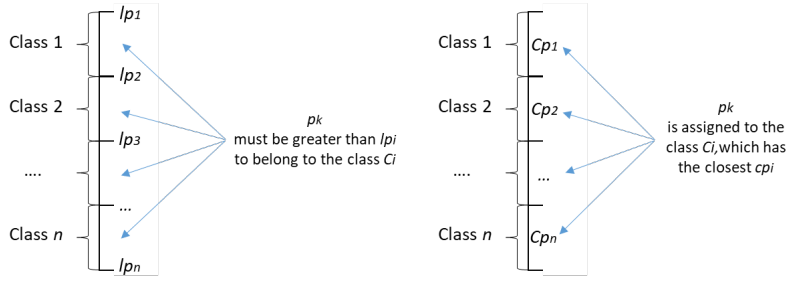

Fig. 1 - Sorting with limiting profiles and central profiles

Multi-criteria methodologies such as AHP Sort can be applied in the context of organizational control functions, in the automotive sector, for problems emerging from the implementation of production cycles. In particular, it can be used to support organizational control systems in the automotive sector, in particular on the subject of

[1] *To identify the separation point between one class and another, limiting or central profiles are defined.*
[2] *$A \cdot p = \lambda \cdot p$; dove: A è la matrice di confronto a coppie, p è il vettore priorità / peso, λ è l'autovalore massimo.*
[3] *If limiting profiles have been defined, the alternative a_k is assigned to the class C_i which has lp_i just below the global priority p_k*
[4] *If the decision maker has difficulty defining a limiting profile, he can define the central cpi profiles. The limiting profiles are deduced from (cpi + cpi + 1) / 2. The alternative ak is assigned to the class Ci which has the central profile cpi closest to pk. In case of equal distance between two central profiles, the optimistic assignment view assigns ak to a higher class, while the pessimistic assignment view assigns ak to the lower class.*

prioritization of errors and analysis of critical processes. The use of multi-criteria methods offers the possibility to contextually consider a varied set of criteria and to involve the Decision Maker and experts in the sector in the construction and definition of the multi-criteria model of decision support. The analysis of the existing tools used for the prioritization of errors in the WCM methodological paradigm shows that with respect to the construction of the criteria that contribute to the formation of the priority index, it is possible to intervene with multi-criteria methodologies on various points:

- Priority scales for alternatives. The analysis conducted shows that the scales used for attributing weights to alternatives (errors) are different depending on the criterion considered.
- Allocation of weights to the criteria. From the analysis of the criteria it appears that the criteria have different weights, however, this is not explicit. With this in mind, we believe it is appropriate to use methodologies that allow we to attribute weights to the criteria. In literature there are several methods for determining the most intuitive weights for the Decision Maker, for example, it could be the SRF method (Abastante et al., 2020)
- Aggregation and robustness of the priority index. The issues related to aggregation and the robustness in the construction of synthetic indices for prioritization are widely discussed in the literature (Greco et al., 2019). We believe that in order to improve the process of identification and construction of priority errors, it is appropriate to use more sophisticated techniques such as Sigma-Mu efficiency analysis (Greco et al, 2019b).

4 Conclusions e innovations of research

As highlighted, one of the most critical aspects of organizational control functions for automotive companies is the definition and prioritization of problems emerging from the implementation of production cycles and the prioritization of errors that occur in the factories. The WCM methodological paradigm offers a series of tools to identify, prioritize, find the root causes and the relative solution for each quality problem of the plants. The goal of this research lies in the comparison of WCM's own tools with innovative multi-criteria methodologies in order to improve and integrate knowledge in complex work environments. The use of multi-criteria methods, such as Ahp Sort, would allow the company to use a new multi-criteria methodology that can improve error prioritization mechanisms in the automotive sector. The experimentation of this experimental methodology will be tested in a giant in the automotive sector such as FCA; in this experiment we expect a more accurate prioritization of errors compared to the tools used in the company and consequent increase in knowledge of the phenomena in the company which will lead to an improvement of the organizational control models. The strength and innovations of the use of multi-criteria models in complex organizations are certainly identifiable in the construction of the models as it provides for the direct involvement of Decision Makers; in the construction of classes that allow to analyze the

problem in terms of priorities but also to have a certain range of overlap of the same; in consideration of a multitude of criteria and alternatives, in the possibility of adapting the model during implementation and in defining a flexible model with respect to the context and business dynamics.

Abstract

This paper investigates how board members perceive the reliability of Big Data (BD) as a new source of information for their decision making. To understand the dilemma "*real time and effective vs reliable and compliant information*", we analyse a real case, addressing this problem to reflect on the decision making of a board of directors. In detail, within the context of a digital bank, we explore how the board assessed the quality of BD, gathered from social media and processed in the form of indicators, to define worthwhile measures for monitoring the bank reputational risk.
Our data reveal interesting findings in two areas. First, there is evidence of a shortfall in cognitive capabilities concerning BD. Second, we show how BD impacts responsibility/control within the board context. This study points to areas for development at three levels of our analysis: individual directors' cognitive capabilities in relation to BD, the board as a collective intelligent decision maker and at the organisational level, supporting a broader view of the big data flows in and out the firm's boundaries.

Keywords – Big Data**,** Social Media, Board Decision Making, Reputational Risk

Paper type – Academic Research Paper

1 Introduction

This paper investigates how Board members perceive the reliability of Big Data (BD) as a new source of information for their decision making. As a matter of fact, BD has the potential to 'disrupt' the senior management of organisations, prompting directors to make decisions more rapidly and to shape their capabilities to address environmental changes (Merendino et al., 2018).

In the era of BD produced thanks to technologies that have allowed the collection and storage of an increasing quantity of granular information, as well as the processing and

extracting the information, even in the field of managerial reporting, expectations for new opportunities have emerged.

In particular, expectations concern the possibility of overcoming two limits of traditional reporting for decision making, that is:

a) Big data may enable real-time reporting (Serafeim, 2014),

b) Big data, thanks to the possible views they offer, allow us to extract valuable information that supports achieving corporate performance (LaValle et al., 2011; Lycett, 2013).

Hence, a board of directors may benefit from a wide range of data that offers insightful information for their decision making rather than financial transactions alone (Moffit and Vasarhelyi, 2013).

However, at the same time, there are many limitations to this kind of data concerning their reliability. Indeed, some authors have talked about big data mythology, which relates to the common belief that a vast pool of data provides true, objective and accurate knowledge (Boyd and Crawford, 2012). In practice, so far, chief financial accountants serve as gatekeepers of accounting-based information provided to the Board, which prevents reporting based on big data from leading to misrepresentation and unfair decision-making (Al-Htaybat and von Alberti-Alhtaybat, 2017).

To understand the dilemma, it can be summarised as:

"real time and effective vs reliable and compliant information",

therefore, we have analysed a real case addressing this problem to reflect on the decision making of a board of directors. In detail, within the context of a digital bank, we will explore how the board assessed the quality of BD, gathered from social media and processed in the form of indicators, to define worthwhile measures for monitoring the bank reputational risk.

Indeed, the literature on BD information quality for corporate decision making finds supporters and detractors who develop their analysis within the frameworks developed in their own disciplines (mainly information systems and accounting). Furthermore, in most cases, it does not offer case studies or surveys on how the quality of data is perceived within the company, with only some exceptions (Merendino et al., 2018). For these reasons, we believe that this preliminary paper could shed light on an issue that deserves greater attention and that it will be increasingly important in the future.

This paper is structured as follows: section 2 illustrates the debate on the quality of big data for decision making; the methodology is presented in section 3. Section 4 draws on empirical evidence and provides the main findings of our inquiry, while section 5 highlights the implications for research and practitioners.

2 The debate on Big Data for corporate decision making

The analysis of the benefits and shortcomings of BD can be approached from two different perspectives, namely that of the accountant and the BD expert. Therefore, we have proposed a parallel analysis which is summarised in table 1.

Table 1. Benefits and shortcomings of Big Data for decision making

	Accountant	*Big Data expert*
Benefits	Real time information useful when decisions need to be timely within a setting of limited rationality	Extension of the decision maker's ability to make sense of the present and anticipate future trends
Shortcomings	Possible lack of reliability compared to accounting models and existing regulations	Risk of over-perceiving the value of meaningless patterns found among large quantities of data

2.1. The BD expert perspective

BD has been recognised as a potential driver of disruption in the way firms operate as it enables managers to make decisions based on evidence rather than intuition (McAfee and Brynjolfsson, 2012). Usage of BD, especially when coupled with Artificial Intelligence techniques, is capable of equipping decision makers with both an extended understanding of the present circumstance through a deeper understanding of the market, consumer and competitors, and the anticipation of forthcoming events in the future. Insights and predictions can give firms a competitive advantage as they support an increase in productivity and an improvement in the speed and quality of decision making (Agrawal et al., 2018). At the same time, decision makers who are not fully equipped with knowledge about BD methods might make some wrong decisions as they fail to consider the level of confidence behind findings (Seely-Gant and Frehill, 2015). For example, a frequent limitation of BD models is overfitting which can lead decision makers to see non-existing patterns simply because large quantities of data can offer connections that apparently radiate in all directions, as noticed by Boyd and Crawford (2012). Until organisations obtain a minimal level of fluency in BD methods, data scientists and business analysts will have the additional responsibility to coach others on best practices, emphasising both the value and the possible shortcomings of analytics projects (Davenport, 2020).

2.2. The accountant perspective

In the field of corporate reporting, the contrast emerges because data scientists process information in an abductive way (Arnaboldi et al. 2017), while accountants ensure the quality of the data with respect to consistency with a determined accounting model (Demartini, 1999). Hence, accountants serve as gatekeepers of accounting-based knowledge, which prevents reporting based on big data from leading to misrepresentation, and unfair decision making (Al-Htaybat and von Alberti-Alhtaybat, 2017), which could be even considered as non-compliant with the existing legal or regulatory norms.

Namely, the biggest problem for an accountant is precisely to understand the "quality" of the data. This is mainly due to the fact that they need to use information that is certified

by third parties and that complies with the characteristics required by legal and compulsory regulatory norms. In this sense, the traditional distinction between the quality required for financial data and making well-informed business decisions is fading. This is even more true in contexts regulated by law such as banking.

2.3. The impact of BD on Board-level decision making

To inquire about how the quality of big data is perceived, analysed and discussed by the Board, it is appropriate to recall its functions briefly. In a nutshell, the Board of a company is responsible for the strategic supervision and monitoring of the firm's activities. To effectively perform these functions, both individual directors and the Board, considered as a collective intelligent system (Leimeister, 2010), must have adequate knowledge, competence and skill. For our purposes, it is also important to consider that required knowledge changes over time in light of new challenges businesses. So, it is also important to reflect on the dynamic capability (Teece et al. 1997) and knowledge (Spender, 1996) of the Board.

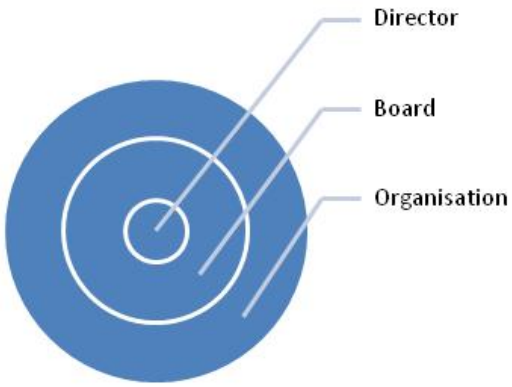

Figure. The different levels of analysis

This attitude should be considered at several levels (see Fig. 1):

- at an individual level, to avoid the negative effects of cognitive biases (Amit & Schoemaker, 1993), such as anchoring (i.e., the old way of thinking) and cognitive dissonance (i.e., holding conflicting beliefs or ideas) (Brennan & Conroy, 2013). The lack of cognitive capabilities of the Board of directors can also cause boardroom or organisational inertia (Tripsas & Gavetti, 2000);
- at the Board level, which acts as a collective intelligent decision maker (Leimeister, 2010);

- at the organisational level, by defining how to manage knowledge flows inside and outside the boundaries of the firm from a cognitive view (Cress & Kimmerle, 2008; Secundo et al., 2016).

3 Methodology

In the following section, we will analyse a real case, addressing the issues mentioned above, to reflect on the decision making of a Board of directors.

The choice of a digital bank stems from the fact that, as we said, the banking sector, on the one hand, has always made great use of new technologies to manage a large amount of data and, on the other, is subjected to strict compliance requirements established by law and numerous national and supranational supervisory bodies. In detail, the choice of a digital bank defines the context of reference even more analytically as we assume that the corporate culture is based on transversal skills with reference to the new communication technologies and that it is accompanied by a certain openness towards the search for innovative solutions, also concerning company reporting. Furthermore, it is expected that members with specific skills in digitalisation will also be present on the Board.

Therefore, we have conducted semi-structured interviews with the Board members of a digital bank to provide a discussion on a specific concrete situation concerning how and whether to use big data for high-level strategic decision making. The concrete situation concerns the design of a framework aimed at monitoring the bank's reputational risk, which will be briefly described in the following section.

3.1. The context of the decision making

The design of a reputational risk framework

The deterioration of stakeholder confidence exposes banks to reputational risk and effects their ability to maintain viability conditions over time. For this reason, and also on the basis of the indications of the supervisory bodies, many banks have adopted a framework for monitoring reputational risks.

The investigation of this specific topic is beyond our inquiry, therefore, only the elements relevant to our purposes will be provided below.

It is sufficient to recall that the reputational risk framework adopted by the bank for monitoring translates into a quarterly reporting dashboard, presented to the bank's Board, containing the management indicators for each stakeholder. The latter are intended to "measure" the quality of the relationship with each stakeholder.

The decision to be made

As part of the design of the bank's reputational framework, the decision on which we have focused our analysis concerns the identification of the indicators for the mitigation of the reputational risk called "brand capital". The latter expresses what the bank defines

as "the synthesis of the perception of customers and non-customers in terms of engagement, competence, integrity of the exchange, reliability and loyalty".

Specifically, we will focus on the discussion developed within the Board around two of the most significant indicators among those selected to monitor the components affecting brand capital, namely:

- Index of negative sentiment online (number of conversations with negative polarity/total conversations recorded in the Quarterly period)
- Litigation index (expressed as the number of complaints received by the bank during the Quarterly period)

The first indicator derives from an external survey conducted by a provider specialised in sentiment analysis and is based on the processing of non-structured big data present online, including web pages, online news, internet discussion groups, online reviews, web blogs and social media.

The second indicator is traditionally provided by the internal office that deals with complaints and has always been monitored by the bank.

This comparison will allow us to analyse how the Board considers the quality of information coming from sentiment analysis, compared to traditional information relating to complaints.

3.2 Data collection and analysis

Data were collected from 2019 to 2020 by one of the authors. Data used for the analysis come from different sources:

- internal reports and documents to analyse the design of the reputational risk framework (i.e., Board meetings minutes, technical reports);
- subsequently, semi-structured interviews with each director focusing on the discussion that arose within the Board on the reliability of the index of sentiment online to monitor the bank's brand capital.

Interviews were the primary source of data. A total of 7 interviews were carried out (see Table 2 for more details on informants and their theoretical and practical expertise). Conversations varied in length from one to two hours. All of them were recorded and later transcribed verbatim for further analysis.

Table 2-Interviewees' profile

No of interviews	*Role*	*Theoretical expertise*	*Practical expertise*
1	Chairman	Auditing and accounting	Professional, member of boards and supervisory board (Legislative Decree no. 231/2001)
1	Board member	Media communication	Founding partner and marketing chief of a digital company

1	Board member	Business administration	CFO/Chief risk officer in the banking sector
4	Board members	Legal and business administration skills and competence	Chief legal officer, Chief Commercial officer, HR responsible in the banking sector Professional

As suggested by Miles et al. (2014), data analysis was an ongoing process. Available data were iteratively analysed to allow a progressive elaboration of a general interpretative framework. In the first step of the data analysis, we created a detailed description of the case, putting together interviews and secondary sources. In the second step, we cycled through multiple readings of the data and, in line with the purposes of our research, in this phase, we identified the following three levels to analyse how the quality of big data is perceived for decision making: the individual director, the board as a collective decision maker, the organisation as a whole. With this purpose in mind, each author read the empirical material independently and categorised the stream of words into meaningful categories, via manual open coding. Furthermore, in our analysis, we found the use of excerpts highly worthwhile as they allow researchers to address the way the actors use language, think and make sense of big data usefulness and reliability.

4 Findings

4.1. The Individual level

At an individual level, directors need to develop the mental models and skills, or managerial cognitive capabilities, to perceive, analyse and process changes in the environment that affect decision making.

It did not surprise us that, apart from one of the directors with a specialist background, the others had not gained in-depth knowledge on big data. Nonetheless, none of the interviewees complained that they did not have adequate knowledge to be able to specifically evaluate the reliability and adequacy of the index of sentiment online for the defined purpose.

If, on the one hand, these affirmations manifest the mental openness of the directors towards the evaluation of new data sources, on the other hand, it can also be the signal of a shortfall in cognitive capabilities in assessing the quality of BD, given that no directors, during the Board meetings, asked for specific information on how the index was calculated. Except for the one with expertise on media communication, the other directors took the data for granted, also because online sentiment analysis had long been a source of information used by the bank's communication office. Hence, the index was used to provide information about technical content, whose quality assessment is up to specialist managers.

This offers valuable insights into why directors may act conservatively, clinging on to more traditional processes which have been institutionalised. Indeed, a more critical approach was only adopted by the director with greater BD expertise, who stated: *it is always advisable to know the sentiment analysis techniques used to understand the meaning of the information provided.*

4.2 The Board

In analysing the data collected, we adopted the view of the Board as a collective intelligent decision maker. The term "collective" describes a group of individuals that work together to find solutions to a given problem. The term "intelligence" refers to the ability to learn, understand and adapt to new circumstances by using knowledge.

In this perspective, it is interesting to observe how, through the dialectic and the contribution of the various actors, the Board reached the final decision through compromise decision making to include both indicators, the more traditional one of complaints and the newer one relating to online sentiment analysis.

In particular, the director with expertise in the field of risk control highlighted the potential predictive value of the information by stating that: "*the sentiment index online can provide an early warning, once the time series allows you to test the data".*

On the other hand, the chairman with experience in auditing and compliance underlined how: "*the complaints index, even if it provides information on the corporate reputation when the relationship of trust with the clientele is already damaged, offers precise indications for the implementation of remedial actions and, in particular, has always been the subject of attention by the inspectors of the supervisory bodies* ".

Overall, the analysis of the discussion within the Board shows that the combination of different skills and experiences gained by the directors offered a solution that also considered the risks and responsibilities of the Board.

4.3 The Organisation

The concept of an organisation as a collective cognitive system elicits that knowledge is no longer only accumulated and created within a firm but is co-created by different actors through collective intelligence.

The case examined highlights how the bank can use external BD suppliers. This specific point highlights a potential weakness of the bank, which does not process the information internally but acquires it from an external supplier. Hence it is necessary to know about the quality of the information acquired, not only because it becomes part of the company's decision-making processes but also because it must be possible to account for it when confronting the supervisory bodies

To sum up, in an organisation as a collective cognitive system, the focus shifts from the processes of internal creation of knowledge to the processes of knowledge transfer.

Hence, interdependencies and knowledge flows between different stakeholders become crucial.

5 Conclusions and future research

Our data reveal interesting findings in two areas. First, we have found evidence of a shortfall in cognitive capabilities concerning BD. Second, we have shown how BD impacts responsibility/control within the board context. This study also points to areas for development at three levels of our analysis: individual directors' cognitive capabilities in relation to BD, the board as a collective intelligent decision maker and a broader view of the big data flows inside and outside the firm's boundaries.

5.1. Implications for future research and practice

With reference to the first aspect, it is necessary to increase the knowledge of the board members in the field of big data, in addition to artificial intelligence and new technologies that increasingly impact the management of companies. We no longer believe that this knowledge is held by single specialist managers. The Board has strategic oversight and control tasks and, today, failing to understand the potential of new technologies appears to be a big shortcoming.

With reference to the second aspect, the Board as an intelligent collective body, we believe that, especially with particular reference to banks, its composition cannot disregard the presence of subjects who have skills in this area. As a result, we believe that there is matter to reasoning on the content of the so-called "fit and proper" regulation, issued on 2014 by the European Central bank which regulates the composition of the boards of European banks. Board members should have the theoretical (knowledge and skills) and practical experience that are indispensable to carry out their functions, which vary according to the specific role and institution. As a minimum, members of the management body must have basic theoretical experience in banking, and additional experience may be required depending on other factors that are important to the particular institution. In detail, the latter currently provides for the presence of members who have basic experience on legal issues and risk control (ECB, 2018 p.10) but do not deal with the issue of technological knowledge functional to the strategic management of a bank.

Finally, regarding the third point, which refers to the corporate level, we believe that another aspect that should be investigated by researchers but is also relevant for practice, is revisiting the design of corporate information flows in light of the relevance of big data. It is important to understand how and who generates the algorithms for the analysis of big data and not take them for granted. We think that a large part of corporate knowledge will be produced by leveraging on big data in the future, and as usual in the rules of the business, it is important to know how to feed, transfer and share knowledge, and also protect it.

When Traditional Sectors go Circular: towards Sustainable Industry 4.0 Value Chains

Inéz Labucay

Department of Economics, Guest Researcher
Dresden University of Technology
01062 Dresden

Abstract

Currently, a range of industries is undergoing a major competitive shift away from unsustainable, energy and resource intensive high-tech to more resource efficient greentech products as a source of competitive advantage. This sustainability turn (although still sluggish in the automobile sector) will force the whole value chain, including small and medium sized suppliers, to diversify as the manufacturing of electric cars will need much less capacity and labour than the production of the combustion engine did and parts can increasingly be printed on demand using 3D printers. At the same time, this shift is characterized by inconsistencies that render this endeavour a particularly difficult one. Wind turbine and electric car manufacturers (considered the core sustainability transition industries), for instance, rely heavily on rare earth elements (Chen and Zheng, 2019) although these elements are at the same time highly risky ecologically due to the extraction of radioactive byproducts, emissions and high energy usage (Pell et al 2019). Therefore, the global sourcing of these sustainability transition industries (Markard, et al. 2012) is highly unsustainable.
Although materials are central to the transition to more sustainable economies, the circularity implications of materials are currently often omitted from the discussion especially as regards design (Peck 2012). Complex materials (Fraunhofer Materials 2016) like plastics compounds used in a wide range of products from automobile parts to multi-layer packages pose particularly severe problems at the end of the use phase of products though. A higher sustainability level at the beginning of the value chain is therefore offset by a lower sustainability level at the end (due to highly complex waste streams) – hampering prolonged product usage and Recycling. Here is where an important role accrues to digitization and standardization in the transformation to sustainable value chains.
The paper analyzes the sketched role of digitization and standardization on the materials/technology level and makes reference to the approach of technological innovation systems (Malhotra et al., 2019, Markard et al. 2012). On a practical level, materials recovered from end-of-life vehicles and post-consumer plastics waste serve as illustrative examples. Based on this, preliminary management implications (derived from the conceptual analysis and to be complemented by an empirical analysis in the mentioned sectors) are formulated for knowledge-based sustainable value chains in traditional industries „going circular".

1 Traditional sectors and the challenge of circularity

1.1 The missing sustainability-digitization link

Currently, a range of industries is undergoing a major competitive shift away from unsustainable, energy and resource intensive high-tech to more resource efficient greentech products as a source of competitive advantage. This sustainability turn (although still sluggish in the automobile sector) will force the whole value chain, including small and medium sized suppliers, to diversify as industry 4.0-automatization allows for bypassing of suppliers by manufacturers (by way of 3D printing) and will cause disruptions in the labour market as well. The manufacturing of electric cars, for instance, will need much less capacity and labour than the production of the combustion engine did and parts can increasingly be printed on demand using 3D printers. At the same time, sustainability transitions like the ones mentioned are characterized by inconsistencies that render their implementation difficult. Wind turbine and electric car manufacturers (considered the core sustainability transition industries), for instance, rely heavily on rare earth elements (Chen and Zheng, 2019) although these elements are at the same time highly risky ecologically due to the extraction of radioactive by-products, emissions and high energy usage (Pell et al., 2019). Therefore, the global sourcing of these sustainability transition industries (Markard, et al., 2012) is highly unsustainable. As a crucial role in industry 4.0 accrues to digitization, concerns are on the rise that improved triple bottom line results like waste reduction and higher rates of recycling may be offset by higher resource and energy consumption resulting from a comprehensive digitization of production and logistics processes (Ghobakhloo, 2020).

In a similar fashion like standardization and modularization before, industry 4.0 has not been focused on sustainability, let alone circularity from the outset. It has originally been established as a concept aiming at increased productivity and facilitating the setup of digital business models based on real-time tracking of production and customer data, making it more akin to approaches like *Design for Assembly* than to *Design for Disassembly* (Bischof/Blessing 2008). Nevertheless, with products becoming data carriers a detailed picture of their 'biography' emerges departing from the production phase, spanning their use phase and encompassing, finally, the recycling/reuse/disassembly of components and materials. This opens up potential for establishing industry 4.0 measures which are not confined to making production processes more efficient but are compatible with the hierarchical levels of the Waste Framework Directive set up by the European Commission in 2008 (Prevention, Preparing for re-use, Recycling, Recovery, Disposal) (EC, 2019).

The Circular Economy (CE) aims at establishing high value material cycles through a cascading system of renewable energy and materials flows comprising both sustainable production and consumption modes which goes beyond approaches confined to recycling (Korhonen et al., 2018). CE models, however, on their part have rightly centred on

substitution and design (reduction of materials' use) at the expense of recycling (recovery) (Di Maio and Rem, 2015) and remanufacture (prolongation of the use phase) which are to be considered as equally important.

While the conceptual overlap between sustainability and the Circular Economy is broad, as exemplified, e. g., in Circular Business Models (Rossi et al., 2020), the case for a joint optimization of industry 4.0 and CE goals is standing on less solid ground. Although it is increasingly acknowledged that industry 4.0 is conducive to building a CE, this claim is poorly backed up by evidence or strategic models to guide further research (Yadav et al., 2020) which is why an industry focused approach is considered crucial, e. g. when developing indicators for building CE business models in sectors such as plastics, textiles and electronics (Rossi et al., 2020).

While the link between digitization and sustainability is obvious when it comes to services, e. g. in the energy sector (e. g., the establishment of smart grids, Radenković et al., 2020), it is far less straightforward in more complex products like lightweight cars made of compound materials which pose challenges for Recycling and Reuse. Also, the plastics (recycling) sector – being part of largely analogue value chains where a large share ends up in Downcycling (e. g., in the construction sector) rather than in Reuse – is still far from being circular. However, recent approaches have explored how digitization and industry 4.0 can contribute to creating high quality waste streams (e. g., by employing high-tech fluorescent markers reflecting light in a specific way depending on polymer type, exact composition and use of materials) thereby increasing circularity in the plastics sector as it reduces the usage of primary plastics and helps comply with the higher recycling quotas mandated in the German Circular Economy Act (BMBF, 2017). Although materials are central to the transition to more sustainable economies, the circularity implications of materials are currently often omitted from the discussion especially as regards design (Peck, 2012). Complex materials (Fraunhofer Materials, 2016) like plastics compounds used in a wide range of products from automobile parts to multi-layer packages pose particularly severe problems at the end of the use phase of products. A higher sustainability level at the beginning of the value chain is thus offset by a lower sustainability level at the end (due to highly complex waste streams) – hampering prolonged product usage and Recycling. Here is where an important role accrues to digitization and standardization in the transformation to sustainable value chains as will be explained next. Standardization both of the formal type (triggered by industry but conducted by standardization bodies) and in its informal variety (e. g., through consortia) will play a crucial role in the adoption of industry 4.0 which remains largely unexplored still (Stolwijk et al., 2017). Moreover, the paper argues that standards act as a linchpin between industry 4.0 and the CE making sure that the latter's potential does not fall short of delivering ecological and social results besides improving economic performance.

1.2 Aim and structure of the paper

The role of digitization in the sustainability transition to a CE is far from being unequivocal considering the sizeable carbon footprint caused by information technology, especially the various streaming services. In the course of the move towards industry 4.0 formerly analogous sectors are relying heavily and increasingly on digitization (manufacturing, the service sector and even agriculture) with the IT sector estimated to be responsible for 4 % of worldwide emissions and expected to exceed the emission share of the mobility sector in Germany within a few years (BMU, 2020).

One aim of the paper is therefore to shed light on the interrelation between high (and expectedly rising) levels of computerization and digitization (in industry 4.0) and the promise of CE. Besides, the role of standardization in the context of the circular economy is discussed and illustrated based on the cases of plastics and the automotive industry.

The paper analyzes the sketched role of digitization and standardization on the materials/technology level. On a theoretical level, the approach of technological innovation systems (TIS) (Malhotra et al., 2019) is combined with the sustainability transitions literature (Markard et al., 2012) to serve as a backdrop of the analysis. TIS are a stream of inquiry which – apart from a few seminal papers– has seldomly been used (compared, for instance, to its regional counterpart and particularly outside energy transition sectors) and has much to offer in terms of Management implications.

On a practical level, materials recovered from end-of-life vehicles and post-consumer plastics waste serve as illustrative examples. Based on this, preliminary management implications (based on the conceptual analysis and to be complemented by an empirical analysis) of how to build knowledge-based sustainable value chains are discussed that may help unleash the potential of traditional industries to „go circular".

The remainder of the paper is organized as follows. Chapter 2 provides a sketch of the function of standards in an industry 4.0 setting and overall for technological development and growth (Tassey 2000, 2017) and links it to the theoretical framework of technological innovation systems. Chapter 3 applies the theoretical background to two illustrative cases (automotive and plastics) acting as benchmark for progress towards not only digitized but also sustainable value chains. Chapter 4 concludes.

2 Standards in industry 4.0 and the Circular Economy

Much of the uncertainty involved in building a CE is rooted in a lack of information. To begin with, the exact composition of plastics compounds may not be available anymore by the time the product is discarded or has reached the end of its lifetime. On the other hand, market related information originating downstream the value chain on consumer acceptance, demand for recycled materials, etc. may not be available at the outset, complicating a coordinated decision making on eligible recycling and reuse channels (Labucay, Xiao and Zhao, 2019). Although high-end cars have been turned into

information platforms, the automobile sector is far from harnessing the potential of digitization to support the move towards more sustainable ecosystems.

The digitization-sustainability link has been mainly explored on the industry and product level (e.g., the dust bins of the ANTA SWISS AG gathering real-time data on replenishment levels in smart cities). Further upstream the value chain, however, the level of materials and technology has been less in focus. Facilitating knowledge and data exchange between materials and their digital twin (Fraunhofer Materials 2016, Blum, 2018) contributes to mitigating supply chain disruptions (Bugert and Lasch, 2018) and increases Recycling and Reuse thereby contributing to building a CE. This is efficiently supported by digitization and standardization (Labucay, 2018). Standards may serve as a linchpin between digitized, industry 4.0 production processes (which on their part require standards in order to run smoothly) and sustainable, CE production processes. With CE standardization still in its infancy, an overview of emerging CE standardization areas is provided in what follows with a particular emphasis on how these efforts may be combined with industry 4.0 standardization which is already farther advanced.

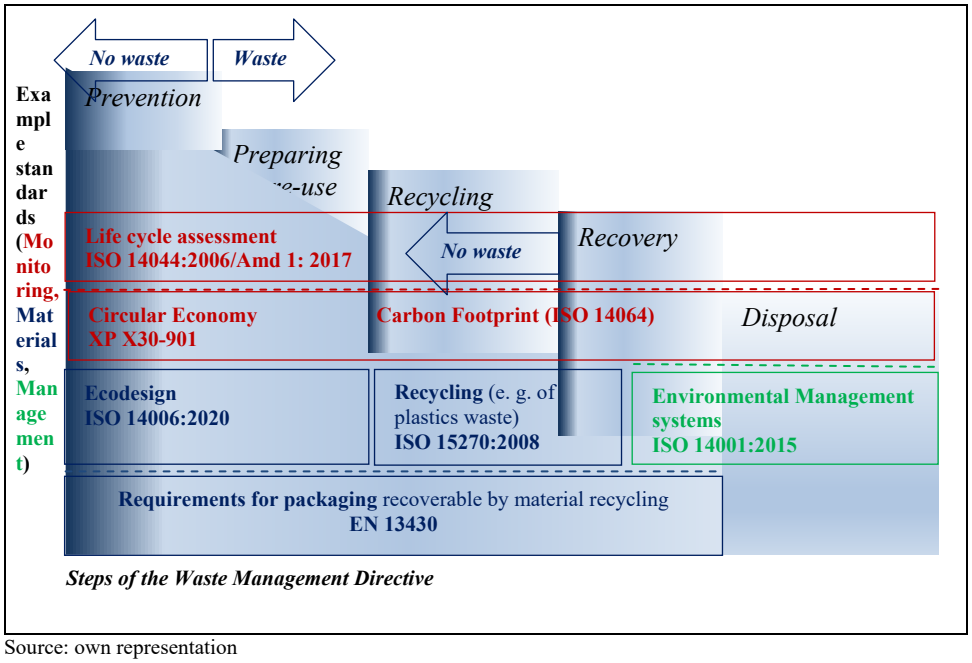
The "birth" of CE standardization coincides with France's presidency of the newly founded ISO technical committee "TC 232 Circular Economy" in 2018 (ISO 2019) which set the agenda by putting the energy sector centre stage in its standardization roadmap. While this appears natural in that the energy sector is amongst the economic priorities of the French government, this choice also helps in building a bridge to longer standing standardization activities in the area of industry 4.0 (with smart grids being the most prominent application area). This French CE agenda itself took shape in the standard XP X30-901 (ADEME 2020).

In the digitized production processes of industry 4.0, standards are required for ensuring interconnectivity between smart machines and existing traditional assembly lines (compatibility standards), for bundling and transmitting information (e. g., on digital designs and production data) to be shared between companies and their suppliers in inter-company supply chains (security and privacy standards for interoperability) and as a means to secure product quality and consumer's rights (quality and safety standards) (Stolwijk et al., 2017). Standards furthermore contributes to further undergirding regulatory measures, e. g. when sustainability standards are referenced in laws and regulations which positively impact on consumer trust building and investment climate. The technological lock-in in inferior lighting technology (unsustainable light bulbs) with LED technology taking decades to take hold in the market was due to the lack of quality standards (Tassey, 2017). Technology cycles are shortened if a timely standardization infrastructure is in place thereby acting as a channel for technology transfer (Frenz and Lambert, 2012).

The *Waste Framework directive* of the European Commission (established in 2008) was the first attempt to formulate EU-wide fields of action which are (in descending priority): *Prevention, Preparing for re-use, Recycling, Recovery, Disposal*. Although the EU directive has originally been designed for energy-intensive sectors it has come to be

applied on a wider scale to all products with high energy usage during their production and/or their use phase (European Commission, 2019) where naturally a range of products are eligible, plastics and compound materials being amongst the first and foremost due to their heavily relying on the chemicals sector.

The following graph provides an overview of how CE standardization is currently evolving. The previously mentioned Waste Framework Directive of the European Commission is matched by standards in the respective fields.



Source: own representation

Graph 1: CE standardization within the Waste Management Directive's hierarchy

Like with other technological innovation systems before, it is promoters and advocates of the CE who influence the dynamic interactions of the TIS components. They do so, e. g., by shaping the development of standards which increases legitimacy as a central function of technological innovation systems and is therefore crucial for the outcome, the technological categories which ultimately become dominant (Berg et al., 2019). In contrast to initiatives aimed at sustainability which reach back until the 1980ies the Circular Economy affords an across-industry and across-value chain approach, i. e. a combined endeavour of product designers, producers, consumers of (e.g., plastic packages) and the suppliers of functional materials (that those packages are made of). In the automobile sector, producers of functional materials, automobile producers and consumers are part and parcel of CE initiatives. This across-industry and multi actor approach to emerging technologies is mirrored in the Cooperative Patent Classification *Y02/Y04S tagging scheme* targeted at technologies which contribute to sustainable

innovation, e. g. by mitigating the adverse effects of climate change. Technological innovation systems come from sectors as varied as transport, building, sewage systems and manufacturing (OECD, 2016). As an illustration, an emerging technological innovation system (CE approaches in the automobile sector) is contrasted with farther advanced initiatives (in the so called CE plastics economy).

3 Illustrative case examples

3.1 The automobile industry as a late-comer CE sector

Circularity has not been amongst the priorities of the automobile sector so far. Approaches like Shared Driving (enabling a more sustainable mobility infrastructure especially in inner-city traffic) and Recycling of functional materials have been the first steps towards a more sustainable business model. In the past, the automobile sector has exclusively centred on approaches which lent themselves to increasing productivity such as standardization of parts and components (aligning suppliers' standards with their own product specifications) and modularity and flexible design (employing generic platforms and product families) which was targeted at *Design for Assembly* rather than *Design for Disassembly* (Bischoff and Blessing, 2008).

Nevertheless, modular and flexible design enabled by industry 4.0 production techniques (Birkel et al., 2019) may serve additional functions besides productivity enhancement, namely the prolongation of a product's life spans through Recycling, Remanufacturing and Reuse. By way of example, Added Manufacturing as a production technique where material and products emerge instantaneously allows for the design of targeted materials with required characteristics (e. g. hybrid materials) (Fraunhofer Materials, 2016) and saves both energy and valuable technology metals, in all relevant stages of production (design, manufacturing, transport, packaging, after sales repair), e. g. the use of tungsten in the moulding of car parts (Kerbrat, 2016). Both carriage and windows of the hybrid car Urbee 2 made by the Canadian company KorEcologica, for instance, are made from printed plastics which allows for different thickness depending on the stability needed as well as for less fuel consumption due to its reduced weight.

Degradation behavior and environmental impact of polymer composite materials over their entire life cycle however are currently still under research. For instance, the behavior of End-of-life-vehicles with heterogeneous compound materials in waste streams is ill-understood, leaving waste management (and accompanying standardization activities) a relatively blank spot (Labucay, 2018). Conflicting aims of sustainability and productivity have hampered a more sustainable design of cars so far. Lightweight materials like carbon fibre composites which are increasingly built in cars (used as stabilizing construction material and in sensors, e. g. in the body of BMW i3 electric vehicle) save energy and transport costs in the early production stages and reduce fuel consumption in the use phase. However, long-term social costs of disentangling the merged components of the

composite materials in the stage of recycling are incurred which are not internalized in current production processes (Labucay, 2018).

The following graph displays the beneficial interplay of digitization (mitigating downside risks by way of information sharing) and standardization (increasing the level of coordination and cooperation on the upside) over the life span of electric cars, starting with their production and including their Reuse and Recycling. A snapshot of relevant national and international standards supporting the different stages are indicated in blue colour.

Graph 2: CE visualization for the automotive value chain

The first automotive company to systematically track their Carbon Footprint (among other factors the amount of greenhouse gas emissions caused by their production processes) has been Audi. Processes at Audi have been certified in accordance with the standard ISO 14064 in addition to a comprehensive Life Cycle Assessment in line with ISO 14040 ff. and the implementation of sustainability standards for its most relevant lightweight material, Aluminium (Tropschuh and Biendl, 2015).

Recycling of NdFeB magnets (the ones built in electric cars) has only recently gained momentum in the EU, partly in the form of collection of magnet scrap from production (with about 40 % of the annual amount of 150 t of magnet wastes being exported to China and Japan for Recycling stemming from magnet production) and increasingly obtained through recovery from applications like wind turbines (Reimer, 2018).

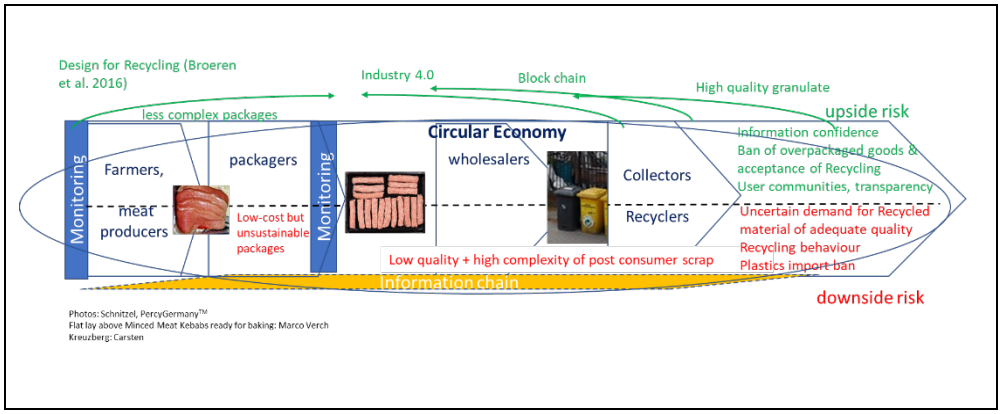
Although recycling of both electronics scrap and high performance magnets is still hampered by a lack of both technically feasible and economically viable techniques, for example at the stage of separation of rare earth compounds (Binnemans, 2013), it is expected that for larger magnets (1-3 kg magnet mass in traction motors of electric cars) containing high quantities of the technology metal Dysprosium (compared to smaller electronic devices), a recycling market will emerge in the near future (Glöser-Chahoud and Tercero Espinoza, 2015: 69f.).

3.2 The plastics sector as a front-runner in circularity

An important step towards a higher resource efficiency in the plastics producing and consuming sectors has been taken by Germany as early as 1996 with its first CE law (Closed Substance Cycle and Waste Management Act) although Japan had set up a national CE law as early as 1991, partly triggered by its lack of own natural resources and accordingly high import levels (Ogunmakinde, 2019). The German CE law has been last updated in 2012 in order to make it compatible with the mentioned *Waste Framework directive* of the European Commission by placing a higher emphasis on Reuse and Recycling (Circular Economy Act, Kreislaufwirtschaftsgesetz). In addition, a system of cascading Recycling fees has been introduced in January 2019 according to which companies pay lower fees with increased recyclability of packaging materials (§ 21 of the German Verpackungsgesetz (VerpG)).

The most pressing problems for managing the Circular Plastics Economy (European Commission, 2018) is the reduction of the usage of single-use plastics items (for which a ban has recently been put in place) and of short-lived plastics packaging.

The following graph provides an overview of how digitization and standardization can contribute to decreasing supply chain related risk (Jüttner, 2005; Jüttner and Maklan, 2011) and to increase the level of circularity along the value chain (e. g., by a higher degree of recyclability) of (especially short-lived foods) plastics packaging by way of employing (standardized) recyclable materials already at the level of Design (e. g., Broeren et al., 2016 for plastics). The WEF mandates the development of across-industry materials of standardized purity (WEF 2014), for example the "de facto standard" of recyclable PET bottles which can be reused for beverages and manufactured into fibres for secondary usage like in the textile and construction industry.



Source: own representation based on Labucay, Xiao, and Zhao, 2019

Graph 3: CE visualization for the food plastics packaging value chain

Companies like the German Werner & Mertz GmbH have rightly reminded that current German CE legislation does not distinguish between post-producer and post-consumer plastics scrap with the latter being a fast and easy way to meet recycling quotas although it cannot be considered to be real recycling as the underlying materials never left the factory; by contrast, the packaging of their Greencare Professional cleaner, marketed under the "Frosch" label, is made of recycled HDPE polymers stemming entirely from post-consumer plastics waste (Werner & Mertz GmbH, 2020).

Although prior approaches had already allowed for an intensive tracking of products along the value chain, e. g. by means of RFID sensor technology, the use of block chain technology in industry 4.0 enables the setting up of a decentralized infrastructure where events in the supply chain are immediately (in real-time fashion) mirrored in a changed information chain (Min, 2019). Data security concerns have to be addressed which can in part be done through a system of access rights, e. g. like in the evan.network of the textile industry which can be transferred to plastics producing and plastics consuming industries.

4 Conclusion

Considering that the majority (88%) of the 14.4 million tons of plastics consumed in Germany in 2017 have been made from virgin plastics and only 12 % from recyclates, it is clear that there is still a long way to go towards a circular plastics economy (CHEManager, 2018). However, some progress has been made towards achieving that goal when allowing for the fact that – for the first time in 2016 – the most heavily used channel of recovery/disposal of plastics has been Recycling (40%), for the first time slightly exceeding the ratio of energetic disposal (38%) and of landfill disposal (20 %) (Plastics Europe, 2018).

The role that standards have been playing in industry 3.0 processes (compatibility enabler, quality signal) are further reinforced in an industry 4.0 setting as the following expert statement from a survey into industry 4.0 risk management underscores: "The market requires technological standards, especially regarding communication and interfaces. The customer does not want to run several systems." (Birkel et al., 2019: 16).

In terms of management implications, a short summary ensues of how CE, standardization and digitization can be beneficially combined. As much of the uncertainty involved in building a CE is rooted in a lack of information it is of interest to monitor information-related supply chain risk (Labucay, Xiao and Zhao, 2019) and to unify the multitude of enterprise resource planning and manufacturing execution systems (Birkel et al., 2019) as their fragmented nature (and of the standards employed therein) poses a risk of its own kind. Cooperative risk mitigation measures by companies that reach beyond the immediate supplier have therefore to be put in place (Birkel et al., 2019; Jüttner and Maklan, 2011; Jüttner, 2005) revitalizing and enlarging existing supply chain risk management approaches (Jüttner, 2005). Apart from particularly risk-sensitive sectors (such as the pharmaceuticals industry, food retailers and chemicals industry), a holistic risk management across supply chain stages (let alone one catered to the needs of closed

loops supply chains) is hardly in place to date (Enyinda and Szmerekovsky 2008) although a recent screening of corporate supply chain risk models showed that 90 % of companies are at least involving more than only the direct supply chain partner (Bugert and Lasch, 2018) and are thus aware that they are part and parcel of larger networks and that management needs to mirror those dependencies. This is where digitization (in the setting of industry 4.0) making logistics data available in a real-time fashion, can help in building a CE at lower cost (e. g. in combination with block chains) and with a lower risk exposure. Technological innovation systems which emerge from making the automotive sector (e. g. the emerging electric cars sector) and the plastics sector more sustainable may induce social innovations, especially if combined with block chain technology (Stanford Graduate School of Business, 2019).

A field yet to be explored by companies is the prolongation of the use phase of products – through repair and reuse at the top of the pyramid of the Waste Management Directive. Particularly for high value machinery, business models have been established by US machines producers which reuse parts of the motor (rich in valuable technology metals) and offer the refurbished machines at affordable prices (Tait and Gereffi, 2016).

Facilitating knowledge and data exchange between materials and their digital twin contributes to mitigating supply chain disruptions (Bugert and Lasch, 2018) and increases options for Recycling and Reuse (e. g., by electronic materials‘ passports) thereby contributing to building a Circular Economy. Standardization and modularization (Gereffi et al., 2005) enable the flexible reuse of elements of the product architecture with the latter being a key element of the Circular Economy (Kalmykova et al., 2018) as reuse prolongs the lifetime of products and contributes to economizing on scarce resources.

The establishment of eco-industrial parks (e. g. of the automobile, chemicals and manufacturing industries) which function based on the principle of industrial symbiosis, like in China and Japan (Yeo et al. 2019), has shown promise as these can be considered seed beds for Circular Economy cycles on a more global scale.

Abstract

Knowledge and innovation are the main strategic keys for creation of new sustainable value of organizations (Dankbaar, 2003; Hayter, 2016). In according to Pacheco et al. (2014), the introduction of new knowledge is a driver for smart and sustainable growth in economic sector. The main producers and disseminators of new knowledge are Universities and Higher Educational Institutions (HEIs). Moreover, the university is opening up towards the entrepreneurial system. The main effect of this strategic orientation of University is the creation of collaborative ecosystems oriented to Knowledge Transfer (KT). This collaborative ecosystem opens reflections, for management and organization studies scholars, on the process of knowledge transfer between universities and firms. In effect, the introduction of new knowledge in traditional sectors, such as agri-business, shows more effects and are more problematic than other sectors. Agri-food organizations are based on consolidated managerial (and knowledge) practices and a low propensity for innovation. The Agri-food sector requires new practices that increase the competitiveness of firms.

In particular, a growing area of research is focusing on the study of the academic knowledge transfer process and on the Key Organizational Factors (KOFs) that influence the KT process. For this reason, the present study intends to analyse the KT mechanisms (with particular focus on academic spin-offs) and KFOs with the aim of understanding the dynamics ecosystem for sustainable value in wine sector. This study is based on an exploratory and descriptive study. In particular, the first objective of this research is to understand the main theories on knowledge transfer phenomenon between university and agri-business firms. In this phase, we analysed some scientific databases (Scopus, Science Direct and Google Scholar). The second phase uses the interview method as a data collection tool on a sample of companies in the agri-food cluster. The

study offers a mapping of main theoretical framework on Academic Knowledge Transfer in agri-business. Furthermore, it provides reflections on knowledge transfer mechanisms between universities in the agri-business sector. The results of this research offer an overview regarding main theories of knowledge transfer and effects of the third mission in agri-food sector. The study can help universities to manage KT's mechanisms more effectively with the aim of generating new business organizations

Keywords – Knowledge Transfer, Academic Knowledge, Agri-business, Sustainable value, Key Organizational Factors (KOFs).

Paper type – Academic Research Paper

1 Introduction

Growth is the goal of any organization. In a hyper competitive context, such as that of the knowledge economy, organizations must adopt new strategies for sustainable growth (Buys et al., 2014). The concept of sustainable growth of organizations, taking as reference the Triple Bottom Line (TBL), refers not only to the economic dimension but also to the social and environmental dimension in which an organization is active. As a result, organizations aim to survive by creating economic, social and environmental value that meets customer needs and produces benefits within society (Romanelli, 2018).

The theme of sustainability, considered as a systemic concept (Buys et al., 2014), in managerial sciences, is recent. Organizational sustainability, in managerial terms, represents not only the economic but also the social and environmental pillar (Machado et al., 2020); that is, a set of guiding principles for the survival of organizations.

The results of Faisal (2010) highlighted how the concept of sustainability at the organizational level has received different meanings and the different meanings could lead to different corporate objectives.

In this perspective, not only economic resources but also environmental and social resources are limited and competition arises to acquire a greater quantity of resources.

From the reference literature, it emerges that the objectives aligned with the TBL should be transversal to the company (Infante et al., 2013).

Organizational sustainability, in its various meanings, focuses on knowledge management and innovation (García-Alvarez, 2015; Gaziulusoy et al., 2013). Innovation based on knowledge, environmental, social and economic criteria allows the creation of a sustainable basis for competitiveness in organizations (Buys et al., 2014). In other words, the innovative skills generated by knowledge can play an essential role for organizational sustainability (Sanders and Linderman, 2014). Developing sustainable new products adds levels of complexity to the traditional process of developing new products, but is equally a potential source of income for the economy, society and people (Thome et al., 2016).

By adopting a perspective based on the sustainable growth of the organization (Heikkurinen and Bonnedahl, 2013) knowledge, and knowledge management, becomes a transversal resource (Infante, et al., 2013) able to combine economic, social and

environmental objectives. This principle assumes a crucial role in the agri-food sector (Prahalad and Bettis, 1986 page 490). The integration of knowledge management into business processes aims not only to protect a company's intangible assets, but also to develop and exploit assets, stimulating the creation of goods and services more suitable for customers.(Nissen, 2005). Business processes are the main elements of connection between the work and skills of the members of an organization and the wishes of their customers (Seethamraju and Marjanovic, 2009), also becoming tools for the implementation and formalization of knowledge management in the company and for the realization of its potential benefits (García-Alvarez, 2015). To the extent that knowledge becomes an essential and strategic resource, organizational success increasingly depends on the company's ability to produce, collect, store and disseminate knowledge. Several studies have shown that agri-food organizations play a key role in terms of environmental and social sustainability. Baregheh et al. (2014) stress that the agri-food industry has a low level of innovation and development of new technologies compared to other sectors. In the conclusions of the work, Baregheh et al. (2014) underline the presence of a growing strand of studies dealing with the key role of innovation and innovative behavior, however, affirm that further research is necessary in relation to innovation drivers or obstacles to the same.

There is no single definition of "agri-food sector". The term "agri-food sector" is very broad and commonly used in research to indicate only the relationships with respect to the "agricultural sector" due to the limited availability of regional statistical data for the agricultural sector (CE, 2007). Therefore, in this study, we decided to adopt the term in a very broad sense in order to ensure the identification of the largest number of variables that influence innovation in the sector. So, with the term agrifood we mean, in this work, all the organizations that are active in the agricultural sector and in the production of food and drinks. Agrifood organizations find themselves in situations where it is necessary to find and implement new innovative ways of creating, providing and acquiring value in order to be able to face existing challenges and emerging opportunities. It is clear that the agrifood sector is unable to generate new knowledge on its own. Indeed, this knowledge could be outside the boundaries of societies (Gaziulusoy et al., 2013). knowledge begins to be acquired through partners, or together they acquire the skills necessary to generate innovation and knowledge thanks to their complementarity (Chesbrough, 2006). For this reason, the agrifood sector can generate new sustainable value through the transfer of knowledge. The concept of knowledge includes information, experiences, beliefs, values, intuitions, know-how and skills. In the knowledge economy, the main producers of knowledge are universities and Higher Educational Institutions (HEIs). The knowledge produced by universities or HEIs is called academic knowledge (Reina and Vesperi, 2018). The study tries to understand the main factors and determinants that can influence the transfer of knowledge from universities (or HEIs) to the agrifood sector and respond to the most important, indeed existential, concern of organization studies (OS).

The study contributes to develop contributions on Key Organizational Factors (KOFs) in agri-food sector. We present the study as follows: after this introduction, the theoretical framework on Academic Knowledge transfer, inter-organizational relationship and Key Organizational Factors, the methodology used; the analysis and results of test. Finally, the main conclusions and suggestions for future research.

2 Theoretical Framework

A vast literature has focused on analyzing the knowledge transfer process from universities (and HEIs). Few studies have focused on agri-food sector organizations and relations with universities. The process of knowledge transfer (especially academic) at an inter-organizational level, has focused the attention of scholars in recent years. The studies carried out by Szulanski (1996), Kostova (1999), Argote and Ingram (2000) laid the foundations for the study of knowledge transfer. To better understand the transfer of inter-organizational knowledge, and the Key Organizational Factors (KOFs) that influence the transfer of knowledge, it is necessary to deepen inter-organizational collaborations.

2.1 Inter-organizational relationship and Knowledge Transfer

Agri-food organizations, and in general all organizations, have different alternatives to acquire and exploit new knowledge. Some alternatives widely discussed in literature have an internal perspective (Osterloh and Frey, 2000), while other alternatives have an external perspective such as interorganizational collaboration (Jarillo, 1988; Kanter, 1989; Santoro and Gopalakrishnan, 2000; Franco and Pinho, 2019). The growing competitive drive and the need for new knowledge has generated a growing need for organizations to overcome organizational boundaries with the aim of safeguarding their own growth and survival (D'Aveni and Gunther, 1995). For this reason, focusing on inter-organizational collaborations, several studies highlight the complementarity between the two organizations that have distinct but mutually synergistic resources necessary to advance new knowledge (Teece, 1987). In inter-organizational collaboration, in the knowledge economy, they are born with the aim of creating and having available new knowledge and skills that individual organizations can hardly access. At the same time, complementarity is a key factor for I / U partnerships. Entrepreneurial organizations also rely on universities to have access to new technologies and knowledge, based on research results, highly qualified students and professors (Vesperi and Gagnidze, 2018). At the same time, business organizations can enjoy an improvement in corporate image and reputation or ease of access to economic resources or university structures (Gagnidze, 2019). On the other hand, universities (and HEIs) interact with the main objective of attracting additional research funding. In addition, universities from business relations access industrial techniques exposing teachers to practical problems and offer job opportunities to university graduates (Piirainen, et al., 2016; Secundo, et al. 2017). This was part of the

university's third mission, often linked to the concept of a triple helix (Stal and Babri, 2020)

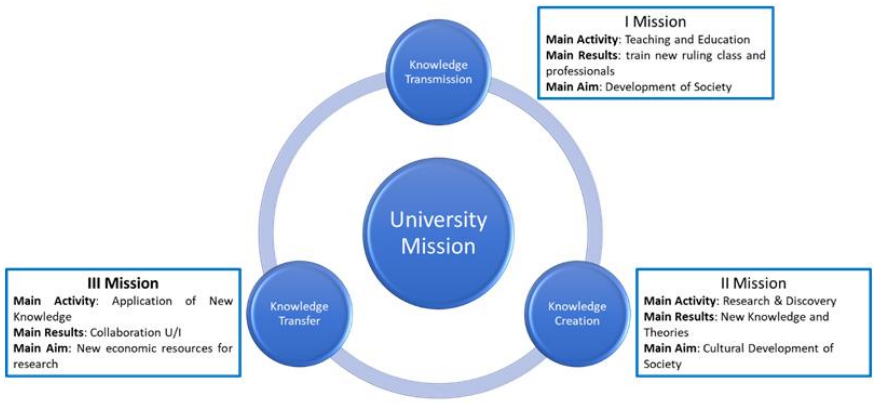

Figure 1 – Framework of the role of knowledge in university missions – Source: Our Elaboration

Although knowledge is characterized by intangibility (Teece, 1998; Mahdi and Nassar, 2019) the knowledge transfer process represents tangible results (Argote, et al, 2000). The process of knowledge transfer, especially academic knowledge, is a dynamic and complex one that requires modeled activities to share knowledge between different organizations. The inter-organizational collaborations, which take place between businesses and universities, consist of a series of specific activities such as joint participation in research consortia, staff exchanges, development of professional training courses or creation of new businesses (spinoffs and startups).

Figure 2 – Framework of academic knowledge transfer process – Source: Our adaptation on Szulanski and Cappetta (2003)

From a Resource Based View (RBV) perspective, the competitive advantage is determined by the ownership and use of a precious resource, regardless of the source, which allows better performance than competitors (Collis & Montgomery, 1995). Furthermore, the RBV suggests that the resource on which the competitive advantage is based must be heterogeneous and sustainable. The concept of sustainable value is not a new approach. The idea of sustainability offers a new way of thinking about organizations by offering new possibilities and new challenges such as an economic performance connected to social and environmental challenges. A definition of the concept of sustainability is given by the 1987 United Nations Brundtland Commission according to

which "sustainable development is development that allows the satisfaction of the economic, environmental and social needs of current generations without compromising the development of future generations" (ISEA, 1999). In knowledge era the sustainable competitive advantage is dependent on exploiting of core and new knowledge in business process. This new focus creates a new declination of RBV, in Knowledge Resource Based View (Halawi, et al., 2005). Creating sustainable value confirms the need to generate triple bottom line benefits for the environment, society and the economy (Evans et al., 2017).

In a complex context, such as that of agri-food organizations, sustainability is closely connected to the ability of agricultural systems to react and adapt to shocks and stress.

the long-term survival of the economic system depends on its ability to create and maintain sustainable economic processes, which involve the creation of value and the satisfaction of current needs without compromising the needs of future generations (Ghisetti et al., 2015).

3 Methodology

The study has an exploratory and indictive nature. In order to achieve the research goal, the methodology is based on a qualitative approach. A qualitative study seemed particularly suitable for the purpose of the research and the complexity of the phenomenon, since it allows to take into consideration the specific characteristics of the context (internal and external) of the organization (Eylon and Bamberger, 2000), as well as to explore the knowledge transfer process academic in agri-food organizations. For this reason, the study started from an analysis of the main literature on the topic of knowledge transfer, inter-organizational relationships and sustainable value. In particular, the study examined the main scientific contributions, in order to define the main Key Organizational Factors (KFOs) that influence the process of transferring academic knowledge to agri-food organizations. The collection of the articles took place through the consultation of scientific databases. Subsequently, the case study was identified. A cluster of small organizations (in Italian consortium) in the agri-food sector has been identified as a case study. The cluster is made up of around 50 small organizations, set up with the aim of helping participating organizations to be more competitive. Interview are used as collection method. Through a semi-structured interview, according to the methods and instructions suggested by Yin (2009), we tried to validate what emerged from the literature. The interview, lasting about 45 minutes, was conducted by a researcher who proceeded to record the conversation (with the interviewee's consent) anonymously. Subsequently the interview was listened to several times, in order to better understand the answers and the connection with the research question. The main results were emphasized in the discussion section. In order to increase the quality and quantity of the information collected, the authors carried out an analysis of the cluster documents. This methodology establishes its main limitation of the generalization of results. The aim of this study is not to draw conclusions of universal validity, but rather to draw some suggestions for further

and more in-depth analyzes on KOFs and the transfer of academic knowledge and its organizational impact.

4 Results and Main Findings

The results of this study can be divided into two categories: theoretical and empirical. The first macro category of results is derived from the analysis of the main theoretical references connected to the phenomenon under investigation. From the literature, we have identified a series of KOFs that can influence the AKT. The main theoretical reference is represented by the 7-S framework model proposed by Santoro and Gopalakrishnan (2004). The complexity of the AKT derives from the inter-organizational relationship between university and business (Gamm, 1981; Dill, 1995; Bozeman, 2000; Nieto and Santamaría, 2007). At the same time, the characteristics of knowledge represent an additional element of complexity. Although a vast literature on the subject identifies knowledge as a strategic resource (Yair, et al., 2001; Amin and Cohendet, 2004; Zaim, 2019), the characteristics of immateriality (Manikas, et al., 2019) and the connection with universities make the process of transferring it particularly complex.

Table 1 shows the main key organizational factors that emerged from the literature.

Table 1 – Key Organizational Factors (KOFs) – Source: Our Elaboration

Key Organizational Factors (KOFs)	Main References
Type of Academic Knowledge	Thorburn, (2000); Sekeran, (2003), Langford, et al., (2006); Susanty, et al., (2012); Vesperi, et al., (2016); Neves and Franco (2018).
Organizational Culture	Lahti and Beyerlein (2000); Lee and Suliman (2002); Gibbert et al., (2002); Cummings and B.S. Teng (2003); Chuang, (2004); Ko, et al., (2005); Yang e Chen, (2007); Susanty, et al., (2012); Alattas, and Kang (2016);
Organizational Structure	Lahti and Beyerlein (2000); Hall (2001); Lee and Suliman (2002); Gibbert et al., (2002); Goh (2002); Peachey, (2006); Girdauskiene, (2013); Gonzalez and De Melo (2018)
Information Technology System	Hendriks (1999); Bolisari and Scarso, (1999); Lee and Suliman (2002); Syed-Ikhsan and Rowland (2004); Malhotra and Majchrzak (2004); Yang and Chen (2007); Peachey, (2006); Pandey, S. C., (2018)
HRM	Szulanski (1996); Goh (2002); Tsai (2002); Cummings and B.S. Teng (2003); Zheng et al., (2010); Lee, et al., (2013); Sanchez-Vidal and Sanz-Valle, (2018)
Rules of University for KT	Bailetti, (2011); Berbegal-Mirabent (2015); Hayter (2016); González-Benito (2016); Vesperi, et al., (2018);
Intensity of collaboration with the university partner	Benneworth, and Charles (2005); Bstieler, et al., (2016); Ghomi and Barzinpour, (2018); González-Benito (2016); Guerrero, et al., (2016);

The results of this study identified some KOFs, in consideration of the ability to achieve the effectiveness of KT. The study identified some factors: IT system, human resource management, structure, culture, intensity of collaboration with the university partner and the university's role for KT. In literature, the authors have often given different names to these key organizational factors, even if they mean the same concept. For this reason, we have decided to adopt a very broad classification which could bring all the definitions provided.

The second category of results is of an empirical type deriving from the interview with the head of the cluster. In the first instance, they were asked to define their own concept of "sustainable value". The interview showed that the concept of sustainable value is certainly intended as the creation of economic, financial but above all social and environmental value. Hence, the creation of new sustainable value is generated by the search for a balance between the various aspects. In the agri-food sector, the connotation of environmental value emerges from the interview, is generated both through the bio treatment of plants and through the recovery of traditions. While, from a social point of view, the creation of value is generated through the hiring of young, unemployed or disadvantaged workers. This aspect generates an indirect value for society, namely the contrast to undeclared work and exploitation.

Subsequently, an attempt was made to investigate the KOFs, through an interview.

Key Organizational Factors (KOFs)	Main References in interview
Type of Academic Knowledge	The acquisition speed depends on the type of academic knowledge transferred. The transfer of new knowledge regarding the care of plants has very slow times, especially linked to a discussion of biological times. The introduction of new technology, on the other hand, is faster.
Organizational Culture	Organizational culture can represent the main obstacle to the transfer of knowledge. In particular, mainly manual and operational value, traditions and operating practices are deeply rooted in the culture of agri-food organizations. Furthermore, the presence of entrepreneurs who are not prone to change can slow down the process of absorbing academic knowledge
Organizational Structure	The organizational structure in agri-food organizations is rigid. There are small organizations in the cluster, often on a family basis. Not very relevant.
Information Technology System	IST in agri-food are of two types. Those related to the production and management of plants and those related to the sale and post-sale (tracking, packaging, etc...). The introduction of new knowledge in the first category is very difficult. Instead in the second category there is a great need
HRM	It is the main tool for introducing new knowledge within agri-food organizations. Hiring young graduates or those with international experience is a way to convey new knowledge. Same principle for the support and staff.
Rules of University for KT	The current relationships with the university consist of training placements and experimental theses
Intensity of collaboration with the university partner	It is very difficult for single small or micro-sized organizations to make agreements with research institutions or universities. The criticality also lies in the technical times for the stipulation of often very long agreements. There is a need for contracts and institutional relations with research bodies and universities both locally and nationally

The interview also shows that often the introduction of new innovation (or more generally of knowledge) is often hampered also by the financial aspect. A second revealing aspect is the morphology of the soil and the particularity of the plant.

5 Conclusions

The study identifies and analyzes the main organizational factors (KOF) that influence the transfer of academic knowledge in the agri-food sector. The results achieved are of

two types. The first deriving from the review of the main theoretical references, which brought to light the main KOFs identified by scholars. The second type of results, related to the interview, highlighted further aspects not emerged from the literature review. The study tested the KOFs identified with a case study.

In particular, "Type of Academic Knowledge" is a controversial KFOs. While in literature it represents a generic and very broad element, from the empirical validation it emerges that these KFOs must be divided into two aspects. The type of academic knowledge transferred assume a different relevance according to the phase of the production process in which it is inserted. In production, academic knowledge appears to be of little relevance, while, in post-production phases, it assumes a greater relevance. KOFs referring to "organizational culture" are very relevant, and can represent the main obstacle to the introduction of new knowledge. The KOFs "Rules of University for KT" and "Intensity of collaboration with the university partner" which in literature are often considered complementary, are defined in the interview as opposed to their importance. While the "Rules of University for KT" appear not very relevant, the degree of "Intensity of collaboration with the university partner" is instead considered very relevant. In this regard, organizational dimensions often impose agreements and programs shared at national or territorial level. This study may represent a first element of reflection in the debate on the transfer of academic knowledge and the influence and the agri-food sector. In particular, it can help understand how the results of academic research can promote value in a particularly complex sector such as agrifood characterized by a low level of innovation and absorption of new knowledge. The study is not without limits. In particular, the theoretical part needs further implementations. The theoretical results must be implemented and more validated through a greater number of interviews. In addition, he must understand if there are other factors that have not yet emerged. From a practical point of view, the study highlights how knowledge, in particular academic knowledge, has become a strategic resource for businesses. For this reason, those responsible for the transfer of academic knowledge and entrepreneurs are called upon to encourage the introduction of new knowledge within organizations in order to survive and compete on the market. Successful knowledge transfer therefore becomes vital for organizations.

Abstract

Seems that many organizational needs are to be matched with a simple solution of digitalizing the operation or a part of it in order to support and to develop it. The information technology (IT) -related skills and capabilities are different in different organizations and the level of know how varies similarly. In practice this interprets to the operation needing support to realization of the intended digitalization measures, basically in every case. We present two cases of digitalization. One, in which a smart city initiative was introduced and implemented to a city in Finland, large in its context and another in which a web-based open source service was implemented for municipalities and companies that enables digital application of construction permits and other permits related to infrastructure. The cases show that the quite technical-sounding issues require simultaneous human aspect to be taken into account. The support needed covers the technological aspect, but it is advisable not to forget the human side either. The organizations offer various kinds of measures to match the needs of their employees, but the ability to take on the support needed and presumptions to assess the need for this are different resulting in various amount of support offered, needed, expected, and accepted.

Keywords – Digitalization, Experimenting, Smart city, Support

Paper type – Practical Paper

1 Introduction

Digitalization is a 'buzzword' one encounters in many contexts and surroundings these days. In public discourse and in everyday news but also occasionally in more official statement's digitalization is sometimes seen as an omnipotent solution for many a problem and an answer to various challenges both in private and in public sector organizations. In our paper we focus on the phenomenon in the public sector and services related to public services to keep the observations within a manageable scope. The

previously mentioned problems and challenges may have something to do with the rigid and unyielding organizational structures or with costly ways of offering public services. The public sector is largely just about providing services to the citizens (De Vries et al., 2016; Higgins, 2017). One is also able to read news about digitalization being a solution to match a growing need of improved service offering; services come in various shapes and forms. This is obviously quite easily said. At the same time, the public sector in general is faced with a growing pressure to streamline its operation and to reduce costs. All these factors: the citizens' increasing expectations for better and more refined services, the public pressure to gain more outcomes from different operations and the pressure to reduce the use of resources, form a situation that gives a very difficult problem to solve. In order to respond to the demand public organizations have launched multiple various digitalization and smart city initiatives (Bakıcı et al., 2013; Denhardt and Denhardt, 2015; Taylor Buck and While, 2017). Digitalization, by definition to create and execute "changes associated with the application of digital technology in all aspects of human society" (Stolterman and Fors, 2004, p. 23), may indeed change the way employees interact with one another, their places of employment, and their actual objectives and goals of working as well as to how they perform their tasks (Parviainen et al., 2017). A fundamental question is whether this may be made into an 'everyone wins' type of situation, giving employees larger personal freedom and enable creativity at work, while simultaneously increasing productivity in organizations, and providing citizens with improved (self-)services. If this is indeed the case, how can it be achieved, what kind of support does it take to make this happen?

2 Cases and background

2.1 Case Digiprogram

The *Digiprogram* was a subprogram of a smart city initiative. The larger initiative was originated by the city's top management of which the CIO is a member of. The *Digiprogram* was initiated in the city's CIO's office where the headquarters of the program would be. A program manager was appointed along a few other staff members at the CIO's office, but the main focus would be elsewhere, in the service areas. Already in the planning phase some areas proved to be more eager, some at least willing, to take part in the initiative were recognized. The *Digiprogram* then committed a number of city employees from these areas to act as project managers, another number of people to be related development managers. In addition to these, there were also steering groups to oversee and guide the endeavors.

The program itself consisted of numerous experiments in the various service areas of public administration in the city. The ideas for the experiments stemmed from the service areas as there was the outlook and vision on what and how the digitalization could be made the best use of. The objective of these experiments was to scout whether there

would be emerging service innovations that may be later applied and upscaled to permanent service offerings of the city administration (Hellsten and Pekkola, 2019). In addition to the mere experimenting, the overall attitude towards improving the city administrative operation through experimenting with digitality was regarded as an additional target for development. Goes almost without saying, but these executed experiments varied by their nature. They came in various shapes and sizes; some were smaller (how to conduct day-to-day conferencing more effectively by using econferencing, such as Skype), some rethought their whole operational process anew.

The people involved were ordinary workforce of the service areas. Perhaps with the exception that they were more eager than average person in the city's payroll to participate in such initiative (as at least some of them volunteered to this program). Not necessarily always when it comes to their technical capabilities, but their attitude was the key. To summarize, the program aimed at finding out whether it would be possible to come up with innovations providing interoperable, high-quality public sector services via digital channels to improve cost-efficiency, create savings, and generate benefits. As beneficiaries may regarded everyone, from citizens, to businesses, to organizations and to local and government authorities. All these need new solutions that are easier to use for the end user but also cheaper to produce and use for the offering side (Helander et al., 2020; Hellsten and Pekkola, 2020).

2.2 Case Lupapiste service

Lupapiste is a web-based open source service that enables digital application of construction permits and other permits related to infrastructure. *Lupapiste* service was developed as a part of Action Program on eServices and eDemocracy (SADe programme) set by the Ministry of Finance in Finland (Saarijärvi et al., 2016). The program aimed at providing interoperable, high-quality public sector services via digital channels to improve cost-efficiency, create savings, and generate benefits to citizens, businesses, organizations and local and government authorities. Special attention was paid to the achievement of cost benefits to municipalities. *Lupapiste* was one of the sub-projects in the program coordinated by Ministry of Environment. After a competitive bidding, Solita Inc. was chosen as a service provider for *Lupapiste*. *Lupapiste* service was developed in co-operation with municipalities that worked as pilots in the project, and later during the evolution of the service the ownership was transferred to Evolta Inc. a spin-off company from Solita Inc (Helander et al., 2020).

Lupapiste service is today used in about 60 % of Finland's municipalities and there are currently about 100.000 users ("Lupapiste" 12.06.2020). In this case 16 interviews were conducted with corporate representatives operating in construction, city planning, architecture and electric engineering (Table 2.). The interviewees used *Lupapiste* service in their work regularly and applied for permits in various fields (architecture, electric

engineering etc.) and in different municipalities in Finland. The overall user experience was positive and the interviewees felt that the service has lightened the application process of different permits.

3 Research settings

In this paper, we report findings from two single case studies (Yin, 2008) involving *Digiprogram* in the city of Tampere, Finland (with appx. 230,000 inhabitants and 15,000 employees in +2,000 sites) and *Lupapiste*, a nation-wide service aimed at streamlining the building permit application and following up the possible granting thereof for various parties around this theme. The city officials recognized and acknowledged existing systems and services being no longer up-to-date or even appropriate.

The city has set up a smart city program, of which the *Digiprogram* is a part, to modernize its operations. The *Digiprogram* in the longer run aims at developing digital services to facilitate the everyday life of the city residents, improve their wellbeing and security, promote smoother migration to and mobility within the city, and create new businesses by enabling cooperation among various stakeholders ("Smart Tampere," 2017). Similarly, the authorities overseeing the area of services among the building and construction permit in the national ministry level together with *Lupapiste* administrators saw the need for updating the service model and possibilities to streamline the services as a whole through well-planned digitalization initiative. Various other development schemes and aspirations about digitalization also exist at the national level.

In the case *Digiprogram* the city CIO's office manages and provides ICT services to different departments and units, ranging from the top management to the city customer service. The stakeholders have different needs and capabilities in using various technologies for their work. The number and the complexity of the ICT systems pose challenges for users and the management as well as to the citizens. To understand the potential impacts of the smart city program as a whole and its *Digiprogram* in particular, we conducted a set of semi-structured interviews to collect qualitative data from different parts of the city. The CIO recommended interviewees from various projects within the *Digiprogram*. Snow-ball sampling (Morgan, 2008), ie. asking the interviewees to recommend potential candidates for future interviews, stakeholders with knowledge to share, was also used to seek the best sources of information. In total, 20 face-to-face interviews visible in the Table 1. were conducted.

Table 1. *Digiprogram*; interviewees in the city administration.

Position
CIO
Program manager
Productivity controller
ICT manager (AK)

Service designer
Enterprise architect
Digimarketing manager
Development manager (city planning)
Development manager (customer service mgmt)
Development manager (employm. services, SO)
Project manager (city concept)
Project manager (city planning)
Project manager (customer service)
Project manager (early education, pre-school HK)
Project manager (employment services, JT)
Project manager (employment services, MV)
Project manager (grammar school)
Project manager (infrastructure; tram project)
Project manager (space allocation, JS)
Project manager (town planning)

The interview themes were discussed with the CIO and some of his key staff member before starting the actual project and suggestions were dealt with in order to clarify the best ways to approach the theme. The studied themes were based on the city strategy and reflected the program objectives and their 'surroundings'. After the initial talks, the objectives were formulated into themes and subsequently questions. A plan on how to execute the interviews was made. The interviews focused on the initial phase and the foundations of the *Digiprogram*, including the resources, participants, and impacts. Additionally, questions about the process itself were included. The interviews, lasting 60 minutes on average, were audio-recorded and transcribed.

The data analysis followed the interpretive research approach (Walsham, 2006). The first author in the project acquainted himself with the material to form an overview of the topic and each interview. The issues identified as potential impacts and their background were labeled and listed for later use. Process diagrams and stakeholder maps were also drawn and iterated with the city representatives to see how they corresponded to the eventual issues. All findings were collaboratively discussed among the authors and with the city representatives to ensure the accuracy of the interpretations and the conclusions. Finally, the findings were compared with those of the existing literature.

The *Lupapiste* service empirical data consist similarly of qualitative interview data. The qualitative interviews (altogether 16, depicted in Table 2.) were semi-structured and they were mostly conducted by one researcher, whereas content analysis and multiple researcher triangulation was used in the analysis of interview results. The interviews contained a small survey (more later in Table 3) with the Likert number-scale to help to tackle especially the analysis of feelings regarding support and communications about and within *Lupapiste* service. This survey was analyzed by going through the empirical

material and recognizing and classifying the themes pointing towards various formats of support and other emerging phenomena.

Table 2. Lupapiste service; interviewees in companies.

Company	Roles of interviewees	Number of interviews per company
Architecture office	Construction design Design/Architect	2
Engineering office	Project manager	1
Energy company A	Project managers	2
Energy company B	Regional manager, Field planner	2
Energy company C	Network engineer	1
Energy company D	Developers of district heating, Network engineer, Developer manager of electronic network, Designer of electronic network	5
Infrastructure company A	Technical assistant	1
Infrastructure company B	Project designer, communications network, Planner, documentation	2

4 Findings

The *Digiprogram* entailed a number of experiments testing a number of various approa ches to ease the operation with digitality-related tools. The experiments comprised both functional and technological ideas, novel in their surroundings. This manifested itself through the fact that the idea of the 'digitalization' concept varied significantly between the departments. In some areas and departments, digitalization meant that they used Skype for conferencing or customer contacts while in others the whole process itself was considered when digitalization was planned to be implemented. The planned benefits of Smart city program were mostly the experiences from the experiments: how these issues should be addressed in the city operations and on what organizational level, not direct and simultaneous benefits for the citizens.

The support offered to different experimenting 'teams' thus varied significantly. Similarly, the level from which the personnel started their 'journey into digitalization' was quite heterogeneous. The CIO's office offered technological and technical support to consult and assist when and where needed as the area to which the digitalization was to be implemented varied as did the type of intended digitalization itself. This support was in forms of various technologies regarding the intended case-specific need. The CIO's office needed to use their resources to assist the project managers in their tasks, which meant familiarizing themselves with some newer features and technologies in addition to those they already had in their disposal.

The support in *Digiprogram* became physical in 'the program days'. Every Thursday was dedicated to the program issues. The project managers thus assembled on Thursdays on the invitation and under the command of the program director. The Thursdays contained training, for example in procurement and acquisitions in the public sector and to discuss current issues and urgent emerging matters, ie. offer and get peer support for

and from one another. The program days were very well-liked feature. The interviewees were in unison that this particular activity, trainings and discussions, gave them the most important support. Even if the precise training on a given day wasn't quite the most urgent theme, they were accepted because during the day the thoughts and opinions could be discussed with project managers in the similar situation. Also, the possibility that the issues in the trainings would emerge in one's own project was seen a noteworthy one, thus motivating the participation in the shared experiences.

We were able to recognize that the overall experience with the usage of *Lupapiste* was positive in the various companies and fields (Table 3). All the interviewees recommended the *Lupapiste* service to other companies. The system in itself was easy to use, most of the users only participated in the initial introduction seminar held usually together with the municipality and the service provider. The *Lupapiste* service survey reveals that nine out of 16 responders have not used the *Lupapiste* service customer support at all and at the same time 13 of them found the user experience satisfied (values 4 and 5).

Table 3. *Lupapiste* service survey.

Answer/responders 16	**0 (zero = has not used**	**1**	**2**	**3**	**4**	**5**
Lupapiste service helps significantly building license application process				5	6	5
I am satisfied with the features in the Lupapiste service				3	13	
I am satisfied with the Lupapiste service providers willingness to develop the Lupapiste service				5	6	5
I am satisfied with the company accounts characteristics and features				5	7	4
I am satisfied with the user experience of Lupapiste service			1	2	10	3
I am satisfied with the customer support and help of Lupapiste service	9			1	3	3
I am satisfied with the user training of Lupapiste service	5		2	3	4	2
I am satisfied with the communications regarding the Lupapiste service				8	7	1
I am satisfied with the municipalities' efforts regarding the implementation of Lupapiste service and the efficient use of Lupapiste service (one responder did not want to give an estimate)		1	1	5	8	

The communication in the system (front page news and chat) and from the system provider (emails, newsletters) was considered good and sufficient. However, the cooperation between the authorities within the various institutions of the municipalities was perceived as a challenge, and the operating methods were not the same in the

municipalities. This lead, to that the corporative users had to deal with a different set of rules depending on the municipality although the information system remained the same in each case (Helander et al., 2020).

The networks inside *Lupapiste* service as well as outside with project group, were considered essential and significant. The *Lupapiste* service is only a part of the construction project, but the network remains almost the same in the *Lupapiste* service during the project. The communication and chatting with the project network inside the service with the different participants was considered useful, for instance the municipality could inform the applicant that a new document was needed, or experiences were shared etc. The *Lupapiste* service was used in some cases as communication base for the different actors in the projects, and this was possibility perhaps not originally recognized when creating this digitalization project. A specific, more permanent, user group, ie. a network of related parties did not spur overwhelming interest, even if it was not completely rejected. Mainly the respondents were shy of this because it represented yet another time-consuming endeavor to an already packed daily life of everyday business. Instead, an annual gathering, a conference of a sort organized by *Lupapiste* itself was proposed.

5 Conclusions

We conclude that the support, whenever digitalization is concerned, cannot well be defined conclusively without acknowledging the intended target of implementation. Having said that, there are a few issues that stand out: sufficient technological expertise and consultancy to support emerged ideas, well executed communication about and around the operation, and sufficient peer support to give space to uttering the sentiments and getting confirmation to one's thinking from one's equals.

Perhaps the biggest impact of digitalization was that the objects benefited from learning a new culture and how to make this happen. The processes and the attitude towards the innovations as a whole were largely perceived positive. The city operations are now more visible for internal stakeholders, and the city's organizational culture has moved towards a more modern, innovation friendly atmosphere. Similarly, the *Lupapiste* has taken a step towards more modern modus operandi through the same motions and notions.

The change towards digitalization requires vision, knowledge, and technical skills, but also understanding of an overall situation as well as the context. The organizational culture and the processes facilitating the actions are essential. Thus, a need to replace the old ways of working with the newer ones emerges. Still, before this can happen, old practices need to be unlearned and new ways of working need to be learned instead. This whole process needs support from the organization. The support is needed from the organization itself, the management and the peers in order to make the innovation successful and the change happen. Some issues need to be further developed. These include for example the support to recognizing the uncertainties in the individual tasks

and their connections as well as to make them even. Similarly, defining and setting expectations and objectives need to be clear for all stakeholders, sometimes they cannot do this by themselves. Even if the improvement actions were commonly agreed, the actual steps how to meet them, were not always clear. For example, the mere definition on what is meant by digitalization varied; is it about the processes or the tools? And again, when something is 'good enough' and 'what is enough'. These kinds of initiatives are a combination of technological innovations with a change to prevailing attitudes. The relief of the humane resistance for change can be supported by actively involving the personnel into the initiatives and empowering them to active members of the operation.

There are several limitations for this paper. This is just of two cases, even if the other one has more experiments. However, we argue that it is plausible to assume that similar settings would provide comparable results. Hence, further research is needed. Secondly, we derived the conclusions from the data. This needs more validation.

Abstract

A conceptual model focuses on the supply chain finance (SCF) built on Blockchain technology (BTC). The model, derived from the advantages of BTC, i.e., transparency, security, immucable, is assumed to construct information sharing among supply chain members to optimize the financial transactions across boarders, different currencies. Some use cases of BTC were illustrated by the definition of disruption innovation. The optimized decision of SCF can be drawn upon learned price discounts that are beneficial to supply and buyer sides.

Paper type – Practical Paper

1 Introduction

Blockchain is a distributed ledger technology that facilitates peer-to-peer transactions. First introduced in 2008, blockchain technology (BCT) was originally built as a platform for trading Bitcoin (Nakamoto, 2008). Some unique features of blockchain technology available to its users include anonymity, transparency, and immutability. Blockchain-based approaches can bring the opportunity to drive business value throughout their supply networks. By monitoring events and metadata associated with a product,

Blockchain can provide security, greater information transparency, access to trusted, secure, and unaltered information.

To understand better how Blockchain can help knowledge management, four key components of knowledge management are reviewed (Lawson, 2003):

- Knowledge creation: the conscious effort to search and define relevant knowledge and its sources from both within and outside an organization.
    - Certain standard operating rules or knowledge of platform will be established when introducing an innovative use of existing technology or adopting brand new technology.
    - Using historical transactional information to predict a new discount rate or bid information for the future transactions.
- Knowledge storage: at this stage, storage and retrieval mechanisms are developed to enable effective and quick access to knowledge.
    - Blockchain provides decentralized data storage features and relies on private keys (Deloitte, 2017) to securely store data locally.
- Knowledge transfer: it is the process of transferring codified knowledge to meet the specific needs of users for knowledge.
    - Blockchain offers transparency in transferring information or transactions.
    - Blockchain has immutable and irrevocable properties, which makes sharing information effective and ensures traceability (Deloitte, 2017).
- Knowledge application: denotes the use of knowledge in new situations where users can learn and generate new knowledge.
    - Transparency in transactions ascertains the origin of data though its linked chains (Ali et al., 2018).
    - While there are different customs, tariffs, and digital documents crossing national borders, the applications are modified based on the existing information or operational rules.

From a business perspective, enterprise blockchain possesses three main characteristics: 1) transparency to complex business processes; 2) tamper-resistance to business processes; 3) streamlined work orders across different currencies/borders.

2 A Disruptive Innovation - BCT

Do these characteristics make BCT a disruptive innovation? Is BCT a disruptive innovation? Its destiny is yet to be determined. Innovation is considered disruptive when a well-established incumbent business structure is successfully challenged by one with fewer resources (Christensen et al. 2015). Using technology in new ways to increase efficiency in business processes improves alignment with business goals. According to the third global survey of Blockchain by PricewaterhouseCoopers (2019), it found that only 15% of blockchain implementations went fully live. The rest was in progress, development, or in research mode.

BCT may have the capacity to transform the relationship between businesses (B2B), their customers (B2C), and also, regulators. The success of blockchain disruptiveness is heavily reliant on the modification of the blockchain system to fit business needs in specific industries. The BCT adoption interrupts the business processes of various industries. However, is it a worthwhile trade-off to endure the disruptions for more streamlined business processes?

Due to the increasing adoption of Blockchain, there are consortiums formed, i.e., R3, Hyperledger to provide necessary transparency to participating members enterprises, industry-leading standards from various industry leaders. The International Standards Organization (ISO), International Telecommunication Union (ITU), and the U.S. National Institute of Standards and Technology (NIST) are driven to formulate a protocol that prevents security threats, administrator risks, and cyber-attacks.

3 BCT Use Cases in Various Supply Chain Management (SCM)

SCM comprises stages involved in the planning, controlling, and execution flow of goods and services. These stages range from the early stage of acquiring raw materials, then the production of the goods/service, through distribution to final products. SCM helps organizations manage the information flow, financial transactions along with products/materials/assets beyond the physical boundaries of the organization. The complexity of supply chain networks depends on the different actors. They include suppliers, distributors, manufacturers, retailers, and end consumers. Members of forecast-driven supply chains generally focus on estimating demand at the next link in the chain and consequently often face problems created by poor forecasting, which results from a lack of transparency of the actual demand (Shih et al., 2012). An effective solution to such problems is to promote the efficient flow of information in the supply chain.

Lacking transparency, tracking, and security in multiple layers and facets of SCM, the BCT platform may alleviate these challenges to provide process efficiency/integration, multiple direction updates, concurrent planning. As indicated in Figure 1, innovation-driven enterprises may leverage change to add business values and realizations. For example, Walmart and Maersk are both located in the high disruption and high innovation quadrant. The innovation of Blockchain brings business values worthwhile for disruptions in business processes.

Using the traceability function of Blockchain, Everledger, RMG, and Mycelia have each used Blockchain to register and record objects of high value. Everledger is a hybrid model, i.e. a combination of public and private blockchains that is used to permanently record and digitally certify diamonds. Similarly, RMG keeps records of gold using this technology. Finally, Mycelia uses BCT to keep records of proof-of-ownership for artists. Because in these three cases, BCT is used simply to keep records with no major industry disruption, in a manner that has little to do with innovation, we place them in the low disruptive-low innovation quadrant.

Maersk partnered with IBM in a Joint Venture (JV) to design a trade digitization platform intended to completely transform the process of international shipping. In 2018, this JV debuted their trade digitization platform and made it available to other players in the shipping industry including their competitors as a way for them to revolutionize and streamline global trade by utilizing blockchain technology to drastically increase the efficiency and transparency of global shipping processes around the world. Should this platform be adapted across this industry, this highly innovative use of BCT would be highly disruptive to an existing process.

Although not nearly as disruptive as the global shipping industry, Walmart has also partnered with IBM to use BCT to facilitate origin tracking of produce from farmers to retail stores. This use of Blockchain digitally tracks the movement of products both domestically and internationally, keeping track of data such as farm origin, batch numbers, factory and processing data, expiry dates, and other shipping details. While this is a brilliant and innovative use of BCT by Walmart to food supply chain management and logistics, it does not revolutionize the entire industry as drastically as the Maersk platform. Hence, we consider this use of BCT to be less disruptive, as seen in our quadrant diagram.

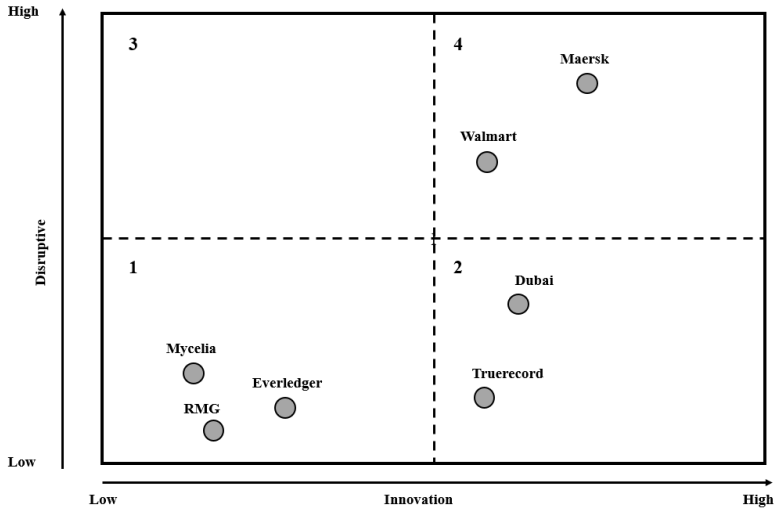

Figure 1: BCT Potentials to Accelerate Supply Chain Management

4 Supply Chain Finance (SCF) on BCT

Due to the increasing level of competition and risk from globalization, many enterprises encounter multiple challenges within their businesses. First, due to the information asymmetry, double financing, which means the same expenses are being financed twice from different sources, is considered a major concern within the supply chain. Another critical challenge is the difficulty of validating transactions, which makes

it an easy way for money laundering. System integration, trust and communication are problems among supply chain partners. The system integration is mostly centralized without scalability. Moreover, the inputs that are localized in the enterprises' internal databases make it impossible for supply chain forecasting, leading to low visibility among the supply chain partners. Indeed, a lot of unnecessary, redundant, procedures are not streamlined within their businesses. It is, claimed, the support of the business eco-system is lacking.

In SCM, the main challenges derived from complexity and uncertainty in business workflow come from different financial platforms to support each business transaction. The BCT provides digital footprints on each business transaction of SCM, as well as the shared information. The finance of each business transaction, however, may need to be strategically planned to save costs. The digitization of the whole value chain can bring all SCM channel members together into a digital, proactive, and collaborative environment while granting them access to real-time information related to material, data flows, and financial transactions.

4.1 Dynamic Discounting Mechanism

SCF uses short-term credit to balance working capital between the buyer and the seller. It reduces supply chain costs and increase liquidity by providing an efficient platform to streamline the payment process. SCF is used by many focal firms to optimize the workflow and allocation of financial resources in the supply chain (Omran et al., 2017). Because of forward financing or the contractual agreements, SCF reduces transactional costs and improves financial flows. In a broader sense, SCF optimizes liquidity with different payment options offered to all partners within the network. A dynamic discounting of SCF aims to relieve buyer and supplier payment tension (Omran et al., 2017). Further, using BTC to provide a secure, transparent technological platform to share data transaction information.

As shown in Figure 2, using BCT as an integrated infrastructure for the entire supply finance eco-system allows buyers, suppliers or actors to be electronically and financially connected. Therefore, they can build up a trust network by approving the performance parameters within the smart contracts. Ongoing relationship reduce buyers' concerns on seller performance and the sellers' concerns on buyer repayment risk. BCT is capable of improving the payment process between buyer/supplier and/or actors in SCM. The SCF built on the BTC helps to remove the inefficiencies in the financial flows.

As BCT applied to SCF via smart contracts, this will enable all participants in an SCF to communicate on a single shared ledger. Each participant, including the supplier and manufacturer, will only update, view, and share their parts of the transaction while achieving a high level of efficiency, trust, and transparency on an immutable ledger record. The buyer accepts an invoice with a discount at an earlier payment date and pays the supplier with a discounted payment. The dynamic discount triggers by a centralized

BTC platform. Then, the stored transaction data feeds into the future prediction of bids or discounted pricing of supply that benefits all partners in the supply chain. The learned data cycles optimize decisions on bids or discount pricing to supply chain members.

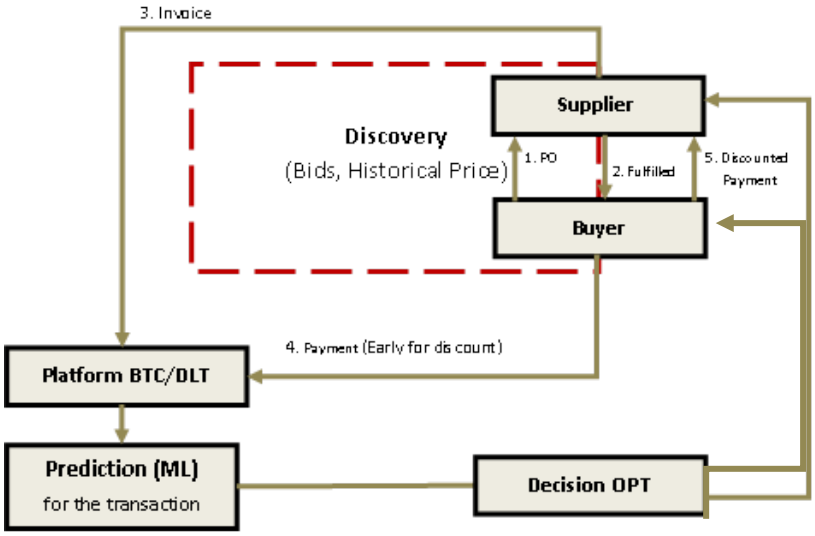

Figure 2. Proposed Application BCT to the SCF Eco-system

5 Conclusions

This manuscript provides a conceptual model to the advantages of BTC to revolutionize the financial operation in supply chains. BTC has proven its strength in ensuring visibility, transparency and efficiency to several industrial fields. The adoption of BTC may be higher than the fully implementation rate that is barely 15% in various industry (PricewaterhouseCoopers, 2019). The ecosystem may not be supportive of BTC. Some people in FiTech wonder if the digital ledger technology is totally enough. It is not necessary to change over to BTC, waste manpower, time, effort and drastic disruptions of operational routines. Changes can be painful but financial gains are foreseeable if the face-lift is successful like use cases -- Walmart, Maersk.

The BTC evolves over time. The supply chain on BTC makes sense, especially the standardization of currency exchanges, tariff, custom documents. BTC application to the SPF provides transparency, security, centralized/decentralized transactions and information sharing platform. Through information sharing among supply chain members, further discounted pricing and reduced costs can be predicted, then automated the optimized decisions to both supply and buyer sides.

Abstract

The technological revolution and the intense use of digital devices have allowed people to generate huge amounts of much heterogeneous data, called Big Data. Especially in the tourism field, Big Data has continuously been exploited for the management of Tourism Destinations and marketing strategies. In particular, the generation of that subset of Big Data, called Big Social Data, through the voluntary sharing of personal information and content generation on various online social

networks, has created several opportunities for useful analysis for many tourism stakeholders, such as Destination Management Organizations (DMO), which can exploit strategic tools based on Big Social Data and analytics, for data-driven decisions with a growing emphasis on how generated insights are increasingly valuable when they come to anticipate visitor behaviour and shaping communication strategies.
This paper aims at describing the comprehensive valuable insights into tourists' behaviour through the analysis of Big Social Data. Data considered in this work consists of large dataset from Flickr online social network and Twitter micro-blog. A Big Data Analytics framework, that implements multiple tasks such as topic extraction, geographical data clustering, time series modelling techniques, sentiment analysis and image analysis, is presented and it constitutes the innovative contribution of this work. Results show that the generated insights could allow DMO to use new knowledge about unknown clusters of Point Of Interests discovery, trend and seasonal patterns of tourist demand identification, e-WOM monitoring, attractive places identification that, in turn, will allow the DMO to address its needs in terms of decision support for the management and development of the destination, the enhancement of destination attractiveness, the shaping of new marketing and communication strategies, and the planning of tourist demand within the destination. The approach described in this paper is adopted in the NEST (NEtworking for Smart Tourism development, INTERREG-IPA CBC Italia-Albania-Montenegro) project which aims at enabling a cross-border cooperation between Albania, Italy and Montenegro, in order to create a common branding of the Adriatic-Ionian area as a smart tourism destination at a macro regional level and to develop common tourist routes and products.

1 Introduction

In the last years, the technological revolution, on the one hand, and the intense use of digital devices, on the other one, have allowed people to generate huge amounts of much heterogeneous data, called Big Data. This topic has attracted more and more increasing attention by researchers and business decision-makers, with the aim of offering innovative services in data-intensive applications and domains, such as healthcare, banking, tourism, education, public administration and intelligent manufacturing (Elia et al., 2019a). A particular category of Big Data are Big Social Data (BSD), defined as Big Data "generated from technology-mediated social interactions and actions in digital realm, and which can be collected and analysed to model social interactions and behaviour" (Olshannikova et al., 2017) and representing about 90% of all Big Data (Gandomi et al., 2015). Especially in the tourism field, BSD has continuously been exploited for the management of Tourism Destinations and marketing strategies (Giglio et al., 2019). In particular, the generation of data through the voluntary sharing of personal information and content generation on various online social networks has created several opportunities for useful analysis (Miah et al., 2017). This has contributed to a common knowledge about visited places and people's behaviours, information that could be very important for tourism stakeholders within a destination such as local administrations,

professionals and intermediaries, Destination Management Organizations (DMOs) and so forth (Giglio et al., 2019). As emerged from literature, detailed information at the individual tourist level can be useful for the development of a segmentation of future tourism demand, for infrastructure development, and for service allocation and budgeting. Thus, there is the need to outline a solution method that, exploiting BSD, can provide a comprehensive insight into tourists' behaviour and better predict future tourism demand, to support the decision-making of destination managers in the context of smart tourism destination management (Song & Liu, 2017; Femenia-Serra et al., 2019; Kontogianni & Alepis, 2020). This paper aims at describing the comprehensive valuable insights into tourists' behaviour through the analysis of BSD. A Big Data Analytics process, that implements multiple tasks such as topic extraction, geographical data clustering, time series modelling techniques, sentiment analysis and computer vision analysis, is presented and it constitutes the innovative contribution of this work. Data considered in this work consists of large dataset from Flickr Online Social Network and Twitter micro-blog for the Italian south-eastern region of Salento that represents our first real case applicative scenario. Thus within the tourism destination:

- geo-tagged pictures data and user's context data in Flickr, have been analysed for the identification of both Point of Interests (POIs) and clusters of dense geo-located POIs in the area of interest;
- data coming from description texts in Flickr have been analysed for the extraction of emerging topics;
- user's profile data have been analysed for the estimation of tourists seasonal patterns and presence trend for each cluster of POIs;
- contents (such as tags, tourist destination geographical bounding box) extracted from Flickr is used to retrieve tweets from Twitter that has been consequently analysed to establish users' sentiment;
- pictures from Flickr have been analysed for the identification of the most representative picture for each cluster.

The approach described here is proposed in the NEST project which aims at enabling a cross-border cooperation between Albania, Italy and Montenegro, in order to create a common branding of the Adriatic-Ionian area as a smart tourism destination at a macro regional level and to develop common tourist routes and products. Working to implement the transition towards the paradigm of a macro region with a unique brand, means, on the one hand, managing a process of transformation, avoiding leaving the key steps to chance and, on the other, being able to integrate the interests and projects of local stakeholders involved. In this perspective, and in the context of cross border cooperation and smart specialization strategies, a framework of tools and techniques, based on smart technologies such as BSD, is crucial to favour the knowledge transfer between different regions belonging to the program area.

This paper is structured as follows: sections 2 presents the related literature background, while section 3 the analysis framework implemented has been described.

Section 4 describes the experimentation and the main results of our analysis for the case study of Salento. Finally, section 6 discusses the results achieved and highlights some limitations of the study, which can open new paths for further research.

2 Related Literature

Big Social Data, but more in general Big Data, has opened up possibilities to directly apply in data-intensive industries such as tourism, particularly for DMOs in the context of Tourism Destination planning and operations. BSD has been defined as data "*generated from people's actions and interactions within social media services and platforms, sharing a subset of Big Data properties, that needs to be collected and analysed through specific technology and analytics to provide crucial insights into human behaviour, people's preferences and relationships, social interactions and transformations, and real-life event outcomes.*" (Elia et al., 2019). "Social Media" is one of the richest sources of BSD and it provides voluminous, varied and fast data of potential value to decision makers. Data from social media platforms are generated by using social networking applications and websites, such as Facebook, Twitter, LinkedIn, Tumblr, TripAdvisor, YouTube and Flickr. Contents are typically user-generated as blog posts about real-time activity, photos, short videos, comments or opinions and personal information.

BSD and analytics can directly apply in data-intensive industries such as tourism, particularly for DMOs in the context of Tourist Destination planning and operations. In this context, most analytics have been used earlier for travel recommender systems (TRS) as in Kurashima et al. (2013), where sequences of locations in tourists' shared geo-tagged photos were used to identify, recommend and personalize travel routes.

Lately also BSD have been used for social media data and thus designed for use by DMOs, demonstrating that insights emerging from BSD analysis were valuable in terms of tourist behaviours understanding (Xiang & Gretzel, 2010), tourism demands prediction and decision making support (Miah et al., 2017), new market trends identification (Sigala et al., 2012), and in creating contextualized real time offerings in relation to customer needs (Buhalis & Foerste, 2015).

In addition, other studies focused on the BSD visual contents analysis such as in Önder, et al. (2014) where Flickr geo-tagged photos have been used to assess the presence of tourists in Austria, showing that the method provides more reliable outcomes for cities than regions, or in Shi et al. (2011) where geo-tagged photos sourced from Flickr were used to recommend landmarks, personalised to individual users specific tastes. Finally there are many research works that provide a notable exception with sentiment analysis of a large corpus of user generated contents using machine learning techniques (Support Vector Machines, naïve Bayes classifiers, latent semantic indexing, etc.) such as in Menner et al. (2016), Saif et al. (2016) and Piryani et al (2017).

In this vein, Big Data, resulting from tourist generated content in social media platforms, along with their aggregation, interconnectivity, analysis, integration, real time synchronization and intelligent use of data (Tu & Liu, 2014; Gretzel et al., 2015) becomes

the major driver for value creation in smart tourism.

All these various studies point on one hand the underexploited potential for social media data to inform the DMO's strategic decisions and, on the other hand, the inability of most of the existing support tools to cope with the sheer volume and rich data diversity that characterises the domain.

This work, by making use of BSD and analytics, tries to provide DMOs with a tool for finding accurate answers to the following questions: which interests and which locations attract tourists when visiting a destination? How personal experiences at each of the visited attractions influence tourists so that it is possible to forecast future tourist demand? (Miah, 2017).

Answering these questions will allow a DMO to obtain comprehensive insights on tourists' activities, their experiences and personal reflections.

3 Analytic Methods based on Big Social Data

3.1 Research context

The NEST project aims at creating a cross-border smart tourism destination, also through the creation of a Tourism Intelligence Observatory (TIO) that will give insights about smart tourism destinations, generate market intelligence for orienteering decision making among companies and professionals, and generate specific contents for orienteering decision making among tourists. Moreover, for a DMO the TIO can represent a strategic tool allowing data-driven decisions for marketing strategies throughout the industry, with a growing emphasis on how generated insights are increasingly valuable when they come to anticipate visitor behaviour and shaping communication strategies. In fact, the TIO generates market intelligence also to orientate decision making in the public sector, strengthening tourism as a strategic activity for social and economic development of the Ionian-Adriatic macro area.

A subset of the services offered by the TIO exploits BSD and analytics, offering insights to destinations about visitors' behaviour that would be complex and maybe even impossible to get from traditional information gathering methods. For example, there's practically no way to economically implement a survey to find visitors' patterns of movement across Albania, Italy and Montenegro, but it's relatively simple to understand tourism flows if we measure their presence in different areas from the contents shared on social networks. Thus, the exploitation of this kind of information can be used i.e. for managing the destination's tourism supply or designing a unique marketing plan addressing different strategies for specific markets.

3.1 Research framework

Framed in the above premises, our research framework relies on the TIO as the environment for insights generation starting from two BSD sources (i.e. Flickr and Twitter) and focuses on an integrated approach considering multiple BSD sources, different analytics techniques on heterogeneous data types, and complementary expected results. Data ingested are user-generated contents, voluminous and with heterogeneous formats (i.e. pictures, geo-tagged information, text). Data feed different analytics tasks (i.e. clustering, topic extraction, sentiment analysis and time series modelling) to generate insights on tourist behaviour as emerged from their social media activities.

In particular, the tourism Intelligence Observatory will use data from Flickr such as geo-tagged photos with metadata, user profile public information and post's description (comments and hashtags); data from Twitter is textual contents within a geo-located box.

This data will feed the following analytical processes:

- Geo-tagged data clustering to detect users' areas of interest, starting from geo-referenced Flickr posts. A density-based clustering algorithm, DBSCAN (*Density-based spatial clustering of applications with noise*), was applied to identify the most photographed areas in the Salento region. The use of DBSCAN is motivated by the idea that clusters will be areas where many observations are densely packed together and makes no assumptions of cluster shape.
- Topic Identification to extract from Flickr users' posts which are the main discussion topics within a destination. The algorithm used is the *Latent Dirichlet Allocation* (LDA), which is a popular approach for unveiling latent topics through a multinomial probability distribution over terms. The LDA method attempts to give support in the identification of the key topics, their meaning, how much they are prevalent and how they relate to each other.
- Image analysis to identify the most representative image within a cluster of POIs. The analytic process implemented takes the pictures belonging to a cluster of POIs and extracts features through *Speeded-Up Robust Features* (SURF) (Bay et al., 2008), an advanced feature descriptor used for representing photo content. Then, K-means clustering is applied to construct a visual word vocabulary, from all the features extracted and then the most representative image is chosen by Kernel Density Estimator (*KDE*) after a dimensionality reduction.
- Time series decomposition to analyse trends of tourist demand and seasonal patterns based on Flickr user information.
- Sentiment analysis on Twitter geo-tagged posts to understand which was the sentiment related to the emerging topics within the destination. To this aim, Sentiment Analysis has been performed using a preliminary training set and then validating the polarity assigned to the different tweets available on Twitter social network platform. The approach used to establish the sentiment

is supervised, implementing *SVM* (Support Vector Machine) with cross-validation to classify feature vectors of textual information streams in three classes: positive, negative and neutral.

The generated insights allow DMO to use new knowledge about unknown clusters of Point Of Interests (POIs) discovery, trend and seasonal patterns of tourist demand identification, e-wom monitoring, attractive places identification that, in turn, will allow the DMO to address its needs in terms of decision support for the management and development of the destination, the enhancement of destination attractiveness, the shaping of new marketing and communication strategies, and the planning of tourist demand within the destination.

This research framework allow a DMO to take advantage of new knowledge acquired from multiple BSD sources, by combining several analytics tasks on heterogeneous (structured and unstructured) data types, with complementary generated insights.

4 Case study: Salento

4.1 Data collection

The geo-tagged photo dataset used in this study was collected from Flickr using its API. A bounding box (with coordinates lon_{min} 17.75, lat_{min} 39.78, lon_{max} 18.53 and lat_{max} 40.51), was designed to cover the entire geographical area of Lecce county within the Salento region. The photo timeframe was 5 years, covering the period from January 2015 to November 2019. In total, 17920 photos were collected from 748 tourist's accounts. Photo metadata were extracted, including geo-tags, textual tags, titles, descriptions and UserIDs. The actual photos were downloaded, using 'medium' size (as defined within Flickr), which is adequate to display content sufficiently clearly for subsequent processing stages while reducing computing costs.

From Twitter, tweets have been retrieved according to: a) the topic emerged from analysis on Flickr contents; b) time range (2016-2019); c) a radial search with centre in Lecce (Italy) and 85 Km radius. The total number of tweets retrieved is 15625.

4.2 Results

In order to discover unknown Point of Interests (POIs) in the destination, geo-referenced Flickr posts were analysed with the density-based clustering algorithm DBSCAN. In particular, DBSCAN has been used setting eps (the maximum distance between two observations to be considered as neighbour) to 0.08, min_samples (the minimum number of observations to create a cluster) to 3 and euclidean as the distance metric used by eps.

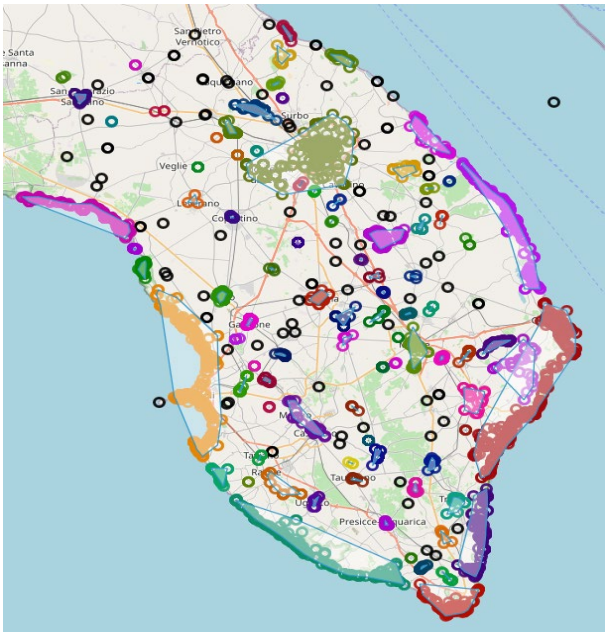

Figure 1. Identified clusters of POIs in Salento.

Results are shown in Figure 1. Between the 89 clusters of POIs identified, the most renowned touristic areas on Ionic and Adriatic coast have been spotted (Porto Cesareo Area; Gallipoli Area; Marina di Ugento Area; San Cataldo Area; Torre dell'Orso and Laghi Alimini Area; Otranto, Santa Cesarea and Castro Area; Tricase Area; Santa Maria di Leuca Area). Since they attract a high number of tourists due to the naturalistic and recreational attractions, the correspondent clusters are the biggest in terms of the number of POIs contained. Other smaller clusters identified are related to some villages and towns that are characterized by historical monuments or architectures (Maglie, Galatina, Matino-Casarano, Calimera, Poggiardo-Vaste). Finally it is worth noting that few other clusters, referring to areas whose distinctiveness is the wine production (e.g. Copertino, Leverano, Salice Salentino, Guagnano, San Pancrazio Salentino), the presence of prehistoric dolmen and menhir (Giuggianello) or recently renewed historical attractions (Santa Maria di Cerrate Abbey), have emerged only in the last two years within the monitoring time.

Once the clusters of POIs have been identified, "hot topics" for each cluster have been detected analysing the textual contents in Flickr's posts. This analysis could help the DMO to understand in which way tourists are talking on social media about destinations in the territory. LDA algorithm has been applied in order to extract and identify topics for each of the 89 clusters, Results for the most densely populated clusters are shown in Table 1 where, for each cluster, the number of posts analysed from Flickr, the most

representative topics (hot topics) and a tag cloud of all the topics emerged, have been represented.

Table 1. Brief description of the most densely populated clusters.

ID cluster: 1 - Lecce Area	
N. post: 3889	
Hot Topics: “lecce", "piazza sant'oronzo", "barocco", "lecce cathedral", "centro storico", "santa croce", "piazza duomo", "anfiteatro romano"

ID cluster: 0 - Gallipoli Area	N. post: 1831	
Hot Topics: "gallipoli", "santa caterina", "santa maria al bagno", "torre uluzzo", "porto selvaggio", "castello gallipoli", "punta suina", "gallipoli salento"	

ID cluster: 9 - Torre dell'orso Area **N. post:** 683 **Hot Topics:** "sant'andrea", "torre dell'orso", "melendugno", "roca", "alimini", "faraglioni", "grotta poesia", "san foca"	
ID cluster: 11 - Porto Cesareo Area **N. post:** 651 **Hot Topics:** "porto cesareo", "torre lapillo"	
In order to provide the DMO with a comprehensive set of insights that would allow it to monitor e-WOM, we have analysed tweets from another BSD source (e.g. Twitter) restricting the tweet search to the same destination of interest, time range, and including the topic previously emerged from Flickr. A sentiment analysis has been performed to allow DMO to monitor, besides the topics for each cluster, the sentiment associated.

Specifically, the textual sources have been pre-processed to obtain a noiseless and clean dataset through the use of filtering operators for a wide number of goals (e.g. removing HTML tags, tokenization, stop words removing, stemming). Features extraction has been performed by calculating tf-idf coefficient (Na et al., 2004) and finally, feature vectors have been used for classifying the sentiment using SVM (Support Vector Machine) with Cross Validation, to classify textual information streams in positive, negative and neutral sentences. Results of this analysis are shown in Figure 2.

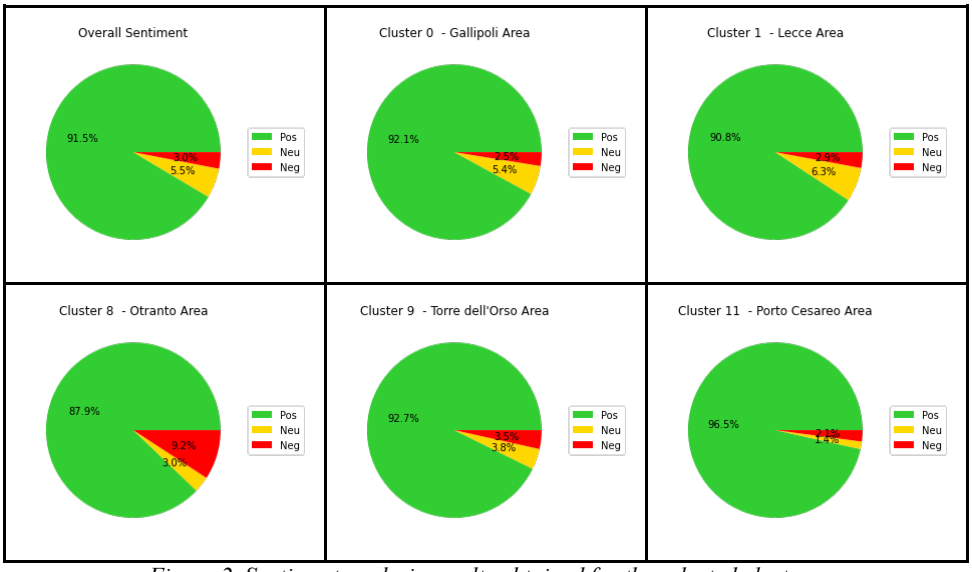

Figure 2. Sentiment analysis results obtained for the selected clusters.

As it can be seen, a strongly positive sentiment has been detected for all the inspected clusters, with a positive overall sentiment of 91.5% (first panel on top-left in Figure 2).

For the attractive places identification, we have processed all the images taken from Flickr during the observational period in order to extract the most significant picture representing each cluster of POIs. An image analysis has been carried out to discover particular interests belonging to tourists' experience and provide DMOs with insights useful to enhance destination attractiveness and elaborate differentiated travel packages or personalized experiential paths.

In particular, for each cluster of POIs pictures have been processed through SURF for features extraction, a visual word vocabulary has been generated with K-means, finally the top images with highest probability densities have been identified by KDE as the most representative photos. Results of the attractive places identification, for the five most populated clusters, are shown in the next Table.

Table 2. Most representative images for the five most populated clusters.

ID cluster: 1 - Lecce Area		
View of Santa Irene Church in Lecce old town	View of bell tower of Piazza Duomo in Lecce old town	View of "Porta Rudiae". One of the three gate to the old town

ID cluster: 8 - Otranto Area		
Nightly view of monument to martyrs of otranto	View of the harbour of Otranto	 View of the coast of Santa Cesarea Terme
ID cluster: 0 - Gallipoli Area		
View of the Gallipoli old town	Details of a bell tower in Gallipoli old Town	Nightly view of the Puritate beach in Gallipoli old town
ID cluster: 9 - Torre dell'Orso Area		
Underwater picture of a jellyfish taken in Torre dell'Orso beach	Sunrise at Torre dell'Orso	Sunrise at Stacks of Torre Sant'Andrea
ID cluster: 11 - Porto Cesareo Area		
Lightning from a beach in Porto Cesareo	Stormy weather from a beach near Porto Cesareo	Dune beach with watchtower in background near Porto Cesareo

Finally, in order to provide the DMOs with information about trends and seasonal patterns, time series analysis has been performed on the number of pictures posted on the social network in the period of observation. Specifically, this analysis gives us insight on

patterns emerging from social network activities, useful for both strategic planning and decision-making.

In order to deeply understand the patterns behind our data, a time series decomposition has been executed. Generally, every time series may be split into four components: *Base Level*, *Trend*, *Seasonality*, *Error*. Thus, a decomposition of the time series has been applied by considering the series as a multiplicative combination of the base level, trend, seasonal index and residuals. Figure 3 shows the decomposition of data observation in Residual, Seasonal and Trend.

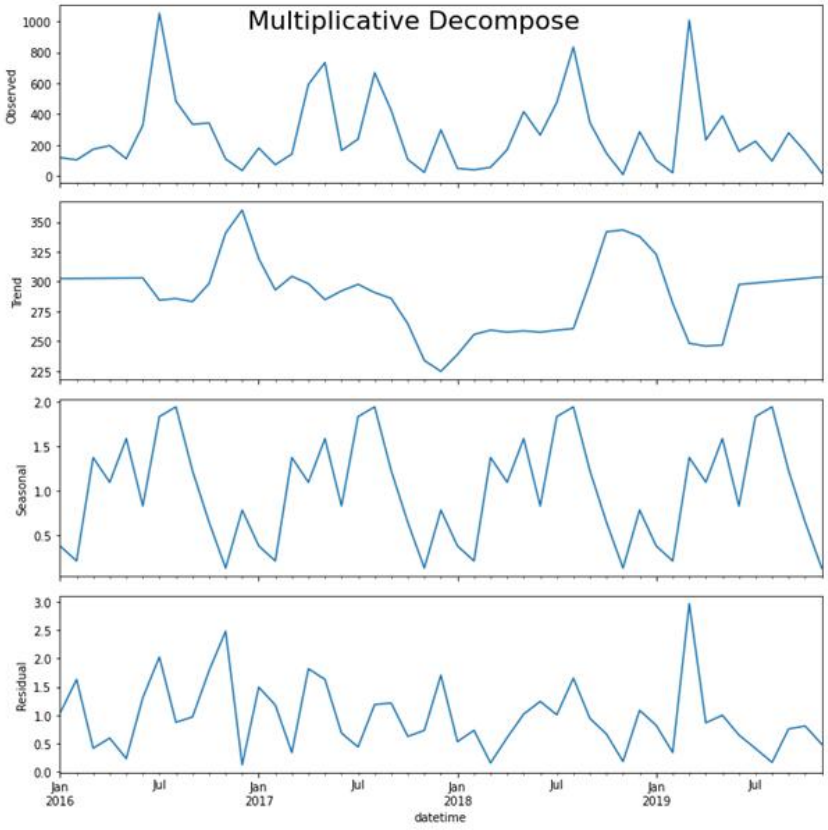

Figure 3. Decomposition of the time series in Residual, Seasonal and Trend.

Results show a strong seasonality component, with peaks during Summer, and a periodical component with a period equal to 12 months. Through this decomposition, the seasonal component is clearly visible and it is easy to observe how the trend can be distinct in four time intervals, during which it shows different behaviours. Specifically, between 2016 and 2017 the trend has been increasing, then, between 2017 and 2018, it

has been strongly decreasing, and, finally, it returned to increase starting from August 2018.

5 Discussions and Conclusions

In this paper a framework that, exploiting Big Social Data, helps DMOs to extract insights on tourist behaviour for their decision support needs has been presented. The originality of this work is in the use of BSD and analytics techniques for giving DMOs specific insights on a destination in a deep and wide fashion. In particular, grounding on the idea that large groups of people are collectively smarter than individual experts, the collection and analysis of the "wisdom of crowds", for extracting insights of tourist characteristics, images, attitudes and preferred destination attributes, can represent a unique mean for problem-solving, decision making, innovation and prediction. Thus, DMOs and tourism stakeholders can use BSD to plan seasonal promotions, plan the timing and placement of advertisement campaigns, create personalized advertisement and define which market segments are growing most rapidly (Del Vecchio et al., 2018; Karathiya et al., 2012; Magnini et al., 2003).

Geo-tagged cluster analysis of POIs has shown that besides well-known destinations, some others are arising in the last two years of the monitoring time and that DMO can take advantage of this information to shape in time new tourist offerings or ad-hoc marketing campaigns. Moreover, by extracting hot topics for each cluster and complementing the analysis with the sentiment of Twitter contents, gives the DMO the opportunity to monitor specific areas within the destination in terms of e-WOM and the related sentiment and, therefore, the opportunity to understand reasons underlying critical situations and thus intervene promptly when they arise. Results from most representative images show that insights into tourists' perspective and perception could help the DMO to design marketing materials, develop marketing strategies that suit the interests and perceptions represented by the images. In the same way, DMO could rely on these insights to promote less-visited parts of a cluster, which DMO has a responsibility to promote. Finally, the time series modelling has shown trends on tourist presence which has a strong seasonality component. This analysis could help DMO for launching ad-hoc initiatives for seasonal adjustments and then assessing their effectiveness and estimating whether social networks can proxy official statistics in a suitable manner.

This work presents some limitations: social media contains other valuable type of unstructured data (e.g. videos) that could complete the collected data. Moreover other sources of BSD from other social networks (e.g. Facebook, Instagram) could be included to provide richer insights. Finally, analytic tasks could be extended to provide DMO with a more comprehensive knowledge about tourist behaviour.

Implications of this work are twofold: for practitioners, this approach well supports the decision-making process for Destination management, as it allows to extract insights from available BSD useful for a DMO to better understand what kind of policy measures or tourism strategies could be planned and adopted in order to ameliorate the regional

tourism. In this perspective, integrated analytics techniques offer to practitioners comprehensive insights for destination management. In fact:

- geographical clustering helps to better understand how to reshape a destination with detected sub-regions and tourists targets;
- hot topics extraction and e-WOM monitoring help to better understand collective tourist sentiment and related destination weaknesses and strengths;
- image analysis helps to find representative user contents that can be used by the DMO to implement ad-hoc marketing strategies;
- time series help to highlight trends and seasonal patterns of tourism demand, assessing official data about tourists presence.

For researchers, this approach could be used along with other methods of data collection and analysis, in order to obtain more meaningful results. Finally, the approach of using integrated techniques of data analytics could be further developed for extracting added value from big data and applied in other domains than smart tourism.

Abstract

Social media and its analogous applications allow millions of users to express and spread their opinions about a topic and show their attitudes by liking or disliking content. The amount of data accumulating on social media is known as Big Social Data which can be analysed to provide valuable insight in many application contexts. Measuring public opinion during events like elections is one of the most promising BSD applications either for predicting results or analysing online debate during electoral campaigns. In this paper, the analysis of political debate on social media during the 2020 regional election in Emilia Romagna (Italy) is presented. Candidates' programs have been analysed in order to extract topics within the official action plans. Leveraging Big Social Data, the interactions of Italian citizens on Twitter candidates' pages have been monitored and analysed, in order to understand how action plans within candidates' programs has been perceived by citizens through the lens of social media; which are the most relevant topics emerged from online debate in the social networks; which is the sentiment emerged in the overall debate; how the online debate have polarized on emerged topics and how certain communities of users have contributed to the information diffusion. Results have shown a mismatch between the action plans in the candidates programs and the topics emerged online debate, along with a unidirectional communication approach followed by the three candidates that has resulted in the polarization of the debate on some of the topics emerged during the campaign.

Keywords – Big Social Data, real time monitoring, opinion mining, regional election, polarization.

Paper type – Academic Research Paper

1 Introduction

Social media and its analogous applications allow millions of users to express and spread their opinions about a topic and show their attitudes by liking or disliking content (El Alaoui et al., 2018). All these constantly accumulating actions on social media generate high-volume, high-velocity, high-variety, high-value, high-variability data termed as Big Social Data (BSD). In general, this kind of data refers to "that subset of Big Data generated from people's actions and interactions within social media services and platforms, properly collected and analysed to provide crucial insights into human behaviour, people's preferences and relationships, social interactions and transformations, and real-life outcomes prediction" (Elia et al. 2019). BSD and analytics soon became a unique means for monitoring the hot topics on the Internet (Shang et al., 2015). Opinion mining on BSD has emerged as a notable direction of research with scientific trials and promising applications being explored substantially (Kumar & Sharma, 2017). In fact, the effective analysis of public opinion is valuable for both governments, which can better understand the public's views and aspiration, and for business, which can acquire the evaluation of products and services, and provide better personalized products and services (Tao, 2014).

In particular, measuring public opinion through the collection and analysis of relevant data from social media could also predict the outcome of elections (Robles et al., 2018) and be a useful supplement to traditional polling methods (Sang & Bos, 2012; Schober et al., 2016).

In this perspective, in this paper we present the analysis of political debate on social media during the 2020 regional election in Emilia Romagna (Italy). Candidates' programs have been analysed in order to extract topics within the action plans presented. Leveraging Big Social Data, we have then monitored and analysed the large interactions of Italian citizens on Twitter candidates' pages, in order to understand:

- how action plans within candidates' programs has been perceived by citizens through the lens of social media;
- which are the most relevant topics emerged from online debate in the social networks;
- which is the sentiment emerged in the overall debate;
- how the online debate have polarized on emerged topics;
- how certain communities of users have contributed to the information diffusion.

This paper is structured as follows: sections 2 presents the related literature background, while in section 3 the methodological framework implemented has been

described. Section 4 describes the experimentation, that has been carried out between November 2019 and January 2020, and the main results of our analysis. Finally, section 5 discusses the results achieved and highlights some limitations of the study, which can open new paths for further research.

2 Related Literature

Big Social Data (BSD) is a concept developed by Lev Manovich (2011) and it gained great interest in research on digital culture and society, and it has become lately an emergent research topic. BSD can be considered a particular category of Big Data argued to represent about 90% of all Big Data (Gandomi et al., 2015), and broadly refers to large volumes of data generated by users and describing social behaviour and interactions in digital environments. BSD has been studied from several perspectives (Manovich, 2011; Cambria et al., 2013; Cotè, 2014) and defined in different ways.

In the last years, some researchers have agreed on the peculiar aspects related to BSD sources and applications. In this sense, Olshannikova et al. (2017) refers to BSD as Big Data "generated from technology-mediated social interactions and actions in digital realm, and which can be collected and analysed to model social interactions and behaviour", while Elia et al. (2019) refers to BSD as Big Data "generated from people's actions and interactions within social media services and platforms, properly collected and analysed to provide crucial insights into human behaviour, people's preferences and relationships, social interactions and transformations, and real-life outcomes prediction".

In fact, BSD have been widely used for generating different forms of value and there have been a noteworthy number of research papers in which BSD are referred as the means to offer new insights to understand deeper user's social behaviour and interactions (i.e. Vepsäläinen et al., 2017). Besides, other researchers highlight value in terms of impacts on advancement on society, generation of relevant knowledge for users and companies, prediction of real-life outcomes, and generation of new opportunities to study city dynamics and urban social behaviour (El Alaoui et al., 2018; Del Vecchio et al., 2018).

Moreover, various computational social science studies demonstrated that BSD have been extensively used to foster democratic conversation about social and political issues such as the Arab Spring (González-Bailón, et al., 2011), Occupy Wall Street (Conover, et al., 2013a; Conover, et al., 2013b) and many other civil protests (Varol, et al., 2014; González-Bailón, et al., 2013; Bastos, et al., 2014), Twitter and other social media seemed to play an instrumental role to involve the public in policy and political conversations, by collectively framing the narratives related to particular social issues, and coordinating online and off-line activities. The use of digital media to discuss politics during election times has also been the subject of various studies, covering the last four U.S. Presidential elections (Adamic & Glance, 2005; Diakopoulos & Shamma, 2010; Bekafigo & McBride, 2013; Carlisle & Patton, 2013; DiGrazia, et al., 2013; Wang, et al., 2016), and other countries like Australia (Gibson & McAllister, 2006; Burgess & Bruns,

2012), and Norway (Enli & Skogerbø, 2013). Findings that focused on the positive effects of social media such as incrementing voting turnout (Bond, et al., 2012) or exposure to diverse political views (Bakshy, et al., 2015) contributed to the general praise of these platforms as a tool to foster democracy and civil political engagement (Tufekci, 2014; Yang, et al., 2016). Nevertheless, few research efforts have been made to understand the extent to which the political debate on social media differs from candidates' programs.

An important inquiry in disciplines across the social sciences, in which BSD has been exploited, is related to evaluate the extent of the influence of social media on political polarization (Bakshy et al., 2015; Barberá et al., 2015; Bond & Messing, 2015; Bennett & Segerberg, 2012). Results show that political polarization occurs in a so-called "echo chamber" environment, where individuals are exposed only to those information and communities that support their own views, while ignoring opposing viewpoints. The presence of political polarization on social networking sites, blogs and other various web 2.0 platforms may be explained by a well-known phenomenon in sociology called homophily (McPherson et.al., 2001), where people in social networks tend to group around similar backgrounds and interests, including shared political views. Gruzd & Roy (2014) suggested that there are some pockets of political polarization on Twitter, but at the same time Twitter as a communication and social networking platform may be able to facilitate open, cross-party, and cross-ideological discourse. There are a few exceptional studies (Garimella & Weber, 2017, Yardi & Boyd, 2010) that took a longitudinal approach to political polarization such as changes in opinions and emotions in social media messages. Therefore, our study examines whether individuals who use social media will develop polarized political preferences by directly measuring the aggregate shift in political opinions toward a greater extreme over time. We measure opinions and topics emerged in the online debate and verify how they vary from the candidates' public programmes.

3 Methodological Framework

In order to analyse the political campaign in the regional election, taken in January 2020, we considered many traits: i.e. social network involved, messages and tweets on social networks, polarity of the messages, topics emerged from the messages, interactions between users, community dimensions, etc.

In this section we present our framework designed to organize the data sets that will be analysed, which kind of analysis perform, how data sets and analysis are connected and interrelated and which analysis algorithms will be used. A methodological framework has been implemented which, through various steps, provides us with quantitative data that can be easily interpreted facilitating sense making and understanding.

Through methodological framework, researchers are allowed to systematically and logically approach a problem, setting a definite driving force behind their lines of investigations. Specifically, when developing a framework, the related issue should be break down into sub-components as to create a mental model that operates as a guide for

data collection and analysis (Chataigner, 2017). In Figure 1, it is presented the methodological framework used in this work.

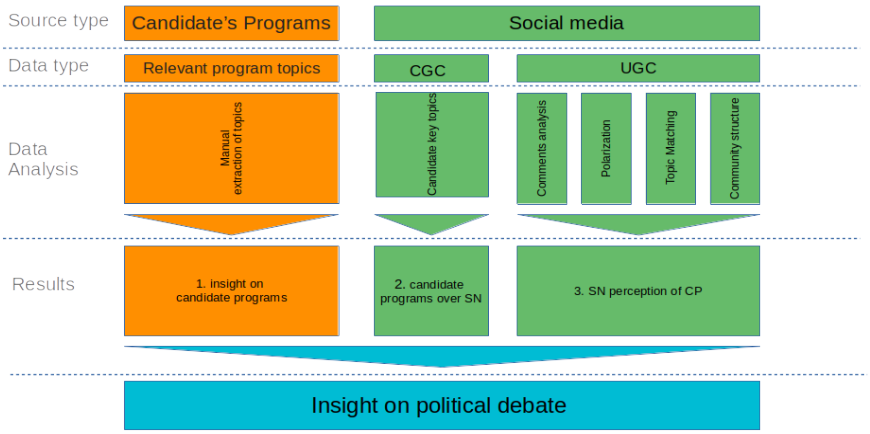

Figure 4. The Methodological Framework adopted in this paper.

In the designed framework there has been a Source Type layer composed by:

- **Candidate's Programs** (the official published candidate's programs) in which political actions are well described, rich in details, and summarized in self-consistent points.
- **Social Media,** referred to the Big Social Data source from which online data are extracted and analyzed. In our case the BSD source is Twitter.

The Data Type layer is made of the specific data type that feeds our analysis. In particular, this layer is composed by:

- **Relevant program topics** emerging from the analysis of candidate's programs.
- **CGC (Candidate-generated contents)**, that is the set of the contents published on the Social media by each candidate.
- **UGC (User-generated contents):** that is the set of the contents published by the community of users that have interacted with candidates. These contents are in reply to the candidate's posts.

The Data Analysis layer is made of the techniques used for analysing data. In particular, this layer is made of:

- **Manual Extraction topics:** the topics are manually extracted from the candidate's programs. This step was conducted through the reading of the programs by each author of the paper and the extracted topics are the result of the union and harmonization of each results.

- **Candidate key topics:** Candidate key topics, applying LDA algorithm (Latent Dirichlet Allocation), are extracted analysing all the messages text published from candidate on the BSD sources.
- **Comments Analysis:** Comments analysis, applying LDA algorithm, extract topics analysing all the messages text published from the community, as specified into "Social Network" on the BSD sources.
- **Polarization:** This step aims to extract the polarization of each topic, using *Sentiment Analysis*. The polarity of each message is calculated by a classification algorithm that marks the message as positive, negative or neutral.
- **Topic Matching:** it's identified either how the action plans within the programs have been perceived by citizens through the lens of social media and which is the ratio of action plan contents to the overall contents published by candidates.
- **Community structure:** how the online community has been structured and evolved using *Network Analysis* metrics.

As for the Candidate key topics and Comments Analysis, LDAvis, which is a python implementation of the LDA algorithm[1] has been used. LDAvis gives support in the identification of the key topics, their meaning, how much they are prevalent and how they relate to each other, by using *distinctiveness*, *saliency* (Chuang et al., 2012) and *relevance* (Sievert & Shirley, 2014). Furthermore, LDAvis allows to reveal the most relevant terms for each topic, to select a term and to reveal its conditional distribution over topics, to provide a global perspective of the topics, showing the inter-topic differences and the prevalence of each topic in the corpus.

Sentiment Analysis has been performed on the results obtained in the topic modelling, using a preliminary training set to validate the polarity assigned to different tweets. The textual sources have been pre-processed to obtain a noiseless and clean dataset through the use of filtering operators for a wide number of goals, then feature extraction has been performed by calculating tf-idf coefficient, and, finally, feature vectors have been used for classifying the sentiment using SVM (Support Vector Machine) with Cross Validation, to classify textual information streams in three classes: positive, negative and neutral.

Finally, SNA is a methodology that represents interpersonal communications as directed graphs and makes use of different metrics in order to determine the functional roles of the individuals within the network (Thomason et al., 2004). A graph is made up of nodes, that represent the actors of a network, and edges, that represent relationships between the nodes. In Table 1 the metrics here adopted have been briefly described.

[1] *https://pypi.org/project/pyLDAvis/*

Table 3. Social Network Analysis metrics adopted in this paper.

Metric	Description
Network density	The ratio of existing edges to potentially existing ones.
Average path length	The average number of steps along the shortest paths for all possible pairs of network nodes.
Modularity	The strength of division of a network into modules (also called groups, clusters or communities).
Degree distribution	How many neighbours a node has.
Closeness centrality	How close a node is to all other nodes in the network.
Eigenvector centrality	How much influence a node has on the network.
Betweenness centrality	Number of times a node acts as a bridge along the shortest path between two other nodes.

The Results layer encompasses results of the previous analysis tasks and offer insights on the whole political debate in terms of: how the campaigns have been polarized, how much users have influenced the spread and diffusion of the ideas of candidates, how the candidates have taken advantage from the Social Networks to communicate their ideas and how much important the Social Networks were for their campaign.

4 Findings

The experimentation here presented concerns the analysis of political debate on social media during the 2020 regional election in Italy, taken place on January 26th. To this aim, Twitter candidates' pages have been monitored during the period from 1st November, 2019 to 02nd February 2020. The whole dataset is made up of 60174 tweets, produced by 17489 unique users. The tweets are considered as unstructured data, meaning that they do not have a predefined data model, nor they are not organized in a predefined manner. Within this dataset, 1792 tweets belong to the three candidates, not uniformly distributed: 646 for Bonaccini, 1002 for Borgonzoni, 144 for Benini, while the rest of the tweets are user comments or the text of retweets. In Figure 2 the temporal trend of the number of tweets published by the three candidates is reported.

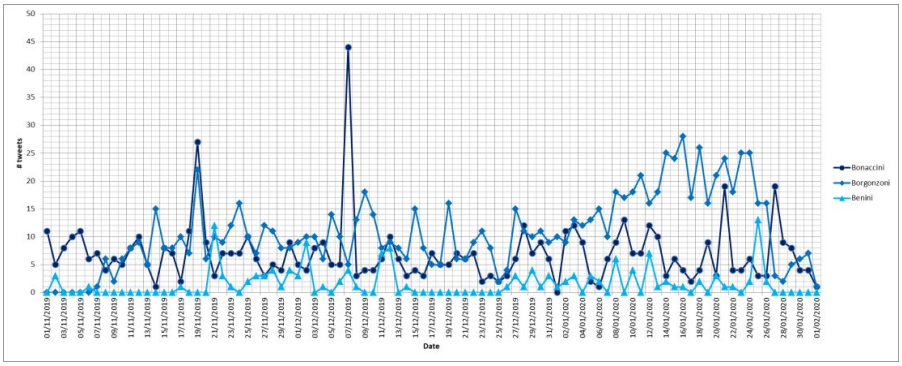

Figure 5. Temporal trend of candidates' tweets.

As it can be seen, during the last days of the election campaign the total number of tweets increased, as expected. Moreover, it is clear that, while a candidate has a low number of tweets published with his own twitter account, another candidate published more than the rival candidates. In the next paragraph, results from data analysis are discussed.

4.1 Topic extraction from candidates' programs

The analysis of the candidates' programs has manually been performed in order to extract relevant program topics within the action plans presented. This preliminary desk analysis serves as a basis for comparisons between candidates' programs and the debate that have taken place on social media. Despite the fact that all the candidates have presented their programs structured in a different way, they organized their action plans in macro-topics. Simone Benini has presented a list of 30 actions grouped in 15 macro topics[1], Lucia Borgonzoni has presented a list of actions grouped in 28 macro topics[2], while Stefano Bonaccini has presented a list of about 40 actions grouped in 4 macro topics[3].

4.2 Online Candidate's key topics analysis

In order to establish which candidate's key topics have emerged from all their tweets published on Twitter, a topic extraction has been performed using the dataset containing 1792 tweets with *LDAvis*. During the procedure of topic extraction for each candidate, the number of topics to be extracted and the final assessment of LDA results have been done by answering to these three questions:

1) is each topic interpretable?

[1] *https://www.simonebenini.it/wp-content/uploads/2020/01/programma5stelle2020.pdf*
2 https://borgonzonipresidente.it/programma/
3 https://stefanobonaccini.it/wp-content/uploads/2019/12/Vol_A5_Bonaccini_programma-1.pdf

2) Is each topic unique?
3) Are all the topics exhaustive (i.e. are all the documents well represented by the topics)?

Thus, in order to avoid the presence of different topics with the same words (which would make the second question to fail) 7 clusters for Bonaccini, 4 for Borgonzoni and 4 for Benini have been extracted. While in Figure 3 the distribution of the tweets for each cluster is shown, in Figure 4 it can be seen the most relevant terms of each cluster for each candidate.

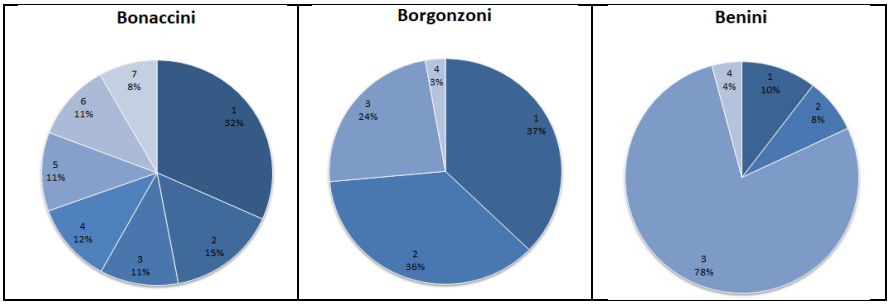

Figure 6. Distribution of tweets within the clusters for the three candidates.

Figure 7. The most relevant terms for each cluster and topic extraction.

As it can be seen, some issues relating to the action plans have been addressed by the three candidates: *Rights and duties* (i.e. right to health, prevention and well-being, quality of life, home plan, health, safety, dignity of work), *Culture* (i.e. free nursery, right to study, enhancement of cultural heritage, education in music and sport, digital, technical and scientific skills, film culture and music), *Work and opportunities* (i.e. NEET

reduction, 2030 manufacture, hospitality, trade, advanced training and research) are well distributed between the three candidates; *Sustainability* (i.e. maintenance, green economy, circular economy, renewable energy, water protection, sustainable agriculture) comes out only for the third candidate. Another difference coming to light from this analysis is given by the large presence of *Other discussions* (i.e. "sardine" cultural movement, the case of Bibbiano's children, the problem of illegal immigration) relating to Italian news events, whose occurrence somehow shifts the political debate focusing no longer on the electoral program, but on the relative regional and (sometimes) national events.

4.3 Comments, Polarization and Topic Matching analysis

In order to understand what kind of discussions emerged in the overall debate, the whole dataset of 60174 tweets has been processed using LDAvis. The assessment of the LDA results, as previously explained, has suggested the extraction of 10 clusters. In Figure 5 the distribution of the tweets for each cluster is shown.

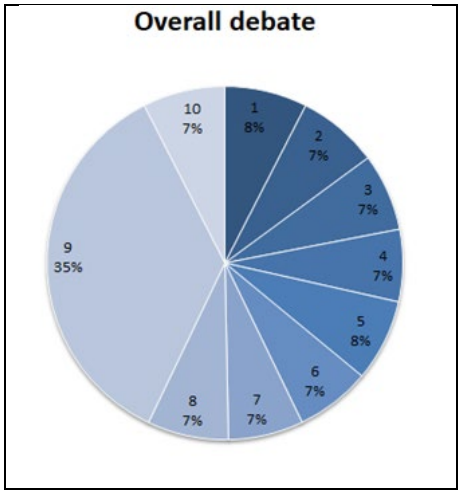

Figure 8. Distribution of tweets within the clusters.

A first analysis of these tweets has aimed to understand which is the sentiment emerged in the overall debate. As it can be seen in Figure 6, the overall sentiment for the whole debate, estimated on the whole dataset, is positive for the 73.7%. In particular, the sentiment analysis shows that the sentiment percentages are quite similar during the three months. Nevertheless, a growth of negative percentage in the last month has been observed, probably due to the vibrant tones used during the debate of the last few days before the vote.

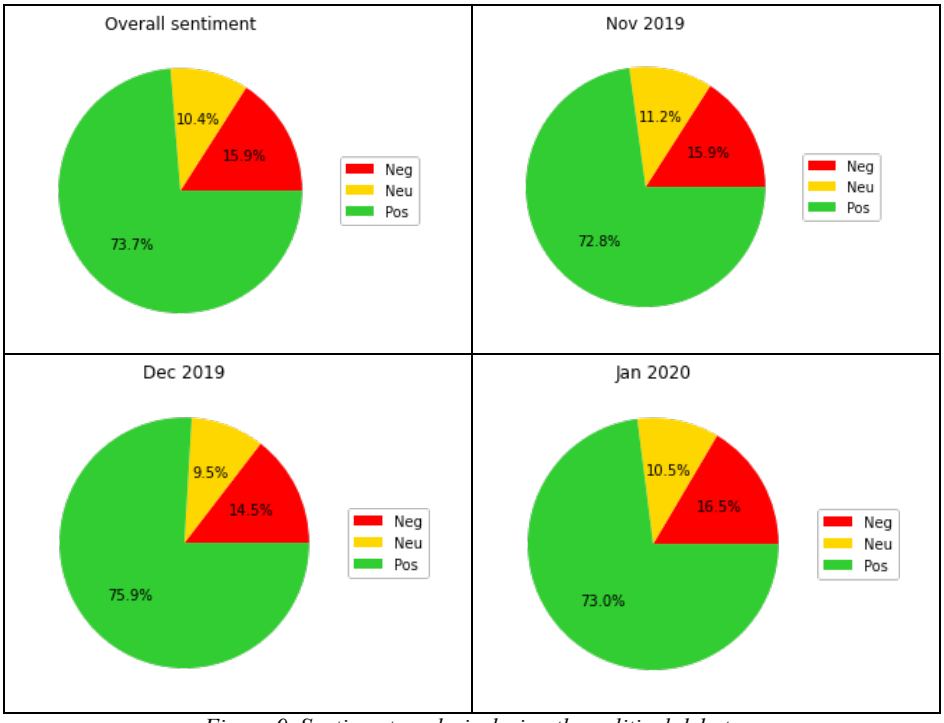

Figure 9. Sentiment analysis during the political debate

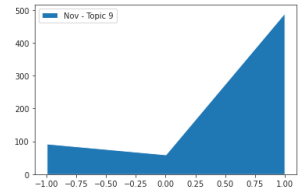
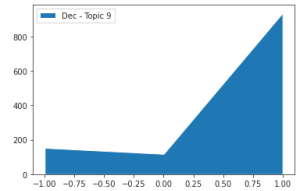
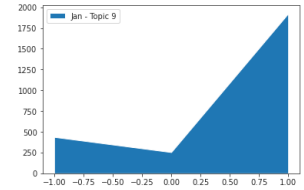
Moreover, it has been studied how the debate polarizes during the observation period. In Table 2, it is reported the details for 5 of the most significant clusters: for each cluster, the most relevant terms per topic and the variation of polarization is shown. The first evidence is given by the fact that in the overall debate a low percentage of topics are related to the action plans: *Rights and duties*, *Culture*. On the contrary, a high percentage of *Other discussions* dominate the political debate. Additionally, the debate is highly positively polarized for each topic. This is probably due to the low attitude of candidates towards a real "constructive" political online debate. In fact candidates' communication has been mostly unidirectional so that their answers to people's posts have not contributed to a flatten polarization curve.

Table 4. Most relevant terms per topic and the variation of polarization.

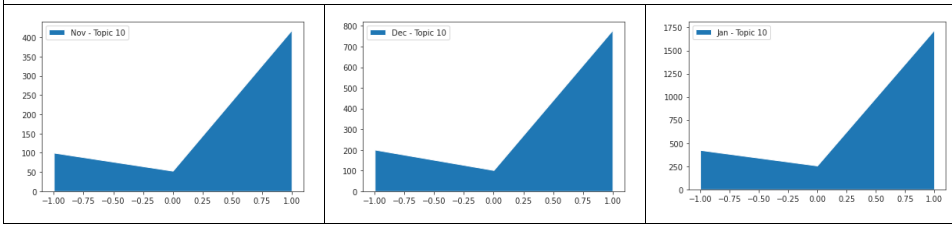
Topic 1 - bravo, volto, salvini, senato, montanaro, storia, vergogna, vita, fascista, sociale, padre, genitore → **Other discussions, Rights and duties**
  Topic 3 - ragione, giusto, milione, euro, fiducia, ospedale, campanello, dimettere → **Rights and duties, Other discussions**
  Topic 7 - vittoria, casa, sardina, paura, potere, opposizione, capitone, propagandare, minaccia, cultura, vivere, film → **Other discussions; Culture**
  Topic 9 - Bibbiano, bambino, famiglia, parlaci, arroganza, gatto, ignoranza → **Other discussions**
  






Topic 10 - Sinistra, destra, buonista, povero, signore, clandestino, competenza, magistratura, risorsa, matteo, senso, serietà

→ **Other discussions**



4.4 Community Structure analysis

Finally, the overall dataset has been processed within *Gephi*[1] in order to understand how contents spread in the digital realm through social media and how some network of users contributes to the information diffusion. Analysing the data through the lens of SNA means building the graph with nodes, representing users, and edges, representing the action accomplished with other users: replying to or retweeting the candidates' contents. Many nodes have only one connection (meaning degree equal to 1).

In Table 3 the summary of the global network is reported.

Table 5. Summary of network properties.

Nodes	Edges	Density	Av. Path Length	Modularity
17312	57148	0.00	2.08	0.39

The *network density* is 0.00, meaning that this network is very sparse and contains a very low number of edges relatively to the maximum possible number of edges between all the nodes. The first evidence is that the candidates, while generating a lot of content on social networks, have paid little attention to user responses, thus a dense network of exchange of opinions between candidates and users has not been created. This is highlighted also by the low number of the *average path length*: the action of a user is able to influence another one following an averagely 2.08 casual path. Finally, the *network modularity* is 0.39, meaning that there is a low presence of structural clusters of variables in the network. Thus, in order to gather information about central nodes, it has been decided to reduce the graph analysis only to the core part of the network.

To this aim, in Figure 7 the graph obtained for *degree* values greater than 40 is shown. With these selections, the graph is made up of 107 nodes and 7596 edges. Edges are coloured by polarity, while nodes are coloured by degree (red for high degree, blue for low degree). The dimension of nodes is proportional to degree.

[1] *https://gephi.org/*

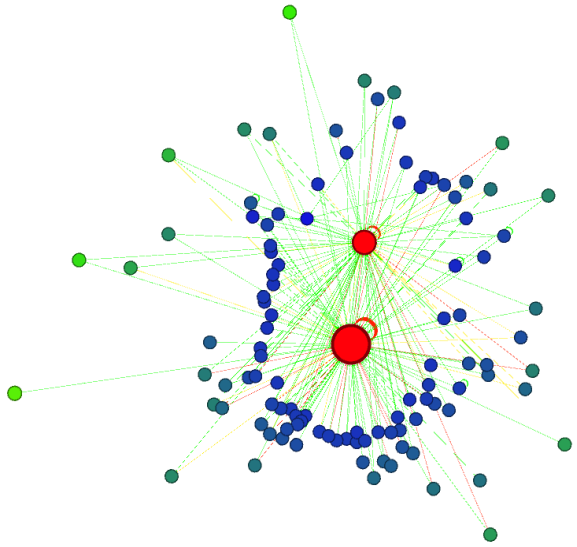


Figure 10. Social network graph obtained for degree values greater than 40.

It is evident that the red nodes correspond to two candidates (Borgonzoni and Bonaccini), while the third candidate is not visualized as his node does not have a degree greater than 40 (it is equal to 16). In the Table 3 the most influential vertices related to *degree*, *closeness*, *eigenvector* and *betweenness centralities* are shown.

Table 6. The most influential vertices related to degree, closeness, eigenvector and betweenness centralities.

Id	***Degree***	***In-Degree***	***Out-Degree***
2	30206	30198	8
1	26414	26303	111
9643	323	0	323
1938	220	0	220
1397	199	0	199
935	164	3	161
9420	146	0	146
1173	140	0	140
8697	136	0	136
1752	135	0	135

Id	***Eigenvector Centrality***
2	1,000000
1	0,404064
520	0,006908
3012	0,006908
594	0,006908
691	0,006908
43	0,006908
17191	0,001968
3819	0,000516
953	0,000166
1460	
1245	

	Closeness Centrality
1436	1,0
2902	1,0
2722	1,0
4705	1,0
5604	1,0
6285	1,0
9299	1,0
9643	1,0
9705	1,0
9888	1,0
12506	1,0

Id	*Betweenness Centrality*
1	0,041509
520	0,000167
3012	0,000087
594	0,000016

Id 1 and *id 2* correspond respectively to Bonaccini and Borgonzoni, while the other ids indicate common users. A high value of *in-degree* and a very low value of *out-degree* for both the two politicians confirms the thesis expounded above, namely that the candidates have paid attention to the publication of the contents but little to reading and responding to the users, thus not generating a real virtual political debate. *Id 9643* is the third node with a higher degree and it is also within the top ten nodes with higher closeness centrality, indicating which nodes are able to easily transmit a content throughout the whole network. Finally, it is worth noting that those nodes which have higher *eigenvector centrality* (*id 1*, *520*, *3012* and *594*) also show the highest *betweenness centrality* values. While *eigenvector* measures how much a node is important taking into consideration the neighbours, *betweenness* indicates those nodes which control the information flow between all the nodes. This means that these nodes, on the one hand, are levers within the network that intervene during the debate, and, on the other hand, are able to control the information flow.

5 Discussions and Conclusions

This paper aims at demonstrating the extent to which the political debate on social media differs from candidates' programs and the effect of the polarization in the political communication during the campaign. The originality of this paper is in the application of Big Social Data paradigm for monitoring of the political debate on social media, as it shows how the combination of Big Social Data and machine learning can lead to deeper insights into the relationship between social media and political campaigns.

Data from Twitter were collected and analysed starting from two months before the election date and analytics processes for performing multiple tasks (i.e. sentiment analysis, topic extraction, network analysis and social media metrics) are presented.

Results have shown that only a few of the action plans in the candidates programs have been treated in the online debate. For example, *Rights and duties*, *Culture*, *Work and*

opportunities, *Sustainability* were topics that candidates have dealt with on social networks, but they are just a small number respect to those in their action plans. Moreover, the large presence of *Other discussions*, which are related to national news events, often shifts the political debate no longer on the electoral program, but to regional or national issues. Finally, the analysis of the community network shows that candidates have used a unidirectional communication approach, so that while they have posted a lot, they have paid little attention to user responses. No real online debate has been created, and this has resulted in a sparse network of opinions exchange between candidates and users. Another resulting effect of candidates communication approach is the polarization of the debate on some of the topics emerged during the campaign. In fact, their rare answers to people's posts have not contributed to a flatten polarization curve.

This work has some limitations: for example, this study does not take in consideration whether the online political discussion has been influenced by the presence of social bots, which could have raised significant issues on the results achieved. BSD sources considered for this analysis could be expanded to other social networks such as Facebook. Moreover, social media metrics such as reach, mentions, and engagement could have been taken in consideration in order to better understand how candidates' contents disseminate through the social network.

Implications of this work are twofold: for researchers, this approach could be used along with other methods of data collection and analysis, in order to obtain more complete insights. In addition, many of our key findings need to be empirically tested in contexts broader than Italian regional elections debates. Nevertheless, this approach could be further developed for integration with existing elections prediction works based on Big Data analytics. For practitioners, this work gives the opportunity to study political discussions to media organizations and political elites. The multi-task analysis gives the opportunity to identify the drivers of political communication in terms of sentiment generated, topics and effectiveness.

Who is Responsible and Who Takes the Credit? An Investigation of the Legal and Ethical Implications of the Digital Economy for the Intellectual Capital Development

Elena Dinu

Department of Management – Doctoral School
National University for Political and Administrative Studies
Bd. Expozitiei 30A, Bucharest, Romania

Abstract

This research paper explores the legal and ethical aspects of the digital technologies that offer opportunities for growth of the Intellectual Capital (IC). At the same time, the possible negative impacts are outlined, while it is argued that business ethics should be prioritized.

Keywords – Intellectual Capital, digital technologies, legal and ethical considerations, business ethics

Paper type – Academic Research Paper

1 Introduction

Private enterprises and governmental organizations all over the world are facing challenges to adapt to the changes brought by the digital economy (OECD, 2017), while focusing on the data-driven innovation (OECD, 2015). This encompasses various industries and sectors, from manufacturing to banking, from healthcare to agriculture, from infrastructure to smart cities. The ever evolving Information and Communication Technology (ICT) supports the digital transformation which affects not only the economy, but also the society, while forming the ground basis for sustainable development at the same time (ICC, 2017). Topics such as Big Data, ICT ecosystem, e-government, future of work, artificial intelligence (AI) ethics, privacy, data security, have become recurrent. New technologies drive new opportunities to develop the organizational Intellectual Capital (IC), new business models, improved management of resources and processes, while at the same time sudden technological advances can prove disruptive, or can raise legal and ethical concerns.

This paper aims at presenting an overview of the legal and ethical aspects related to utilization of data in the digital economy, and how they can impact sub-components of the Intellectual Capital. The first section will look into the opportunities offered by the digital economy and the underlying technologies for the development of IC. Next, the legal and

ethical challenges related to the exploitation of data for IC growth will be discussed. Finally, the paper will present the conclusions of the analysis.

2 Growth opportunities for Intellectual Capital in the digital economy

Edvinsson and Malone (1997) explained Intellectual Capital very briefly as knowledge that turns into value. As organizations endeavor to develop elements of their IC - human, structural and relational (op.cit.; Petty and Guthrie, 2000) - such as know-how, intellectual property, customer relations and networking systems, they employ ICT to expand intangible assets with the view to optimize business processes (Turban et al., 2013), to develop new products and services, to gain insights to ground strategic decisions and to achieve competitive advantage. The growth value brought by investments in intangibles like computerized information, innovative property and economic competencies based on ICT has been demonstrated in the literature (Corrado et al., 2005).

Data has become a commodity, a factor of production (Canavillas et al., 2015) and data-centric technologies provide opportunities for economic and social growth. In order to avoid poor decision making, data quality (characterized by relevance, timeliness, accuracy, easiness of use and security - Turban et al., 2013) is of utmost importance The key technologies for development are deemed to be the Internet of Things (IoT), especially when employed to monitor through sensor networks the health and activity of humans and animals, as well as the industrial and environmental processes; the Big Data analytics serving purposes such as business intelligence, decision making, machine learning; the artificial intelligence, utilized in increasingly autonomous robots; and the blockchain technology, which enables secure and trustworthy transactions (OECD, 2017). Other trending technologies that support business operations are cloud computing, social media, augmented reality (AR) and virtual reality (VR). Using the power of social networks and crowdsourcing opportunities, certain companies have expanded their profits and reach.

Most organizational operations and processes nowadays involve data collection, storage, processing and analysing, creating an intelligent learning ecosystem (Erickson and Rothberg, 2017). Digital technologies offer means for management of knowledge, for improved communication and real time connections with stakeholders, access to and management of data, information and knowledge resources, collaborative enterprises, smart machines and artificial intelligence endeavors. OECD (2015) called for a free flow of data among nations and organizations to promote innovation and societal well-being, while noting the need for corrective policies against information asymmetry, as a powershift from individuals to companies and from governments to data-driven enterprises takes place.

Big Data exploitation drives development, sustainability and disaster management efforts (UN Global Pulse, 2009), networking and connectivity of people and objects, e-government platforms and smart cities. Donation of medical data or DNA information for research purposes (Prainsack, 2019), processing of electronic health records and data

sharing (Kaplan, 2016), create opportunities for better healthcare and comprehensive public health strategies (e.g. WHO influenza monitoring program). In addition, ICT based progress in medicine has led to the bionic prostheses that extend physical capabilities beyond the regular human ones, the beneficiaries being referred to in the literature (Leenes et al., 2017) as the first cyborgs. Ubiquitous technologies and data sharing sustain education, civic initiatives, transparency and accountability (OECD, 2015).

Powell and Snellman (2004) stressed the blurring of the distinction between manufacturing and services, as smart products incorporate new technologies, which allow companies to offer additional services in relation to their products. At the same time, as part of their intellectual capital, firms utilize stocks of knowledge besides R&D, to increase productivity and to gain competitive advantage. To transfer such knowledge, companies rely on ICT. However, the authors underline the findings of research which showed that technologies also allow extensive monitoring and control, possibly leading to what Clarke (1988) named ''dataveillance''. More recent developments, where certain private companies have access to an unprecedented wealth of data, escalate the debates sometimes at international level, to the realm of state sovereignty and information asymmetry (Wired, 2019). Some authors (Hooker and Kim, 2019) even refer to the possibility of a new social contract between business companies and society.

Smart technologies can support not only the operational management (e.g. transport and distribution, quality checks), but also strategic tasks (like resource planning, staff selection) thus changing the work function and structure, though impersonal autonomous systems that interact with people might also interfere with the employee's freedom of decision (Gerst, 2019). Other concerns have been expressed with respect to the "amazonization" of work in industrial environments, where the customized production is combined with rigid operations and low-skilled work (Butollo et al., 2017). Frey and Osborne (2013) have noted the deskilling of workers, because of digitization. An ever increasing number of countries are pressured to review the labour regulations and policies, in light of new forms of work enabled by the ICT e.g. teleworking, informal work contracts favored by the sharing economy, open co-working platforms or crowd sourcing, human-machine collaboration, and others (OECD, 2017).

For individuals the main concerns related to the digital economy advancement and the utilization of data as economic resource gravitate around job security, work environment, privacy and personal data rights. As organizations introduce advanced technologies to increase efficiency of work processes and reduce costs, certain categories of employees are at increased risk of being made redundant. Various authors (Frey and Osborne, 2013; Gerst, 2019) have addressed the polarization of the labor market, which favors jobs where high cognitive skills are required. In the data based economy the workforce' competences are shifting more towards STEM fields (science, technology, engineering and mathematics), while interdisciplinary approaches (e.g. technical and legal in security, compliance and business analysis) and soft skills (creativity, problem solving and communication) are sought after. Frey and Osborne (2013) have concluded based on their

research that 47% of the total jobs in the USA pertain to the high risk category, deemed to be replaceable by computerized technology. Other authors (Gerst, 2019) have challenged these findings, underlining that decision lies with the companies and new technologies, while replacing jobs, have created others.

Big Data and AI based robots will push self-reliable automation even further in the workplace, from enhanced surgical robots to driverless cars. Robots replace humans in dull, dirty or dangerous activities (Lin, 2012). Intelligent vehicles development aims to better traffic safety, decrease fuel consumption and CO2 emissions, and improve comfort (Cheng and Lai, 2011). In order to achieve these goals, vehicles are endowed with sensors, technologies for wireless communication, geolocation, video cameras and others, which can be used to collect data about the product and the way it is being used. AI can serve many beneficial purposes, including monitoring compliance with norms and detecting violations thereof. AI based algorithms have been employed e.g. to offer services in financial investment, based on machine learning, though concerns remain in respect of inappropriate decisions because of design faults or high fluctuations in data patterns, which could make the provider liable for damages. However, there is currently no legal definition of robots or a legal framework for their use and development (Fosch-Villaronga et al., 2019), nor for many other trending technologies for that matter.

The Japanese authorities stated that the country's strategic goal is to become the world' s most advanced IT nation, and as a consequence they have published a strategy for promoting the use of robots in all socio-economic sectors (Japan, 2013; 2015). As noted by Nambu (2016), Japan needs next-generation robots to assist the elder, as the country has seen a decline in birthrate and an ageing population. However, the use of such robots is not covered by the legislation, unlike the industrial robots, which are pervasive in Japan. In addition, for fully autonomous vehicles to be allowed on public roads, the legal framework should change, as a (human) driver should be by law in the control of the car. As is many times the case with advanced technologies, export authorizations are required, which could slow down investments in next generation robots or autonomous vehicles for the global market (Nambu, 2016).

A range of topics related to the utilization of AI based autonomous robots have been debated in the literature, from the robots' interactions with humans in the workplace; to psychological effects of rejection induced by intelligent, human like entities, represented by Mori (1970) in "the uncanny valley" graphic (in Bekey, 2012); to ethical dilemmas linked to the use of robots for military or law enforcement purposes (Sharkey, 2012) and responsibility of military robots (Lockhorst and van den Hoven, 2012); to robots and privacy invasion (Calo, 2012). Sharkey and Sharkey (2012) have particularly addressed the long term effects that robot carers could have on the right to liberty and privacy of children and the elder, as well as the effects of lack of human contact and socialization on these categories.

The legal standing of AI based autonomous robots has been widely analyzed by various authors, and there seems to be an understanding that, as long as robots cannot

pass the Turing intelligence test (where an interviewer should not be able to tell the difference between a machine and a human), robots do not qualify as moral agents (Abney, 2012) and are not entitled to personhood as legal subjects (Asaro, 2012). Though robots are already capable of (co-)creating intellectual products guided by humans, they cannot enjoy authorship and cannot hold intellectual property rights (Holder et al., 2016). A robot does not have rights under the civil law, and cannot be held criminally responsible (Nambu, 2016).

This section has had the purpose to provide an overview of how various digital technologies can be employed by private and public organizations in order to support their work processes and ensure sustainable growth. Nevertheless, as the organisations collect, store and manage data from internal and external stakeholders to develop intellectual capital (Secundo et al, 2017) and to expand their profits, they find themselves entangled in a growing legal and ethical debate. But the most affected by the consequences of poor decisions because of faulty design, inappropriate data quality, unethical business models or security and privacy breaches are in the end the individuals (Wigan and Clarke, 2013).

3 Legal and ethical challenges in the digital economy

The philosophy of law and ethics have developed in parallel in the Western philosophy (Del Vecchio, 1940). Socrate believed that to know and to do is one and the same, as virtue is the application of knowledge. Virtue implies abiding by the laws, both written and unwritten. Kant has made a clear distinction between law and morals, as in his view the law is concerned only with the external, physical action, while ethics grounds the motives, the internal actions and it is imperative and rational in substance. Kant stated that moral duties extend greater than the legal ones, and that duties to the other people are based on the respect they are entitled to. Therefore people should always be treated as a scope and never as a means. Later on, the utilitarianism through J.S. Mill underlined the role of the individual's conscience in promoting the general happiness of the society.

Practice has constantly shown that entrepreneurial efforts in the realm of the digital economy, while focused on profit, seem to overlook legal and ethical aspects related to the use of data for profit. This might be favored by a lack of or inadequacy of regulations to address specific new technologies, and sometimes by the absence of insight into the consequences of treating data just like any other commodity. Though the limited legal provisions in some respects might induce the conclusion that everything which is not forbidden is allowed, all members of the society, either natural or legal persons should inform themselves and involve themselves with the implications of the legal and ethical consequences of the pervasive, ubiquitous and always connected society.

As dependency on digital technologies and pervasive connectivity increase, so do security and privacy challenges. Smart home technology, as well as wearables are designed to interconnect with other devices, or to send feedback through producers' applications, increasing the potential for major breaches, which should make security a

priority, both in terms of personal data, as well as business confidentiality. Even though, in principle, customer data is to be anonymized, re-identification is possible, especially when it comes to wearable technology (Sahmiri, 2016). Robots and IoT can facilitate monitoring or even surveillance of users, either by design, when accompanying applications which collect usage data connect to producer's servers, or through cyberattacks. Biometric, AR and VR technologies can be used to acquire personal data about users and even analyse their medical or psychological state (Royakkers *et al*., 2018).

Algorithms based on machine learning and statistical analysis process users' data e.g. for speech recognition or can provide recommendations by analyzing the customers' specific interests. But biased or erroneous analytical models have disruptive consequences on people's lives, from credit score calculation, to pre-employment screening, to performance appraisals. When prejudiced assumptions based on race, income or geographical location make their way into the algorithms, the results can prove disastrous for those concerned, given three elements - opacity, scale and damage inflicted (O'Neal, 2016).

Data concerning the customers' shopping habits, electronic financial transactions, and movements is being collected on online platforms sometimes beyond the business scope, allowing insights into private matters. On the other hand, selective provision of information, advertisement and targeted content on social media can hamper the freedom of information and objectivity (op.cit.), while diversity could collapse (Helbing, 2015). Web based service platforms generate and control great volumes of data as byproduct of their main business, amplified by the network (OECD, 2017). Such business models profit from data based services on all sides of the market, and given their size and power, they are no longer mere participants in the data market, but they appear as market regulators. In fact, such companies have access and control to more information than governments.

Persuasive technology promotes psychological manipulation not always for the user's benefit. Location based marketing and geofencing track users' mobile devices and employ big data analytics and social information to profile, select and target customers (Brown and Harmon, 2014; Goncalves *et al*., 2013), which raises privacy concerns. Similarly, web search engines accumulate a substantial volume of data about the users, to provide better search results and customized advertisement, but at the same time profiling can reveal sensitive information about somebody (Rodrigo-Gines *et al*., 2018), like political views, sexual orientation, health issues, or movements. This is a matter of actual interest, as the Covid19 pandemic has given a new impulse to such applications, justified by public interests arguments.

In the workplace, the potential of digital technology for monitoring has been underlined by Munier *et al.* (2013), who have noted the risk of using metadata for tracing users and their activities online e.g. in teleworking, for establishing when staff has logged on to a platform, and the potential of using this data as evidence in later legal

proceedings. Furthermore, technology is a driver for the gig economy, where more people are left with short term jobs and the possible solutions that are discussed are the universal basic income - though it is seen as limiting self-determination and the right to a fulfilling work life – and economic incentives by stimulating participation of individuals to profit sharing (Hooker and Kim, 2019).

Another area of concern is the data privacy breaches in relation to healthcare data, which forms a major market, while patients might not be aware of how their data is being used, by both public and private organizations (Kaplan, 2016). The processing of such data is sometimes outsourced to companies in countries with more permissive legal regimes. In other cases, data collection takes place on sites which promote exchanges of data and information for a common good e.g. obtaining insights on how effective specific treatments are for certain diseases, but data can be further sold to pharmaceutical or other companies for aggregation. As in other situations, people contribute the data voluntarily, and this is further used in ways unintended by the provider, who does not make a pecuniary gain (op.cit.). Furthermore, genetic data could be used for screening of personnel assigned to be deployed for specific posts or tasks, and people could face discrimination based on propensity to future health problems (Armstrong *et al*., 2010).

The processing of personal data is governed in the European Union by the General Data Protection Regulation 2016/679 (GDPR) since 2018, which covers such activities undertaken not only by the EU organizations, but also by foreign companies conducting business in the EU (Murphy and Barton, 2014), or concerning EU citizens. The GDPR has set down principles like: technologically neutral protection of personal data processing of identified or identifiable person, by design and by default; clear, affirmative, informed consent, which can be withdrawn by the data provider; transparency of data processing, which must be adequate, relevant and limited; data security; the data subject has right of access, opposition to processing for direct marketing and profiling, rectification and erasure (the right to be forgotten); responsibility and liability of controllers and processors for regulation breaches and the obligation to notify the supervisory authority and the data subject when rights and freedoms can be affected; the data portability right and the right to obtain a copy of the data in a commonly used electronic format; the right to judicial remedy and compensation. According to art.9 of GDPR processing of specific categories of personal data "revealing racial or ethnic origin, political opinions, religious or philosophical beliefs, or trade union membership, and the processing of genetic data, biometric data for the purpose of uniquely identifying a natural person, data concerning health or data concerning a natural person's sex life or sexual orientation shall be prohibited", unless prescribed conditions are met.

A specific problem in the digital economy is that services based on data processing would be denied to customers who would not agree with this processing. Such clients do not have real alternative options. Even when users tick the box confirming acknowledgment of terms of service, for most of them they may be ambiguous, tedious to go through or even of no interest as long as the consequences are not immediately visible

to them. A welcome solution is privacy by design, based on the notion of privacy as ‘‘informational self-determination’’ (Ishii, 2017). In the EU the GDPR has aimed to overcome this, by transferring more responsibility to the companies, by imposing a much stricter legal regime, enforceable under the EU jurisdiction and which prescribes more severe pecuniary sanctions in case of breaches of legal provisions.

Privacy and consumer protection should be a business priority (OECD, 2017). The right to privacy is protected by article 12 of the Universal Declaration of Human Rights (UDHR, 1948), as well as art.7 of the EU Charter of Fundamental Rights (EUCFR, 2012) which enshrines the right to respect for private life and communications. Art.8 of EUCFR establishes the right to protection of personal data. Art.21 of the Charter sets down the right to non-discrimination, while art.31 foresees the right to working conditions that respect the worker’s dignity, health and safety. The extent of the right to privacy can vary, and protection of privacy can be restricted depending on the legal system applicable and priority of other public or social values to be defended.

Certain business models have already clashed with existing regulations or revealed the need for the extension thereof, as exemplified by the experience of business models based on sharing economy in several countries. Breeching public transport safety regulations can be an issue in the peer to peer economy, as stressed by Costantini *et al.* (2015), as drivers must comply with legal requirements on skills, record of good behaviour and technical certification of the vehicle. As for the business side of the equation, other legal and ethical concerns to be considered are the labor rights, competition regulations, tax law and non-discrimination breaches, data security, malicious acts facilitated by lack of governmental oversight. Such businesses take advantage of the information shared by users, by controlling the data about offer and demand, by facilitating communication and matching of needs, by providing easily accessible ICT based services.

In what concerns the legal and ethical issues related to autonomous robots and AI-based vehicles, a project conducted for the European Commission (2019) has identified aspects like testing, certification, liability, insurance and management of risks as areas in need of further regulatory clarification and harmonization. While most Member States assign legal responsibility to the driver for traffic violations, the manufacturers are liable for damages caused by the product. However, it can happen that both parties are held responsible in various degrees. A similar solution has been identified by Cheng and Lai (2011) for the US market. In such cases, it is expected that data compulsory collected and stored by the vehicle and service providers to be used as evidence. Additional complexities are envisaged as automation is predicted to come gradually, which could imply other actors responsible for the products and services they provide e.g. software, connectivity etc, while malfunctioning and cybersecurity risks (hacking, phishing, eavesdropping, malicious manipulation) to products, data and privacy, and data rights should be resolved. When it comes to robots, general rules on product liability apply for regular industrial robots, which are treated as machines. Exoskeletons would fall under the legal regime applicable to the personal protective equipment, or possibly medical

devices. Intelligent and autonomous robots e.g. collaborative robots working interactively with humans, would have to comply with the labor safety and health regulations. In Japan, civil liability for damages produced by robots would apply accordingly, based on product liability, labor safety breaches or negligence (Nambu, 2016).

4 Conclusions

Various elements of the IC can be affected by unlawful or unethical use of the digital technologies. Violations of rights and freedoms such as non-discrimination or work safety, have the potential to harm especially the human and structural capital, while breaches of privacy could extend from corporate culture to the relational capital, by affecting customer loyalty, trust and company reputation. Security and protection of privacy and human rights should be prioritized and embedded in the managerial philosophy. Compliance with regulations and attention to business ethics are part of a company's corporate social responsibility assessment (GRI) and important building blocks for sustainable growth.

Patterns of External Fragmentation of Production in the Republic of Moldova

Marica Dumitrasco

Center for political research and international relations
Institute of Juridical, Political and Sociological Research
bd. Stefan Cel Mare, Chisinau-2000, Republic of Moldova

Abstract

In the modern world, most of the trade between countries is carried out within Global Value Chains (GVCs), which have become a strong driver of global economic growth. Also, not all countries are sufficiently penetrated into these chains and can benefit from integration in there. Most developing economies and former communist countries not only suffer from the lack of strategy framework of including local intermediate products in GVC, but didn't have developed country's research on this topic. Our research will fill in the gap for the Republic of Moldova. We paid special attention to the exploitation of the potential of Foreign Trade Agreement (FTA) between the Republic of Moldova and EU and elaboration on the adequate economic mechanisms for this scope. We explore the measure of engagement of RM in external fragmentation of trade, using the wide range of WEB simulation tools of International institutes. The study showed that backward participation is the predominant type of engagement of the Republic of Moldova in the external fragmentation of production. It also revealed that the list of products engaged in external fragmentation of the country is highly concentrated as well as their markets. Articles of apparel, accessories are the main product of external fragmentation of production, provided in the customs regime of inward processing. Our research found that Moldova did not make enough use of the benefits of FTA between RM and EU to deepen the penetration of products into the value chains of European space, being represented in their low-medal and low-income nets. The results of the study can be used in the process of implementation of FTA with the EU by decision makers and the private sector.

Keywords – Regional economic integration, Global Value Chains, Fragmentation of production

Paper type – Academic Research Paper

1 Introduction

Regional integration through trade and investment agreements in Central and Eastern Europe has been connected to the large international networks of production. At present Europe is one of the most important hubs in complex GVC networks activity and the main attention of this study will be painted in this region. A number of empirical studies demonstrate the dynamic integration of the entire region of Central and Eastern Europe with the global economy, especially with the European Union. Grodzicki M.J. (2014) has summered that detailed case-studies demonstrate an ongoing industrial upgrading in the GVC the of Visegrad region. If initially, their exports were based on

commodities and natural resources and were focused mainly on assembly operations, in time more and more tasks of higher complexity are being fulfilled in the region (Hotopp et al., 2002; Zaghini, 2005; Fertö, I. & Soós, K.A., 2008).

Implementation of Foreign Trade Agreement between RM and EU is at the government agenda, beginning with moment of ratification. Valorification the economic potential of this agreement should be through elaboration of adequate mechanisms and policies. It is related first of all to the deeping trade between partners. Patterns of external fragmentation of production via processing trade are not studied in country's research at present. In this context the study of the participation of the Republic of Moldova in processing trade, as well as estimation of the share of European countries in it, is important. To be mentioned that economic integration by the processing trade can be considered as a new conception for industrial and economic recovery of country.

Besides its introductory part, the paper has four parts, including the theoretical and methodological background of research as well as all outlining the aspects external fragmentation of Moldova, determining the place of the country in GVC, and concluding remarks. The theoretical part of the study examines recent GVC features and is constructed in such a manner as to be useful in the explanation of experimental findings of research and formulation concluding remarks.

2 Theoretical background of research

Last decades in the economic literature dedicated to trade topics have discussed the importance of trade liberalization for fragmentation of production that consistently led to the appearance of global value chains (GVCs).

It is a consensus regarding that trade tariff reduction has stimulated trade exchange between countries that in line with the growth of the volume of international trade was expressed in the global fragmentation of production.

The evolution of this concept can be seen in a number of studies of past years.

In the economic literature increasing trade of big parts and components of manufacturing goods between countries has been variously called.

Besides mentioned above, for a description of this globalization process has been used the following notions: vertical specialization, processing trade, slicing up the value-added chain, outsourcing, offshoring.

There are differences in the reflection of international fragmentation of production in the economic literature of the end of twenty century and in the recent studies of the twenty-first century accompanied by the analysis of accumulated experimental dates.

At the earlier studies, there have been to explain the fragmentation of production based at classical theories of the trade, using Ricardian and Heckscher-Ohlin type models (Deardorff, A. V., 1998; Jones, R. W., and H. Kierzkowski, 2000; Görg, H. ,2000). So, the main drivers of these phenomena were the big production firms in high developed countries that have been interested in reducing production costs in order to increase their

competitiveness. They pursued this strategy by the vertical division of the production process at the stages replaced in different countries.

At present GVCs are often taken as a determinative peculiarity of the current wave of globalization. According UNCTAD estimation, at present about 80% of trade takes place in international production chains linked to multinational companies (UNCTAD, 2013).

GVCs have become the main driver of global economic growth. In the global world, trade and transport tariff reduction as well as IT dissemination allowed further international division of labor and specialization by countries, transferring competition from the firms to their departments and individual jobs through participation in global value chains.

One of the undeniable features of contemporary economic development is that services play an extremely important role in external fragmentation of production. GVC activity in manufacturing reveals that a large fraction of the value-added is created in services. Services often are important inputs (such as research, design) in the production process as well as link the different stages (such as marketing and distribution) of value chains of manufacturing goods (World Bank, GVC Development Report, 2017).

With essential and evident global economic and welfare benefits, trade segmentation enhanced wage disparity, especially between developed and developing economies.

In context, to be mentioned some of the important studies that contributed to the economic analysis of the modern picture of the world by estimation of consequences of the current wave of globalization for EU as well the profound critical evaluation of classical trade theories.

So, one of the main conclusion from the Baldwin (2006) study is that the globalization opened new opportunities for rising productivity of EU's firms. To use this opportunity it should be made adjustments in a set of government policies, preponderant in R&D, labor market and education. It has important implications for competitiveness Strategy of EU the same, because the study argued that the second wave of globalization is favourable for high skill sectors/workers in Europe and vice versa.

From the study of Eric Sheppard (2012) is following that classical trade theory in explaining of the globalization process is not sufficient. The similar conclusion was made by Krugman (1995) that noted the vision of traditional theoretical approaches is limited for explaining the tremendous growth and changes of world trade landscape.

Some recent studies highlight the relationship between GVCs and different aspects of production: the influence of the international fragmentation of production on trade and specialization in the manufacturing of country (Laura Dell'Agostino, Silvia Nenci ,2018), correlation between GVCs and productivity (Constantinescu, C., A. Mattoo; M. Ruta, 2017), others studies pain attention on sustainability in global production networks(Alexander, R., 2018 and 2019). According to Stollinger (2016) and Sampath and Vallejo (2018) since the advent of the GVC, the manufacturing sector has undergone significant structural changes towards expansion and has become a major driving force of economic growth.

Besides the works studying the development of trade fragmentation, to be mentioned the research dedicated to its measurement. Traditional trading indicators (gross export / import, trade balance and their trends) are also limited as traditional theoretical approaches to explain the external fragmentation of production.

In economic literature notes that trade in intermediate goods between countries is often used as a suitable indicator for trade fragmentation (Götz Zeddies ,2007; Beltramello, A., K. De Backer and L. Moussiegt, 2012).

Also in the economic literature is mentioned that analysis of the new global trade landscape is suffering from lacking appropriate models and good data and is difficult to interpret (Hubert Escaith, 2009).

Recent OECD studies are based on the approach to the measurement of GVC participation, elaborated at the synthesis of the number of experimental research. According to this "value chain participation is defined in terms of the origin of the value added embodied in exports both looking backward and forward from a reference country: backward when it comes to foreign value added embodied in exports, and forward when it refers to domestic value added which is used as inputs to produce exports in the destination country" (Kowalski, P. et al.,2015, p.13).

Some aspects of applied this approach are explained in the next sections in the determination of engagement of the Republic of Moldova in external fragmentation of production.

3 Methodological background and objectives of research

This study is based on the analysis of trade flows of intermediate goods between countries for measurement engagement of countries in external fragmentation.

The methodological base of study is a wide range of WEB simulation tools of International institutes that allow estimating the engagement of Republic of Moldova in external fragmentation of production and the best ways it can be done, among which are: Trade in Value Added (TiVA) instrument, developed by OECD for the comparative analysis of GVC integration across countries of different levels of development, the Market Analysis Tools of International Trade Center (ITC) of the World Trade Organization and the United Nations.

TiVA database incorporates important information regarding to the trade in goods by the end-use categories, including intermediate goods. It offers information dealing with participation in GVCs via intermediate imports embodied in exports (backward linkages) and domestic value added in partners' exports (forward linkages) the same. At the same time, trade statistics included in TiVA database is not completed in the case of Moldova. So, domestic value added content of gross exports is not separated from foreign value ones in the case of Moldova.

It should be noted that the simulation results extracted from the databases are additional in the study. However, this approach is limited to the various product classifications used in databases. The International Standard Industrial Classification of

All Economic Activities ISIC Rev. 4 will be used for the information incorporated in TiVA database.

Trade map of ITC contains bilateral trade statistics of goods that are re-exported in the country from which was imported previously. It allows the determination of goods that have acquired domestic origin through processing and are engaged in backward participation. Republic of Moldova is included in the list of 70 countries that having reported their reexport.

Based at the methodology, there are following objectives of the study:

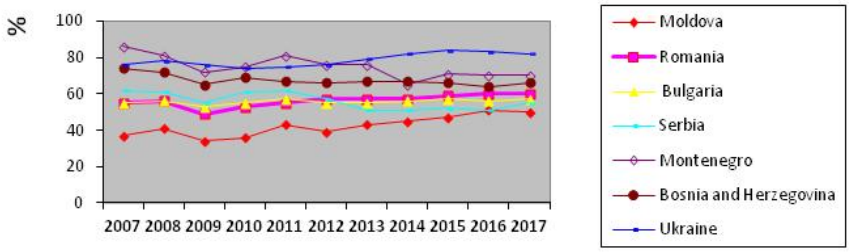
- Comparison records of external trade by intermediate goods of Moldova with other Eastern European countries,
- Determination of particularities for backward engagement of Moldova in GVC,
- Estimation of product' specialization and predominate market concentration of trade fragmentation of country.

4 External fragmentation of production of the Republic of Moldova

4.1 Records of external trade by intermediate goods of country

Trade in intermediate goods between countries is one of the suitable indicators for an estimate of trade fragmentation of the Republic of Moldova.

In comparison with Moldova, all countries have the initial (2007) and final (2017) levels of expansion of intermediate goods in export to be higher. It speaks that they are more profound integrated in regional and global value chains in comparison to Moldova **(Figure 1**).



Source: Elaborated by the author at the Bilateral Trade Database by Industry and End-use category

Figure 1. Shares of intermediate goods, by industry in export, % selected Eastern European countries

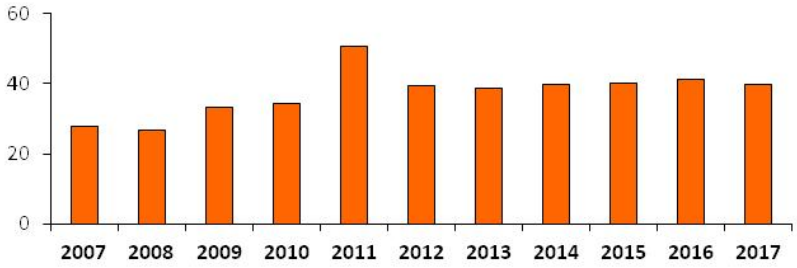
It can be observed that the share of intermediate goods is reduced in 2009 - the first year of economic crisis and it already recovered in the second 2010 in all counties.

Ukraine, as well as Montenegro, Bosnia, and Herzegovina, show the highest shares of intermediate goods in export.

Romania and Bulgaria demonstrate similar trends in developing trade by intermediate goods. During the 10-year period of the country's EU membership (2007-2017) it was changed insignificantly. Romania's share in the trade-in intermediate goods increased between 55% and 60%, but Bulgarian's one between 55% and 57%. Moldova's export has unlike structure to all countries included in the analysis. Household consumption has prevailed category of export for the exception of recent years when the structure was changed. So, Moldova's share of household consumption was reduced from 56% (2007) to 43% (2017) while the export of intermediate goods has expanded from 37% to 50 % during this period. To be mentioned that in Moldova the rate of growth of intermediate goods was higher than the rate of growth of exports in general. So, if the country's export increased in 1.8 times in 2017 in comparison with 2007, the intermediate goods export expanded in 2.4 times in the same period.

Analyzed records approve indirectly the extension of penetration of Moldova in external fragmentation of production as well as the efforts for identification of their niches.

It should be mentioned that 39.8% of the total import of intermediate goods of Moldova in 2017, was embodied in export, it is above the share in 2007(27.8%), but lower than in 2011(50.3%), when produced the recovery of the economy (Figure 2**)**.



Source: Calculated by the author at the Bilateral Trade Database by Industry and End-use category and Market Analysis Tools ITC

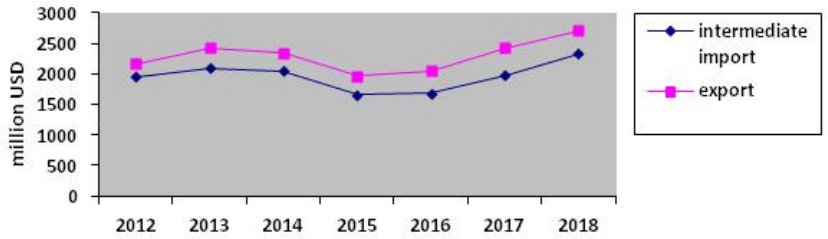
Figure 2. Reexported intermediate import as % of intermediate import of Moldova

Figure 2 also reveals that the share of reexported intermediate import was increasing till 2011, including the crisis years of 2009 and 2010 thanks mainly to a decrease in imports.

In Moldova, beginning with 2012 it stabilized on the level of about 40%, close to Romania of 37.8% but below the share of Bulgaria (54.6%) there were in 2016. Taking into attention that the indicator provides a measure of intermediate imports as a source of

international competitiveness, it can to speak that reexported intermediate import of Bulgaria are more competitive than of Moldova and Romania.

It can be observed a strong correlation between intermediate import and total export of Moldova (Figure 3). This means that Moldova uses significant share of intermediate imports in its export production.



Source: Elaborated by the author at the Bilateral Trade Database by Industry and End-use category

Figure 3. Intermediate import and total export of Moldova

To be mentioned further that the reexported intermediate import has reached 57 % of total intermediate export of Moldova in 2018. So, intermediate import embodied in exports has acquired domestic origin through processing and are engaged in backward participation.

Following analysis will be based at the study of engagement of Republic of Moldova in backward activity.

4.2 Backward engagement of Republic of Moldova in network activity

At present list importing markets for products reexported by Moldova includes the 15 countries that demonstrate significant shares in value in Moldova Republic's reexport that are considered for this study more than one percent during one of the years 2010-2018. But only few countries dominate in list of importing markets. (Table1)

Table1. Share the main importing markets for the products reexported by Moldova

importers	**Share in value in Moldova Republic's reexport,%**								
	2010	2011	2012	2013	2014	2015	2016	2017	2018
Romania	24,9	22,3	11,1	12,3	17	19	24,3	26,8	31,9
Italy	16,9	11,9	7,6	8,8	17,1	17,7	18,5	18	18
Germany	5,4	4,1	2,2	2,3	3,9	4	5,8	6,1	7,6
Russian Federation	24,1	37,9	53,3	49,4	30,2	21,6	14,8	11,1	6,8
United Kingdom	7,7	4,8	3,9	4,6	7,9	8,1	6,7	6,1	6

Turkey	5,2	3,1	4	3,3	3	3,1	3,5	3,2	3,4
Ukraine	3,5	3,6	3,3	2,7	2,7	1,8	1,8	2,4	2,6
World	100	100	100	100	100	100	100	100	100

Source: Elaborated by the author at the Trade map of ITC

It can be observed that tree European countries: Romania (31.9%), Italy (18%) and Germany (11.1%) composed more than sixty percent of value in Moldova Republic's reexports in 2018.

Further analysis shows that the share of European countries has a tendency for increasing beginning in 2013 in the reexport of Moldova. More huge reexported growth in value was reached for Romania (30%) and Germany (37%) in comparison with total growth (9%) for 2018.

The opposite trend is observed regarding the Russian Federation. So, the Russian Federation's share is decreased from 53% (2012) to 6.8% (2018). At the same time, the reexported value of Russian Federation has essentially decreased between 2013-2018 years, and especially in last three years. In 2018 the decline in the reexported value composed about 86% compared to the 2012 year.

Similar to Russian trends, Ukraine's share in the reexport at the end of the analyzed period has reduced in comparison with its beginning.

Reexport of Republic of Moldova is geographically divided mainly between former USSR republics and EU countries. It can be observed the same that it concentrated in Romania from European states as well as in Russian Federation from ex USSR countries. Republic of Moldova will been included into industrialization process historically after World War II and now has been oriented at the assembly production dealing with this region as a result of the actions taken by the governments.

The most important conclusion from our analysis that can be deduced is the Moldova's reexport is leaving the countries of the former USSR to favor the EU states. It can be explained by the impact that produce the implementation of Deep and Comprehensive Free Trade Agreement between Moldova and EU that started to take effect on 1 September 2014. In turn, it is the extreme important for economic modernization of the country.

It should be mentioned that the list of products reexported by the Republic of Moldova is limited the same. So, from the 97 product groups, selected according HS4 trade classification, reexport is highly concentrated only in three groups: electrical machinery and equipment and parts thereof; sound recorders and reproducers (23%); articles of apparel, and clothing accessories, not knit or crochet (22.7%); articles of apparel, accessories, knit or crochet (9.6%) in 2018.

Table 2. List of main products reexported by Republic of Moldova

Product label	Share in value in country's cluster import,%								
	2010	2011	2012	2013	2014	2015	2016	2017	2018
Electrical machinery and equipment and parts thereof; sound recorders and reproducers	17	16,7	5	7,9	11,1	12,7	17,1	20,7	23
Articles of apparel, and clothing accessories, not knit or crochet	19,3	14,1	9,6	11	19,8	20,9	21,1	22,1	22,7
Articles of apparel, accessories, knit or crochet	14,4	10	8,1	8,8	11,2	10,4	10,5	9,6	9,6
Pharmaceutical products	8	6,5	10,2	11,7	13	8,2	4,8	5,6	6,3
Furniture; bedding, mattresses, mattress supports, cushions and similar stuffed furnishings	5	7,3	10,6	5,7	4,4	3,7	5,6	4,7	3,2
Footwear, gaiters and the like, parts thereof	4,2	4,4	3,6	2,5	3,6	3	3,2	3,2	3,1
Nuts, fresh or dried, whether or not shelled or peeled	6,5	4,3	5,8	4,7	5,1	8,7	2,4	2,3	3,1
Vehicles other than railway or tramway rolling stock, and parts and accessories thereof	1,6	3,4	5,1	4,5	2	1,5	3,3	2,7	2,2
Machinery, mechanical appliances, nuclear reactors, boilers; parts thereof	5,2	6,8	5,7	4,9	3,7	3,6	2,7	2,4	1,9
All products	100	100	100	100	100	100	100	100	100

Source: Elaborated by the author at the Trade map of ITC

The share of above product groups in value in country's cluster import was more than half in 2018. The portion of other 94 product groups varies from few percents till to hundredths percents. Analysis shows that the articles of apparel, accessories are the major specialization product of trade fragmentation of country.

At the same time main goods included in processing trade of Republic of Moldova are concentrated at the different importing markets. (Table3).

Table3. Selected products reexported, destined to main importing markets in 2018

countries / products	Share in value in Moldova Republic's reexport,%								
	Russian Federation	Romania	Italy	Germany	United Kingdom	Turkey	Netherlands	France	Ukrain
Electrical machinery and equipment and parts thereof; sound recorders and reproducers		69,4	3,7	10,3					1,4
Articles of apparel, and		21,5	45,5	9,1	15,3	0,9			

clothing accessories, not knit or crochet									
Articles of apparel, acces sories, knit or crochet		7,4	34,7	1,4	23,7	30,4

Furniture; bedding, mattresses, mattress supports, cushions and similar stuffed furnishings	4	5,4	3	23,2			21,7		
Footwear, gaiters and the like, parts thereof		74,4	21,2						
Vehicles other than railway or tramway rolling stock, and parts and accessories thereof	6,7	57,4		13,3					7,5
Machinery, mechanical appliances, nuclear reactors, boilers; parts thereof	17,3	35,8	1,5	23,3	2				2,9
Nuts, fresh or dried, whether or not shelled or peeled		0,7	3,3	15,8		1,6	5,7	52,9	

Source: Calculated and elaborated by the author at the Trade map of ITC

About the 70% of *electrical equipment* is reexporting in Romania.

Reexports of *articles of apparel, accessories, not knit or crochet* are divided between European countries, more than 45% of which are importing by Italy.

Subcontracting relations between Moldavian enterprises and Italian firms have been constructed in 90-th years based at the cheap and qualified labour force. As one of the good examples should be mentioned the largest clothing factory in Moldova - “Ionel” that produces clothing based on Italian technology, is modernized with equipment from European branded companies. The company promotes such brands as Ionel, Giovanni Primo, Bella Prima, and makes articles for successful brands from which are Luisa Spagnioli, Pizza Roma, Patrizia Pepe, J.W. Tabacchi, Oviesse, UPIM, Conbipel, Trussardi, etc.

The other example of the clothing industry from Moldova engaged in the external fragmentation is the “Tricon” factory. It is one of the main producers of apparel knitted or crocheted. It fully modernized the equipment, implement new technologies in the collaboration with famous brands from Germany, Italy, and other counties.

Importing shares of articles of *apparel, accessories, knit or crochet* belong preponderant Italy (34.7%), Turkey (30.4%) and United Kingdom (23.7%).

The assortment of products reexporting in Russian Federation is including the leading positions *in pharmaceutical products* (74%).

Furniture and its accessories are mainly reexported in Germany (23.2%) and Netherland (21.7%).

It attracts attention that dried apricots, prunes, apples, peaches, pears as well as dried leguminous vegetables and fresh or chilled vegetables are absent in the list of main products reexported by the Republic of Moldova. Taking into attention that the vegetal products are the main export category with a share of 25.4% in 2018 according to official statistics, it seems the big contrast. In fact, the fresh and processing fruited and vegetables are mainly engaged in forward external trade.

It can be observed the same that only pharmaceutical products participate in trade fragmentation with former USSR countries: Russia (74%) and Ukraine (19.2%). The markets of trade fragmentation for all other products are divided between former USSR countries and EU countries.

Taking into attention the large assortment of goods reexported in Romania and significant importing shares in electrical machinery and equipment *(*70%), *footwear and parts thereof* (74.4%), *machinery* (35.8%), and *vehicles and parts and accessories thereof*(57.4%)it is one of the main markets for trade fragmentation of Moldova. Italy and Germany are important markets for backward trade fragmentation the same for seven product groups from Moldova.

It can be mentioned some measures of economic policies that have had an influence on this structure of reexport.

First, from the analysis of the reexported products is fallowing that the materials and accessories were imported in the Republic of Moldova in the customs regime of inward processing where products were transformed, and then were reexported from Moldova to EU countries, especially, when it comes to clothing articles and textiles, footwear, articles of leather etc.

The customs regime of inward processing allows that the foreign goods to be used in Moldova in one or more processing operations (processing, including erecting or assembling or dropping them to other goods), that intended for removal from the customs territory as compensating products without payment of import duties and without application of economic policy measures.

So, the created situation is not favorable for economy of Republic of Moldova, for the reason that the reexporting, based at the customs regime of inward processing, is not part of the gross additional value process and the process of taxing the company's income.

Second, the list of operators entitled to extension of the deadline for payment of VAT and customs duty for during the production cycle, but not more than 180 days at raw materials, materials, accessories, and primary packaging and completing items imported exclusively for manufacturing goods destined to export, was approved according to Government Decision Nr. 359 of 26.05.2014.

List of goods of Republic of Moldova engaged in external fragmentation of production is mainly gets into one from two mentions above economic regimes.

5 Conclusions

The backward participation is predominant type of engagement of Republic of Moldova in external fragmentation of production. At the same time the backward activity is concentrated in four markets, including Romania, Italy, Germany and Russia. This collaboration is based on the previous long-standing relationships – with Russia when the Republic of Moldova was a part of Soviet Union, but with European countries – with first years of independencies - beginning with 90-th years. At the same time Moldova's reexport is leaving the countries of the former USSR to favor the EU states. It is explained by the impact that produce the implementation of Deep and Comprehensive Free Trade Agreement between Moldova and EU that started to take effect on 1 September 2014.

List of products reexported by Republic of Moldova is highly concentrated the same, primarily in three groups. This is a consequence of the extensive process of deindustrialization, which took place in Moldova during the years of independence. According to our calculations based on the World Bank provided data, the share of the manufacturing industry in GDP decreased by about 2 times in 2016 compared to 1995, from 22.3 to 11.8 percentage points. Despite the fact that the program documents calculated the annual growth rate of electronics production up to 16 -18 percentage points (the Program for the development of the electronic industry until 2015) and an increase in the industry in GDP - up to 20-22 percentage points (the Development strategy of the industry for the period up to 2015 year), a decline was achieved in 2015.

Articles of apparel, accessories are the main product of external fragmentation of production, provided in the customs regime of inward processing.

The most part of Moldovan external commerce is characterized by the vertical specialization that involves the use of import components (the technologic, design, and capital intensive) for the assembly or final production of goods which are exported afterward. This specialization of Moldova implies intermediate import and export of goods simultaneously that take part in the same commercial category but on the different stages of technology processes.

Goods from Moldova are insufficiently penetrated in income value chains and mostly presented in low income nets of European countries.

Advantage of geographical approximation to Europe the one of the main manufacturing hubs around of which is organized GVC activity is practically unused by Moldova. It should elaborate strategy framework of penetration of local intermediate products in global value chains.

Technology Innovation and its Role to Enhance Regional Development

Konstantinos Kalemis

Department of Education, University of Athens., Greece
Refugee Education Coordinator
Ministry of Education and Religious Affairs
National Centre for Local Government and Public Administration

Abstract

Research, technological development and innovative activity are currently one of the most important factors influencing the competitiveness of both the economy and the individual regions. The accumulation of know-how, knowledge acquired from experience (learning by doing) and the results of diffusion of knowledge (spill over effects) related to the development of technology; allow the existence of self-sustaining self-sustained endogenous growth for the regions.
The main objective of the work is to focus on examining the role of innovative activity and in particular the role of the results of research and technology policies in relation to the assistance of regional development.
It will examine the role of the use of research and technological development policies in the less developed regions with a view to creating proposals for the development of procedures that will allow the gap with the most developed regions to be reduced. More specifically, work will analyse the supply of technology at regional level, examine current research, technology and innovation programs supporting technological infrastructure and research and technological activity in regional level, will analyse the region's environment that supports and facilitates innovative activity, including the financial system, industry, research canters and other technological Infrastructure, will examine and analyse the needs of the productive sector, the role of the markets at regional level in the selection of appropriate technologies and will examine the needs in technology of small and medium-sized enterprises at regional level, will make analysis of the gap between the demand for technology from businesses and consumers and the supply of technology from the state infrastructure and from businesses, will analyse the needs for technological development and finally will examine the relationship between technology and employment at regional level. Businesses face significant problems in developing their technological and innovative activities. They speak of a lack of communications and communications infrastructure, problems of financing and cooperation between universities and production, and the absence of an effective and decentralized organisation of public administration and policy. The lack of a basic technological infrastructure leads to technological and economic underdevelopment of the region and thus to an increase in regional disparities.
A general conclusion is that all successful innovative companies worldwide were forced to compete with other companies in the domestic and international market. In most cases, because the domestic market is not great, if companies do not compete in the international market, they cease to be competitive.

Keywords – innovation, technology, regional development, human capital, innovative entrepreneurship

1 Introduction

Technology is one of the key factors contributing to both economic growth and the social and regional development of an economy. This chapter attempts to refer to the delimitation of the basic conditions relating to innovative and technological activities, as well as a presentation of the key statistical measurement and evaluation indicators of innovative activities (Holtermann, 2010).

Technology can be defined as a set of elements of practical or theoretical knowledge concerning know-how, methods of procedures, experiences and also machinery and equipment, which through technological knowledge can be combined for the production of goods and services (Hughes, & Meckling, 2018). .

In other words, technology is a combination of productive factors, qualitative and quantitative, in relation to certain outputs of products and services or production processes through scientific, technological, organizational, economic and commercial activities. An effective combination of production factors requires knowledge, which can be distinguished in integrated and non-integrated. Integrated technological change refers to design improvements or the quality of new capital goods or intermediate inputs and concerns existing machinery and equipment (Graafland, 2020). The unintegrated technological change concerns a shift in the production function over time and refers to: (a) competences, (b) experiences of effort and technological solutions and (c) knowledge and achievement (Volberda, Mihalache, Fey, & Lewin, 2017).

Innovation is the process through which an economy creates and transforms new knowledge into useful products, services and processes, leading to both value creation for entrepreneurs and a higher standard of living for society. In more detail, innovation can come from a range of changes and improvements across the entire range of the production process and extends to all production activities, from basic production methods and workforce performance, to external promotion and disposal markets for a product or service. A technological innovation is considered to be implemented if it has been introduced to the market (in the case of product innovation) or if it is used in the production process (in the case of process innovation), and a company introduces new products or services to the market either when it adopts new ways of producing new products or services.

In recent years, the literature on the intrinsic development model in which innovation is produced through the structures of the enterprise has explored the idea that investing in knowledge and learning can influence the growth of economic aggregates in the long term, in which case the position has emerged that the productivity of human resources in the future is influenced by the moods of the present, i.e. , decisions to make the necessary financial and technological resources available and to encourage business executives to diffuse knowledge and take initiatives (De Souza, Ying, & Yang, 1998).

It is equally important to see the difference between innovation and invention: the term innovation is vague and ambiguous; in scientific research it means both a process and its result. So invention is an idea of how existing technological knowledge could be

transformed into new and different applications while innovation is the transformation of an idea into a new product or service of commercial importance. To turn a business into an invention, it needs to combine knowledge, skills and financial resources. For this reason, there are time gaps between invention and innovation, usually due to the lack of appropriate conditions for commercialization of the invention. Invention is neither necessary nor capable of innovation as it can lead to a patent, however, most of the time, it does not result in a commercial transaction.

On the other hand, developments in the theory of economic development have renewed interest in the role that innovation plays in the development process, underlining the links between investment in innovative activities, technological change and economic development. The exploitation of innovation offers new solutions to economic problems and thus makes it possible to meet some of the needs of the individual and society. As a driving force, it pushes businesses towards long-term development objectives and the renewal of their production structures in order to maintain elements of growth, competitiveness and employment, with investments in the introduction of new technologies (Marion, & Friar, 2019) aimed at modernizing the production process and enhancing competitiveness. The reason is that new technologies lead to increased productivity of inputs, contributing to the long-term improvement of competitiveness and sustainable development. This approach leads to a theoretical shift, from the view of an economy based on productive factors, to an economy based on innovation and knowledge through innovative entrepreneurship.

In this context, the innovative process is considered a complex and interactive process of technological and economic development. Technology is one of the key factors contributing to both economic growth and the social and regional development of a country (Hagedoorn, Koetse, Van Beukering, & Brander, 2020). .

Important, however, is the observation that despite the remarkable contribution of research and technology to economic development, their connection with more and more productive resources does not automatically lead to economic benefits, nor is knowledge equally distributed in space, between countries or regions, nor is it to the same extent accessible to each region. Although innovation usually takes place in nearby enterprises or sectors, the economic benefits do not automatically spread to the regions in which the innovative activity takes place. In order for a region to benefit from research and development, it must also have developed a local industrial base that can use new ideas and new knowledge; otherwise they may go to more organized regions that can exploit them.

In the age of globalization, research and technological development are developing rapidly thanks to the exchanges of researchers, information and scientific results, which move from one country to another more freely, more rapidly, through the encouragement of cooperation between partners from different countries through framework programs (Hyland, & Soosay, 2008).

2 Innovation in the Places of Business

Entrepreneurship is now recognized by all international organizations as an important factor that defines economic growth, competitiveness and employment and is an important driver of innovation. The management of innovation, namely how a new idea is created, how and by what criteria it is evaluated, how it is financed, etc., is a particularly arduous and demanding process which is a key element of effective entrepreneurship.

As part of the development of a strategy to promote innovative activities, the company should define the objectives, instruments, framework within which the effort will be initiated and the criteria for the adoption of ideas or proposals. It is necessary to integrate creative thinking for the production of truly original innovations but also to control the "products" of creative thinking in terms of their applicability (commercial sustainability). In a small business there is a greater need to transform innovation because a single failure can lead it to bankruptcy. The need for methodical development and introduction of new products to the market is essential and in the large enterprise, which usually deals with a range of products, risks larger capital has a more complex and cumbersome organization.

In order to be constantly innovative, companies should make strategic choices in critical areas. Firstly, strategic options for target markets to which a company wishes to enter are important and the identification of the kind of innovative products or services it will introduce into them. In other words, it chooses the market that interests it in principle and immediately after the competitive and innovative product or service with which it will be placed within it (Voutilainen, Turunen, & Ojala, 2020).

This category includes options regarding the design of a prototype, its development and testing and further research for improvements, before its promotion in mass production and then its "placement" on the market. In the third category we have options that play an important role in the development of innovation and business performance, such as new production technologies, the purchase of know-how, development or hire of special executives, equipment, or intermediate inputs that incorporate innovations.

The concepts of technology, knowledge and innovation are directly linked. Technology refers to the result of the application of (theoretical) scientific knowledge with the aim of creating an object with practical benefit. Sometimes, it refers to the methodology that characterizes such a procedure. Technology is the systematic application of scientific or other organized knowledge for the execution of practical purposes. Technology consists to a large extent in the application of knowledge created by both science and practice and experience (Olsson, & Paik, 2020).

Technological knowledge has characteristics of a public good if: (a) the cost of making it available to a general user public is low in relation to the cost of development and (b) after its diffusion; access to it can no longer be prevented. The latter feature creates two main problems for individuals who attempt innovations. The first relates to the fact that the social performance of innovation is usually higher than private, i.e. with positive exogenous effects. The second problem, which is a sub-case of the former, relates to the fact that knowledge cannot be self-interested. However, when an innovative company

cannot reap all the benefits generated, its incentives to invest in innovative activities are reduced. Thus, where technological knowledge has characteristics of a public good, there is a malfunction in market forces that would push companies towards innovation.

3 Entrepreneurship and Innovative Activities: An Analysis of the Impact on Competitiveness and Economic Development within the European Union

3.1 Innovation in the Places of Business

Companies invest in innovation to create new products or production processes but also to develop and maintain their capacity to adopt and exploit technological information available from external operators. Furthermore, the exploitation and improvements in the skills of the workforce play a particularly important role and contribute significantly to enhancing productivity. As the life cycle of products and services decreases and the emergence of new technologies is becoming ever faster, businesses are forced to innovate more often. Market access time is becoming increasingly important as factors of competition. The dissemination of new techniques, products and services makes it possible to exploit innovation in full in relation to competitiveness. The main factors that motivate businesses to undertake innovative projects are:

• The incentive to undertake a profitable investment where the efficient allocation of resources to innovative processes enables the company to reduce its costs, strengthen its relative position in the industry and its market and increase its profits.

• The incentive for a strategic advantage consisting in obtaining a strategic advantage by introducing and operating improved products and processes that can increase the company's market share.

Human resources, and in particular teachers and research organizations, play a key role in growth and competitiveness. Investment in human resources has a direct positive impact on the rate of development of technological change. The growing importance of technological change in global production and employment has been one of the hallmarks of recent decades. Technological changes determine a country's place in international competition and affect its level of modernization (Tazzara, 2020). Developed countries tend to give greater weight to policies aimed at encouraging development and strengthening the development process through research and technological activities. New technologies play a particularly important role in a country's productivity and competitiveness. The fact is that small and weak technological countries have fewer resources than larger countries. Small and weak technological countries are usually forced to choose only 'certain sectors', where they have the opportunity to invest and develop their research and technological priorities. Advanced technological countries usually have a longer-term strategy and planning, while the priorities in the areas of research and technology they choose are for high-tech sizes.

The existence of skilled human resources and the large investments allocated to research and technology and technological activities, as well as the availability of resources in large countries, give an additional advantage to developed countries, which identify and "drive" trends in the fields of research and technology. Therefore, small countries usually tend to follow the "directions" set by developed countries. Development policies are directly related to human resource development policies, as well as to improving technological progress and modernization of the production base (Thapa, Kumar, Roy, & Joshi, 2020).

Entrepreneurship is now recognized by all international organizations as an important factor that defines economic growth, competitiveness and employment and is an important driver of innovation. The management of innovation, namely how a new idea is created, how and by what criteria it is evaluated, how it is financed, etc., is a particularly arduous and demanding process which is a key element of effective entrepreneurship.

3.2 Innovation and regional development

Technology and innovative activities now play an important role in wealth creation and economic development, directly affecting economic operators, institutions, social norms and governance structures. The capacity to develop a region is usually linked to innovative activities and business productivity, their ability to 'unite' networks and exploit human resources and institutional framework, influenced by geographical proximity.

Innovation is analyzed not simply as an economic process, but as a social activity and process that includes the dynamics of many different enterprises, research bodies, universities and regional development actors in general. The innovative potential of the region depends both on the capacity to learn and produce innovation and on the ability to interact and collaborate on network operators (Vanhaverbeke, 2017). .

In the context of regional analysis, regional competitiveness can be approached as the capacity to produce goods and services that meet the demand of international markets, while maintaining high and sustainable levels of income or more generally the ability of regions to create, while exposed to international competition, comparatively high incomes and jobs.

In other words, regional competitiveness is a region's ability to create or maintain an 'attractive' microenvironment for the development of economic and social activities under conditions of domestic and international competition. The aim of regional competitiveness is to improve the well-being of the citizens of a region, i.e. in terms of income, employment while improving opportunities and quality of life.

Based on the definition of regional competitiveness, i.e. the capacity to maintain and improve the well-being of the region's citizens under conditions of domestic and international competition, which is seen as a complex and continuous process that refers to a wide range of determinants. More specifically, the main determinants are considered to be:

- the quantity and quality of the production factors;
- the degree of accumulation
- productivity,
- the immediate regional environment,
- the structure of the markets;
- integration with international markets;
- Investments in social, human and material capital.

Strengthening competitiveness contributes to the achievement of the objectives of an economy and a region, including, for example, competitiveness, increasing employment and real income, reducing unemployment, and enhancing opportunities and opportunities, both within and outside national borders, as well as improving the standard of living of citizens (Vahidian, 2018).

Regional competitiveness depends on a region's ability to generate satisfactory levels of exports and maintain an increasing level of income by ensuring full employment for citizens. A determining factor in this effort is the productivity of inputs for goods and services produced at local and regional level. The competitiveness of a region depends both on the competitiveness of the enterprises established therein and their cooperative or competitive strategies and on the business environment of the region, i.e. local institutions, social capital, public and regional services, and social culture.

The competitiveness of a regional economy depends on its economic activity. Regions where declining sectors and productive sectors of low value added and low-integrated technology are concentrated usually have a serious 'development delay' and severe structural difficulties in adapting to competition. On the other hand, regions with a diversified economic structure and dynamic industries based on technological innovation, learning capacity and business networking have a comparative competitive advantage.

A region, as part of the country, is affected by 'general macro-competitiveness'. More specifically, the determinants and "forces" of competitiveness are directly related to:

- Economic policy;
- Social, political conditions and the institutional framework;
- The wider 'long' international environment;
- Innovative activities and new technologies;
- The opening up of markets and exposure to competition.

The differences between the competitiveness of economies can largely be explained by the existing differences in the performance of innovative activities between economies, as well as differences in levels of technological development. Regional disparities occur, in particular, due to disparities in productivity and competitiveness, while affecting the rate of economic growth seen as a function of the capacity to innovate in the production process, the introduction of new products, the reduction of costs with innovations and the increase in market adaptability (Rojas, 2020).

Strategic planning is a process of defining long-term objectives and selecting implementation policies based on scientific analysis, international experience,

participatory processes and specific conditions prevailing in the economy, society and infrastructure of each region. In shaping the regions' development priorities, particular attention must be paid to taking account of both the exploitation of comparative advantages and the treatment of the development problems and weaknesses of each region. Regional disparities are defined as disparities in opportunities in individual spatial units: opportunities for economic activities, investment, employment, career, study, care, recreation, cultural activity, etc.

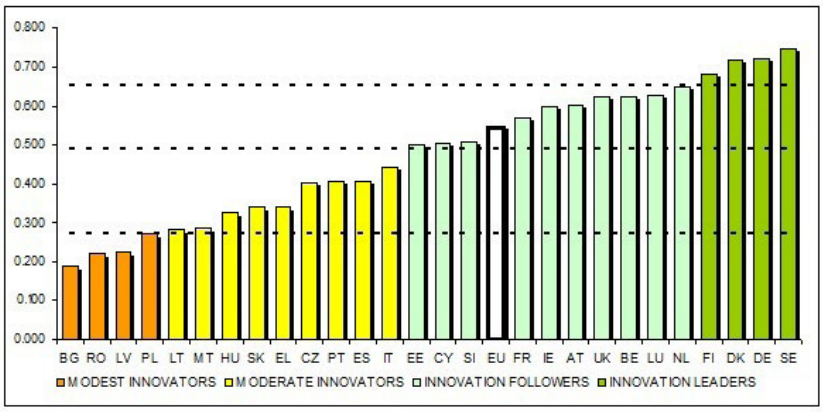

Figure 1: Innovation performance of EU Member States

Innovation performance in the EU has improved year-on-year, despite the ongoing economic crisis, but the innovative gap between Member States continues to widen. While the most innovative countries have further improved their performance, others are not making progress.

The overall ranking in the EU remains relatively stable, with Sweden at the top, followed by Germany, Denmark and Finland. Estonia, Lithuania and Latvia are the countries that have seen the biggest improvement since last year. Factors for the development of innovation in the EU are SMEs and the commercial exploitation of innovations, as well as excellent research systems. However, the decrease in business investment and venture capital investment in the years 2008-2012 has adversely affected innovation performance. The most innovative EU countries have a number of common characteristics in terms of the advantages of their national research and innovation systems, including the key role of enterprises and the higher education sector in innovation efforts. The business sectors of all innovation pioneers are performing very well in terms of research and development spending and patent applications. They are also characterized by a highly developed higher education sector and strong links between industry and science (Noor, Van der Kroef, Wattam, Pinnock, Van Rossum, Smit, & Brussaard, 2018).

Of paramount importance is the development of macroeconomic policies that contribute to the creation of a stable business environment, facilitate access to investment and protect intellectual property. At the same time, macroeconomic and development policies should focus on establishing sufficient incentives to develop innovations and ensuring the creation of new knowledge, with the state taking responsibility to finance basic research, while also improving the effectiveness of government spending on innovation by introducing competitive processes in the selection of state-funded actors, as well as addressing organizational and administrative deficiencies that appear to affect business involvement in innovative activity. Policies related to the identification of innovative systems, weaknesses and their capabilities, the creation of information centers and technology centers, the broad and flexible financing of innovation and technology transfer programs can be initiated in this direction.

The level of state policy also includes policy on enhancing interaction between the actors of the existing innovation system and the cultivation and exploitation of networks between enterprises. This should focus on actions such as establishing contacts through industrial circles or sectoral groups and facilitating the rapprochement between enterprises, encouraging the creation of ombudsmen or exploiting existing structures that could take on the role of communication and mediation (Hansen, 2020). Specific actions could include the organisation of a dialogue on strategic issues, the provision of strategic information through technological perspective studies and the effectiveness in informing enterprises of the advantages associated with the transfer of innovative technologies and the existence of effective mechanisms to support enterprises in the process of dissemination and transfer of technology, through the creation of information centers and technology centers.

4 Conclusions

The examination of factors that enhance the competitiveness of the company and ensure its sustainability independently of the sector in which it operates has become a point of analysis of economic research at international, national and regional level. In the knowledge economy, competition is not based on low production costs, but on the advantages of know-how and innovation. The innovative performance of a company consists both in the endogenous development of technological and scientific knowledge achieved by the participation of highly qualified and qualified scientific staff and by the effective absorption of technological inputs. Moreover, with new markets constantly emerging, technology evolving rapidly and with good ideas quickly copied, there is a constant pressure to provide new and better products and services faster. The fact is that innovation is now one of the most important parameters for growth, both at the enterprise and national level, and is placed in a high priority position in the policy of almost all countries in the world. In fact, the differences in competitiveness between national economies can at least be attributed to different levels of technological and innovative returns (Novak, 2019).

The investment in knowledge is linked to the increase in the production capacity of all other factors of production and contributes to the development of new products and production processes. Since knowledge is characterized by increasing returns and is not exhausted by the use, it is necessary for companies to develop systematic and methodical mechanisms for the administration and development of organizational knowledge, reducing the shortcomings of their cognitive resources.

Since innovation is a collective phenomenon with obvious spatial dimensions, economies of concentration and in particular business clusters due to the creation of positive externalities are becoming capable of creating an innovative environment. The geographical proximity of economic factors within the clusters facilitates the exchange of inextricable knowledge which is an important factor in innovation and since inextricable knowledge is distinguished by a high degree of locality, the business clusters give a boost to the development of innovative activities. The geographical proximity of economic factors or not within clusters transforms regions into learning organizations as through learning the know-how is disseminated, a common information code is acquired and knowledge is more efficiently integrated into the organizational culture of enterprises.

However, it was not only the government that had no vision. Insufficient demand was perhaps a major cause of technological stagnation. Most of the licensing contracts concerned low-tech sectors that could well have been developed domestically, while the relatively more advanced technology sectors only introduced simple assembly methods. There has been no attempt on the part of companies to adapt even these simplistic technologies to local conditions. There was no feedback mechanism between the productive experience and problem solving and therefore there was no accumulation of knowledge. The technology was used as another influx and the licenses to use know-how as a substitute for in-house development activities. Businesses face significant problems in the development of their technological and innovative activity. They talk about a lack of transport and communications infrastructure, problems of funding and cooperation between Universities and production, and the absence of an effective and decentralized organisation of public administration and policy (Cao, Weersink, & Ferner, 2019). The lack of basic technological infrastructure leads to technological and economic underdevelopment in the region and thus to an increase in regional disparities.

In the light of these problems and their adverse effects on the development and competitiveness of the region and the economy as a whole, national and local policy makers are invited to take measures to promote research, technology and innovation at regional level. The policy measures which may be implemented are summarized as follows:

- The technological infrastructure of many regions shall be considered inadequate. It is necessary to increase public investment in infrastructure, in particular in laboratories, training bodies, as well as in cooperation and networking bodies between operators.

- Better information is needed for businesses on policy measures supporting innovative activity. A large number of companies are ignorant of policy measures – national and regional – that support research, innovation and technology.
- Policy measures relating to funding bodies and cooperation facilitation bodies shall not be effective. These measures have little or no effect on funding and cooperation institutions in the field of research, innovation and technology.
- Finally, there is a need to reduce the bureaucratic procedures of the State and improve public services.

It is therefore necessary to review the nature of these measures. For example, measures to support the development of venture capital entities are desirable. A general conclusion is that all successful innovative companies worldwide have had to compete with other companies in the domestic and international market (Balan-Vnuk, & Balan, 2015). In most cases, because the domestic market is not large, if companies do not compete on the international market, they cease to be competitive.

Abstract

Higher Education Institutions nowadays are getting attention for their special role in attracting students to the market needs for education skills and knowledge, and serving to business for their needs. More than creating centers within them, or just trying to put students forward to the business models, their role must be evaluative and challenges. Research in entrepreneurial education is a young field that is still in need of legitimation in terms of theoretical, conceptual and methodological foundations

In this paper some theoretical aspects regard to differences between traditional and entrepreneurial HEI, the concept of Entrepreneurial HEI and entrepreneurial education, and are given some insight that how universities can itself evaluate their proper dimensions towards entrepreneurial education, and some strategies that how they can sustain not only business but even the student, serving meanwhile to the whole educational market for more knowledge and skills. The aim of this study is to take better insight in entrepreneurial universities and challenges that face Universities of Albania to take this orientation considering the emergence of entrepreneurship education in higher education as a research field.

Main conclusions and recommends, with objective of going toward entrepreneurial education, underline the fact that universities must apply not only administrative tools to adapt their strategies to business (and other stakeholders), but need to have a new challenges approach in entrepreneurial education which is quite different from those that attend traditional or administrative approach. This means that with the aim of being of an entrepreneurial university, an HEI need to include in its philosophy the following elements/dimensions of entrepreneurial marketing which will allow to path of EE: Innovation, consumer intention, risk taking, opportunity driven, proactivity, value proposition, resource leveraging. Also, universities should position themselves not only between among competitors but even to other stakeholders as: students, businesses, community, parents, investitors, etc.; so some entrepreneurial positioning strategies need to be followed and developed by HEI in order to get more entrepreneurial.

Keywords: Entrepreneurial education (EE), HEIs, Innovation, co creation, value proposition

Paper type – Academic Research Paper / Practical Paper

1 Introduction

Research in entrepreneurial education is a young field that is still in need of legitimation in terms of theoretical, conceptual and methodological foundations. Higher Education Institutions nowadays are getting attention for their special role in attracting students to the market needs for education skills and knowledge, and serving to business for their needs.

Theoretical aspects regard to differences between traditional and entrepreneurial HEI, the concept of Entrepreneurial HEI and entrepreneurial education are still missing in the orientation of HEIs to EE. But being oriented towards an entrepreneurial education philosophy for a non-traditional university means that HEI need to include in its philosophy the following elements/dimensions of entrepreneurial marketing which will allow to path of EE: Innovation, consumer intention, risk taking, opportunity driven, proactivity, value proposition, resource leveraging. Also, universities should position themselves not only between among competitors but even to other stakeholders as: students, businesses, community, parents, investitors, etc.; so some entrepreneurial positioning strategies need to be followed and developed by HEI in order to get more entrepreneurial.

2 Methodology and Data

This descriptive research is built upon:

- a series of reports and studies on entrepreneurship education, which treat widely on European experiences;
- As well as on some very important data from Ministry of Education and Science, Institute of Statistics of Albania (INSTAT).

Official statistics of admissions to public and private universities show that within a span of less than 10 years, the number of admissions to Bachelor programs has almost doubled, from 16588 students in the 2004-2005 academic years to 34874 in the academic year 2011-2012. And in total, from 63257 students in the 2004-2005 academic year, to 174421 in the 2012-2013 academic year (Report on Higher Education Reform and Research, p. 38).

Other data on the structure of the workforce; internal migration of the population from rural to interurban areas (according to INSTAT 2011, 53.7% of the population lives in the city and 46.3% in the village); prioritizing employment in the private sector (non-agricultural and livestock) as well as the business structure in Albania, where 99.8% of businesses created are SMEs and 96% of all businesses are microbusinesses (INSTAT, 2010), thus being 1 -4 persons, prove that personal enterprises constitute the largest source of employment in the country.

3 The emergence of entrepreneurship education in higher education as a research field

The main strategic references of the European Union suggest and direct towards the structuring of initiatives capable of stimulating the entrepreneurial spirit through education, learning and the development of synergies between education-training and the world of work.

Education is one of the most powerful things a country can have, as education is the strongest weapon of any individual. Also the education of a people also affects the social welfare of the country. Education is the link of a long chain that has to do with technology, economic growth, employment, etc.

Research in entrepreneurial education is a young field that is still in need of legitimation in terms of theoretical, conceptual and methodological foundations (Fayolle et al., 2018)

Despite the importance of higher education in Albanian economy, *it has received little attention in focusing the EE, which will end in creating entrepreneurial mind-set of universities*.

The predominant focus has been on the career choice to become an entrepreneur, and almost all the efforts of universities has been concentrating on how to orient student to become entrepreneur through start up, new venture or different entrepreneurial portal. But orienting, working and focusing on student skills in efforts to create an entrepreneurial behaviour within them is quite on important stage/part of EE within higher education.

Entrepreneurial education in not only about "creating and producing" entrepreneurs and universities must be concentrate for sure not only on this if they seriously want to adapt an entrepreneurial education approach. Entrepreneurship education is widely promoted by European Union and is considered one of the eight key components for lifelong learning (EC, 2006). From an EU perspective, EE should be both increasing entrepreneurship through the creation of new ventures, as well as about educating change agents who will create value in society in settings beyond entrepreneurship, through application of entrepreneurial competences (Longva, 2019).

The emergence and evolution of entrepreneurial education must be analysed and a research field, and with the rise of entrepreneurship as a research field, research on entrepreneurial education has emerged as a sub-field of entrepreneurship that aims to describe and understand the development that is taking place. In fact, entrepreneurial education is now a frequent feature worldwide and at all educational level.

4 Toward some entrepreneurial mind-set of universities

Nowadays the concept of being or going towards being entrepreneurial is becoming a must, especially for public sector and sector of services. In east European public

universities it is noted a huge sense of traditional policymaking while a lot of potential for an entrepreneurial approach is needed.

From the other side, the market to which is serve and furnishing public universities are requesting more and more entrepreneurial skills, capabilities and knowledge, and concept of entrepreneurship in all disciplines. Also, an entrepreneurial education (EE) sense needs to be faced even in everyday lives of public universities like:

- Creating an *entrepreneurial positioning strategy* which through competences and profits for all stakeholders will deliver e *better unique proposed value* than others. The proposal of a unique value constitutes the public communication of the promise of a basic and essential value that consumers will receive from the HEI's entrepreneurial education and that they will not receive from others HEIs. All this, i.e. the construction of a unique value proposition is based on the distinctive competencies of a university in the path of EE creating so sustainable competitive advantages. Further, on such a basis an effective marketing plan should be further built.
- Basing not in only one marketing plan (or even one strategy of institution/university), but *more than one plan is needed*. Entrepreneurial universities needs multiply plans to go ahead to entrepreneurial thinking and leading: a plan for all stakeholders (business, community, etc.), a plan for human resource (administrative and academic staff), for investitures, etc.
- *Co-creating value* instead trying to create one value for market. This mean that value that is perceived and delivered must be create by together with students, business community, and all other stakeholders.
- *Bottom up model*, which means that instead of trying to begin research from up to down, universities must attract all stakeholders and other units that are directly involved in this entrepreneurial mindset to co create value that start from needs of market, businesses, institutions to up towards creating value in the home of entrepreneurship: university;
- Instead on basing in the model with 3 main topics that triplex model propose other elements to be added that sustain or add sustainable value to any sized company must be aid: branding and capital share, or even more elements that flow from an entrepreneurial mindset.

5 Public university against private university as education service providers

Universities are public and/or private service providers whose marketing mostly is more difficult to be done. This means that public universities as providers of public teaching services find it much more difficult to market their services in the target market than private universities. This is due to the fact that:

1. The concept of service itself is difficult to marketing in relation to a physical product. So a company that offers tangible products has it easier to do marketing compared to companies that offer services. Hospitals, culture and education providers, due to service concept of their product has to use tangible element as infrastructure or persons/professors/doctors, etc. in their marketing campaigns to market their institutions, to promote their products, etc., to their target market.
2. Public universities suffer from luxury infrastructures or modern capabilities. For this reason, public universities therefore have more difficulty because they have little or no tangible elements that they can use to market their service. While private universities use good and quality infrastructure, giant campuses and tangible infrastructure investments to market the name of their private university.
3. Private universities invest a lot in digitalization of their services, in creating and communicating with alumni and other stakeholders. Private universities are more concentrate in creating extra value through other services than public universities.
4. Public universities since mostly are longer in market, has more problem with burocracy, transaction, applying in projects, are more oriented in teaching that in researching. But what is evident is related that due to their lifelong education services in market, public universities are more qualitative in regard to: quality service offered and quality of students.

What is missing in Albanian public university is related with:

- a study of university curricula, not just of economics, because business schools are not the only place to learn entrepreneurship; business ideas and innovation most likely come from technical, scientific and creative studies;
- A study to determine how much the Bachelor-Master study cycle creates the premises for developing an entrepreneurial mindset and self-confidence among students that self-employment is a way to enter the job market.
- Alumni database for public universities as a strategic tool for creating networks, links, value and further steps;
- A close related link between at least triplex model which connect university, students and business, in order to give milestones on what is the value that university is creating for the business through knowledge of students.
- Study initiated from universities which gives a panorama on:
- Are universities creating knowledge, skills and capabilities for those gaps that business needs and faces?
- Creating, launching and developing of curricula is a process bottom up, co creating value and strategic oriented?

All those analyses has create in a massivitation of students that get a diploma in a university and extended of variety of diploma, without knowing if really is relate to the market needs. No matter the problems that arise from this increase in the number of students, no vision and market study, no exclusion of all the issues of the quality of diplomas and teaching, this massivization has brought about studying at university, it is a right for anyone now in Albania, but getting a degree is no longer a privilege to be converted into a job.

6 Situation in Albanian universities: The Challenges of adaptation in Albanian Universities

Albania has taken steps towards education over the years, but of course there are still gaps and it should improve the quality of education. Education is not going to solve every problem that our country has, but it is an investment for every individual to make sure steps towards a better future and social welfare.

If you educate an individual, you have educated a whole nation. At the moment we are talking about an individual its key point is education. Education leads to the growth of an individual's knowledge, both socially, culturally, and in the labor market. In all countries of the world education has its downsides, and of course Albania is no exception. Of course, the universities in Albania to meet European standards need a lot of work and investment.

In Albania, we have noticed that in recent decades, education has expanded, noting the connection with citizenship, economic development, equality, culture and so on. Of course, educational institutions and pedagogues have a key role in promoting social progress, who must work every day to move education up and down. Education has four goals, which are: humanitarian, civic, economic promotion and justice.

If a university is or not going towards entrepreneurial path, this is oriented by multi-disciplinary areas, which means that if a university is not entrepreneurial this means that there are a lack of finical funds in research, curricula's are not oriented towards market and business need, there is not value creation and other strategies that lead towards innovation and creativity, etc.

Albanian universities are also a victim of low government funds. While a few private universities, especially located in Tirana, have the financial means to initiate extra curricula activities in areas such as entrepreneurship, public universities, in particular those located in other cities of Albania, are faced with decreasing student's numbers, resulting in lower budgets provided by the government. Additionally, even though the government aspires to a triple helix model of innovation, little can be seen of these aspirations at a university-level. Research is stalled by lacking funds and the need for additional income generating activities by academic staff, leaving little time and scope for research. Adding to this challenge, PhD programmes in universities located in the regions are scare. Innovation and entrepreneurship are thus not on the agenda of many

universities. However, while entrepreneurship promotion is gaining traction in universities in Tirana, to most public universities in other cities than Tirana, it remains an unknown concept. The few structures supporting entrepreneurship that are currently being implemented in public universities outside of Tirana are mostly part of European funded programmes. (Entrepreneurial & Innovation Ecosystem in Albania, Author: Kate Hach & Eileen Trenkmann, NOVEMBER 2019). There is a need to promote entrepreneurial education in the Albanian higher education, as a very important way to promote creativity, innovation and self-employment; the need for universities to gradually transform into entrepreneurial universities, as there is a need to stimulate entrepreneurial mentality among young people, encourage start-ups of innovative businesses and foster a culture that is entrepreneurial friendly. Other directions that show a low level of entrepreneurial efforts is directly concerned with the link university-industry collaboration are currently very low with both sides not recognizing potential to cooperate. Universities are unable to provide structures and methods for start-ups to develop innovative solutions as they on the one side miss the outreach to the industry that could create demand for start- up products and services, and on the other side miss knowledge on entrepreneurship and commercialization of ideas that aspiring entrepreneurs could learn from. (Entrepreneurial & Innovation Ecosystem in Albania, Author: Kate Hach & Eileen Trenkmann, NOVEMBER 2019).

7 An entrepreneurial university in the theory of entrepreneurial marketing approach

Concept of an entrepreneurial university is related directly with element of marketing and entrepreneurship. The idea of connecting one university as service provider with the concept of marketing and entrepreneurship, is because the effort of trying to include a university in an entrepreneurial education system means first of all to deal with concept that link marketing and entrepreneurship inside this university.

So, looking inside the entrepreneurship theory, while trying to identify those element that make a university going towards the entrepreneurial path, the following element can be identified:

- Proaktivity than reactivity
- Inovation in offering education services but also even other services for other stakeholders than only students;
- Risk taking;
- Opportunity oriented.
- From other side the main elements that one university should take from marketing in order to be toward an entrepreneurial path are as:
- Value proposition. This means that the main value that one diploma (level of study even in bachelor, master or PhD level) should have in market is relate

with fulfillment with the market need for the knowledge that diploma (as a product/service) offer for all stakeholders starting from business, start up, etc.

- Customer intensity. This is related with the main concern that universities as education service provider must furnish market with knowledge for what is really missing in the market, for example knowledge in tourism skills, increasing sustainable education capabilities. The customers that are serving from the universities are not only students, but other different stakeholders that are missing and looking for skills, capacities and capabilities related to the knowledge.
- Resource leveraging.

So, the highlight of an entrepreneurial university in the theory of entrepreneurial marketing means that it is necessary that a university to be oriented towards the entrepreneurial paths, needs to fill out some dimensions/elements of entrepreneurial marketing. An entrepreneurial university does not mean that a university should be always entrepreneurial in all elements, during all its lifetime, but must be oriented to some elements and to convert its effort in other elements in different time. So for a period of time, one university can profit from a financial/ecological/economic crisis and chose/take an opportunity in order to develop new capabilities to further develop new ideas or products due to this opportunity. After some years that university can be oriented to value proposition or being proactive than reactive. This means that the same university which before some years ago profit from a national crisis and took an opportunity, now can be oriented towards a new value proposition. This means that the same university can leverage its resources and offering a new product in market with a customer intensity. For example, one department of University of Tirana, Faculty of Economy, can launch not a simple product/service in the form of a simple diploma for the market, but can try to co create a value proposition form the market needs identified by all stakeholders. Stakeholders can be all business that will profit from this diploma in the future. And, Faculty of Economy in University of Tirana (FEUT), in order to be competitive and entrepreneurial in serving to the business needs lead to a new concept and role that can in fact can held in this process: together with all other business and stakeholders identify their needs and lacks in knowledge, transfer those lack of needs in needs for skills and competencies, translate them in key terms, and include in new curricula. So the launching of new diploma is not a simple and common traditional way of developing a curriculum, but is a way which leads to entrepreneurial path, since is based in:

1. *Co-creation of value*: this means that the perception, needs, lack and missing of skills are identified from all stakeholder and business that their need will be fulfill with the knowledge that this diploma will offer and cover. This values is the knowledge that diploma include and is co-created not only from on actor (FEUT), and not based in a simple market research, but is co create from all the necessary actors that will profit from human resource that will be deliver from FEU with this knowledge.

2. *Community based model:* Considering community all actors involved in the network of knowledge need for a simple curriculum, this is community based model.

8 Conclusions and recommendations:

Research in entrepreneurial education is a young field that is still in need of legitimation in terms of theoretical, conceptual and methodological foundations.

In east European public universities it is noted a huge sense of traditional policymaking while a lot of potential for an entrepreneurial approach is needed

With objective of going toward entrepreneurial education, universities must apply not only administrative tools to adapt their strategies to business (and other stakeholders), but need to have a new challenges approach in entrepreneurial education which is quite different from those that attend traditional or administrative approach.

This means that with the aim of being of an entrepreneurial university, an HEI need to include in its philosophy the following elements/dimensions of entrepreneurial marketing which will allow to path of EE: Innovation, consumer intention, risk taking, opportunity driven, proactivity, value proposition, resource leveraging.

Also, universities should position themselves not only between among competitors but even to other stakeholders as: students, businesses, community, parents, investitors, etc.; so some entrepreneurial positioning strategies need to be followed and developed by HEI in order to get more entrepreneurial.

Towards EE, HEIs must develop models that are based on at least the following:

1. *Co-creation of value*: this means that the perception, needs, lack and missing of skills are identified from all stakeholder and business that their need will be fulfill with the knowledge that this diploma will offer and cover.
2. *Community based model.*

Rethinking Social Innovation and Entrepreneurship within Urban Communities

Mauro Romanelli

Department of Business and Economics
University of Naples Parthenope
Via G. Parisi, 13 Napoli 80132, Italy

Abstract

Promoting social innovation and fostering social entrepreneurship help drive value creation processes within communities opening up to new opportunities to develop sustainable social and economic growth. Rethinking the role social innovation and entrepreneurship act within social-driven economies and societies helps to understand the drivers of shared and social value production within communities. Cities are moving into the future in order to drive and design a sustainable, inclusive and healthy urban growth over time. Cities are drivers of social growth and can support social entrepreneurship that benefits urban planning and environments. Urban social innovation practices and strategies contribute to driving urban growth and development. Urban communities emerge as contexts where social innovation and entrepreneurship contribute to promoting shared social value creation within cities and urban communities.

Keywords – social entrepreneurship, social innovation, urban communities, social value.

Paper type – Academic Research Paper

1 Introduction

Within contemporary world and open societies and communities, increasingly entrepreneurship and innovation jointly develop to benefit the communities and contribute to generating social, economic and public value within territories and urban spaces (Angelidou and Mora, 2019; Carvahlo, 2017). Within global economies, social innovation and new social value creation are the issues of social entrepreneurship. Thereby, social entrepreneurship normally leads to innovation or pattern-breaking change (Munshi, 2010). The aim of this study is to rethink the role of social innovation and entrepreneurship as drivers of shared and social value within urban communities. Even if studies and research provide evidence about distinction of the concepts, the need to view organizations, institutions and citizens as actors that provide various inputs to value creation within communities is opening up to considering social innovation and entrepreneurship along a *continuum* whereas the organizational framework and infrastructure help bring together social innovation as the issue of organizational forms and structures that rely on social entrepreneurial projects as the strategic choice for driving social shared value creation processes. Cities of tomorrow achieve sustainable

urban development fostering inclusive economy and society, enabling social innovation practices and sustaining and bringing together social entrepreneurship opportunities and urban planning, developing bottom-up collaborative and governance processes, contributing to urban development policies (Korosec and Berman, 2006; Angelidou and Mora, 2019; Garcia, Eizaguirre and Pradel, 2015; Carvahlo, 2017). Cities have to contribute to sustainable urban development (Haughton and Hunter, 2004).

With an increasing attention to social issues of economic activity socially responsible individual behaviours, bottom-up provision of services by group of citizens and social innovation practices emerge (European Commission, 2013). Social economies and enterprises contribute to engendering value in several ways (European Commission, 2016): high quality and inclusive job creation and development; social inclusion and poverty reduction; integration and inclusion of migrants and refugees; reinforcing territorial and community based economy; gender equality and solidarity. Within social and responsible economies and societies the key driver of strategies of companies and organizations relies on the concept of shared value to be defined in terms of policies and operating practices that enhance the competitiveness of a company while simultaneously advancing the economic and social conditions in the communities in which it operates. Social innovation was emerging as a new view to engender public value creation Learning how to create shared value helps legitimize business again driving companies as leaders in bringing business and society together. Shared value is a new way to achieve economic success (Kramer and Porter, 2011). According to Carvalho and Jonker (2015) value propositions relate to economic, social to the impact on the community, environmental to ecological issues and psychological to contribute to a new state of mind. Entrepreneurship, communities, and social transformation are becoming increasingly related because social entrepreneurship leads to social change relying on organizations that generate value for citizens (Daskalaki, Hjorth and Mair, 2015). In following the strategic entrepreneurship construct and view (Ireland, Hitt and Sirmon, 2003) only firms that engage in both opportunity-seeking and advantage-seeking behaviours have a chance to actively contribute to wealth and value creation for their customers and their owners by developing competitive advantage and innovation to benefit society and communities. In particular, social entrepreneurships stresses the discovery of opportunities that contribute to driving social change (Robinson and Woods, 2005).

According to Cunha, Benneworth and Oliveira (2015) social innovation and social entrepreneurship contribute to driving social change and development in the structure of society in order to achieve a progressive purpose and human well-being, increasing the capacities of individuals and groups. Promoting market-oriented social innovation has a crucial role in the development of social entrepreneurship for new business models meeting the needs of people and communities towards societal well-being, by promoting shared and multiple value co-creation processes (Carvahlo, 2017). According to Cunha, Benneworth and Oliveira (2015) a social entrepreneur creates something new taking existing ways of doing things and creatively transforming them into an effective way of

meeting needs, social innovation focuses on the process of change identifying a potential reality and bringing together the resource to make that happen. In particular, Cunha, Benneworth and Oliveira (2015) have defined social value like the value that accrue to society from social entrepreneurship/social innovation initiatives and that allow to solve social problems and create social capital. The concept of social refers to the development of new way of thinking about or doing something that reflects in a social change.

Social innovation and social entrepreneurship contribute to developing innovation as a source to meet and solve social needs and problems (Farinha, Sebastião, Sampaio and Lopes, 2020). In this scenario, social innovation is strongly related within any social entrepreneurship venture opportunity and to the concept of entrepreneurship too. Howaldt, Domanski and Schwarz (2015) have elucidated that «social entrepreneurs can be understood as actors which invent, develop and achieve a new frame of reference of entrepreneurial action and thereby a new social practice in the society» (p. 96).

With regards to entrepreneurial failure, it is emerging the potential of successful social entrepreneurships to contribute to value creation within society (Dacin, Dacin and Matear, 2010). A social entrepreneur plays a proactive role for change and behaves as an agent of change by adopting a mission to create and sustain social value, recognizing opportunities of social value creation, and engaging in a continuous process innovation-oriented promoting accountability without being limited by available sources (Dees, 1998). Howaldt, Domanski and Schwartz (2015) have stated that «social entrepreneurs are agents of social innovation by acting entrepreneurially in a new frame of reference and thereby inventing, developing and achieving a new social practice in the society» (p. 95). In particular, «social entrepreneurship represents a specific form of social innovation, which has manifold interactions with other forms of social innovations» (Howaldt, Domanski and Schwartz 2015, p. 96). In particular, entrepreneurial principles serve to promote social innovation (Howaldt, Domanski and Schwartz, 2015).

The paper is structured as follows, After the introduction, a literature review on social innovation and entrepreneurship is presented. In the third section, cities aiming to become sustainable urban communities are spaces where social innovation and entrepreneurship drive social value creation. Finally, conclusions are outlined.

2 Methodological section

The study is theoretical and relies on understanding the relationship between social innovation and social entrepreneurship considering the urban context where cities aim to design sustainable future for their tomorrow in terms of social and economic growth of urban communities over time. The selected contributions refer to the relationship between social innovation and entrepreneurship as sources and issues that contribute to advancing cities towards sustainable urban development. The selected contributions are interpreted in a narrative synthesis to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods, Agarwall, Young, Jones and Sutton, 2004).

3 Social entrepreneurship as a source for social value creation

Entrepreneurship is a promising and relevant field of study because of both lacking a conceptual framework and relying on different social science disciplines (Shane and Venkataraman, 2000). According to Schumpeter (1964) entrepreneurs are agents of change and innovators that contribute to identifying new ways of doing things moving the economy forward. It is important to define what is social entrepreneurship and elucidate who are social entrepreneurs. «Social entrepreneurs can be understood as actors which invent, develop and achieve a new frame of reference of entrepreneurial action and thereby a new social practice in the society» (Howaldt, Domanski and Schwarz, 2015, p. 96). According to Martin and Osberg (2007) the successful social entrepreneur takes direct action and generates a new and sustained equilibrium. In particular, «the social entrepreneur should be understood as someone who targets an unfortunate but stable equilibrium that causes the neglect, marginalization, or suffering of a segment of humanity; who brings to bear on this situation his or her inspiration, direct action, creativity, courage, and fortitude; and who aims for and ultimately affects the establishment of a new stable equilibrium that secures permanent benefit for the targeted group and society at large» (Martin and Osberg, 2007, p. 39).

As elucidated by Marti and Mair (2006) the concept of social entrepreneurship is still poorly defined also in terms of its boundaries. Thereby, the wide goal of social entrepreneurship as action for change within society is to promote social changes to advance progress in the society. Studying the conceptual development of social entrepreneurship helps us understand how organizations both create social value and develop competitive advantages (Short, Moss and Lumpkin, 2009). As stated by Dees (1998) social entrepreneurship contributes to driving social change to advance the progress of societies. The author has proposed a working definition of social entrepreneurship as a process involving the innovative use and combination of resources to pursue opportunities to catalyse social change and/or address social needs. So, social entrepreneurship refers to a process oriented to create social value or meet social needs and to support the creation of a new organization in order to serve as entrepreneurial venture innovation. In particular, opportunities at the heart of entrepreneurial can develop in social entrepreneurship (Corner and Ho, 2010). Perrini and Vurro have defined social entrepreneurship «as a dynamic process created and managed by an individual or team (the innovative social entrepreneur), which strives to exploit social innovation with an entrepreneurial mindset and a strong need for achievement in order to create new social value in the market and community at large» (p. 78).

According to Sullivan Mort, Weerawardena and Carnegie (2003) social value creation is the goal of social enterprises, and «the social entrepreneur then is one who is *socially entrepreneurially* virtuous, and whose mission is to create social value for the social organisation with which they are associated» (p. 83). Weerawardena and Sullivan Mort elucidate that «social entrepreneurial organizations need to adopt a culture aimed at innovativeness, proactiveness and risk management» (p. 33).

Social entrepreneurship, a sub-discipline within the field of entrepreneurship, differs from the traditional conceptualization of entrepreneurship in terms of its ability to combine business and volunteer sectors' elements (Certo and Miller, 2008). Social entrepreneurs are agents of social innovation by acting entrepreneurially in a new frame of reference and thereby inventing, developing and achieving a new social practice in the society. According to Carvalho (2017) social entrepreneurship supports social innovation as social issue that occurs when a social entrepreneurial action has success in the market and contributes to driving social and economic, ecological and psychological sustainability.

Social entrepreneurs play a vital role by generating new and disruptive models of organizing human activity focusing on creating social value (Auerswald, 2009). Entrepreneurial activity in markets and the reinvestment of residuals enable the possibility for engendering economic growth and social progress. Entrepreneurs act to create social value by engaging in activities socially impactful beyond what they are doing by breeding positive externalities (Auerswald, 2009). According to Dees (1998) «social entrepreneurs are one species in the genus entrepreneur. They are entrepreneurs with a social mission» (p. 2). According to Korosec and Berman (2006) *social entrepreneurs* are defined as individuals or private organizations that take the initiative to identify and address important social problems in their communities.

Despite of many definitions about the concept of social entrepreneurship, it interesting refer social entrepreneurship as a means for driving social change. In this vein, Roberts and Wood (2005) defined social entrepreneurship as the construction, evaluation and pursuit of opportunities for social change that are part of a construction process that involves the working and reworking of ideas and possibilities. Social entrepreneurs as special breed of leaders are moving the society forward and drive social improvement of communities (Dees, 1998). Entrepreneurship is a creative process that pursues an opportunity to produce something new. Austin, Stevenson and Wei-Skillern (2006) identify innovation and social value creation occurring all the sectors and interaction as distinctive features in the concept of social entrepreneurship. According to European Commission (2011) «a social enterprise is an operator in the social economy whose main objective is to have a social impact rather than make a profit for their owners or shareholders. It operates by providing goods and services for the market in an entrepreneurial and innovative fashion and uses its profits primarily to achieve social objectives» (p. 2). According to Austin (2006) social entrepreneurship stresses the concept of innovation because entrepreneurship is a creative process that opens up to an opportunity for something new, and enables social value creation transcending sectors and organizational forms occurring across collaborative interactions among sectors. Social entrepreneurship leads to social change and drives sources and forces towards sustainable development (Bansal, Garg and Sharma, 2019).

4 Understanding the meaning of social innovation

According to Edwards-Shachter and Wallace (2017) innovation is a learning-based process that refers to social change and sustainable. According to Nicholls (2010) a social innovation view considers social entrepreneurship as a process of change in the delivery of public goods and social and environmental services. Social innovation is a source for enabling shared public value creation (Moore, 2003). Thereby, social innovation stresses the need of governance change and bottom-up participation, protection of the rights of citizens and collective decision-making systems (Moulaert, MacCallum, Mehmood and Hamdouch, 2013). Phills, Deiglmeier and Miller (2008) have defined social innovation as «a novel solution to a social problem that is more effective, efficient, sustainable, or just than existing solutions and for which the value created accrues primarily to society as a whole rather than private individuals» (p. 36). According to Cajaiba-Santana (2014) social innovation is emerging as a driver of effective social change. «Social innovation takes form when a new idea establishes a different way of thinking and acting that changes existing paradigms» (p. 44). Thereby, «social innovations are new social practices created from collective, intentional, and goal-oriented actions aimed at prompting social change through the reconfiguration of how social goals are accomplished» (Cajaiba-Santana, 2014, p. 44). According to Cunha, Benneworth and Oliveira (2015) social innovation changes social systems and refers to novel solutions that contribute to creating social value and promoting community development by fostering collaborative process and action by involving social institutions and citizens. According to Mulgan (2006) «social innovation refers to innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly diffused through organizations whose primary purposes are social» (p. 146). Social innovation is considered as the issue of social entrepreneurship intervention and choices. As stated by European Commission (2011) «social enterprises contribute to smart growth by responding with social innovation to needs that have not yet been met; they create sustainable growth by taking into account their environmental impact and by their long-term vision; they are at the heart of inclusive growth due to their emphasis on people and social cohesion» (p. 3). In particular, «the social or societal objective of the common good is the reason for the commercial activity, often in the form of a high level of social innovation» (European Commission, p. 2). However, despite this growing awareness of the significance of social innovation, a sustained and systematic analysis of social innovation, its theories, characteristics and impacts is still lacking. The innovation occurs at the level of social practice. An innovation is therefore social to the extent that it, conveyed by the market or non-/without profit community is spread through society or certain societal sub-areas as a result of imitation practices (Howaldt, Kopp and Schwarz, 2015).

5 Fostering social entrepreneurship and promoting social innovation for building a pathway for sustainable and inclusive cities

Cities contribute to shaping urban growth of communities living in urban spaces. As reported by Korosec and Berman (2016) «communities benefit from having a cadre of energetic social entrepreneurs who bring solutions to the common problems they face» (p. 457). As engines of economic, social and cultural growth in urban areas, cities aim to become sustainable communities promoting social interaction and innovation by improving the wealth of community and driving people to experiment high quality of life (Bencardino and Greco, 2014). As services providers, and social incubators of change and innovation cities help develop sustainable growth for change. As knowledge-oriented communities, cities tend to achieve social, economic and environmental issues. Today, cities are becoming urban spaces that enable new opportunities for opening up to new entrepreneurial ventures and businesses that contribute to creating social and shared value within urban contexts and places. Cities of tomorrow should be inclusive, liveable and sustainable communities that contribute to wealth and social and public value creation, promoting sustainable urban development (Haughton and Hunter, 2004).

Cities of the future achieve sustainable urban development fostering inclusive economy and society, enabling social innovation practices and sustaining and bringing together social entrepreneurship opportunities and urban planning, developing bottom-up collaborative and governance processes, contributing to urban development policies (Korosec and Berman, 2006; Angelidou and Mora, 2019; Garcia, Eizaguirre and Pradel, 2015; Carvahlo, 2017). Attractive, creative and innovative cities aiming to design the future urban development have to support social innovation projects and issues in order to drive urban communities into tomorrow. Social innovation can act for the enhancement of social cohesion and for new and more sustainable ways of living that benefit citizens and people living in urban communities. Fostering social innovation helps shape sustainable urban governance leading cities to become more inclusive communities by involving civil society in sharing common values of cooperation and social cohesion (Gerometta, Hausserman and Longo, 2005). With regards to smart urban development Bencardino and Greco (2014) have stated that the practices of social innovation offer both an innovative answer to some needs and new ways of decision-making processes and action by enabling networks, coordination and cooperation mechanisms. Social innovation practices and actions in urban communities enable forms of democratic resistance to neo-liberal vision (Moulaert, Martinelli, González and Swyngendouw, 2007). With cities becoming smart and innovative places in order to be social urban communities «the innovation becomes a catalyst for social change, a collaborative process through which citizens participate actively in the development and implementation of projects, programs and services aimed at them». The use of information technology helps cities move to technocratic to social change becoming social cities enabling people to act as co-creators of liveable and lively cities strengthening a civic empowerment. In this sense, smart urban growth leads to social urban innovation that contributes to social value creation processes within urban communities (Bencardino and Greco, 2014).

Innovation is the structured development of new ideas to place them into more effective solutions to facing and solving social needs. Innovation is emerging as social attribute in urban growth questions. Cities become innovative social urban communities. A socially innovative city has to generate ideas in response to changing needs and translate ideas into action and processes for continuous sustainable development of urban communities. Engaging with multiple stakeholders, fostering relationships and networks, and placing people at the centre of social innovation projects helps drive urban and social growth of cities. Bottom up social innovation practices contribute to fostering community development by involving private and public organizations that interact with citizens. Social innovation strategies rely on proactive citizens and civil society organizations that contribute to shaping new forms of urban governance (Garcia, Eizaguirre and Pradel, 2015).

Promoting social innovation and entrepreneurship helps support local and national development policies (Carvalho, 2017). With regards to social innovation within urban communities, it is possible to appreciate the real experience of people participating in developing social systems and institutions as central elements of social innovation (Cajaiba-Santana, 2014). Increasingly, social entrepreneurship is seen as a key driver of urban innovation. In particular, identifying a relationship and coordination between urban planning and social entrepreneurship helps drive and promote increased social value within urban communities (Angelidou and Mora, 2020). Social entrepreneurship helps develop culture of openness and social inclusion within urban communities. Increasingly, it is acknowledged the important role of cities in sustaining and promoting social entrepreneurship initiatives and projects as a source to drive sustainable, inclusive and healthy urban growth. In particular, cities aiming to adopt a smart approach to urban growth invest sources to stimulate and develop social entrepreneurship in urban context. Social ventures contribute to increasing the smartness of cities (Bernardino and Santos, 2018). According to Korosec and Berman (2006) cities that aim to successfully improve their local environments for both citizens and businesses encourage social entrepreneurs to be proactive in urban context and provide support to social entrepreneurship by enhancing levels of social entrepreneurship in their communities. Cities aim to support social entrepreneurship in order to create a sustainable local business ecosystem, enable fair and decent jobs and inclusive labour markets, promote community development and social inclusion, enhance urban innovation and smart solution bottom-up, and to experiment new business models for high social returns, to promote community-drive forms of social care and social investments. As reported by Korosec and Berman (2006) cities working on community engagement and involvement help successful development and implementation of social entrepreneurship ventures because «the development of comprehensive support programs and policies for social entrepreneurship often reflects prior engagement with private individuals and organizations, as local managers may feel comfortable with these individuals and organizations based on their track records and community acceptance» (p. 456).

6 Conclusions

Today, the orientation to providing opportunities for social and economic sustainable value is opening up to strengthening social entrepreneurship in order to create new organizations that contribute to sustaining processes of social innovation as issue and source for driving change towards sustainable development. As proceeding towards a sustainable pathway, cities rely on bringing together social entrepreneurship development and social innovation issues and processes in order to build an urban community that is sustainable, liveable, healthy and inclusive for citizens and people living in the city. Healthy, liveable, inclusive and sustainable cities need to shape the urban environments and spaces as a place that enables opportunities for strengthening social innovation practices by fostering social entrepreneurship opportunities to drive social and urban change within the community.

Abstract

More and more innovative technologies and business plans are formed at interfaces of highly divergent disciplines as a result of an increasing demand for specialized solutions combining different sectors and competence fields. This market driven evolution requires new cross-connections between regional industry clusters that had no, or only a few connections before. But especially in Europe the cluster landscapes have grown very path-dependent and cluster managers still follow traditional concepts. The paper introduces strategies and tools that were designed and proofed within the two-year-project "Cross Cluster Cooperation C3-Saxony" (Germany) co-funded by EU (2014-2015) and also in follow-up sessions rethinking regional industry clusters and their management.

The paper describes novel approaches for cross-cluster strategies using three different views on clusters: a) "Cluster Landscape" describing the different clusters in one region, b) "Cluster Network" standing for all organisations in one cluster, and c) "Cluster Management" being responsible for the performance of one cluster.

Up to now, cross-clustering processes are only described from the organisational perspective of companies or research institutions initiating cross-sectoral projects, or from a systemic point of view focusing cluster landscapes. The paper brings the discussion to the core of cluster development – the cluster management – and introduces novel approaches as well as guiding principles to trigger and increase cross-cluster performances.

The described strategies and tools help ministries and cluster managers to classify current cluster performances and deduce measurements to re-orientate in gridlocked economic situations.

Keywords – Cross Cluster, Co-operation, Entrepreneurship, Start-Up, Open Innovation

Paper type – Academic Research Paper

1 Introduction

In the past, big companies with a narrow focus and a high specialization were the dominant sources of innovation. But more and more novel technologies and business models appear at interfaces of highly divergent disciplines. The demand for specialized solutions combining different branches and competence fields is increasing (Wei 2012). It is a market driven evolution that demands new cross-connections between regional industry clusters that had no, or only a few connections before (Fang, Yang & Hsu 2013). It follows the principle of friendly co-opetition that is based on the mutual dependency to dominate or even survive market dynamics (Brandenburger & Nalebuff 1996).

But especially European companies are struggling with this new development. The historical background is that companies and also cluster landscapes have grown very path-dependent in Europe and did not have to leave their ivory tower (Gräning, Roettger & Noennig 2013). Thus, there was no need to deviate from traditional concepts (Porter 1991, 2000). Now alarm signals are on and within, and also between clusters new consortia have to be formed (Schmiedgen & Noennig 2014). But while trying to trigger cross-sectoral innovations in their member companies and with other networks, many cluster managers themselves forget to be part of this change process too and do business as usual (Billington & Davidson 2013; Chesbrough 2011; Langford 2010; Schüßler, Decker & Lerch 2013).

The paper describes new strategies and tools that help to kick-off cross cluster approaches and that were developed and proofed in the two-year-project "Cross Cluster Cooperation C3-Saxony" (Germany) co-funded by EU (2014-2015) (Noennig et al. 2015). Upon this introduction, chapter two explains the novel methods on three different levels and lines out how they were applied in specific workshops. Chapter three shows results and learnings and the paper closes with the conclusion and an outlook.

2 Methods

To understand the field of application of the novel approaches for cross-cluster strategies three different views on clusters have to be clarified: a) "Cluster Landscape" describing the different clusters in one region, b) "Cluster Network" standing for all organisations in one cluster, and c) "Cluster Management" being responsible for the performance of one cluster. Every level plays a crucial role in fulfilling the goal of highly innovative cross-connected industries. In the following novel methods and tools are explained for every level empowering cross cluster co-operation:

- Cluster Landscape: cross-cluster strategies
- Cluster Network: cross-cluster matchmaking
- Cluster Management: cross-cluster service sharing

2.1 Creating cross-cluster strategies

To develop cross-cluster strategies ministerial experts for regional economic development in Saxony (Germany) were invited to discuss a target-actual-comparison of 2000 and 2015 to find out which strategies were successful and which one have to be rethought or replaced by new ones. The workshop started with a retrospective analysis. Ministerial experts had to name the positive and negative status quos in all three levels (cluster landscape, cluster network, and cluster management) in 2000. Then, the ministerial experts lined out the strengths and weaknesses for their industry politics, SME politics, and innovation politics and tried to remember the defined goals in 2000. Based on that, all measures in the time between 2000 and 2015 were collected. The results of the first step provided an insight what were the starting points in the past and how were the goals and measures defined.

In step two, the ministerial experts had to look at the present. So they described what are the current positive and negative aspects in all three cluster- todays. Then they discussed what strengths and weaknesses theirs industry politics, SME politics, and innovation politics have today. By looking back in the year 2000 and also reflecting current pros and cons they defined new goals for a cross-cluster strategy and pointed out measures with high potential to solve nowadays challenges. At the end, these measures were broken down to the level of cluster management. Figure 1 shows the structure that was used twice – a) as a tool to lock back and evaluate the performance of the past and b) to analyse the current situation and find a new strategy.

		STATUS QUO		GOALS
CLUSTER	*Cluster Landscape*	STATUS QUO Cluster Landscape positive +	STATUS QUO Cluster Landscape negative −	Cluster Landscape Goals
	Cluster Network	STATUS QUO Cluster Network positive +	STATUS QUO Cluster Network negative −	Cluster Network Goals
	Cluster Management	STATUS QUO Cluster Management positive +	STATUS QUO Cluster Management negative −	Cluster Management Goals
		STRENGTHS	**WEAKNESSES**	**MEASURES**
POLITICS	*Industry politics*	Industry politics Strengths +	Industry politics Weaknesses −	Industry politics Measures
	SME politics	SME politics Strengths +	SME politics Weaknesses −	SME politics Measures
	Innovation politics	Innovation politics Strengths +	Innovation politics Weaknesses −	Innovation politics Measures

Figure 1. Cross-Cluster Strategies

2.2 Cross-cluster matchmaking

To trigger cross-cluster co-operations all cluster managers of Saxony were invited to a matchmaking event in December 2015. In the first part of the workshop all managers had to name three co-cooperation demands of their clusters. To visualize it they wrote down three competencies that are needed in their clusters. All these competencies were placed on the right side of a poster-wall. On the left side the names of the attending clusters were already placed. Then, all managers had to connect their own clusters (one the left) with clusters that need their competencies (on the right) (see fig. 2). While doing so, mutual co-operation interests for named demands appeared line by line until there was a big network for cluster co-operation.

In the second part of the workshop pairs of cluster representatives with most cross-connections were formed and they started discussing potential co-operation projects more precisely. In detail, they filled out templates where they noted on the one side needs for action and own project ideas, and on the other side offers got more concrete by explaining competencies and experiences as well as existing projects.

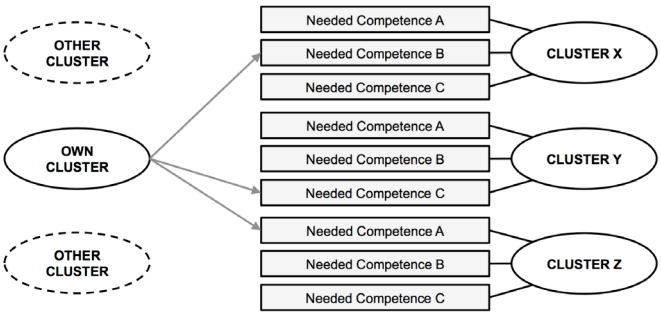

Figure 2. Cross-Cluster Matchmaking

2.3 Cross-cluster service sharing

To develop novel cluster concepts with cross-cluster focus, lean business models for shared services should be considered (Vanderstraeten & Matthyssens 2012). One example is to form a joint Open Cross Cluster Incubator (OCCI) that combines incubation services and providers of different clusters supporting start-ups at their intersections in a virtual network (Schmiedgen 2015). To create an OCCI, in first step all necessary players should be identified. In the following a suitable workshop concept is explained.

Managers of different clusters, incubation service providers, and other stakeholders were invited to a workshop and separated in five groups based on their main incubation competencies: business consulting, providing spaces and infrastructure, offering access to networks, financial support, or product development. In the first step, they had to a) name

services that were already offered by them or also third party providers and b) share opinions of services that could be created especially addressing cross-sections in the future. In step two, they differentiated a) existing roles and their functions and b) roles that could ideally support co-operation projects or early stage start-ups especially in their inter-sectoral needs. In the third step, the target-actual lists of services and roles were combined by designing novel use cases and sketching the processes behind it. The results were presented to all groups so that the other participants had the change to add and also place themselves as experts in these defined fields of service offers or roles. Figure 3 gives an overview showing the template of the workshop.

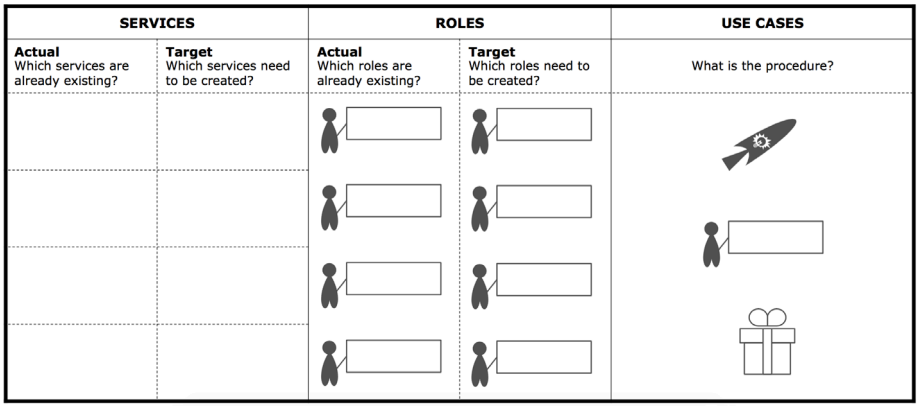

Figure 3. Cross-Cluster Service Sharing

3 Results and discussion

The application of the introduced tools and workshop formats produced a variety of concepts and project ideas and also provided important insights on the status quo of cross-cluster co-operations and how clusters and their managers are facing the challenges in connecting different, specialized branches. The process of connection is still at the beginning but the fundaments were built in the workshops. In the following, the main results of the workshops are presented and discussed.

Creating cross-cluster strategies: A main consent of the ministerial experts were that there should be an instance coaching and controlling cluster managers in building cross-sectoral networks. For that, a new understanding of cluster management has to be established forming modern types of cluster managers. Especially for cross-cluster activities cluster managers have to train additional qualifications far beyond classical skills. In former times, site marketing and networking events within one cluster were the essential tasks. But cluster managers have to move further and should also have the capabilities to build lean clusters that are able to filter and concentrate on effective activities based on market dynamics. By reducing inflationary handshake-smile- and shotgun marketing events, resources are released for more advanced activities. For

example they can run regular cross-sectoral visits in member organisation and circulate concrete co-operation plans. For that, they have to scout permanently rising trends and develop visionary thinking. Furthermore, cluster managers must be able to spot business models with high potential and offer custom-tailored incubator services by arranging packages of contacts and merging cross-sectoral knowhow. These criteria will be translated into future guidelines for cluster managers. The fulfilment of these guidelines will also be a condition for upcoming cluster funding programs.

Cross-cluster matchmaking: A prototypical cross cluster map was a central result of the workshop with all cluster managers (see fig. 4). It helps them to keep the overview of the cluster landscape showing the grad of connectivity between clusters (arrow thickness), the direction of interests (arrowhead), and a set of first project sketches (docs on arrows). The map is still growing by adding new co-operation needs and clusters. And also first projects that were triggered at the workshop and popped up at the connections are now in the planning phase for realization. The quintessence of the workshop was that all clusters decided to start this format for project ideation as a series.

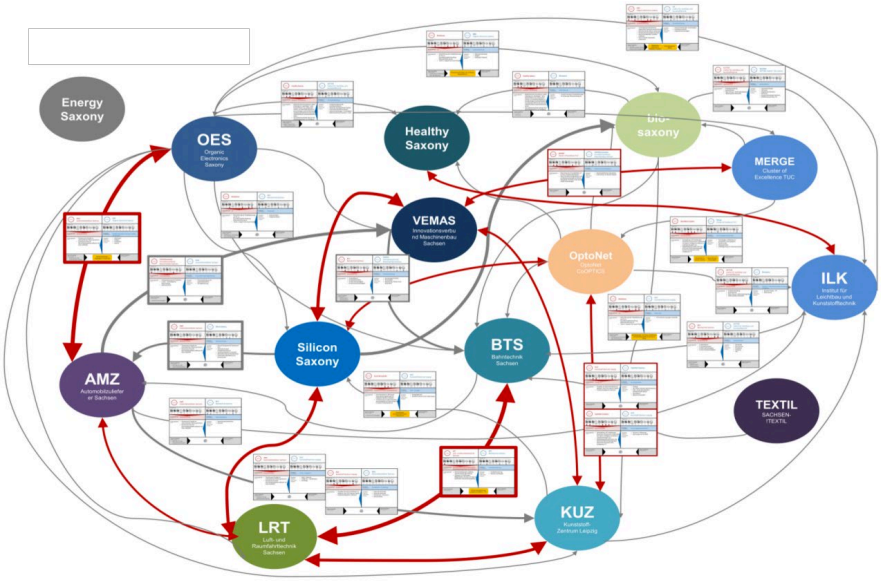

Figure 4. Cross-Cluster Map

Cross-cluster service sharing: This workshop was the kick-off for developing cross-cluster incubator concepts and supported the crucial first step of identifying all necessary service providers in an inter-sectoral ecosystem. In contrast to the long-term benefits of the cross-cluster strategies and cross-cluster matchmaking workshops, the cross-cluster sharing got stuck after some months. The reason was that the cluster managers were not able to activate personal resources building up databases and co-operations with

incubation service providers. Instead of cleaning out timewasting activities releasing manpower or creating sustainable revenue streams around their connector role, the managers asked for (more) public funding.

And here the circle closes. As explained before in the cluster strategies, a new type of cluster manager is needed who is able to support businesses at intersections but also who can create business models for offering incubation consulting and services – in this case an independent OCCI as an virtual NPO. Without these capabilities they will sooner or later lose their expert role and fail to innovate and prepare their cluster members (or potential new ones) for upcoming market trends and dynamics. In the worst case, they are digging their own graves when their performance and (in the end) their work are questioned by their member organisations.

4 Conclusions and outlook

Up to now, cross-clustering processes were only described from the organisational perspective of companies or research institutions initiating cross-sectoral projects, or from a systemic point of view focusing cluster landscapes. The paper brought the discussion to the core of cluster development – the cluster management – and introduces novel first-step-approaches, methods, as well as guiding principles to trigger and increase cross-cluster performances. For that, three workshop formats and tools were introduced on every defined level: Cluster Landscape (cross-cluster strategies), Cluster Network (cross-cluster matchmaking), and Cluster Management (cross-cluster service sharing).

The results have shown that the first two formats were successful and that crossing disciplines is a crucial trend as well as a future success factor. Especially the cross-cluster strategy brought to light that the old-fashioned cluster manager concentrating only on site marketing and undirected events is an obsolescent model. New managers with entrepreneurial spirit, visionary thinking, and effective approaches are needed and their performances should be monitored by a controlling instance. But the road from the strategic view to the operational level is a long one. Most of the cluster managers are not aware of the pressure to radically change their concepts or are not equipped with necessary capabilities. The ability of creating a lean contact point for inter-sectoral incubation services is just one example. The quintessence is that for the future cluster managers have to gain or buy-in more professional skills in business developing, trend scouting, and incubation within cross-sections to keep up with market developments and not to be overrun by them. It is a long way and it is better to start now.

Abstract

Business and entrepreneurial education encompasses a number of methodologies used to provide students with basic and advanced skills concerning the processes of decision making, management, business start-up, operational procedures and others. According to the challenges and the characteristics of the new economic and social scenarios - also determined by the effects of the COVID-19 - business and entrepreneurial education is asked to be reinvented in a continuous innovation perspective. The centrality of the digital transformation and of the information and technology-driven innovation suggests to identify and analyze new conceivable learning patterns that stimulate mindsets and capabilities of the students. (Vanhuele, 2019). Digital technologies have already changed the learning experiences; communication and access to information are the fields where most of the transformations have occurred. Excellent educational contents are often freely available, information about any different topic are easily accessible and the communication is effortless. The lecturers can experiment innovative forms of pedagogy, deciding to implement and use, in an effective way, digital tools inside the classroom, to support students' learning. (Meriaux, 2019) In order to verify the effects of the 4.0 technologies and exploit their potential for the learning patterns, there is the need to make some strategic decisions capable to align pedagogical objectives with the use of innovative tools. A good management of the educational experience starts

with the understanding of solutions and tools that can give a real value added to a business course, and what are the best ways to implement them. Educators are always more willing to share teaching materials, create online activities or assignments, deliver small online courses, interact with live-polling, telepresence robots, video, podcast and so on. These tools, if used in an effective way, can create engagement and increase students' attention. Concerning the entrepreneurial and business education, beyond the already mentioned technologies, many specific trends are arising that combine new technologies with new ways of teaching and learning. Among the most diffused ones there are: flipped classrooms, immersive and augmented reality, business games and blended labs. (Arvind Mallik, 2018; Finch, 2018). Despite this relevance, there are still limited contributions related to the analysis and the assessment of the effectiveness of the virtual learning spaces for the business and entrepreneurial education. In order to contribute to fill these gaps, this paper aims to analyse the background, the state of art and the level of implementation of the digital contents and technologies in business and entrepreneurial education, trying to identify strategic patterns, potential of the ICTs, enabling and hampering conditions and implications both for theory and management, with a particular focus on the possibilities of adoption by small and medium universities.
The first phase of this research will be carried out by reviewing the existing literature – in terms of contents, experiences, cases, practices - in order to gain a complete picture and the state of art of the virtual learning spaces for the business and entrepreneurial education at a national and international level. On the base of the main insights of the first phase, the second phase will be aimed to identify and delineate a set of implications and suggestions for the successful implementation of the virtual learning spaces for the business and entrepreneurial education in medium and small universities.
The main value of this study is the identification and the critical analysis of contents and practices related to the elaboration and the implementation of the virtual learning spaces as well as of the modalities that detemine a better understanding of the conditions grounding the success or the failure of the business and entrepreneurial education courses and experiences. The results consist in the identification of a set of characteristics and conditions for each of the innovative methodologies, in order to decide to frame and follow the patterns of the technological innovation to enhance the business and entrepreneurial learning experiences.
The analysis and the set of implications deriving from the study could be useful to many actors as, for example, lectures, universities, educational institutions, consultants, companies and public administration offices to inspire and drive them in following projects and initiatives capable to stimulate and support virtuous cycles of learning and innovation.

Keywords – Business and entrepreneurial education; Virtual learning spaces; Digital transformation; Gamification.

Paper type – Academic Research paper

1 Introduction

The introduction of new technologies in the everyday life attracts interest from different research fields as e.g. tourism, healthcare, biology etc. In this picture, the role of the new technologies in the education field is largely debated. Within this debate, many learning theories arose. They highlight new learning methodologies different from the traditional transmission mode as, for example, connectivism, lifelong learning, blended learning and e-learning. (Siemens, 2006; Barnett, 2010). The integration of new technologies in the field of the education emerges as a key theme that radically transforms and innovates the way of teaching and learning (Umachandran and Jurčić, 2018). The

advantages that the technologies can bring in education - if used in an effective way -are many as, for example, optimization of access and utilization of the resources, improvement of the student – centered learning, connection to shrike the distances, real time transfer of knowledge, digital infrastructures that facilitate the learning by doing approach and so on.

Despite the relevance of the research, there are limited contributions related to the effectiveness of the virtual learning spaces, mostly in the field of business and entrepreneurial education. Exploiting the potential of the technological innovation for the learning patterns has a strategic importance and means to make decisions that align pedagogical objectives with the use of innovative tools. A good management of the educational experience starts with the understanding of solutions and tools that can give a real value added to a lesson, and what are the best ways to implement them (Meriaux, 2019) Specific solutions capable to combine new technologies with new ways of teaching and learning can be identified, among the others, in the *flipped classrooms immersive and augmented reality*, *business games* and *blended transversal labs*. (Arvind Mallik D.M., 2018; Finch S., 2018). Creating a set of implications and conditions for the innovative methodologies in business learning is fundamental both for academic and scientific purposes as well as for managerial and policy implications. For this, the study aims to analyse the state of art and the diffusion of the digital technologies in business and entrepreneurial education, trying to identify strategic patterns, potential of the ICT and barriers for their implementation, mostly for business and entrepreneurial education in medium and small universities.

2 Background and Main Insights

In the current digital world it is widely acknowledged the growing importance of the business education. It involves not only cognitive approaches but also emotional processes and, for this, it influences and empowers student's values, attitudes, behavior, knowledge and skills. (Schworm et al, 2015). Business education provides students with basic theories of management and production, decision making, business start-up, use of business tools and operational procedures and it encompasses a number of different methodologies (Oladunjoye, 2016) All the aspects are fundamental for a student's learning experience because aim to enhance important skills and competences as leadership and managerial skills, communication skills, brainstorming, time management, research and analysis, business ethics, writing skills, public speaking, intellectual capabilities, critical thinking, ability to process and filter elaborate information, problem solving and others. (Tarabasz et al., 2018) According to the challenges and the characteristics of the new economic and social scenarios - also determined by the effects of the COVID-19 - business and entrepreneurial education is asked to be reinvented in a continuous innovation perspective, also to fill some gaps concerning required competences for the real world and academic knowledge provided by the universities. (Farashahi and Tajeddin, 2018) The centrality of the digital

transformation and of the information and technology-driven innovation suggests to identify and analyze new conceivable learning patterns that stimulate mindsets and capabilities of the students. (Vanhuele, 2019) Otherwise, younger generations will have a lack of competences and skills concerning this system that could penalize them and their competitiveness in the future (Umachandran and Jurčić, 2018). A disruptive innovation, through digital transformation, could become a key for the success of the educational institutions and foster a competitive advantage. The educational sector has the opportunity to reinvent the learning experiences in a perspective that anticipates the challenges of the business ecosystems. (Tarabasz et al., 2018) The integration of the technologies in a business classroom is a complex process, not a passive approach and the key role for a successful implementation is of the human resources that manage the virtual learning space. Today, educators are always more willing to share teaching materials, create online activities or assignments, deliver small online courses, interact with live-polling, telepresence robots, video, podcast and so on. Digital technologies have already changed the learning experiences; communication and access to information are the fields where most of the transformations have occurred. The educators can experiment innovative forms of pedagogy, deciding to implement and use, in an effective way, digital tools inside the classroom, to support students' learning (Meriaux, 2019). Before the implementation of an innovative tool in a business learning environment, there is the need to design innovative learning experiences aimed to foster a skillset that enable learners to respond to the challenges and develop a successful career in the future. When an educator designs an innovative learning experience, he must take into consideration three fundamental concepts: technology, pedagogy and space. The overall ecosystem surrounding an individual can be considered the learning space, the classroom burdens have to be broken, all the students are connected and can access to the information thanks to the ICT. (Tarabasz et al., 2018) Among all the learning topics, business and entrepreneurial education could obtain real value added from the technologies because of its nature, its structure and the interconnections that already exists between business and technologies. Business leaders have always considered technology as an important means for the success of their business strategies, but recently a new approach to strategy development called technology–driven business arose and underlined the importance of the interrelation between the two realities for growth and innovation perspective. (Berman and Hagan, 2006) First of all, an advanced and dynamic management of the business and entrepreneurial learning experience can provide it with immediate actions and transformations that support learning to become more innovative and technology oriented. The ICT can provide immersive experience that foster a high level of engagement, social connections, personalized learning, student centric learning and new ways of discovery and achievement. In order to provide insights and conditions useful to improve the management of the virtual learning spaces for business and entrepreneurial education, this study focuses on four specific approaches: flipped classrooms, immersive and augmented reality, business games and blended transversal labs.

2.1 Flipped Classrooms

A *flipped classroom* is a paradigm change in education that revolutionized the idea of traditional lecturing. It can be considered as a specific type of blended learning design: the lectures are done, with the support of technological tools, outside the classroom and, inside the learning environment, the students are allowed to spend valuable time immersed in practical activities. (Arvind Mallik, 2018) Learners, outside the classrooms, have their first exposure with the didactics material provided by the educators through video lessons, podcast, images, business scenarios to solve and other interactive contents. They work at home, by deepening the materials provided and answering to the educators' requests. In class, they are involved in teamwork, practical activities, problem solving situations and can revise their materials with the support and the continuous feedbacks of the educators. The personalization is chosen over the traditional lectures and many synergies are created between learners. Considering different studies (Huang and Lin, 2017; Arvind Mallik, 2018; Cohen and Sanders, 2014), business learners involved in flipped classroom activities claimed to be more confident in their ability to learn because this non-standard type of classroom has many strengths. It is considered as way to meet educational needs of each learner because it engages a wide spectrum of them; they have more incentives to be prepared in class, the assessment of their understanding is easier and the in-class activities can be focused on cognitive approaches that involve also value and ethics. Moreover, this approach foster student-centered activities, collaboration, team-working and interactive guidance. The result is an active involvement that promotes engagement, satisfaction, achievement and motivation and make learners able to clarify their thinking and enhance their learning experience. To assess the overall functioning of a flipped classroom it is important to take into consideration also some limitations that characterize the approach. First of all, the educators find themselves to face an increased workload; a more detailed preparation for the lessons require more efforts and activities that are time consuming. On the other hand, the success depends also on all the students' motivations and self-paced learning. Sometimes learners can find difficult to focus on some topics and, for this, not all ideas and contents are collected in depth. Furthermore, the teamwork is inspiring, but there can be some cases in which students are embarrassed to ask for too much help to their peers or cases where some team members work more or less than others. (Huang and Lin, 2017; Arvind Mallik, 2018) The implementation of a flipped classroom can bring a real value added to the business and entrepreneurship education, however it is important to design clear and helpful programming lines, in order to obtain successful results for business students.

2.2 Immersive and augmented reality

It is widely recognized that immersive and augmented reality have the potential to radically transform the educational experiences. They can change the ways to teach, learn and communicate and can be used to foster learners' engagement, creativity, curiosity and

attention by recreating and showing vivid experiences (Finch, 2018) Virtual reality reproduces artificial environment that can represent imaginary or real word that users accept as a real environment. With the augmented reality, the immersion is not complete; it is a virtual interface that enhances the real world by adding information and digital contents (Elmqaddem, 2018) In brief, both tools support the human – machine relationship and create entertainment and stimulating conditions for meaningful learning experiences. In business and entrepreneurial education, particularly, learners can experiment creative ways to access to contents, virtual trips, language immersions and training with simulators to improve communication and management skills (e.g. with practice for public speaking) (Hwan et al, 2017; Stenger, 2017) In comparison with traditional lectures, it has been proved that VR and AR improve the level of attention and involvement through presence, immediacy and immersion (Elmqadden, 2018; Stenger, 2017) They support cognitive development and efforts of the learners, reduce the time for the processing of information and help to enhance cooperation and learning of practical skills to apply in the real business and entrepreneurial scenario. At operative level, educators should be able to implement and integrate VR and AR into learning settings by choosing to emphasize role, location or tasks of the students. (Wu et al., 2013) For instance, engaging learners into roles means to recreate participatory simulations where they become managers, scientists, investigators, doctors a so on. In this way, they learn practical skills in a motivating, engaging and entertaining way. The researches in this field are still in an early stage in the education sector, even though its development is fast. The methodologies show some weaknesses such as the high costs and the complexity for their implementation that challenge the educators. (Kaufmann, 2003; Dunleavy et al., 2009) Professionals with technical capabilities must careful reflect to actually transform the AR and VR potential into educational efficiency. Beyond the technical issues there are also some potential learning issues because learners could be overload by a large amount of information that make them fell confused and overwhelmed. (Wu et al., 2013) In conclusion, AR and VR do not meet all the educational needs but it is an option to consider in a continuous innovation perspective in the field of education.

2.3 Business games

The educational institutions are making efforts to implement unconventional and experiential leaning methods and, among all the recent trends, the *gamification* is one of the most valued, not only in schools and universities but also for employees' training. The gamification can encourage virtuous cycle of learning, through the classical game's leverage. A likable and enjoyable interface, the immediate feedbacks, the humanisation of the human-machine interaction and the trial and error approach stimulate the development of competences as social intelligence, motivation, empathy, agility and collaboration. (Fiertler, 2020) In the context of business and entrepreneurship education, the *business games* are simulations aimed at increasing competences with the learning by doing

approach, useful to stimulate attractiveness and engagement of the students. They are diffused as training tools that, though the simulation, «*reproduce the dynamics and logics of a particular economic scenario*[1]». The students involved can take part, individually or as a team, to different simulations and scenarios with the aim to solve some companies' problems or to support their business development. According to recent studies concerning the assessment of the effectiveness of business games (Fu et al., 2009; Zantow et al., 2005; Urquidi and Tamarit, 2017; Hernández-Lara et al., 2018; Oluchi, 2016) the strengths of this innovative tool are various because they create the ideal conditions to enhance general and managerial skills. The simulations are linked to concrete business actions or support the increase of knowledge in the business and management field and the lecturers become active builders of their knowledge. (Lacruz, 2017; Hernández-Lara et al., 2018). This process widens the learning perspective and provides different benefits directly linked to the game's structural aspects (e.g. professor, team, duration, competition, feedback, debriefing etc.). Generic skills that stem from business games are great autonomy, intrinsic motivation, competitiveness, team working, problem-solving and leadership. However, they are becoming more valuable in the business market because of their ability to foster specific skills, linked to the different academic disciplines. Despite this, they are not always easy to implement, and their success strictly depends on a set of variables, from the effort and the preparation of the educators to the learners' cultural, social and ethical backgrounds. (Hernández-Lara et al., 2018) In order to make a valuable assessment of the business games, more empirical researches are needed and educators should be aware of all the conditions and the possible gaps before to implement them.

2.4 Blended transversal lab

Teaching environments (Lab) are virtual or blended spaces of applied didactics that allow students to apply in practice what they learnt at the university. The blended transversal labs are more general approaches, in respect to ones showed previously and, additionally, they can foresee, during their activities, immersive experiences or business games. Labs are becoming widely diffused tools for teaching and learning in higher education mostly in scientific, technological and engineering fields (Potkonjak et al., 2016; Govaerts et al., 2013; Faulconer and Gruss, 2018). In Business Education, labs can be focused on a specific topic, as, for example, potential of the qualifying technologies of the 4.0 industry, smart manufacturing, business transformation, applications and potentials of the green economy and rearrangement of activities of the health supply chain in an economics – managerial perspective. A blended transversal lab can involve students from different areas of interest and its purpose is to increase the participants' knowledge and to create relationships with the business and entrepreneurial environment. Online Labs, if implemented in an effective way, could foster many advantages and benefits;

1 www.artèmat.it

they are cost efficient and flexible systems where many students can access at the same time and participate to lectures, test their knowledge, gain contents and information, receive immediate and enhanced feedbacks and cooperate with other students and educators. (Potkonjak et al. 2016; Heradio et al., 2016; Faulconer and Gruss, 2018) Like the other approaches, even the blended transversal labs show some weaknesses that could prevent a successful implementation. First, in less interested students, online labs can provoke lack of seriousness, responsibility, and carefulness. Moreover, educators can find some complexities from the use of technological tools and platforms. (Potkonjak et al. 2016; Faulconer, and Gruss, 2018).

3 Conditions, Implications And Conclusions

The literature concerning virtual learning spaces in business and entrepreneurial education is highly fragmented. Generally, every methodology has some peculiarities and factors that determine the success and give a value added to a Business Course. Choosing the best methodology and tool to implement requires an in- depth analysis of the state of art and the conditions that characterize the school, university or other institution where the virtual learning space is applied. Concerning the national and international diffusion of technologies in the educational field, the elements to take into consideration are different. Even though the health crisis provoked by the COVID 19 has given an impulse to the adoption of digital technologies, there are some obvious gaps that mostly the national educational context discloses from the digital maturity point of view. The use of 4.0 technologies, indeed, continues to be fragmented and discontinue or restricted to situations of crises. There is the need to stabilize the increase of the digital maturity level in the Italian educational context, by ensuring a support even in the post emergency period and by rethinking and enhancing the learning ecosystem vision, more oriented to a digital perspective (Giovannella, 2020). The non-homogeneous diffusion of the technologies in education strictly depends on the general degree of use and integration of the digital tools in a state or in a local territory. By considering the DESI index (2020), the AGCOM study (2019 - *Educare in digitale*) or the Eurydice Report (2019) it is possible to notice that the level of adoption and use of digital technologies is different for each country and one of the most influential factor that determine the gaps is the rate of digital literacy and competence. Different territorial backgrounds show totally different rates of adoption and the efficiency, therefore e-learning cannot be the same everywhere. The most important condition for the application of the methodologies analysed previously is a deep analysis of the territorial conditions because the reactions to the virtual learning spaces are different concerning cultural, social and ethnic background. The maturity of the technological offer and of the local context should be at the same level. (Hernández-Lara et al., 2018; Tricarico and Bielli, 2019) The tool chosen should be the easiest to use in respect to the conditions of the territory where it is applied. For example, it is not recommended to implement a VR where the digital maturity is still low because, otherwise, its potential cannot be exploited and it enhances complexity and high

investments, mostly for small and medium universities. (Elmqadden, 2018; Stenger, 2017) In this vein, the educational institutions and the educators have to be technologically prepared in order to inspire the change of the educational system. Small and medium universities should make investments connected to an adequate development of the digital culture and the needed competences before to choose the right methodology. (Tricarico and Bielli, 2019) Another important condition is the development of a plan that starts from the definition of objectives and results to achieve. The plan should follow a step by step implementation that foresees design and contents of the lectures, matched with the tool and methodology that is better suited with the pedagogical objectives and the context. (Arvind Mallik, 2018) At the end, it is needed a case by case assessment of the results obtained and the factors that contributed to the successful or unsuccessful implementation for each reality in order to support a digital innovation process even in those contexts that have lack of digital maturity.

This paper have tried to provide a contribution in this direction, presenting some conditions and implications that small and medium universities must take into consideration if aimed at implementing a virtual learning space for business education. On these basis, the idea is to develop a wider research project with the purpose to increase the knowledge in this area of research. Through the development of business games and blended transversal labs in a small university, the project will aim to enhance the value of a business and entrepreneurial course, by assessing all the features, factors, enabling and hampering conditions of application.

In sum, integrate technologies in a learning space is a long and complex process, not limited to an easier access to contents and information. All the innovative tools have to be used in an effective way, by emphasizing the key role of the human resources involved and by designing a plan that highlights all the steps and the competences required. Another assessment to do before the implementation is the level of digital maturity of the territory taken into consideration, by understanding if the territory is mature enough to embrace a specific technology. Small and medium universities can be inspired by global best practices, e.g. prestigious universities such as Cambridge, Polimi, Harvard and so on that already integrate the most advanced digital technologies in learning settings, but it is important to adapt every methodology to the context and create a connection with the peculiarities of the business and entrepreneurial reality.
