Knowledge generation in healthcare has accelerated in the past years due to the abundance of data captured and information produced. The main reason being the evolvement of the health system into a connected care model which is supported by the advances in medical and other technologies. This accelerated innovation brought more risks related to managing knowledge assets and flows. Extant research suggests that the fields of knowledge risks (KR) and knowledge risk management (KRM) in health has not received adequate attention yet.

This paper aims at developing a KRM framework for healthcare organizations. This framework profiles relevant KR found in healthcare and proposes control measures to mitigate them. It also maps responsible units and personnel for implementing the proposed control measures. The development of the framework builds on recent work by the authors, who developed a knowledge risks (KR) taxonomy for healthcare organizations. This paper provides a basic KRM framework within the healthcare context, which is the first of its kind.

This paper hopes to further promote discourse in KRM literature and raise the awareness and understanding of KRM practices among healthcare researchers and practitioners. Additionally, the proposed framework can have practical implications when applied in healthcare organizations for improving the overall quality of care, efficiency savings and promoting sustainability of health organizations.

## 1 Introduction

The healthcare system is facing multiple challenges to provide quality care including rising costs and limited number of providers (Kyedar et al., 2014), and an aging population (Chouvarda et al., 2015). The situation is unsustainable as around 60% only of healthcare services are provided according to guidelines (Sackett et al., 1995; Braithwaite and Donaldson, 2016), with the waste in treatment and medicine mounting to almost one third of their total cost (Gautam, 2017) and the rate of complications not dropping significantly in the last decades (Braithwaite, 2018), despite the scientific and technological advances.

Recently, the healthcare sector has realized that technology on its own is not enough to guarantee the sustainability of healthcare organizations (Sardi et al., 2020), with the need for more efficient and seamless information flow and knowledge exchange among scientists, researchers and health professionals (Karamitri et al., 2020). Something that is regarded an essential element for the provision of better care to patients (Balas and Boren, 2000). This interactive nature of knowledge synthesis echoes Ferlie et al. (2012) argument that knowledge exploitation has moved beyond the traditional hierarchical and one-to-one exchanges to a more organic and networked model.

Moreover, the collective orchestration, safeguarding and utilization of knowledge are considered the key components of healthcare sustainability. On the one hand, knowledge management applications are synchronous to quality management (Linderman et al., 2004) and were found to greatly improve the quality of care (Hosseini, 2019), when actionable and trusted knowledge is made available to the right health professional at the right time (Bigby and Gadenne, 1996; Karamat et al., 2018). On the other hand, knowledge management strategy and practices are critical to the success of healthcare organizations (Tretiakov et al., 2017) and they are also viewed a source of competitive advantage to medical practices (Stefan et al., 2016; Nonaka and Takeuchi, 2007), as well as the role they play in improving the efficiency and effectiveness of service delivery in health environments (Bose, 2003).

However, knowledge is also considered a source of several risks (Bratianu, 2018; Durst et al., 2018; Olander and Hurmelinna-Laukkanen, 2015) which can disrupt the operations and performance of organizations (Martins and Meyer, 2012; Perrott, 2007). Thus, it is becoming more important than ever that researchers and organizations pay more attention to issues of knowledge risks

(KR) identification and management, regardless of the industry (Temel and Durst, 2020). Healthcare organizations, being knowledge intensive ones (Bose, 2003; Abidi, 2007; Karamat et al., 2018), are objectively more susceptible to knowledge risks and should demonstrate a stronger knowledge risk management (KRM) orientation.

Still, the field of knowledge management is not a familiar discipline among healthcare experts (El Morr and Subercaze, 2010; Karamitri et al., 2020), and only witnessed an increasing attention recently (Kothari et al., 2011; Karamitri et al., 2020). The only real attempt to discuss knowledge risks and develop a taxonomy for them within a healthcare context is the work Hammada and Durst (2021), identifying 23 knowledge risks in healthcare organizations and expounding on their potential impact. This paper aims at building on the taxonomy developed by Hammada and Durst (2021), by providing recommendations and actions that will help healthcare organizations address the identified knowledge risks, thus eliminating or controlling their effects. The following two research questions were formulated to address this purpose:

*RQ1: What are the potential control measures needed to mitigate each of the identified knowledge risks in healthcare organizations?*

*RQ2: Which unit/ department/ personnel is responsible for implementing the proposed control measures?*

This paper is structured as follows. In the next section, we will review extant literature on knowledge risk management in general and knowledge management in healthcare. Then based on our findings and building on the previously conceptualized taxonomy of Hammada and Durst (2021), we discuss the possible measures healthcare organizations can take to eliminate or control those risks. In addition, we map those measures against the departments responsible for their implementation within the healthcare organization. Following that, we discuss the implications of the developed knowledge risk management (KRM) framework on academia and industry, and the limitations of our paper being of conceptual nature. Then, we propose an agenda for advancing research in the fields of knowledge risks (KR) and knowledge risk management (KRM) in healthcare.

## **2 Literature review**

### ***2.1 Knowledge risk management***

Knowledge risk management (KRM) is the process of identifying, analyzing, managing, and controlling risks which are pertinent to the acquisition, storage, exchange, and usage of knowledge and information (Durst and Zieba 2019). In academic literature, KRM act as a common pool which links two separate research streams namely risk management (RM) and knowledge management (KM), according to Massingham (2010). While some researchers seem to regard KRM as a subset of the risk management field (Durst and Zieba, 2020). Akin to its bridging academic nature, knowledge risk management is also a transversal competence in any organization. As Temel and Durst (2020), argue that the different actors and teams within the knowledge organization are affected by one another, they then must contribute collectively to the identification of possible measures to deal with knowledge risks and their implementation.

Research has found that there are several areas that organizations can address to mitigate knowledge risks, such as their processes (Serenko and Bontis, 2016), structures (Agndal and Nordin, 2009), policies, remuneration, and incentives (Lambe, 2013) or improvement of certain parts of the organization (Durst and Zieba, 2019). While Durst (2019) argues that some risks can be removed almost entirely when an organization has the utmost control over them, other risks that fall beyond the full control of the organization are rather hard to eliminate but can still be managed or mitigated. This opinion accords with Massingham (2010) views on risks' manageability; arguing that organizations should be able to predict and control risks, even if they do not have the capacity to rule it out of the equation completely.

KRM was found to be directly linked to an organization's sustainability. Durst et al. (2019) found that there is a positive impact on organizations' innovativeness, agility, sustainability, and growth, as well as their successful digitization (Temel and Durst, 2020). The latter also views KRM essential for successful adoption and implementation of technological innovations. It may also be used as a methodology for bringing together the disparate components of the organization's ecosystem to work collaboratively towards a unified agenda (Durst et al., 2019).

Despite its importance, research on KRM is still nascent (Durst and Ferenhof, 2016). Although it started raising interest among scholars, it still is an underdeveloped area (Aven, 2016). Durst and Zieba (2017) noticed that there are only few studies covering this topic, most of which are disconnected and concluded that there is yet to be an agreement on the definitions, dimensions, and boundaries of this young research field.

## **2.2 Knowledge risk management in healthcare**

In healthcare, even the wider field of knowledge management is under researched and is almost unrecognized among practitioners (El Morr and Subercaze, 2010). So far, there has not been a due focus on knowledge risk management research within a healthcare context, beyond the cyber risk area (Sardi et al., 2020). In recent years, the liberalization of the healthcare industry with the rapid advances in medical technology and information exchange, has intensified competition (Lee and Hong, 2014). This has demanded a focus on better identification and management of healthcare knowledge and its risks, as it constitutes a competitive advantage to medical practices (Karamitri et al., 2017). One use case that demonstrates the pressing necessity for knowledge risk management in healthcare is the World Health Organization (WHO, 2020) recently reporting a five-fold jump in cyberattacks and Sardi et al. (2020) review, finding a staggering increase in the number of cyber-attacks in the healthcare sector.

This resonates with Durst and Zieba (2020), recommendation that future research work on knowledge risk management should consider its application in the different sectors rather than focusing on traditional industries only. Moreover, Temel and Durst (2020) and Martins et al. (2019) urge researchers and all organizations, regardless of their type and sector, to pay careful consideration to knowledge risk management methodologies and their applications.

## **3 Methodology**

To develop the proposed knowledge risk remediation and control strategies and tactics, we did extensive literature review on approaches to knowledge risk management such as Durst and Zieba (2020), who studied knowledge risks from an organizational sustainability perspective and proposed actions to overcome them; Temel and Durst (2020), who followed a similar path but within the small

and medium sized enterprises (SMEs) context with a focus on technology risks; Durst et al. (2019) who conducted an empirical study linking KRM measures to organizational performance; and Massingham (2010) who developed a comprehensive and methodological knowledge risk assessment and management framework building on the risk management theory. The proposed framework is building on the work by Hammoda and Durst (2021), who developed a knowledge risk taxonomy for healthcare organizations. They identified 23 knowledge risks and categorized them into three groups: human, technology and operations. They then explained how these risks could manifest in a healthcare environment and discussed their potential consequences.

Following our literature review, we combined our findings with the authors' insights based on their experience in the health field as practitioners and managers, and used the previously developed taxonomy on healthcare knowledge risks to develop a set of remediation and control measures for each of the 23 identified knowledge risks as explained in the following subsections and in appendices I, II, and III. We then mapped the relevant units and personnel inside a healthcare organization that would typically be responsible for the implementation activities against the recommended control measures for each risk area. We used this mapping to develop a responsibility map, as depicted in Figures 1 and 2.

#### **4 A knowledge risk management (KRM) framework for healthcare organizations**

We propose a framework for managing the 23 knowledge risks identified in healthcare organizations by Hammoda and Durst (2021). These are categorized into three groups: human, technological and operational. We profile each risk and discuss possible control measures that can be implemented by the healthcare organization to overcome it.

##### ***4.1. Human-related knowledge risk management in healthcare***

The attitudes, behaviours, and individual factors of organizational members were seen to constitute a considerable obstacle that must be resolved when applying knowledge management practices in organizations (Robinson, 2004;

Kothari et al., 2011). Hence, identifying them and developing suitable control measures for each is essential to overcome those challenges.

#### *4.1.1 Hiding*

Knowledge hiding occurs when (clinicians or commercial) staff (in hospitals) keep knowledge or learning opportunities to themselves and do not share it with other team members (Connelly et al., 2012). It affects transparency and trust among colleagues and can lead to opportunistic behaviours. Possible measures to overcome this issue could be mandating intra-departmental training activities and including it in the annual appraisal, while providing senior clinicians with more advanced training opportunities. In addition, commercial teams should have a shared file management system for contacts and documents for transparency purposes.

#### *4.1.2 Hoarding*

Senior clinicians keeping training opportunities to themselves and participating in scientific events exclusively, are typical examples of knowledge hoarding in a healthcare environment. Such behaviours can concentrate knowledge and organizational representation in the hands of a few staff members (Webster et al., 2008), thus jeopardizing service continuity and possibly the organization's reputation. To avoid this issue, there should be a clear events and training agenda for each department/ team, made publicly available across the hospital, with each participating member tagged to it.

#### *4.1.3 Attrition / unintentional forgetting*

Infrequent application of certain (diagnostic or surgical) skills and techniques (Bouton, 2000) can lead to clinicians and health professionals losing the grip of them. As a result, the medical practice is forced into referring / losing patients to other providers. In such a case, a possible solution leveraging advanced technology would be making virtual training programmes on procedures not commonly performed available to the medical staff.

#### *4.1.4 Unlearning / active forgetting*

Unlearning refers to (the health professional) being disinclined to replace old and outdated knowledge and techniques and learn new things in its place

(Cegarra-Navarro et al., 2013). Thus, clinicians are rendered unable to perform advanced or up-to-date procedures, which are usually more effective with lesser complications. As a result, patients and corporate clients might shift their attention to other providers who keep pace with advances in clinical practice. Overcoming the unlearning challenge is mainly a task that involves ensuring up-to-date guidelines are being adopted and followed across different medical departments.

#### *4.1.5 Resistance / comfort zone syndrome*

Clinician resisting the different scientific sources and training provided to them are left behind, unable to implement updated techniques or use new technologies and tools. On an organizational level, this leads to lower return on investment (ROI) on new equipment and the rather expensive clinical skills training programmes. Hence, it is essential to involve the departments and teams' leads in designing new service models and the procurement of needed tools, with sufficient onboarding activities conducted amid any new service introduction.

#### *4.1.6 Upskilling / inadequate competences*

Upskilling here refers to the lack of needed competences (Durst and Zieba, 2019), among clinicians and other health professionals to perform necessary procedures and use new tools. Thus, awarding a pressing need to improve their skills. The healthcare organization must regularly audit its skill pool and benchmark it against other providers, to identify missing resources and underdeveloped competences. It also needs to have training and learning plans in place for the entire staff.

#### *4.1.7 Continuity / loss*

In the current hypercompetitive environment, an organization might struggle to keep its most valuable assets (Lambe, 2013). In a healthcare context, this translates to the medical practice's ability to preserve its skilled clinicians and health professionals. Departure of critical resources leaves gaps in the organization's knowledge and skill map, which could be difficult to replace promptly. Thus, healthcare organizations must follow through the implementation of training programmes delivered to existing staff and develop

partnerships with relevant medical and research institutes to ensure knowledge exchange and an uninterrupted flow of new talents and skilled professionals.

#### *4.1.8 Overload*

The inability of clinicians to deal with the fragmented nature and the accelerated pace of scientific knowledge generation and technology advancements (Rebitzer, 2008), can impact their skill level, quality of service provided and innovation process (Kohn et al., 2000). It is important that the healthcare organization supports its clinical staff by promoting and allowing time to participate in medical research and scientific events. It should also provide access to clinical knowledge management systems to equip them with proven and evidence-based clinical knowledge seamlessly at the point of care.

#### *4.1.9 Habituation / application*

Tan et al. (2006) argues that knowledge can become obsolete quickly due to new knowledge being produced. In medical practice, habituation usually happens when clinicians insist on following certain guidelines or treatment modalities, regardless of them being defunct or replaced by updated ones, The main onus of managing this risk pertains to the process of reviewing the guidelines and policies implemented across the medical practice, and ensuring they align with the up-to-date guidance from regulatory and international bodies.

### **4.2 Technology-related knowledge risk management in healthcare**

Information technology is becoming an essential part of health services delivery (El Morr and Subercaze, 2010), with developments in key areas such as clinical data management and diagnostic technologies (Lee and Hong, 2014), and security of patient information (Sardi et al. 2020). In addition to the controversial impact of social media on all industries (Durst and Zieba, 2019). Thus, managing technology knowledge risks is becoming fundamental to safeguard critical functions within a healthcare organization.

#### *4.2.1 Cyber risk*

Hospitals hold sensitive personal information on their patients. Leaked information can jeopardize (patients') safety and affect (hospital) reputation (Kandasamay et al., 2020). It can also lead to incurring heavy fines by regulators.

Healthcare organizations need to pay considerable attention to updating its security software, data flow frameworks, and applications architecture. As well as training its staff on cyber security best practices.

#### *4.2.2 Legacy systems*

This risk emerges from the use of old technologies (Durst and Zieba, 2019), whether hardware or software. Legacy systems do not communicate well with other applications and tend to create blockages in information and process flow charts, thus affecting productivity and users' morale. It is important though for the IT team to prepare and update the digital technology landscape blueprints annually at least, and ensure digital transformation plans are aligned with functional workflows across the hospital.

#### *4.2.3 Digital transformation / digitization*

Given the complexity of hospital systems (Drucker, 2007), using technology to improve how a healthcare organization works is an arduous change endeavour. The chances of disintegrations, bugs, misalignments, and uneven digitization can lead to localized or even hospital-wide system failures. It is important though for healthcare organizations to accurately identify areas of improvement in existing applications' architecture and plan for the required changes thoroughly. Moreover, transformation activities must take in consideration the triad of people, process and technology (Westermann et al., 2014). Examples of control measures are the performance of technical due diligence, involving relevant clinical and commercial personnel in the procurement and implementation phases, reviewing and updating clinical and business workflows to ensure alignment with the new technology architecture, and planning always for a detailed training, stabilization and support phase following implementation of new technologies.

#### *4.2.4 Social media*

Social media platforms facilitate circulation of ungrounded personal opinions (Aula, 2010), which can harm the (clinician or hospital) reputation (Durst and Zieba, 2019). Marketing teams within healthcare organizations must adopt a proactive approach through opening a feedback channel for patients' complaints and addressing them promptly. In addition, they should leverage social media as a tool for enhanced positioning and engagement with the public.

### ***4.3 Operations-related knowledge risk management in healthcare***

Knowledge management activities are crucial in almost all processes and functions of healthcare organizations (Walburg, 2006; Karamitri et al., 2017) as they witness an infinite number of transactions, agents, and networks of dependencies (Zincir and Rus, 2019). Thus, managing operations-related knowledge risks is important to control any effects it might have on the organization's performance and outcomes.

#### ***4.3.1 Articulation / waste***

In healthcare organizations, it is not uncommon to come across disregarded equipment, tools, software applications, or even patents and innovative research. Some of the ignored assets were purchased based on plans that have never materialized, while others have lost their importance with the subsequent emergence of newer knowledge, technologies, and modalities. This represents a classic form of wasting resources and indents the expected returns on investments (ROI) made (Ferenhof et al., 2015). Hospitals must have a cross-disciplinary team, responsible for exploring, creating awareness about, and exploiting those hidden gems. Thus, generating additional revenue streams from previously sunk knowledge assets.

#### ***4.3.2 Gaps***

Perrott (2007) defines gaps as the difference between the knowledge an organization wishes to possess and that it already has. Promising more than what can be delivered can sometimes happen in healthcare settings, as the lines are blurred when it comes to identifying clinicians' level of competence. Hence, hospitals must make sure their promoted range of services and contractual obligations are aligned with their capabilities, and if necessary, cover any temporary or permanent deficiencies through hiring or outsourcing.

#### ***4.3.3 Acquisition***

The inability of a healthcare practice to procure needed assets, be it new diagnostic equipment, an endoscope, or a treatment modality. This can result in delaying or even preventing an organization from achieving its desired objectives (Lambe, 2013). However, reshaping the organization's growth strategy based on realistic expectations with a deliberate orchestration of financial support means

and balancing the in-house provision of services vs outsourcing non-core ones, can prove a successful strategy to mitigate knowledge acquisition risks.

#### *4.3.4 Complexity*

Hospitals are complex organizations (Karamitri et al., 2017) with multitude of inter-reliant services and teams, and an ever-changing guidelines and workflows. The frequent or unnecessary introduction of new technologies or processes can hamper staff ability to cope and might affect seamless service delivery with subsequent patient dissatisfaction. Hospitals need to carefully plan for any changes in its process or architecture, taking a stepwise approach to any transformation initiatives and following them through with adequate training and stabilization phases.

#### *4.3.5 Integration*

As new members of staff would ideally bring valuable insights and skills to the organization pool of resources, their reception of knowledge and proper integration within existing structures is essential to deliver the expected benefits from their hiring (Baroody, 2003; Schneider, 2012). Hence, to ensure a seamless onboarding process, relevant key team members should be involved in the candidates' selection process, and there should be a documented onboarding process whose implementation is followed through by the human resources team and relevant managerial personnel.

#### *4.3.6 Communication / exchange / transfer*

The healthcare ecosystem is rich with knowledge-laden interactions (Abidi, 2007), whether within concerned organizations or among affiliated external networks. Knowledge communication is mainly based on individual exchanges (Tangaraja et al., 2016), and a lack of coordination can build up to become a barrier in delivering combined services that require inputs of multiple teams/ individuals. Organizational involvement is required through clearly communicating a common and shared vision among internal stakeholders, promoting inter-departmental cooperation in the form of regular meetings, and incentivizing collaborative services and activities by setting collective targets. It should also ensure that an accessible and easy to use communication infrastructure is available to all employees.

#### *4.3.7 Equity*

Unequal distribution of valuable resources such as experienced/ senior clinicians, advanced equipment or financial resources among departments can have a negative impact on individual teams. Equity was shown to be essential for developing trust and collaboration (Pearce et al., 2000), and improving organizational performance (Joshi, 1989). The management of the healthcare organization must develop an oversight of resources availability and distribution across different teams, and the human resources department has to ensure that remuneration packages are consistent throughout the organization.

#### *4.3.8 Outsourcing*

Channeling some services to other providers (Tadelis, 2007), such as to specialized medical centres or using locum physicians is common practice in healthcare. However, this carries the risk of knowledge and revenue loss, and possibly customers' (patients') exodus (Durst and Zieba, 2017). For this reason, healthcare organizations should make permanent/ long-term contracts its first choice when hiring physicians and limit outsourcing to those services that are considered auxiliary and non-core. In addition, a well-crafted plan for training existing resources and investing in new productive assets should be prepared.

#### *4.3.9 Relational / leakage / spill-over*

Knowledge leakage could be intentional or unintentional and could result in unauthorized spread of knowledge to other sources inside or outside the organization (Annansingh, 2012). It is inevitable to happen (Inkpen, 2000), particularly given the huge number of interactions in the health ecosystem. Leakage could threaten the (healthcare) organization's competitive advantage, if valuable information is made available to others (Durst and Zieba, 2017; Coraș and Tanțău, 2013). However, healthcare organizations can limit this risk by ensuring that the required legal documents such as NDAs are in place when exchanging commercial and scientific information with external stakeholders. Additionally, it needs to make its clinicians aware of the acceptable level of knowledge they could share with peers during medical events. Furthermore, the legal team should always be ready to assist and guide hospital staff whenever required.

#### 4.3.10 Restructuring / leadership changes

The success of any organizational or ownership change depends on several factors such as the differences in strategies, structures, processes. It is also affected by the opinions and positions of involved stakeholders (Cartwright and Schoenberg, 2006). Losing valuable knowledge assets when going through the restructuring and handover activities is not uncommon but could carry serious consequences on service continuity and finances (Durst and Zieba, 2019). Hence, it is important that the team concerned with leading the change undertakes prior mapping of all knowledge assets and resources likely to be affected by the transition and ensure there is a clear plan for business continuity preserving all necessary resources with minimal service disruption. Additionally, it is advisory to avoid any dramatic changes and always opt for a gradual stepwise transition, whenever feasible.

## 5 Discussion and conclusions

Dalkir (2011) argues that healthcare organizations are ideal exemplars for proving the value of knowledge management practices, especially with the explosion in knowledge the healthcare industry is witnessing (Lee and Hong, 2014). Thus, the ability of a healthcare organization to provide quality services and maintain a competitive advantage relies on how effective it is at guarding and leveraging its knowledge assets (Heathfield and Louw, 1999; Bose, 2003; Stefan et al., 2016).

This paper proposed several measures to address knowledge risks identified in healthcare organizations by the authors previously, following their approach which grouped them into 3 categories: human, technology and operations. Some of the most recommended solutions that address multiple risk areas, especially those of individual (human) and operational natures include the improvement of skill levels of incumbent staff through the effective design and delivery of training programmes, subscribing to leading research and skills development platforms; and incentivizing senior staff to pass on their knowledge. Another set of measures aimed at ensuring effective intra and inter-departmental collaboration include holding regular joint meetings, setting collective incentivized targets, and making schedules and events plans publicly available internally. Some measures were developed to address technology risks, ensuring better IT governance such as conducting annual reviews and appraisals of the technology landscape, undergoing thorough feasibility studies and digitization planning, and following through transformation projects with proper training, transition and stabilization phases.

However, as healthcare are complex organizations (Karamitri et al., 2017; Anderson and McDaniel, 2000), there is a shared responsibility among the different units and personnel for the development and effective actualization of knowledge risk management strategies and control measures, as demonstrated in figures (1) and (2). We identified 17 different units and leaders within health organizations who would ideally be responsible for the delivery of the recommended measures. The human resources department is represented the most in the KRM framework, being involved in activities aimed at mitigating 11 risk areas. This is followed by the research and training unit (10 risk areas), the heads of units/ departments (8 risk areas), and the technology / IT department (6 risk areas). Contrary to our prior assumptions before developing the framework, the quality assurance (3 risk areas), legal (3 risk areas), and medical records (2 risk areas) units are among the least involved in the implementation of the proposed knowledge risk management framework in healthcare organizations.

### **5.1 Implications**

As the study of KRM is relatively new (Durst and Ferenhof, 2016) and almost non-existent in the healthcare field (Sardi et al., 2020), the proposed knowledge risk management (KRM) framework represents a first step towards equipping

healthcare organizations, experts and policy makers with a reference tool to address the knowledge risks in healthcare organizations identified by Hammoda and Durst (2021), which are evident in everyday activities in medical practices of all size. Responding to the mounting challenges in the healthcare sector, the mitigation of KR can improve the quality of care provided to patients and their caregivers, drive efficiency savings, and improve performance. Moreover, the proposed KRM framework advances the academic rhetoric bridging knowledge management and risk management research fields (Massingham, 2010), through presenting a fresh perspective into one of the most knowledge-intensive, yet under-researched industries (Abidi, 2007). Consequently, it promotes the discourse in the KM field and offers scholars a ground to build on their research in this nascent area.

Source: Authors

## **5.2 Limitations**

This framework is building on recent work by the authors, producing a taxonomy for knowledge risks in healthcare organizations, explaining their manifestations and impacts (Hammoda and Durst, 2021). In addition, an elaborate review of relevant literature on KRM in general and KM within healthcare was performed. Findings were combined with the authors' experience in the healthcare and knowledge risk management fields to develop the proposed control measures. However, we understand that the resultant framework is a conceptual one, which needs to be empirically validated in a healthcare environment to further refine it.

## **5.3 Future research**

This framework can be leveraged by scholars to advance the research agenda in this increasingly important field of knowledge risks and their management, especially within the knowledge-rich and underrepresented healthcare industry. As the majority of current literature on knowledge risks is of conceptual nature (Durst, 2019), empirical papers are needed and can prove valuable if they manage to harness health experts' and practitioners' insights through interviews, focus groups, surveys and other qualitative and quantitative techniques.

### Abstract

How do people's beliefs on the likely system-level consequences of circulating a certain piece of knowledge influence those people's knowledge behaviors? To address this question, we leverage the most recent developments of the theory of the commons as learning systems. According to this theory, people are strongly responsive to perceived threats to the commons they (may) benefit from, and strive to learn and respond accordingly. Through this theoretical lens, we analyze thick qualitative data (January-April 2020) from the Covid-19 crisis, which resulted in unprecedented visibility of commons-related knowledge behaviors. The contribution of this inductive study is fourfold. First, we identify a new emerging taxonomy of knowledge behaviors, including knowledge unleashing and knowledge curbing behaviors. Second, we identify a new emerging taxonomy of commons-related postures, that is, specific cognitive and behavioral attitudes that an individual may display about a certain commons. Third, we identify interesting

emerging regularities in the relationships between specific commons-related postures and specific knowledge behaviors. Fourth, we show that the empirical data, analyzed in the light of the theory of the commons, strongly suggest disentangling knowledge behaviors from their consequences: for example, knowledge withholding proved far from being “intrinsically” counter-productive. We argue that these results open up promising research paths and opportunities for new knowledge management approaches in a wide range of organized and self-organizing contexts, such as innovation ecosystems, sustainability transitions, open innovation, or crisis management.

**Keywords** – knowledge sharing, system resilience, common good

**Paper type** – Academic Research Paper

## 1 Introduction

In the last years, knowledge management (KM) scholars have highlighted the key role of the processes through which people share knowledge, not only in individual organizations but also in wider, boundaryless contexts, such as communities of practice or virtual wikis (Rice et al., 2019). In most of these studies, knowledge sharing is viewed as an intrinsically positive behavior (Zhu et al., 2018) that is key to enabling other processes that are also understood as intrinsically positive, such as knowledge creation and knowledge use (Baskerville & Dulipovici, 2006). Other behaviors that influence knowledge flows, such as knowledge seek (Case & Given, 2016), knowledge hiding (Serenko & Bontis 2016), or knowledge sabotage (Serenko, 2019), are mostly viewed either as complements of knowledge sharing, and then intrinsically good, or as opposites of knowledge sharing, and then intrinsically counterproductive.

On the other side, some studies delineate a more complex picture. The smooth knowledge circulation and use resulting from knowledge sharing may have unintended consequences, even regardless of whether that knowledge is “wrong” (e.g., Lin & Wang, 2020). As early as in 2002, Schultze and Leidner’s seminal paper suggested that KM scholars need “a stronger theoretical base that includes both favorable and unfavorable consequences of knowledge” (p. 231). Several studies do investigate how the expected consequences of knowledge circulation and use influence people’s decisions as for knowledge behaviors (Wang & Noe, 2010). According to these studies, people make decisions on their knowledge behaviors based on their will to achieve (tangible or intangible) personal advantages for

themselves or their individual friends, and/or harm or punish individual rivals (Wang et al., 2019; Serenko, 2019).

Nevertheless, knowledge behaviors may also depend on the expected consequences at the system level (rather than the individual level) of knowledge circulation and use. For example, knowledge sharing may be hindered by concerns over the greater good, such as concerns over harmful collective panic, or unaffordable time waste (Trusson, et al., 2017), which may result from knowledge sharing. In other words, there is a political dimension of knowledge behavior motives, that complements the individual dimension. People may prefer a specific knowledge behavior for the (perceived) sake of their firm's work climate, industrial sector's viability, or social movement's credibility, for example. Hyper-connection amplifies the consequences of each knowledge behavior today. Perhaps, the time is now ripe to investigate the relationship between knowledge behaviors and their (expected) system-level consequences.

How do people's beliefs on the likely system-level consequences of circulating a certain piece of knowledge influence those people's knowledge behaviors? To address this question, a theory that links motivation, individual knowledge behaviors, and the common good is needed. For example, Rice et al. (2019) propose a public goods approach to investigate behavior in an online knowledge sharing portal. We go further up this road and leverage the more recent developments of the theory of the commons, based on systems thinking, as a lens to enable our investigation (Ricciardi et al., 2020). Even if the first seminal studies on the commons focused on traditional common pool resources (Ostrom, 1990), such as fisheries and grazing lands, the commons are everywhere, ranging from communities of practice to global climate or Wikipedia (Ansari et al., 2013). Businesses, too, can be viewed as commons, or key actors in larger commons. In fact, business organizations (may) provide internal and/or external communities with resources that are available on a collective basis, and can only be protected through a collective sense of the common good.

The literature on the commons as social-ecological learning systems (Armitage et al., 2008) highlights that people may have different attitudes towards a certain commons. For example, a person may value a certain commons, be aware of its fragilities, and believe that abiding by a certain set of existing rules is necessary to protect and develop the commons' capacity to (re)generate resources for the common good. This attitude influences that person's knowledge behaviors, for example, his or her decisions to share or hide specific pieces of knowledge. On

this basis, it is possible to argue that people's attitudes towards a commons translate into commons-related cognitive postures that shape their beliefs on the possible consequences of knowledge circulation and use and, consequently, their knowledge behaviors.

In this study, we adopt the theory of the commons as learning systems as a lens to inductively investigate a colossal systemic change, which has provided unprecedented opportunities to observe commons-relating knowledge behaviors in action. In the first months of 2020, the Covid-19 contagion spread from China to the entire world. Italy was the first Western country that was dramatically impacted, with overwhelmed hospitals, dramatic surge of victims, and strict, traumatic lockdown policies enforced. In a few weeks, more than half the world's population was involved in different forms of pandemic control measures. The Covid-19 pandemic and its consequences suddenly impacted innumerable commons at all levels. Many commons were severely disrupted or shaken to their foundations. For example, some excellent health care systems, like Italy's, suddenly lost their taken-for-granted capability to provide all patients with best-practice care. Liberal democracies lost to a significant extent their capability to guarantee personal and enterprise freedom. Small and micro-businesses lost their capabilities to provide decent jobs, cross-generational perspectives, and local, adaptive responses to market needs. The school system lost its capability to allow parents to work during school hours. Tourism destination systems collapsed, as well as most charity systems. On the other hand, however, the Covid-19 pandemic resulted in a previously unthinkable strengthening of other commons. Carbon emission collapsed, reinvigorating the hopes of climate activists. Natural ecosystems were relieved from the human burden throughout the world. Many organizations that had prohibited any remote way of working for years suddenly wiped out any resistance and became capable of smart working. At the time of writing, in May 2020, the long-term consequences of the Covid-19 pandemic are imponderable yet; however, the empirical material collected for this study from January 20th to April 20th, 2020 (about 1,500 pages from a wide range of sources, in Italian and English) allowed a thick observation of knowledge behaviors and the commons-related postures associated to those behaviors.

In this study, we leverage the Covid-19 crisis as an extreme-intensity case study to inductively develop a framework of how commons-related postures influence knowledge behaviors. Our findings allow us to identify six commons-related postures (which we conceptualize as recognizing the commons, adapting it,

contributing to it, depleting it, invading it, and stranding it). Our findings also suggest that these six commons-related postures influence knowledge behaviors (which we cluster around six categories: knowledge intake, search, sharing, withholding, hijacking, and neglect) in complex, intertwining ways. Last but not least, our findings show that knowledge behaviors that the literature would traditionally consider as positive, such as knowledge sharing, may have counterproductive consequences indeed (and vice versa) from the standpoint of a certain commons' cherishers.

Therefore, this study proposes to include commons-based cognitive postures among the factors explaining knowledge behaviors and to overcome the traditional classification of knowledge behaviors into good or counterproductive per se. Our empirical data suggest to disentangle knowledge behaviors from their consequences and to cluster knowledge behaviors into knowledge unleashing behaviors (which include knowledge intake, search, and sharing) and knowledge curbing behaviors (which include knowledge withholding, hijacking, and neglect).

## **2 Background**

### ***2.1 Knowledge behaviors in the KM literature***

In the KM literature, scholars have devoted great attention to the processes through which knowledge flows between and across individuals (Paulin & K. Suneson, 2012). In this respect, most of the research has focused on knowledge sharing. Some scholars have tried to narrow the concept of knowledge sharing distinguishing it from similar concepts such as knowledge exchange and knowledge transfer. Wang & Noe (2010), for instance, distinguished knowledge sharing from knowledge exchange, claiming that the former refers to providing knowledge to others without others explicitly seeking for knowledge, while the latter includes sharing and seeking knowledge simultaneously. In a similar vein, Chhim et al. (2017) pointed that the concept of knowledge transfer is more general than knowledge sharing since it involves both prior and subsequent aspects that range from developing, searching, and locating, through validation, application, and reuse. However, many authors understand knowledge sharing as "the exchange between a contributor and a seeker" (Mirzaee & Ghaffari, 2018, p. 501).

Knowledge flows are today viewed as essential for improving individual and group decision making, increasing organizational performance through creativity and innovativeness, and fostering adaptability to respond to environmental changes (Rice et al., 2019; Mirzaee & Ghaffari, 2018). Consistently, the concept of knowledge sharing has developed over the last years in KM literature, including studies not only in intra-organizational but also in inter-organizational and community contexts (Rice et al., 2019; Forliano et al., 2020).

The expansion of the areas of investigation led to deeper investigations of the knowledge behaviors influencing knowledge flows. Therefore, besides knowledge sharing, the scope of KM scholars' inquiries has embraced new perspectives, introducing the so-called counterproductive knowledge behaviors (Serenko & Bontis, 2016) such as knowledge hiding, knowledge hoarding, knowledge withholding, knowledge sharing ignorance, and knowledge sabotage (Serenko, 2019; Connelly et al., 2012; Israilidis et al., 2015). More recently, some studies have highlighted that considering behaviors such as knowledge hoarding and knowledge hiding as antithetic to knowledge sharing represents an over-rational view of how people think and act. Other scholars have challenged the common assumption that knowledge sharing is essentially virtuous. For example, Trusson et al. (2017), have pointed out that knowledge hoarding behavior is not necessarily dysfunctional as, for instance, in time-pressured and highly contingent environments it might be more pro-organizational than knowledge sharing.

To understand the dynamics of knowledge flows among individuals, KM studies have identified different antecedents such as social norms, organizational incentive structure, job design, and individual traits and motivations (Foss et al., 2009; Xiong et al., 2019; Witherspoon et al., 2013). The theories that are most frequently used to explain the motives of knowledge behaviors are the psychological ownership theory, the theory of planned behavior, the self-efficacy theory, and the social exchange theory (Xiong et al., 2019; Witherspoon et al., 2013). Attempts have been carried out to understand knowledge behaviors and dynamics using the lens of the public goods theory (e.g., Rice et al., 2019), but the more recent development of the theory of the commons, which are based on systems thinking, have been overlooked by the knowledge management literature so far, despite its potential in explaining the processes through which individual and collective knowledge are recursively and dialectical constituted (Paulin & K. Suneson, 2012).

## ***2.2 The commons as a fragile learning system***

In light of systems thinking, a commons is a very particular type of system. It is capable of (re)generating resources for a certain community's collective use and benefit, but its capabilities to (re)generate such resources are vulnerable to its very beneficiaries' misbehaviors, such as over-exploitation or carelessness (Ricciardi et al., 2020).

When people believe that a certain system benefitting them is a commons (i.e., it is vulnerable to beneficiaries' behaviors and/or carelessness), people likely become strongly interested in learning about the state of the system, understanding what behaviors should be collectively adopted/avoided to avert the collapse of the system, and spreading knowledge and social control about these behaviors (Ricciardi et al., 2020; Ostrom et al., 2007). Strong social and emotional rewards reinforce these attitudes, thus supporting the theory of commons-enabling behaviors as hard-wired in human nature (Fehr & Gintis, 2007; Sigmund et al., 2010; Henrich et al., 2010). These dynamics are present in innumerable contexts, spanning from social movements to communities of practice and business organizations (Rossignoli et al., 2018; Hess, 2008).

True, commons-enabling behaviors are not always for the greater good: for example, they may reinforce a predatory commons, such as a group of bullies. True, commons-enabling behaviors may fail to spread to a critical threshold, for example, because they are perceived as unsustainable by most beneficiaries, or because an epidemic of opportunism occurs. However, despite contrarian predictions by classical economics (Hardin, 1968), wide empirical evidence has accumulated that innumerable successful commons exist (including, for example, innovation ecosystems and scientific communities), and some of them are probably the most powerful learning systems that human beings can develop.

Since the 1990s, when the most important studies by Nobel laureate Elinor Ostrom were published, Ostrom (1990), the research on the commons as learning- and interaction-based social-ecological systems has advanced significantly (Dietz et al., 2003; Berkes, 2009). More recent publications converge in identifying poor management of knowledge processes as the key factor for the failure of complex commons (Armitage et al., 2008). These studies converge in identifying resilience as the key purpose of systems governance, management, and learning. This approach is attracting growing attention in organization and management studies, especially in the light of the impending sustainability

challenges (Barnett & King, 2008; Plummer & Armitage, 2007; George et al., 2016).

### **3 Methodology**

To create the empirical base for this inductive study (Bryman & Bell, 2011; Eisenhardt, 2016), we engaged in intense qualitative data collection of newspaper articles, online discussion excerpts, newsletters, blogs, online forums, social media posts, interview transcripts, talk show transcripts, radio broadcasting transcriptions, institutional communications, instant books, and reports, in Italian and English, around the Covid-19 pandemic. Overall, the empirical material resulted in about 1,500 pages available for analysis. The collected sources span a period from January 20th to April 20th, 2020: three months during which the Italian scenario changed from a collective perception that the new Coronavirus was just a Chinese problem to traumatic tragedies, severe lockdowns, and economic disruption.

Like all systems, the commons become much more visible in times of systemic change. When people feel that one or more commons they rely on are under threat, their knowledge processes tend to be monopolized. The pandemic made this phenomenon incredibly intense and wide-spread, and the media made the explosion of the relating knowledge flows visible to an unprecedented extent. Therefore, the Covid-19 crisis provided an unprecedented opportunity to observe knowledge behaviors when the commons are at stake. The data gathering process was an exhausting and inevitably subjective effort, since for the last seven weeks of our observation period, up to 90% of the contents provided by all the media we leveraged as sources had to do with the Coronavirus crisis.

Besides, since universities were closed at the time of data analysis and we could not access any software for qualitative data analysis, we conducted coding with the aid of online calls and a word processor.

In the first phase, we coded for commons-related postures. In a pilot exploration of the empirical material, we identified 1,000 situations (corresponding, for example, to an online post or a TV interview) in which an actor clearly had a specific objective, preoccupation, or attitude towards at least one commons (e.g., the public health system, a tourism destination, Italy's reputation). Then, we clustered these commons postures into categories through

bottom-up coding and collaborative discussion. A taxonomy emerged of six types of commons-related postures.

In the second phase, we analyzed the knowledge behaviors of the 1,000 selected contexts of analysis. Then, we clustered these knowledge behaviors into categories through bottom-up coding and collaborative discussion. A taxonomy emerged of six key types of knowledge behaviors, each associated with at least one commons-related posture as for at least one commons. In some cases, two knowledge behaviors were observable contemporaneously in the same situation, therefore 1,022 coded behaviors resulted from the analysis. In some cases, the actors talked about others' or their own previous behaviors that, out of an emergency, are difficult to observe, such as knowledge hiding. In this phase, we also evaluated the expected consequences of each knowledge behavior on the resilience of the relevant commons.

In a third phase, we analyzed and compared the emerging associations between each of the six commons-related postures and each of the six knowledge behaviors.

## **4 Findings and discussion**

### ***4.1 An emerging taxonomy of commons-related postures***

Our work contributes to the theory of the commons by identifying six specific commons-related postures affecting people's cognitive and behavioral attitudes (Fig. 1).

Three out of these six postures reflect attitudes that the literature has already investigated. "Depleting the commons" corresponds to the cheating behavior predicted by classical economics (Hardin, 1968). "Contributing to the commons" corresponds to the conforming behavior predicted by neo-institutionalism (Immergut, 1998). "Adapting the commons" corresponds to the experimentation and adoption of technologies, rules, and beliefs that seem to better protect the commons; this process has been investigated by social-ecological systems (Armitage et al., 2008), and the literature on institutional work (Barnett & King, 2008).

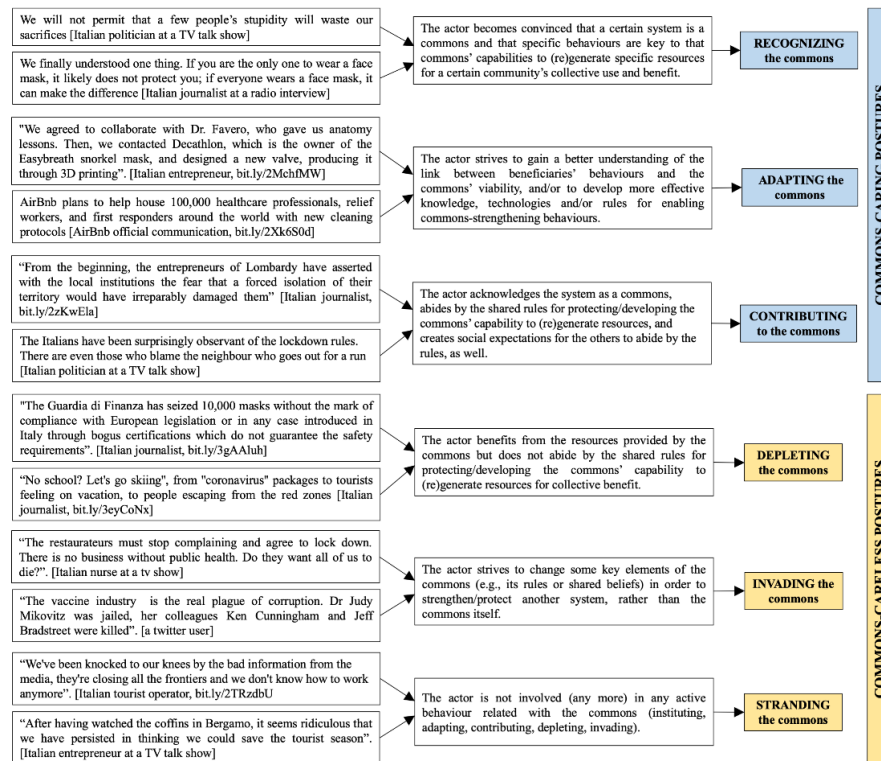

Fig. 1. How the taxonomy of commons-related postures emerged from the empirical material (illustrative quotes).

On top of these three already established phenomena, we identify three further commons-related postures. The first one regards "recognizing the commons", through which the actor acknowledges the commons-like nature of a system and particularly is dependent on beneficiaries' behaviors. For instance, before the pandemic, the Italians did not consider the health system as a commons, but during the crisis, the Italians realized that they had to make sacrifices, such as staying at home and wearing masks in public to protect the health care system's capability to save lives.

A second commons-related posture that emerges from the empirical material but, to the best of our knowledge, has not been investigated so far is the one we labeled as "stranding the commons". When a commons is perceived as losing its capability to provide a certain person with (significant) resources and/or requiring unacceptable sacrifices, it may be abandoned. In that case, the person simply

stops from contributing and from getting anything from that commons, sometimes temporarily, sometimes permanently.

For example, when the magnitude of the crisis became clear, several owners of hotels and restaurants, after engaging for a while for fighting collective panic, declared that they would abandon their business, activity sector, and in some cases, even their country.

Also, the attitude that we labeled as “invading the commons” has not been investigated so far. We found that this cognitive and behavioral posture is typical of actors who feel threatened by a certain commons’ success. In this case, they attempt to undermine and/or delegitimize knowledge, technologies, and rules of the opponent commons. Some exponents of anti-vaccination groups, for example, attacked the vaccine industry accusing it of being responsible for having supersized the C-19 phenomenon to gain economic benefits. In other words, and quite interestingly, the dynamics of a commons and the behaviors it requires can be perceived as detrimental to other personal and/or collective interests. Our context of analysis has allowed us to observe live these “clashes between commons”, which so far have not been investigated accurately by literature.

#### ***4.2 An emerging taxonomy of knowledge behaviors***

Our findings led us to identify six categories of knowledge behaviors. We found that knowledge sharing played a key role in the context under study. However, our empirical analysis shows that knowledge search can occur regardless of whether the knowledge searched for has already been shared. In other words, people may seek knowledge that no one has created and shared yet. Intense knowledge search behaviors, in these cases, may trigger knowledge sharing, rather than resulting from them. The rapid spread of Covid-19, for instance, triggered colossal collective information search on the modes of transmission of the virus causing Covid-19 and the possible causes of immunity even when there was not established knowledge available on that. This also resulted in counter-productive knowledge sharing because this “information appetite” encouraged opportunistic behaviors on the part of some individuals who pretended to be experts, taking on an important role in conveying information whose scientific evidence was not proven.

Furthermore, individuals are not only involved in knowledge search but also in knowledge intake behavior as the process through which individuals absorb

information according to their cognitive frames and inner motivations. For instance, at the beginning of the pandemic, the actors who were recognizing the tourism destination system as the reference commons tended to rely on and process the institutional information aimed at reassuring people that Italy was a safe country.

On the other side, people tend to discard a significant amount of available knowledge as false, useless, or not accessible. The previous literature highlighted that knowledge neglect can derive from evaluation but also overload and ignorance (Israilidis et al., 2015; Peters & Maruster, 2010); however, we found that knowledge neglect is often due to individuals' commons-related posture. For example, knowledge whose perceived implications are negative for the relevant commons (like "let us be realistic: the virus is already here even if we have not found it yet") are likely neglected.

We realized that many behaviors that significantly influenced knowledge flows could not be described with the categories already present in the literature. For instance, an Italian politician engaged in public handshaking in Milan in February 2020 to make the point that there was nothing to be scared of and the economy should not stop because of the virus. We labeled this as a knowledge hijacking behavior from the perspective of the health system as a commons. Knowledge hijacking includes, but is not limited to, the phenomenon of knowledge sabotage introduced by Serenko (2019) since it includes all those behaviors in which one person actively behaves to curb a certain knowledge flow. It is a broad group of knowledge behaviors that have been quite overlooked by knowledge management so far, ranging from purposefully creating fake news to the debunking of conspiracy theories. We found that knowledge hijacking, like all the other knowledge behaviors, may have both positive and negative consequences from the standpoint of a certain commons' cherishers.

Lastly, we identify knowledge withholding as a key knowledge behavior. Depleting the commons or contributing to the commons are important reasons to hide knowledge. In the first case, knowledge withholding assumes its traditional meaning and takes the form of detrimental social behavior such as social loafing and free-riding (Lin & Huang, 2009). In the second case, knowledge withholding behavior assumes a new and under-investigated role of protection of the commons' capability to (re)generate resources. For instance, at the beginning of the pandemic, most scientists encouraged the population to handle information with caution since there was still high uncertainty and limited

knowledge regarding the characteristics of the virus. In this case, they just wanted to protect the members of the commons from possible misunderstandings of complex and contradicting information.

We found that knowledge sharing, search, and intake complement each other in unleashing knowledge flows but are clearly distinguishable from each other since they evolve at different paces and may diverge. On the other side, knowledge neglect, withholding, and hijacking complement each other in curbing knowledge flows. Besides, one of the most remarkable results of our study is that, from a certain commons' standpoint (i.e., a region's health care system, a certain tourism destination, as well as a certain company), knowledge behaviors that KM traditionally considered as positive, such as knowledge sharing, can have negative consequences, and vice versa. Therefore, we refrain from clustering knowledge behaviors into positive/counterproductive, and rather propose to cluster the six knowledge behaviors emerging from the as knowledge unleashing/knowledge curbing behaviors.

#### ***4.3 The influence of commons-related postures on knowledge behaviors***

Our research findings may provide scholars with a comprehensive theoretical framework to examine knowledge behaviors in the light of commons-related postures. We found that each specific commons-related posture may leverage each of the six knowledge behaviors, namely knowledge intake, search, sharing, withholding, hijacking, and/or neglect. We also found that what is beneficial for a commons can be detrimental to other commons. This suggests that the (expected) consequences of each knowledge behavior may be perceived as positive or negative depending on the cognitive and behavioral attitudes of the actors, which in turn are strongly influenced by their commons-related posture. The analysis of our empirical material, however, has revealed particularly strong links between specific commons postures and specific knowledge behaviors. More specifically, "recognizing the commons" is more strongly associated with knowledge intake than all the other knowledge behaviors. Similar stronger associations emerged between "adapting the commons" and knowledge search; between "contributing to the commons" and knowledge sharing; between "depleting the commons" and knowledge withholding; between "invading the commons" and knowledge hijacking; and between "stranding the commons" and knowledge neglect.

## 5 Implications and future steps

Since most organized and self-organizing contexts may be considered as commons, this study provides a complementary lens to address knowledge management challenges in these contexts. For example, while confirming the central role of knowledge sharing (which is the knowledge mechanism that is more frequently adopted to people with the pro-social “contribute to the commons” posture, according to our findings), our results suggest that all of the six categories of knowledge behaviors, including those that have been overlooked by the literature so far (such as knowledge hijacking) deserve attention and may result in positive consequences.

On the other side, our main contribution to the theory of the commons resides in the observations of three commons-related postures that have not been investigated by the literature so far. Last but not least, the cross-fertilization between KM and the literature on the resilience of the commons may provide the latter with concrete management tools that were lacking so far.

### Abstract

COVID-19 has shown how fragile our societies and economies are. Supply chains have particularly been affected. We all had to learn again that the basic supply of some goods is not as crisis-proof as we thought. Moreover, the strong division of labour and the concentration on a few companies in certain areas present considerable weaknesses in case of a new external crisis such as COVID-19; a crisis that is dynamic and whose end is not yet in sight. Small and medium-sized enterprises (SMEs) have been affected by the current pandemic, particularly as they are highly sensitive to external threats. Using data that was collected between December 2020 and January 2021 through semi-structured interviews conducted with owners and/or managers of SMEs located in six different European countries, the paper aims to provide fresh perspectives about how SMEs address supply chain risk management in times of an external and dynamic crisis.

**Keywords** – Supply chain, Supply chain risk management, Risk management, Risks, SMEs

**Paper type** – Academic Research Paper

## 1 Introduction

COVID-19 has shown how fragile our societies and economies are. Supply chains have particularly been affected (Guan et al., 2020). We had to learn again that the basic supply of some goods is not as crisis-proof as we thought. Moreover, the strong division of labour and the concentration on a few companies in certain areas present considerable weaknesses in case of a new external crisis such as COVID-19; a crisis that is dynamic and whose end is not yet in sight.

All companies have been affected to a certain extent by the current pandemic. Small and medium-sized enterprises (SMEs), however, face particular challenges as they are highly sensitive to external threats (Doern et al., 2019; Herbane, 2019). And even though no one was, or could be prepared for the current crisis and its magnitude (Durst and Henschel, 2021), the weaknesses of the crisis and risk management approaches utilized in these companies quickly became apparent, namely being primarily based on known and past data. At the same time, in such an uncertain environment, firm-specific resources are likely to be further dispersed when different types of disruptions caused by a crisis occur simultaneously (Osiyevskyy et al., 2020), which in turn further restricts the possible scope for action.

Against this background, the authors of the proposed paper see a clear need for advancing our understanding of how SMEs cope with the current uncertain, but at the same time, very dynamic time. More precisely, the particular interest is in obtaining an understanding of how SMEs handle their supply chains in increasingly uncertain times. Even before the crisis, supply chains were exposed to a great number of risks; these being triggered by a manifold of developments, such as the increasing digitalization and connectivity of supply chains, but also by political instability and the aggressive actions of big players in the market. Making both supply chains and the risks associated with them very promising and timely research subjects. Regarding the latter, supply chain risk management is intended to reduce an organization's vulnerability from risks (Wieland and Wallenburg, 2012).

Thus, the paper aims to provide fresh perspectives about how SMEs address supply chain risk management in times of an external crisis. Data for this paper was collected between December 2020 and January 2021 through semi-structured interviews conducted with owners and/or managers of SMEs located in

six different European countries (i.e., Austria, Estonia, Germany, Greece, Italy, and Portugal). The SMEs involved cover different company sizes and industries. Considering this variety, the paper provides insights into differences and similarities between the SMEs involved.

The paper is organized as follows. In the next section, the relevant literature is outlined. This is followed by a section that presents and describes the methodology chosen. Then the findings are presented and discussed. The paper terminates with a conclusion section.

## **2 Literature background**

Recent literature regarding SMEs' supply chain risk management (SCRM), indicates that the increasing fragility of SMEs' supply chains and SCRM is one of the dominant topics (e.g., Campos et al., 2019; Fischer-Preßler et al., 2020; Hoek, 2020; Ivanov and Das, 2020). As reasons the increased organizational and geographical complexity of supply chains (e.g., increasing number of partners/interactions and locations) as well as intensified inter-organizational sharing of digital data and imbalanced bargaining power for SMEs in (global) supply chains are named. Furthermore, increasing political and economic uncertainty, which is influencing SMEs' SCRM in general is mentioned (e.g., Ferreira de Araújo Lima et al., 2020). While Chowdhury et al. (2021) found that the global pandemic has further enforced the anyway increasing number of supply chain risks, in particular for SMEs.

The increase in risks relates to all kinds of risks, such as human risks (e.g., missing/inadequate competencies of employees or managers), technological risks (e.g., risks related to cybercrime or digitalization risks in general), and operational risks (e.g., relational risk due to dissatisfactory cooperation by supply chain partners) (see Durst and Zieba, 2019). Additionally, also the classical market (e.g., strong supply and/or demand fluctuations), financial (e.g., payment loss/delay) and geographical long-distance supply chain risks have overall increased (e.g., Campos et al., 2019; Grondys et al., 2021).

Compared to the past, the more recent SCRM literature stresses differences regarding increasing risks in relation to national and industrial context as well as SME firm size (micro, small, medium-sized) (Păunescu and Mátyus, 2020; Chowdhury et al., 2021). The national context, e.g., SCRM regulations of a given country, can influence SME supply chain risks. At the same time, a too strong

dependence of SMEs from international import and/or export of goods and services can further aggravate the situation. The Industry context refers to industry specific regulations and risks. There are clear signs that the market and financial risks for SMEs have developed very differently between industries in the last years.

Despite the afore-mentioned, research on SCRM in SMEs is limited. Furthermore, the few studies available mostly do not differentiate between micro, small and medium-sized enterprises. The study by Grondys et al. (2021) can be named as an exemption. Using an SME survey data from Poland it is stressed that "risk management requires from these entities the awareness, identification, planning, and counteracting threats, which they have not dealt with so far" (p. 16). The authors further point to the assumption (e.g., as a starting point for further research) that in medium-sized enterprises, more "detailed management processes concerning risk are carried out" (p. 15), while smaller SMEs rather follow a more pragmatic, short-term oriented approach.

In the overall picture, financial aspects regarding risk management seem to be more important for micro companies than for small and medium-sized enterprises.

In regard to technological risk management, Fischer-Preßler et al. (2020) stress as one central result from their literature review that the role of IT in identifying, analysing and monitoring supply chain risks is neglected so far in the literature. Regarding operational risk management, Li et al. (2015) identified "risk information sharing and risk sharing mechanism" in SME supply chains as crucial factors for successful supply chain cooperation. These two factors are closely related to a trustful relation between supply chain partners as precondition for sharing critical risk-related information about possible vulnerabilities of the supply chain as a whole or of single SME supply chain partners.

### **3 Methodology**

Considering the underdeveloped research on SCRM in SMEs, a qualitative research approach appears to be appropriate. A qualitative approach allows researchers to get closer to the participants and their way of thinking to scrutinize the entire research problem in depth (Maykut and Morehouse, 1994).

The present study is part of an ongoing Erasmus + project called "SMEs: Be Prepared for Supply Chain Risks" that aims to better prepare SMEs for identifying

and handling supply chain risks. This project consists of six partner countries namely Austria, Estonia, Germany, Greece, Italy and Portugal. In total, 28 small firms have been involved in the study (Table 1).

Table 1. Overview of companies involved in the study

<b>Interview N</b>	<b>Company size</b>	<b>Industry/Sector</b>	<b>Country</b>
Company 1	Medium	Software engineering and consulting	Austria 1
Company 2	Small	Medical equipment (R&D)	Austria 2
Company 3	Medium	Measurement technology	Austria 3
Company 4	Small	Trading company	Austria 4
Company 5	Small	Security service provider	Austria 5
Company 6	Micro	Food production	Estonia 1
Company 7	Micro	Packaging	Estonia 2
Company 8	Medium	Retail solutions	Estonia 3
Company 9	Micro	Steel production and sales	Estonia 4
Company 10	Medium	Retail	Germany 1
Company 11	Medium	Retail	Germany 2
Company 12	Medium	Logistics	Germany 3
Company 13	Medium	IT Services	Germany 4
Company 14	Medium	Clothes manufacturing	Germany 5
Company 15	Medium	Producer of industrial sensors	Germany 6
Company 16	Small	Logistics	Greece 1
Company 17	Medium	Logistics	Greece 2
Company 18	Small	Wholesale	Greece 3
Company 19	Micro	Construction/ Building renovation and refurbishing	Italy 1
Company 20	Micro	Construction	Italy 2
Company 21	Small	Event management	Italy 3
Company 22	Medium	Sanitary ceramic	Italy 4
Company 23	Medium	Sanitary ceramic	Italy 5
Company 24	Small	Paper transformation	Portugal 1
Company 25	Small	Engineering/Plastic injection moulding	Portugal 2
Company 26	Small	Transport consulting	Portugal 3
Company 27	Small	Wastewater treatment	Portugal 4
Company 28	Medium	Moulding and Plastic Injection	Portugal 5

Table 1 underlines that a heterogeneous sample of SMEs in terms of size and industry was involved in this study, thus displaying the reality found in the countries and with SMEs.

Data was collected via semi-structured interviews that have been conducted with the managing directors or owners of the firms. An interview guide supported the interview process. The guide focused upon the following points: some general facts about the companies and their operations and some more specific issues about the companies and their approaches to SCRM. The data was collected online between December 2020 and January 2021. Thus, data was collected during a period when the majority of the participating countries were experiencing lockdowns of varying degrees.

We utilized the tenets of thematic analysis as detailed by Fereday and MuirCochrane (2006) to analyse the collected data. According to these authors, thematic analysis is searching for the primary themes that seem to be most important, after an initial analysis. This analytical approach is appropriate to segment, categorize, and summarize relevant ideas within the dataset as well (Ayres, 2008).

## **4 Findings and discussion**

This section presents and discusses the approaches to/practice of SCRM of the SMEs studied. The section is organized as follows. It is started with the supply chain risks the SMEs were exposed to at the time of the investigation. This is followed by the relevance of SCRM in the firms and the firms' approaches to SCRM.

### ***4.1. Supply Chain Risk Exposure***

Considering the period of data collection, the general risk exposure among the interviewees was focused on COVID-19-related risk. Moreover, the findings suggest that the perception of conventional risks was magnified by COVID-19.

The risks reported by the interviewees are summarized in Table 2.

Table 2. SMEs' risk exposure

Type of risk	COVID-19 related New COVID-19-related Supply Chain risks reported by interviewees.
Financial risk	Sharp decline of profit (Interviewees 6, 8, 9, 16, 18, 19, 21) due to industry freeze (HORECA, tourism, event management, etc.)
	Risk of non-collection of customers' payments that restrict business operations (Interviewees 8, 9, 18)
	Risk of bankruptcy/loss of potential investor (Interviewee 1)
Market risk	Sharp decline in demand (Interviewees 4, 9, 6, 21)
	Raw material price fluctuation (Interviewees 22, 23) due to unstable and unpredictable supply
	Risk of losing major client(s) became more crucial for business sustainability during the pandemic (Interviewees 4, 9, 21, 24)
	Strong(er) price competition (Interviewees 22, 23, 24)
Operational risk	High dependency on resellers and lack of ability to contact/influence end consumers (Interviewees 22, 23)
	Lack of personnel critical for maintaining operations: availability and health safety (Interviewees 6, 9, 18, 19, 24)
	"Flawed" communication within company as well as within supply chain due to lack of personal contact (Interviewees 7, 8, 19, 21, 28)
Supply chain risk	Significant delays in supply or supply disruptions (Interviewees 4, 2, 10, 11, 12, 15, 19, 20)
	Increasingly complicated and costly logistics (Interviewees 7, 11)
	Keeping stock in "equilibrium": problems with "overstocked" warehouses because clients were not able to pick up their orders due to mobility restrictions (Interviewees 16, 17) or problems with receiving enough supplies (Interviewees 2, 4, 7, 11, 12, 19, 20)
	Unsatisfactory quality of supply; has become an even bigger problem due to mobility restrictions (→ no possibility to physically evaluate the quality of products (Interviewees 7, 8, 19)
Regulatory risk	New regulations and restrictions that affected operations to a differing extent: from limiting operations to full stop of business activities (Interviewees 8, 15, 16, 17, 18, 21)
Knowledge risk	Risk of unintentional "knowledge" spillovers due to remote work and communication via social media (Interviewee 3)
	Low level of internal knowledge sharing became clear when companies started considering job rotation due to lack of workforce (Interviewees 1, 28)
Digital risk	Increased "sensitivity" to cyber security risks due to increased number of digital operations (Interviewees 4, 5, 24, 28)
	Integration problems between different data management software became more visible due to increased number of digital operations (Interviewee 25)
	Reliability of IT infrastructure to handle new tasks become an issue (Interviewee 24)

Exposures that were apparently common for all types of SMEs were concerns regarding supply and demand volatility (e.g., customer demand, stocking challenges) and supply chain disruption (e.g., logistics problems, raw material price fluctuation). Some examples are provided below:

*There are a lot of suppliers from abroad... and you have to be able to deliver relatively quickly and in the time like now, when a part is missing, then production is at a standstill and that is of course very critical for the company. (Interviewee 2)*

*We try to avoid being short on stock... On average suppliers take one day to accept the order. Nowadays, they also take three days to send the order. It is a standard time now. It happens due to COVID. (Interviewee 20)*

*The main vulnerability is that the origin of most of our raw materials is outside Italy. That exposes us to the risks of price fluctuations, as well as of potential disruption in the value chain. Moreover, raw materials must show a specific quality, otherwise the quality of the final products will be influenced. Our production plant works on a continuous cycle, and a shortcoming of raw materials, or even a reduction of quantities available, increases the risk of not fulfilling the demand, or of running out of budget for the production." (Interviewee 22)*

Otherwise, some types of risk seem to be more dependent on factors such as geography and size of enterprise. For example, policy-related risks varied according to the regulations and restrictions of a given country. In some countries where restrictions were minor (Estonia, Germany, and Austria), the regulatory risks were considered as low. In countries where a complete lockdown was introduced (Greece), regulatory risk was a dominant factor.

*During the pandemic period, the company was closed for more than 3 months. The clients completed their orders only online. The warehouse of the company until now is full because the delivery company cannot plan and organise the distribution. The company has stopped online orders until the warehouse can host more goods. We are waiting for new regulations from the ministry about how we can proceed with the delays." (Interviewee 18)*

Regarding specific industries, companies involved in the international trade of medical and cosmetics products were affected by new COVID-related regulations (e.g., Germany, Italy).

*We organise events (for medical personnel), and they were forbidden by the government from the very beginning of the lockdown in March. Plus, most - if*

*not all - of our events were targeted for doctors and half of them used either hospitals or hotels and conference centres. However, governmental rules change too often - due to the trends of the pandemic - and they are very complex to interpret. We have to become familiar with the COVID safety protocol for our events. However, the number of exceptions in the planning phase of events increased dramatically. (Interviewee 21)*

Overall, when detailing supply chain risk exposure, the owners/managers of micro companies tended to focus on a short-term perspective, i.e., maintain their operational routine and immediate financial liquidity. For the small and medium-sized firms, on the other hand, the focus appears to have shifted to strategic issues and a long-term perspective (e.g., new competitive and sourcing strategies as well as the consequences of new laws and regulations).

#### **4.2. Supply Chain Risk Management and its position/relevance in the firm**

Based on the findings, the overall approach among the companies to SCRM can be divided into two forms: simple and sophisticated. The simple approach is characterized as an ad hoc approach. Thus, preventive measures to prepare for operational delays and problems are not there but initiated once an issue occurs. By contrast, the sophisticated approach, which is more common among medium-sized companies, utilized an organized and dedicated set of policies, rules, and guidelines, which were prepared in advance to handle different business challenges.

The person or unit in charge of identifying and analysing risks is also heavily influenced by the size of the company. In micro-enterprises, risk was assessed directly by the owner (Interviewees 6, 7, 9, 19, 20). In small companies, that task was conducted by partners/co-owners or board members (Interviewees 2, 4, 5, 16, 18, 21, 24, 25, 27), while in medium-sized companies, risk assessment was handled by management, i.e., by owners/managers and heads of departments, collectively (Interviewees 1, 3, 8, 10, 11, 12, 13, 14, 15, 17, 22, 23, 28).

The major distinction of small and micro-enterprises regarding the relevance of SCRM was that these smaller companies considered a systematic approach unnecessary. Bearing in mind the limited financial and human resources and low probability of re-occurrence of the same types of risk, the owners/managers of these firms preferred to take quick responsive measures to handle the risk, rather than to have them prepared in advance (Interviewees 4, 6, 7, 10, 11, 19, 20). As

one Interviewee described it, "We are not practicing crisis scenarios. If something happens, we will decide what to do in order to maintain operations" (Interviewee 6).

Not surprising, medium-sized enterprises employed more developed forms of preventive risk measures, including risk maps and signalling systems to visualize and systematically assess risks and their relevance, impact, and probability (Interviewees 1, 9, 13, 14, 24, 25). For those companies which followed ISO standards, this approach was determined by adherence to those standards. The following statement may illustrate the approach typical for companies following ISO standards:

*To ensure high quality of services and to be prepared for risks, the company is certified according to several standards (e.g., ISO 9001, ISO 27001) and has developed its own risk management system inspired by ISO 31000 with a business continuity logic. The firm has a risk board which meets monthly. Members are the managing director, head of quality management, heads of units, and an external consultant. The board systematically identifies business risk including supply chain risks, carries out a business impact analysis, and prepares measures. (Interviewee 13)*

#### **4.3. Approaches to Supply Chain Risk Management**

As indicated before, the approach to SCRM differed according to company size. The majority of medium-sized companies had a systematic approach to SCRM (Interviewees 1, 3, 12, 13, 14, 15, 22, 23, 28). By contrast, the majority of micro and small companies seem to have adopted a "problem-solving" (ad hoc) approach (Interviewees 2, 4, 5, 6, 7, 8, 16, 18, 19, 20, 21, 25). It seems that the latter utilized risk management techniques according to the primary business challenges at hand. The chief similarities between the SMEs seem to be found regarding securing trustworthy and stable supply chain relationships, as well as ensuring safe and secure business operating environments. Table 3 details the steps that were taken by the firms studied to handle different types of SC risks.

Table 3. Risk management in SMEs

Initiatives	Specific Steps	Interviewee Examples
Develop a strong and reliable network within the supply chain	Careful selection of suppliers and partners: preference for suppliers with similar values and long-term relationship strategy (Interviewees 14, 19, 20, 21, 22)	A major SC risk is the loss of, or dependency on, a supplier. Therefore, the firm selects (potential) suppliers very carefully and regularly visits them. Policy is a long-term collaboration, and the management looks for family-owned businesses with similar values. (Interviewee 14)
	Establish trust and mutual support with suppliers to minimize risks and financial losses (Interviewees 19, 21, 22, 23)	Experience and a good relationship with our historical business partners helps in reducing these risks. In particular, communication with business partners is crucial to be aware of potential risks and avoid them as much as possible. (Interviewee 21) Reputation of suppliers is another positive factor. With "trusted" suppliers we know we can work timely and with a high-quality standard. (Interviewee 19)
	Increasing share of local or short-distance suppliers (Interviewees 7, 11)	To reduce dependency on suppliers, e.g., for whiteboard production..., we are aiming to bring back as much of production to Germany as economically feasible, working with long-term contract manufacturing partners. (Interviewee 11)
	Enforcing a code of conduct and overall quality and sustainability strategy (Interviewee 14)	The fashion firm has defined a Code of Conduct binding all business partners, which defines requirements for suppliers and partners... Among other things, the Code of Conduct contributes to compliance with social and ethical standards, sustainable environmental protection, and ensures fair working conditions. (Interviewee 14)
	Implementing suppliers' check-ups: quality assurance and process improvement (Interviewees 7, 14)	We perform regular quality checks and audits of suppliers. (Interviewee 14)
Taking measures to ensure continuous	Ensuring stock safety: redundancy strategy for suppliers of important products,	In parallel with these measures, the firm develops alternative vendors for critical products or prospects for possible alternative suppliers. (Interviewee 14)

operation	extra stocking to avoid out-of-stock situations (Interviewees 10, 11, 12, 13, 14, 15, 20)	We try to maintain our own buffer stock to ensure close to 100% availability. (Interviewee 10) We buffer stock in decentralized offices and in central warehouse and have a dual vendor strategy for important parts. (Interviewee 13)
	Setting up “loose” delivery dates for end-customers to compensate logistics delays (Interviewee 8, 19)	A good scheduling of the project and a good planning of extra time helps to compensate potential suppliers’ shipment issues. (Interviewee 19)
	Organizing in-house delivery services to ensure delivery of parts in time (Interviewee 13)	We organized parts delivery to the offices by own vehicles and drivers. (Interviewee 13)
Taking actions to mitigate financial risks	Diversify the client pool to decrease dependency on a single client/industry (Interviewees 6, 15, 28)	As every company in plastic injection, there is considerable dependence on the automotive industry, but we have been trying to diversify the customer base to decrease a high customer concentration risk. (Interviewee 28)
	Concluding NDA contacts with suppliers (Interviewees 2, 15, 27)	Even if the machines are patented, certain information should not spill over to competitors, especially process knowledge which is difficult to patent. All possible agreements (e.g., NDAs) are made with the respective suppliers to prevent unwanted spillover or leakage. (Interviewee 2)
Taking steps to develop a risk-aware culture and organizational defence	Organizing training for the staff in the following domains: quality standards (Interviewee 16, 18); ethical standards (Interviewee 3); process improvement (Interviewee 7); “sensitive data” protection (Interviewee 3)	It is important for the employees and the company to follow the technology and methodologies of the supply chain and address the risks. (Interviewee 18)
	Organizing risk awareness events: risk	There have been regular awareness training sessions for employees at least once a year

	evaluation and mitigation training (Interviewees 1, 3, 12); risk mitigation brainstorming (Interviewee 17)	for new employees when they were hired and then regular updates every year. There have been repeated mailings to the employees, such as newsletters, which summarized some of the most diverse risks. (Interviewee 1)
	Developing personalized data access, i.e., linked to employee profile and functional responsibilities (Interviewees 5, 25, 28)	These days every employee has a profile that allows him to access only what he supposed to for performing his function. (Interviewee 28)
Taking actions to protect data	Multiple encryption solutions (Interviewee 5) and multi-factor authentication (Interviewees 5, 24, 25, 26) and various email protection systems, certificates of emails, backup systems, and VPN tunnels for remote access (Interviewees 1, 5, 27)	We have processes in a quality management system for the archive of projects. Some of the projects are stored in a vault with very strict access. They are very cautious with the application of GPRD. Increasingly, projects are subjected to NDAs. (Interviewee 26) Technologically, several things are used to protect the data and the customers' data. Classification, multiple encryption solutions, multiple multi-factor authentication, different email protection systems, certificates of the emails, backup systems and multiple locations of the backup systems and the data. (Interviewee 5)
Taking measures to protect intellectual property	Concluding NDA with employees and suppliers (Interviewees 2, 15, 25, 27, 28) and patenting newly developed technology (Interviewee 25, 27)	Unwanted knowledge spillover can happen all the time in SCs. Legal measures are difficult to enforce, especially for SMEs and in foreign countries and it takes time to build a sufficient level of trust. (Interviewee 2) When having developed something really innovative, the company patents it before going to the market." (Interviewee 25)

From the table above, one can conclude that a larger share of companies adopted initiatives that ensure stable SC and continuous operations. To a lesser extent, instances in which companies took specific steps to handle financial risks, promote a more risk-aware organizational culture, and secure data/IP in increasingly remote working environments were identified.

## 5 Discussion and conclusions

The aim of the paper was to provide some fresh insights into how SMEs address supply chain risk management in times of an external crisis. Linking the empirical findings with the relevant literature, one can conclude the following.

First, the present study clearly confirms that the global pandemic enforced the already existing and in the last years increasing fragility of SMEs' SCRM for all types of investigated risks. Furthermore, inter-organizational trust has become even more important for SMEs' SCRM management during the pandemic (e.g., Grondys et al., 2021).

Second, the findings allow to draw a more differentiated picture of supply chain risk exposure and SCRM in different groups of SMEs, compared to the small stock of relevant literature. Such differences refer in the first place to the identification of a simple, more ad hoc SCRM approach without preventive measures in micro and small enterprises versus a sophisticated and more organized approach, which is more common in medium-sized enterprises. In this context of different SME size groups, the findings also stress that there is not something like a 'generic SCRM toolbox' for SMEs (c.f., Durst, 2012). The findings rather showed that tailored SCRM approaches are needed that consider both the internal environment like ownership and management structure as well as the skills and competences (e.g., Păunescu and Mátyus, 2020) and the external environment such as the institutional setting (Thukral, 2021) of the respective SMEs.

Regarding the latter, the present study further detailed and illustrated the importance of specific national and industry contexts for SCRM in SMEs. These contexts do not only comprise governmental regulations (e.g., legal or administrative rules). It can also be influenced by the increasing importance of voluntary environmental, social and ethical standards for SCRM in SMEs (see, e.g., Ferreira de Araújo Lima et al., 2020).

In sum, from a theoretical point of view, the present study provides fresh insight into the practice of supply chain risk management in SMEs located in six different European countries. The findings demonstrate how the decision-makers of these firms perceive the current developments triggered by the ongoing pandemic and their possible implications on the companies' supply chain operations. By having involved SMEs not only from different industries and countries but also of different size, similarities and differences regarding SMEs

risk management practices, their fragility or even their absence, can be shown. From a practical point of view, SME managers/owners may learn from the practices presented in the paper to improve their own approach to SCRM considering the company's internal and external environments. Additionally, they can also learn, in case of absence of these practices, about the risks inherent from not having in place such risk management practices and thus the increased fragility of the firms' SCRM and possible consequences for their business operations.

### Abstract

This conceptual paper aims to identify, present, and analyse potential knowledge risks organizations face in external and dynamic crises such as the COVID-19 pandemic. Until only recently, many researchers and practitioners have perceived knowledge primarily as something positive. This view has changed recently with a growing number of studies highlighting risks related to knowledge. The on-going COVID-19 pandemic can be seen as an additional triggering point which has brought several new knowledge risks. Research on knowledge risks, their consequences and potential ways of handling them is still only in its beginning and consequently rather fragmented. To address this situation, this paper is aimed to provide some theoretical insights into knowledge risks and their possible implications organizations are exposed to in an external and dynamic crisis such as the COVID-19 crisis. To reach this aim, this paper presents a continuation of the research by Durst and Zieba from 2018 related to knowledge risks and their potential outcomes. This present study reviewed the up-dated literature on knowledge risks and uses the taxonomy proposed in the paper by Durst and Zieba to identify and analyse knowledge risks organizations are exposed to in the COVID-19 pandemics. Hence, the paper does not only offer fresh food for thought for researchers dealing with the topic of knowledge risks in the COVID-19 crisis and ways of handling them, it also expands the knowledge risks

taxonomy proposed by Durst and Zieba; thereby showing both the taxonomy's dynamic character and usefulness.

## 1 Introduction

This conceptual paper aims to identify, present, and analyse potential knowledge risks organizations face when exposed to external and dynamic crises such as the COVID-19 pandemic. Until only recently, many researchers have perceived knowledge as something positive that has to be shared and disseminated to improve organizational performance (Durst and Edvardsson, 2012; Massingham, 2010). However, this has changed recently with a growing number of studies related to knowledge perceived as a risk, e.g. Durst et al., 2018; Temel and Durst, 2020; Zieba and Durst, 2018. An additional factor that has triggered more knowledge risks is the still on-going COVID-19 pandemic. This crisis represents a new form of an external crisis; one that is dynamic and no end in sight yet (Rapaccini et al., 2020). This new situation has not only forced organizations to rearranging their operations, moving to online work and initiating changes in their normal functioning (Kramer and Kramer, 2020; Mollenkopf et al., 2020; Waizenegger et al., 2020). It has also brought several new knowledge risks. For example, there is a risk of knowledge cherry-picking (some people may select evidence or statistical data so that the information presented agrees with the beliefs of the person making the process). Another example is the risk of deliberate isolation, when a remote employee can naturally lock themselves in their silo, isolate from colleagues, focus on their tasks and not get involved in teamwork, and hence increasing the likelihood of knowledge hiding. There is also the risk that employees are breaking security rules while 'left on their own' (some companies still don't have any special policies for remote workers and there is nothing stopping employees from printing sensitive data from their computers or email files to their private devices). Additionally, many managers and company owners often do not possess skills and tools to accurately assess, examine and manage risks in general (Durst et al., 2021) and knowledge risks in particular. Generally, the research on knowledge risks, their consequences and

potential ways of handling them is only in its beginning and consequently rather fragmented (Durst and Zieba, 2019). To address fill this situation, this paper is aimed to provide some theoretical insights into the knowledge risks and their possible implications organizations are exposed to in an external and dynamic crisis such as the COVID-19 crisis.

To reach this aim, this paper presents a continuation of the research by Durst and Zieba that has started in 2017 related to knowledge risks and their potential outcomes. It uses the taxonomy proposed by Durst and Zieba to identify and analyse knowledge risks organizations are exposed to in the COVID-19 pandemic. Hence, the paper does not only offer fresh food for thought for researchers dealing with the topic of knowledge risks in the COVID-19 crisis and ways of handling them, it also expands the knowledge risks taxonomy proposed by Durst and Zieba; thereby showing both the taxonomy's dynamic character and usefulness.

The paper continues as follows. First, knowledge risks are briefly presented. This is followed by a presentation and discussion of knowledge risks triggered or amplified by the pandemic. The paper terminates with a conclusion section.

## **2 Knowledge risks – theoretical background**

To get deeper into knowledge risk, it is worth getting acquainted with the already developed knowledge risk taxonomy or concept maps. The benefits of concept maps were highlighted by Trochim (1989), it includes expressing the given framework in the language of participants instead of the language of science, which makes the participants more encouraged and helps them to remain on task. A graphic or pictorial product that expresses all major elements and their interrelations is comprehensible to all, it can be presented to the audiences relatively easily and interpreted relatively quickly (Trochim, 1989). Thus, there are also several advantages of creating and analyzing knowledge risks concept maps, reasoned as follows by Durst and Zieba (2019): they are very helpful in visualizing risk, thereby increasing awareness of the knowledge risks and emphasizing their importance, also, concept maps help to understand at what levels in the organization risk is present and how it is related to each other, therefore the holistic view of knowledge in the organization is presented. The map proposed by Durst and Zieba (2019) illustrates the various knowledge risks

that organizations may face and their interlinkages. On the mentioned map, risk has been classified into three categories: human, technological, and operational.

The human risk category includes the following: “knowledge hiding, knowledge hoarding, unlearning, forgetting, missing/inadequate competencies of organizational members” (Durst and Zieba, 2019, p. 2). Another risk that may fall into this category is the loss of knowledge. Organizations experience a loss of knowledge when a key part of the team leaves the company and takes their experience and expertise with them (Brătianu *et al.*, 2020). All mentioned risks are associated with the individual's behaviors, decisions, intentions, ego, inabilities to learn, forgetting, or missing competencies. The risks associated with technology mapped by (Durst and Zieba, 2019) include “cybercrime, old technologies, digitalization, social media”. Ten years ago, only some of the companies relied on the Internet and technology for their business operations, today everyone and every business rely on technology (*The Cost of Cybercrime. Ninth Annual Cost of Cybercrime Study*, 2019), that is why hacker attacks, data theft, old incompatible programs, overreliance on technology, and all dangers related to social media like spreading fake news or trolling accounts are increasing. In the last category, the largest one, the following risks were recognized: “knowledge waste, risks related to knowledge gaps, relational risks, knowledge outsourcing risks, risk of using obsolete/unreliable knowledge, risk of improper knowledge application, espionage, continuity risks, communication risks, knowledge acquisition risks, knowledge transfer risk, and merger & acquisition risks.” (Durst and Zieba, 2019, p. 5). This is a very wide category and all the operational risk are still very actual, because even if organizations once implemented knowledge management processes and systems over the past, they may still face operational risks, as it is not enough to coordinate operational knowledge but to identify and manage potential operational risks (Neef, 2005).

### **3 Knowledge risks in the COVID-19 pandemic**

The COVID-19 pandemic has brought enormous challenges to all kinds of organizations. They suddenly faced the need to adapt rapidly to a new work environment and many of them also to remote work. This changed reality has also brought several new knowledge risks. When working remotely, employees are very task-oriented, such a tendency is effective from the point of view of productivity, however, loneliness and the lack of a common work environment

lead to a decrease in employee engagement and motivation (Mukhopadhyay, 2020). While working remotely many organizations start to experience some form of 'silos' or already existing silos become even worse. The term "silos" refers to grain silos that separate different types of grain from one another, and therefore is a metaphor for separating different parts of an organization. Moreover, when working from home employees can naturally lock themselves in their silo. According to De Waal, Weaver, Day, & van der Heijden (2019) "the concept of a silo refers not so much to the existence of boundaries, but to the mentality through which those boundaries shape behaviors and ways of working that hinder cross-boundary cooperation and collaboration" (p. xxx). Such 'silo-mentality' even more increases the likelihood of knowledge hiding.

The Covid 19 outbreak, the increased number of persons working from home, and thus the increased internet use have also heightened the risk of cybercrime (Wiggen, 2020). E-mail, social media, video conferences, cloud storage, etc. - all of these have been the order of the day in many companies, but the transition to 100% remote work made that all these tools are used even more and more intensively. Technology remains the key when offices are closed, but it is important to ensure that every employee can access and use the technology properly as much as it is needed for a given workload level (Mukhopadhyay, 2020). Not all employees have been adequately trained on Internet security issues, the risk that employees, due to lack of knowledge, break security rules when left on their own increases even more. Home networks, private IT devices, software, and antivirus programs are generally less secure. Overall, it can be concluded that the increasing use of the Internet while working remotely and the growing number of new inexperienced users who have been transferred to the home office suddenly create even more opportunities for criminal activity than before (Wiggen, 2020).

The hurry triggered by the pandemic to switch to home office and remote work has also led to the situation that outdated and underdeveloped IT infrastructures and IT systems clashed with very sophisticated cyber-attacks; thus, technological knowledge risks. This situation has made it even easier for certain individuals/organization to hack themselves in the organizations IT systems to leak sensitive information and knowledge. Given the sophistication of these attacks, many organizations may still have not noticed them. Thus, this situation suggests the presence of both risks related to old technologies and risks of hacker attack (Durst and Zieba, 2018). At the same time, COVID-19 has shown

that risk management skills are underdeveloped in the majority of organizations (Durst et al., 2021). As a consequence, the initiated responses might have been quick but not decisive.

When considering knowledge risk taxonomy, it can be very useful in the analysis of the present COVID-19 situation in companies.

Beginning with the analysis of the first category – human knowledge risks in the context of the COVID-19 situation, we can notice that some of the threats are more serious than before. For example, knowledge hiding during e-work is even easier, there are less personal contact, face-to-face meeting, and the relation between colleagues are getting worse. There occurs also the risk of deliberate isolation and selfish behaviors of employees. Remote work favors isolation, and remote employees may naturally lock themselves in their comfort zone, focus on their tasks and stop being involved in teamwork and knowledge sharing. Companies are trying hard to bring newer and newer innovations in communication technologies that could have the potential to increase knowledge sharing among co-workers, however, the practices of hiding the knowledge remain prevalent in organizations (Connelly *et al.*, 2019). The same applies to unlearning and forgetting, which have become greater threats in times of remote work. They are more common due to a lack of real contact with co-workers. When a worker does not know something or does not remember, he needs to find out the way to contact somebody who can share the knowledge with him. The whole process of finding out the right person, writing an e-mail, calling someone, or even planning the meeting in advance takes very limited time. Missing/inadequate competencies of organizational members to deal with the new situation is also present in the context of COVID-19. Ignorance of safety rules by employees when working at home can have very negative consequences, such as knowledge losses and leaks.

The next category in the taxonomy is technological knowledge risks, risks that have become even more severe during a pandemic. Beginning with the risk of cybercrime which heightened due to people working at home and using a less secure internet connection or generally speaking less experienced users who break security rules. Moreover, some companies did not have enough time to implement special policies for the remote workers, who may not be aware of special rules and may undertake dangerous actions like printing sensitive data from their computers or sending files to their private devices. Less secured devices and less experienced users can easily be caught by phishing attacks, and

are a good target for criminal and malicious actors (Wiggen, 2020). The other risks that companies may face are related to old technologies. Some employees may use computers with outdated programs, which means that the program is no longer eligible for producer security updates. For example operating system Windows 7, which Microsoft ended to support at the beginning of the year 2020 is still in use by millions of users (Wiggen, 2020).

Operational knowledge risks are a broad category when considering the knowledge taxonomy. We can also find some examples of this risk in the context of COVID-19. Knowledge transfer is more difficult when limiting to online tools only. Potential gaps when transferring the knowledge can also pose another risk which is improperly applying knowledge. This risk is also affected by missing face-to-face mentoring, difficulties with a concentration of employees, and facing distractions when working at home. The other risk which occurred recently when working remotely is the "silo mentality". Employees when working from home sometimes lose their organizational culture and are not eager to share skills, knowledge, or information with other peoples, teams, or departments, or even to act as "one company"(de Waal *et al.*, 2019). Lack of proper knowledge sharing and information flow may also increase knowledge waste.

Present COVID-19 situation in companies heightened some of the knowledge-related risks in each category of taxonomy.

#### **4 Conclusions**

From a theoretical point of view, this study provided evidence of the power and usefulness of knowledge risk map taxonomy proposed by Durst and Zieba. Focusing on knowledge risks triggered by an external crisis, i.e. a pandemic, the taxonomy has shown its dynamic character which can be applied to different scenarios/situations.

From a practical point of view, the study provides useful insight for managers and owners of companies who have understood that any organization is fragile with regard to their knowledge and risks related to it. The recommendations may be useful for business professionals to better handle risks related to knowledge, i.e. to eliminate or alleviate the influence of knowledge risks in the COVID-19 era.

At this stage of development, the proposed study is of theoretical character. This limitation will be addressed in future research activities involving a large

sample of organizations from various countries and sectors to validate the risks identified or amend them if necessary.

### Abstract

During COVID-19, it has been common practice for governments to suspend non-essential business activity as a precautionary measure temporarily. As a result, economic activity has slowed in some parts of the world, and businesses in the economic sector are not operating at their maximum capacity. Regularly maintaining the current knowledge management database and methodologies is essential to improving one's ability to handle information and knowledge. In this sense, the bibliometric analysis as a suitable quantitative method in knowledge management can be combined with big data and symbolic data analysis relevant insights. Bibliometric analysis may also analyze semantic cores, revealing other intriguing correlations between the most frequently cited terms in the considered literature and their network location. These strategic responses take various approaches, for example, for family businesses, such as perseverance during the crisis and a short-run strategy based on an adjustment of the business model. The study shows the importance of collaboration and coordination between the various national and international authorities to share pertinent information relevant to disaster mitigation.

**Keywords** – COVID-19, Crisis Management, Bibliometric Analysis, Symbolic Data Analysis, Community Detection

**Paper type** – Academic Research Paper

## **1 Introduction**

Individuals have been affected by the COVID-19 virus pandemic, but the virus has spread around the world. It wreaked havoc on people's lives in all nations and communities. It harmed global economic development in 2020 that was exceptional in more than a hundred years (Jackson et al. 2021). Throughout the world, as COVID-19 spreads, a frequent public policy in response to the pandemic has been to impose a temporary halt to non-essential commercial operations (Cowling et al. 2020). The result is that economic activity is down in some regions of the world, with firms in the economic sector not working at their full potential. However, as the COVID-19 develops into a global economy, this is becoming less of an issue. In some nations, governments have subsidized a portion of the salary income of employees who have been forced to take time off, or they have expanded their welfare programs to include recently laid-off workers or the owners of small businesses (Cowling et al. 2020). In this context, the role of knowledge management cannot be undervalued. It is necessary to consider a context in which it is possible to create and adapt the different companies to accommodate new working methods and collaborate through knowledge management techniques (O Dell and Hubert 2011).

In this sense, effective time management methods increase the company's ability to anticipate what is needed to improve performance. In this respect, managing knowledge within a project is a critical factor. Social networking can be a method of collaboration available which can be helpful in a business strategy. It is necessary to increase knowledge management skills by regularly keeping the knowledge management database and techniques up to date.

## **2 The Research Problem**

The COVID-19 indeed claims a very complex task for businesses nowadays and their decision-making capacity (Dwivedi et al. 2020). COVID-19 requests for every business quick responses to face the crisis. It is necessary to start from disaster management and planning to a mitigation strategy of the damages in practice. Finally, it is necessary to plan a reaction and prepare for economic recovery (Hao 2020). Big data (see, for instance, Chen et al. 2014) can help detect the best intervention strategies and approaches to the crisis. In particular, bibliometric databases, which are typically big or large datasets for the amount of research

produced every year, need to be carefully analyzed to determine a synthesis of the research outcomes (Parlina et al. 2020 Drago and Hoxhalli 2020 Drago and Amidani Aliberti 2018). In this respect, the research question is collecting and synthesizing this research input to obtain the most relevant policy outcomes. In this sense, the approach is to collect and synthesize the existent information on the literature results and obtain new insights. In this respect, the bibliometric techniques can be considered entirely relevant to knowledge management because they allow discovering the contents and the resulting outcomes from the research and the international cooperation between researchers in business that work on a specific topic (Raghu and Vinze 2007). This knowledge can be relevantly considered as an essential basis from the businesses.

A relevant point here that needs to be emphasized is that it is possible to use many different techniques in helpful bibliometric analysis to analyze and evaluate the different patterns on citations and scientific articles, useful to extract relevant scientific insights (see Ponce and Lozano 2010). Moreover, these insights can be very relevant for the business processes (Bhatt et al. 2020).

The development of information markets is one strategy for ensuring the long-term viability and high-quality research outputs. Furthermore, the knowledge market may be a long-term source of funding for advancing knowledge research and a motivator for businesses to collaborate on research projects (on knowledge markets and businesses see Hamet and Mitchel 2019).

### **3 Methodology and Results**

#### **3.1 The Methodological Approach**

We propose an approach helpful to face big data as symbolic data analysis (Billard and Diday 2003 and 2006 Drago 2016 with applications to network analysis and community detection). Every symbolic data is based on an extensive network and a community detection helpful approach to identifying the relevant "semantic cores" of literature (Drago 2019, Drago and Bertelli 2021). So we started collecting scientific works related to these terms: ("covid-19" AND "crisis" AND "management" AND "business") refining the search in the Business, Economics, Social Science area in order to select the most relevant works. We start from co-occurrence terms undirected network (Pons Latapy 2005):

$$G = (V, E)$$

V is related to a vertex as a term, and E is an edge (or link) as a scientific work containing both the terms. The analysis aims to identify a partition P on the network (Pons and Latapy 2005), identifying the "semantic cores" (Drago and Gatto 2021) as part of the partition:

$$P = \{C_1, \dots, C_k\}$$

[2]

From the "semantic cores" as a community in the network, the bibliometric analysis, we can discover relevant approaches that businesses are explicitly considering to face with COVID-19. More specifically, we start by identifying the relevant literature considering the relevant keywords ("crisis," "management," "business," "COVID-19"). We construct a bibliometric database containing all the research articles considering these keywords. We determine the co-occurrence network from the original data, representing the literature and the relationships between the themes (represented by the nodes). From the network obtained (see fig. 1 the 15 most central concepts in the literature regrouped into relevant clusters visualized by the different colors), we can extract the relevant information as communities using the walk trap algorithm (Pons Latapy 2005), which is helpful to identify clusters of nodes maximally connected each other but also feebly connected with nodes of the other clusters (Fortunato 2010). The relevant group of nodes identified are the "semantic cores" of the literature and usually identify the relevant themes and the relevant ideas, synthesizing the underlying scientific works. Following Wasserman Faust (1994), in order to adequately interpret each core, we compute statistical measures of network centrality as the betweenness for each node i

$$C_B(p_i) = \sum_{k=1}^N \sum_{j=1}^{k-1} b_{kj}(p_i) \quad (3)$$

(see Marsden 2002). Betweenness is relevant to measuring the global centrality of the concepts in the literature. And then, for each community, we compute the interval. Finally, bibliometric analysis can adequately identify key scientific works and interpret the semantic cores showing other interesting relationships between the most cited terms in the considered literature and their network position. Semantic cores are represented as interval data which can quantify their relevance as relevance on the bibliometric network.

### **3.1 The Results**

In this sense, in the analysis, we identified three crucial elements not only on interpreting the semantic cores but also on the entire literature considered: risk management and viral disease, decision-making, and information management. In this sense, we can analyze possible crisis management strategies and economic responses. These strategic responses consider various approaches, for instance, for family firms, as the perseveration during the crisis (Kraus et al. 2020), but also a short-run strategy based on an adjustment of the business model but also on a long run approach based on the innovation of the business model (see also Wensel et al. 2020). Additionally, our approach shows the importance of risk management (see in the tourism sector Richie and Jiang 2019). At the same time, the relevant literature shows that there is the need for collaboration, but also coordination between the different national and international authorities in order to share the relevant information applicable to mitigating the disaster (crisis reports, for instance) and also identify relevant responses and actions (see Goniewicz 2020 in the context of the tourism industry see Wen et al. 2020). At the same time, there could be an opportunity for a greener sustainable economy (see Ioannides Gyimothy 2020). Our results show that careful risk management of the viral disease, appropriate decision-making, and efficient information management can be reliable tools and instruments for a solid response to the greatest challenge of the COVID-19.

## **4 Conclusions**

A typical public policy reaction to the epidemic as COVID-19 spreads has been to temporarily cease any commercial activity that is not necessary for survival (Cowling et al. 2020).

It is impossible to overstate the importance of knowledge management in this environment. Social networking may be a way of cooperation that is readily available and beneficial in developing company strategies. At the same time, a very relevant tool in modern knowledge management is the use of the scientific literature to enforce strategic decisions in business. In this work, we have considered a bibliometric analysis useful to detect specific insights and discoveries for the business world. In this sense, we have synthesized the relevant literature on the sector, and we have obtained some relevant essential results.

In the investigation, we discovered three components that were critical not only to the interpretation of the semantic cores but also to the interpretation of the entire literature under consideration: risk management and viral illness, decision-making, and information management. These strategic solutions take into account various techniques, such as the perseverance of family businesses during a crisis, for example (see also Kraus et al. 2020). At the same time, the pandemic may present a chance for a more environmentally friendly and sustainable economy (see also Ioannides Gyimothy 2020)

### **Abstract**

Since the beginning of 2020, the world has been hit by the SARS CoV-2 virus that causes Covid-19. To hamper its spread, policy makers of many countries have put in place strong countermeasures, including lockdowns, that have led to significant changes in people's lifestyles and daily routines. The literature highlights that the Covid-19 pandemic has impacted several behavioural aspects. Despite the research on the changes in consumer behaviour due to the Covid-19 pandemic has been rapidly increasing, the study of this phenomenon remains an urgent issue to deepen. Further, the literature on the topic suggests the need to investigate from multiple perspectives the impact of Covid-19 on sustainability.

In this context, this paper aims at assessing the changes in green consumer behaviour in Italy caused by Covid-19. A survey was conducted on 1.535 Italian consumers between December 2020 and January 2021. Respondents have been asked to assess the extent to which their consumption behaviour related to several categories of products (eco-

sustainable, organic, fair-trade, locally produced, made in Italy, sold by neighbourhood stores) has changed due to the pandemic, as well as the extent to which the pandemic has impacted on many other aspects, including their environmental awareness and purchase behaviors.

The results show higher levels of consumption of eco-sustainable, organic, and fair-trade products, as well as of goods sold by neighbourhood stores, produced locally and made in Italy. For these product categories, it is also reported an increase in the consumers' sense of moral duty to purchase and in the willingness to pay a premium price. Further, results show that consumers are more aware of the extent to which their consumption behaviour can have economic, social, and environmental impacts. Consumers have also changed their purchasing habits. Further, this study's findings reveal that the extent of change is strongly affected by socio-demographic variables, such as gender, age, income, and education.

Changes reported in green consumer behaviour suggest implications on multiple levels. These are of great importance to guide marketers to respond promptly and effectively to the new challenges and to guide scholars to extend knowledge on this topic.

**Keywords** – Sustainable consumer behavior, green consumer behavior, sustainable products, green products, sustainability, Covid-19.

**Paper type** – Academic Research Paper

## 1 Introduction

Since the early stage of 2020, humanity has started to be threatened by the SARS-CoV-2 virus, which causes Covid-19. Its contagiousness, its high mortality rate, especially for elderly, and the need for hospitalization and intensive care for the most serious cases led policy makers of many countries to take a number of countermeasures: social distancing, wearing protection masks, restrictions that involve non-essential activities (e.g., restaurants, non-grocery shops), partial or total lockdowns, among others. Together with the fear of the new virus, which has caused severe impacts on the global economy (Brewer and Sebby, 2021), these countermeasures have led to significant changes in people's lifestyles and daily routines (Kirk and Rifkin, 2020; Zwanka and Buff, 2021). Many studies in the literature have been conducted to investigate how and the extent to which consumer habits and behavior can be affected by particular (unexpected) events, such as natural disasters – e.g., hurricanes (Sneath et al., 2009), earthquakes (Forbes, 2017), and terroristic attacks (Baumert et al., 2020; Herzenstein et al., 2015). In line with this literature, research on the impact of Covid-19 on consumer behaviors has been rapidly growing. This topic has been analyzed from different

perspectives, such as consumers' food consumption habits (Coulthard et al., 2021; di Renzo et al., 2020; Murphy et al., 2021), shopping behavior (Moon et al., 2021; Safara, 2020; Wang et al., 2020), mobility patterns (Anke et al., 2021; Nouvellet et al., 2021), physical activity (Faulkner et al., 2020; Martínez-de-Quel et al., 2021), and tourism (Miao et al., 2021). It has been highlighted that consumers constantly change their behavior in response to policies developed by governments to address the health emergency (Yang et al., 2020), suggesting the relevance of studying the impact of the pandemic on consumer behavior. Indeed, understanding changes in consumer behavior is of great importance to guide marketers and policymakers to respond promptly and effectively to these changes (Kirk and Rifkin, 2020). Despite the literature on the topic has been growing and the phenomenon has been studied from different points of view, research on the influence of Covid-19 on consumers behavior is still at a nascent stage (Qi et al., 2020) and remains an urgent issue (Borsellino et al., 2020). Further, the literature recognizes the need to investigate the impact of Covid-19 on sustainability from multiple perspectives (Sarkis et al., 2020).

In this context, this paper aims at assessing the extent of changes in sustainable consumer behavior caused by Covid-19 in Italy. Specifically, this study investigates the extent of changes generated by the pandemic in sustainable consumer behavior under multiple perspectives. Further, the change in consumer behavior for the following six categories of sustainable products is analyzed: organic, eco-sustainable, fair-trade, made in Italy, local, and products sold by neighbourhood stores. Organic and eco-sustainable products are related to the environmental dimension of sustainability. Fair-trade products are related to the social and economic dimensions of sustainability. Made in Italy and local products positively contributes to all three dimensions of sustainability - being produced in Italy or locally, there is a reduced environmental impact due to transportation, as well as a positive impact on Italian/local economy and employment levels). Products sold by neighbourhood stores contribute to the social and economic dimensions of sustainability, due to their impact on the local economy and employment levels.

To measure the extent of changes in consumer behavior, a questionnaire was developed and administered to a sample of 1.535 Italian consumers. Specifically, we asked whether the pandemic has increased consumer awareness (related to environmental problems and the impact of individual behaviors and purchase choices on the environment, society, and economy). Further, we asked whether

the pandemic has increased the consumer sense of moral duty to purchase different categories of sustainable products. Then, we asked whether the pandemic has impacted on the consumer purchase frequency and willingness to pay for the above-mentioned products, as well as and whether the pandemic has affected several consumer purchase behaviors. Differences among the answers provided by groups with different socio-demographic characteristics (i.e., gender, age, income, and education) have been investigated.

The paper is organized as follows. In Section 2, we explain the methodology used and describe the characteristics of the sample. In Section 3, we describe and discuss the results. Finally, in Section 4, we report the implications and conclusions of the study.

## **2 Methodology and sample**

A structured questionnaire was developed to collect data for this research<sup>1</sup>. The *first section* included two questions. A five-point Likert scale was used to measure how much Covid-19 pandemic increased (from “not at all” to “extremely”) consumers’ levels of awareness and moral duty. Specifically, Q1 evaluated, through eight items, the impact of Covid-19 on the increase of respondents’ awareness on the effect of human activities on environmental degradation, as well as the influence of Covid-19 on the increase of respondents’ awareness about the impact of their purchasing decisions on the natural environment, society, and economy (two items from BCG (2020), six items adapted from Kang et al., 2013). Q2 measured, through six items, the changes due to Covid-19 in respondent’s sense of moral duty to purchase different product categories (Sold by neighbourhood stores, Made in Italy, Local, Fair-trade, Organic, Eco-sustainable).

The *second section* included three questions. A five-point Likert scale was used to measure the change, due to the Covid-19 pandemic, in the frequency of different types of actions (from “I do it a lot less often” to “I do it a lot more often”). Specifically, Q3 investigated, through six items, how much the frequency of purchase of different product categories (Sold by neighbourhood stores, Made in Italy, Local, Fair-trade, Organic, Eco-sustainable) has changed due to the pandemic (three items from BCG (2020), three items self-developed). Q4 evaluated, through six items, how much the frequency of carrying out several

---

<sup>1</sup> In this paper a shorter version of the full questionnaire is presented.

purchase behaviors has changed due to the pandemic (two items adapted from BCG (2020), four items self-developed). Q5 investigated the changes due to Covid-19 in respondents' willingness to pay a premium price for five product categories (Made in Italy, Local, Fair-trade, Organic, and Eco-sustainable) (adapted from Moser 2015)<sup>1</sup>. A five-point Likert scale was used (from "greatly decreased" to "greatly increased").

The *third section* included questions on socio-demographic characteristics of respondents (gender, age, education, net monthly household income).

The questionnaire also included some other questions, but in this paper, it was decided to focus only on certain aspects: awareness, moral duty, purchase frequency and behaviours, and willingness to pay.

The developed questionnaire was pre-tested with a sample of 40 people. As a result, small changes were done to improve the clarity of some questions.

The questionnaire was administered through the Qualtrics survey platform. The survey was spread to people living in Italy between December 2020 and February 2021 through multimedia channels (e.g., social networks and instant messaging clients). The final sample is made of 1.535 respondents. The socio-demographic characteristics of the sample are reported in Table 1.

Table 1: Socio-demographic characteristics of the sample.

Variable	Group	Frequency	Percentage (%)
Gender	Male	668	43,52
	Female	867	56,48
Age	18 – 24	347	22,61
	25 – 34	480	31,27
	35 – 44	215	14,01
	45 – 54	235	15,31
	55 – 65	198	12,90
	> 65	60	3,91
Education	Middle school or lower	84	5,47
	High school	563	36,68
	Bachelor's master's degree	705	45,93
	Postgraduate course or	183	11,92
	PhD		
Net monthly household	< 1.500	258	16,81

<sup>1</sup> Products sold in neighbourhood stores have not been included in this question since, differently from the other considered categories, their sustainability only derives from the place where they are sold rather than from clearly recognizable intrinsic product characteristics.

income (euros)	1.500 - 3.000	789	51,40
	3.001 - 4.500	325	21,17
	> 4.500	163	10,62
<i>Total</i>		<i>1535</i>	<i>100</i>

### 3 Results and discussions

In this section, results from data analysis are reported. For each question, results are provided first on the whole sample of responses, then for different groups of respondents, defined according to socio-demographic characteristics. In order to investigate the differences among groups, the nonparametric Kruskal-Wallis test was performed, followed by a Post Hoc test comparing pairwise via Dunn procedure with Bonferroni adjustment.

#### **3.1 Awareness of environmental problems and of the impact of consumer purchasing choice and behaviors**

The results show that the pandemic caused an increase in consumer awareness related to all the considered aspects (Figure 1a). Results show a moderate or extreme increase in awareness of the effect of environmental problems (over 55% of respondents), in the awareness that individual purchasing choices can have a significant impact on the economy and that consumer behavior can make a significant difference in mitigating environmental problems (over 40% of respondents). Concerning the other aspects, over 30% of the answers are on the last two anchors of the Likert scale.

The level of awareness increased for all the socio-demographic groups. Women report significantly higher values than men for all the statements (Figure 1b). Concerning *age groups*, the group "25-34" shows a lower increase in the awareness compared to groups "18-24", "45-54", and "55-65" on multiple statements (Figure 1c). Regarding the *household income*, no significant differences can be noted among groups, except for the statement A (Figure 1d). Respondents belonging to the "1.500 - 3.000" group have increased their level of awareness about the threat by environmental degradation significantly more than the group "3.001 - 4.500". Significant differences are found among *education groups* on multiple statements (Figure 1e). Respondents belonging to the two highest education levels have a lower increase in the level of awareness for environmental problems compared to other groups (statements A and B). For the statements C,

E, and F the "High school" group has significantly higher values than the "Bachelor's or master's degree" and "Postgraduate course or PhD" groups.

### **3.2 Moral Duty to purchase sustainable products**

Results show that consumers' moral duty to purchase the considered product categories is increased due to the pandemic (Figure 3a). The sense of moral duty to purchase Local products moderately or extremely increased for over 50% of respondents, whereas the sense of moral duty to purchase Made in Italy products and Products sold by neighbourhood stores moderately or extremely grew for over 40% of respondents.

The moral duty to purchase increased for all the considered groups. Women report significantly higher values than men for all the product categories (Figure 3b). Significant differences are found among *age groups* for each product category (Figure 3c). Respondents belonging to the group "25-34" increased their moral duty significantly less than respondents belonging to other groups for multiple types of products. On the contrary, the group "55-65" shows higher values than other groups. Results reveal significant differences among *household income* groups only for Organic products (Figure 3d). The "3.001 - 4.500" group shows a lower increase in the level of moral duty to purchase Organic products compared to the "< 1.500" group. Concerning *education*, significant differences among groups are found on Made in Italy, Fairtrade, Organic, and Eco-sustainable products: respondents with the lowest education level report a higher increase in their sense of moral duty to purchase these products (Figure 3e).

### **3.3 Purchase frequency**

Results show that more than 50% of respondents increased the frequency of purchase related to Made in Italy and Local products, around 50% of respondents increased the frequency of purchase products sold by neighbourhood stores, while more than 20% of respondents increased the frequency of purchase of Fair-trade, Organic, and Eco-sustainable products (Figure 4a). These results are consistent with those of the Coop Report (2020) and Severo et al. (2021), which show how the pandemic increased sustainable consumption.

The purchase frequency increased for all the socio-demographic groups. Women increased their purchase frequency for all categories of products

significantly more than men (Figure 4b), consistently with the study by Witek and Kuźniar (2021). Concerning the *age groups*, results do not reveal significant differences among groups (Figure 4c). Regarding the *household income* groups, significant differences are found only for Organic products, where the "< 1.500" group has a significantly higher value than the "3.001 - 4.500" group (Figure 4d). This may be related to the fact that the "< 1.500" income range has a significantly greater moral duty to purchase Organic products than the "3.001 - 4.500" income range, as well as more concern for environmental issues. With respect to *education*, no significant differences are reported (Figure 4e).

### **3.4 Purchase behaviors**

Results show several changes in the purchase behaviors (Figure 5a). More than 50% of respondents increased the frequency of purchasing products online, consistently with other recent studies (Alaimo et al., 2020; Moon et al., 2021; Principato et al., 2020; Wang et al., 2020). Around 50% of respondents avoided, more often, the purchase of non-essential products, in line with Mehta (2020). Similarly, around 50% of respondents limited the number of times they shop in physical stores buying large quantities at a time, consistently with Wang (2020). Conversely, around 25% of respondents decreased the frequency of shopping in large stores. Finally, around 30% of respondents increased the frequency of reading the product labels.

Concerning the results related to the specific groups, it can be noted that women reported significantly higher values than men for all the purchase behaviors, except for Purchasing products online and Shopping in large stores (Figure 5b). Results reveal significant differences among the *age groups* on items B and C (Figure 5c). Respondents under 45 have increased the frequency of shopping online significantly more than older respondents. This result might be due to higher familiarity of young people with online platforms. Respondents over 35 have reduced the frequency of shopping in large stores significantly more than the younger respondents, probably because they are more vulnerable to Covid-19 and shopping in large stores is perceived as a situation characterized by potential infection risks. Regarding the *household income*, no significant differences can be found among groups, except for Purchasing products online (Figure 5d). Respondents with a net monthly household income higher than 3.000 euros increased the frequency of online shopping significantly more than other

respondents whose net income is lower than 3.000 euros. This result may be linked to the greater economic availability and ease of access to e-commerce for the high-income people. Relating to *education*, respondents belonging to the “Middle school or lower” group increased the frequency of online shopping significantly less than the other respondents (Figure 5e). The “High school” group increased the frequency of checking the ingredients or materials used on the product labels significantly more than the “Postgraduate course or PhD” group.

### **3.5 Willingness to pay**

Results show that, depending on the specific category of sustainable product, between 20% and 45% of the respondents indicated an increase in the willingness to pay a premium price due to the pandemic (Figure 7a). Alternatively, between 3% and 6% of respondents decreased their willingness to pay.

The willingness to pay a premium price increased for all socio-demographic groups. Significant differences between men and women are found only for two product categories, i.e., Made in Italy and Organic products, for which women reported a significantly higher increase in the willingness to pay a premium price (Figure 7b). This could be related to the fact that women increased the frequency to read product labels more than men. This result is consistent with Shahsavar and Kube (2020). No significant differences among the *age groups* are found (Figure 7c), as well as among the *household income* (Figure 7d) and the *education* (Figure 7e).

**Q1 - Please indicate how much the Covid-19 pandemic has made you more aware of the following aspects: [from 1 = "not at all" to 5 "extremely"]**

- A. Humans can be threatened by environmental degradation
- B. The climate is threatened by human activities
- C. My purchasing choices can have a significant impact on the environment
- D. My purchasing choices can have a significant impact on society
- E. My purchasing choices can have a significant impact on the economy
- F. My behavior can make a significant difference in mitigating environmental problems
- G. My behavior can make a significant difference in mitigating social problems
- H. My behavior can make a significant difference in mitigating the economic problems of my territory

## 4 Implications and conclusions

This paper investigated the extent of changes in sustainable consumer behavior caused by the Covid-19 pandemic in Italy. Results demonstrated that the Covid-19 pandemic has indeed caused several changes in sustainable consumer behavior and that these changes are different according to socio-demographic characteristics of respondents.

Based on the obtained results, several implications can be developed for both theory and practice.

In terms of theoretical implications, this study contributes to the consumer dynamics literature (Zwanka and Buff, 2021; Baumert et al., 2020) and to the green/sustainable consumer behavior literature (Borsellino et al., 2020; Jian et al., 2020; Qi et al., 2020; Severo et al., 2020) by assessing the influence of an unexpected and disruptive event, such as the Covid-19 pandemic, on sustainable consumer behavior. This study considers the economic, environmental, and social dimensions of sustainability simultaneously, by including different product categories (i.e., Sold by neighbourhood stores, Made in Italy, Local, Fairtrade, Organic, and Eco-sustainable products) related to the three above-mentioned aspects of sustainability. This is a novelty compared to previous studies. This study offers elements of novelty also with regard to the context in which it has been carried out. Actually, previous research conducted on the Italian context on the impact of Covid-19 pandemic on consumer behavior is quite limited and focused on very specific aspects, while our study considers multiple aspects of consumer behavior. Furthermore, our results also show how the changes in consumer behavior can be different according to socio-demographic characteristics of respondents, as significant differences emerged among gender, age, income, and education groups.

Several implications for companies can be derived from this study's results. Specifically, our results show a general increase in both the frequency of purchase and the willingness to pay more for several categories of sustainable products. These changes in consumer behavior highlight growing opportunities for companies to embrace sustainability into their strategies, position themselves as sustainable firms and develop sustainable products. Further, the increase in the frequency of purchase and willingness to pay more for made in Italy and local products may let companies change their production strategies or better promote these characteristics. Moreover, the differences emerged among the

different socio-demographic groups highlight that specific marketing mixes should be developed for each category.

In conclusion, this research offers a general picture of the changes in sustainable consumer behavior that occurred in the Italian context due to the Covid-19 pandemic. Results have shown that this catastrophic and unexpected event led consumers to be more concerned about environmental problems and more aware of individual impacts, and to have a more sustainable purchase behaviour.

### Abstract

This paper is aimed at analyzing the consumers' perception toward products from Industrial Symbiosis (IS) processes (hereafter mentioned as "IS products"), as well as their purchase intention and willingness to pay a premium price for them. IS is one of the key strategies supporting the transition towards the circular economy: accordingly, wastes produced by a company can be used as production inputs by other companies or be exploited to produce new products. Specifically, this paper investigates the consumers' perception of two IS products: (1) electronic products, whose shell is made by industrial plastic wastes, and (2) electronic products, whose battery contains substances extracted by wood wastes. A survey was conducted on 1.224 Italian consumers, aimed at assessing risks and benefits perceived by them, related to the above-mentioned IS products. Results show that consumers do not perceive IS products as risky; alternatively, they perceive several benefits in terms of the quality and functionality of these products. Furthermore, consumers are aware that IS products can contribute to preserving the natural environment. Finally, most consumers declare a purchase intention of the investigated IS

products and are willing to pay a premium price for them. The results of this paper highlight that potential markets for IS products currently exist and suggest companies to include IS products into their product portfolio.

## 1 Introduction

The last global environment outlook accurately describes how climate change poses a serious challenge to economic development, creating risks to natural systems and human society (Ekins et al., 2019). Alongside the climate change problem, the consumption of natural resources and the production of wastes is becoming increasingly alarming, due to the population growth and the increase in per capita consumption rates (World Bank, 2019).

Consequently, the traditional production and consumption model must evolve from a linear to a circular one, able to reduce the inputs of raw materials to the economic systems and close the resource loop to minimize waste production (Korhonen et al., 2018). In this regard, industrial symbiosis (IS) is one of the most impactful strategies able to support the transition towards the circular economy (Domenech et al., 2019). IS deals with replacing – totally or partially – raw materials and production inputs with wastes produced by other companies (Chertow, 2000). By implementing IS relationships, companies can achieve economic benefits from the reduction in their production costs and create environmental benefits for the society, simultaneously (Taddeo et al., 2017). Driven by these potential benefits, the attention received in the literature by IS has drastically increased in recent years (Mallawaarachchi et al., 2020). So far, the literature has analyzed IS from the company perspective, e.g., analyzing case studies – aimed at highlighting the benefits from IS – (Neves et al., 2020), drivers and barriers to the IS implementation (Mortensen and Kørnø, 2019), as well as investigating the impact of operational (Fraccascia, 2019) and social issues (Hewes and Lyons, 2008) on the IS practice. However, scant attention has been devoted so far to investigating IS from the perspective of consumers, i.e., who is going to buy goods produced via the IS approach.

This paper contributes to this research topic via investigating the consumer perceptions towards IS products, as well the purchase intention and the

willingness to pay a premium price for these products. Although many studies in the literature exist that address consumer behavior towards many product categories, including green products (e.g., Dangelico et al., 2021), there are no studies that specifically address IS products. In particular, two categories of IS products have been considered: (1) electronic products (e.g., laptops, smartphones, tablets) whose shell is made by industrial plastic wastes – in the remainder referred to as “IS plastic products” – and (2) electronic products whose battery contains substances extracted by wood wastes, which replaces chemical substances – in the remainder referred to as “IS wood products”. To this aim, a survey has been conducted on 1.224 Italian consumers between November 2020 and February 2021.

The remainder of the paper is organized as follows. Section 2 presents the theoretical background. Section 3 addresses the methodology. Section 4 presents the results. The paper ends with discussion and conclusions in Section 5.

## **2 Theoretical Background**

To investigate consumers’ perceptions towards IS products, along with their purchase intention and willingness to pay a premium price for them, we have referred to the theory of the decision-making process (Engel et al., 1968). This theory is based on the concept that, during the purchasing decision process – i.e., when the consumer is assessing whether to buy the product and how much he/she is willing to pay for it – consumers balance risks and benefits related to purchasing that product (Hamzaoui-Essoussi and Linton, 2010; Mugge et al., 2017).

Risks can be categorized in terms of inherent risk – i.e., those reflecting the consequences of a purchase (Taylor, 1974) – and psychological risk – i.e., the discomfort coming from anticipated post-behavioral reaction (Perugini and Bagozzi, 2001). Nevertheless, the most popular taxonomy comes from Mitchell (1992), who has identified six types of risks: social, financial, physical, performance, time, and psychological. The perceived risk depends on the product characteristics and related available information (Hwa-Wu et al., 2015).

Concerning IS plastic and wood products, consumers may primarily associate a *contamination risk*, if they perceive the product as dirty or unsanitary. Another relevant risk relates to the *perceived safety*, since consumers could perceive the product as not safe. Alongside these two types of risks, the *performance risk* can

be considered through the consumers' expectations on the quality and functionality of the product. The *quality* of a product is the utility resulting from the expected performance, in terms of reliability and degree of customization, as well as freedom from defect, and is affected by the conformance to customer requirements and specifications (Hur et al., 2014; Johnson and Ettlie, 2001). Environmentally friendly products can be perceived as less attractive than traditional products (Micklethwaite, 2004) and consumers may associate a lower quality to them (Magnier et al., 2019; Wang et al., 2013). The *functionality expectation* is related to consumers' perceived utility of a product and their perception of receiving the maximum benefit, in terms of physical attributes, performance, and functionality (Gonçalves et al., 2016; Hur et al., 2014). The quality and functionality knowledge are the main components of the perceived overall value of the product (Churchill and Surprenant, 1982; Hur et al., 2014; Singhal et al., 2019; Wang and Hazen, 2016), having a positive impact on purchasing behavior (Chang and Fong, 2010; Cronin et al., 2020; Styliadis et al., 2020). Finally, it is important to consider the *green perceived utility*, i.e., the environmental benefit of the product perceived by the consumer. Consumers are more likely to purchase environmentally friendly products when they are aware of the related environmental benefits (Magnier et al., 2019).

### **3 Methodology**

#### **3.1 Sample and Procedure**

Primary data was collected through a survey addressed to Italian consumers between November 2020 and February 2021. Two identical questionnaires were developed, aimed at collecting data on the consumer behavior, purchase intention, and willingness to pay a premium price for two different products, i.e., electronic products including parts made of recycled wood (IS wood products) or plastic (IS plastic products), respectively. The questionnaires were validated through a pre-test conducted on a sample of 20 consumers, aimed at highlighting whether the questions were clear enough to respondents, as well as to test the time required to complete the questionnaire. Only small changes were made after the pre-test. The questionnaires were distributed online using social networks, instant messaging clients, and e-mails. The final sample of respondents

was made by 1.224 consumers, 605 for the survey related to IS plastic products and 619 related to IS wood products.

### **3.2 Measures**

The questionnaires were divided into two parts: the former consists of several questions based on the theory of consumers' decision-making process, while the latter focuses on socio-demographic characteristics of respondents.

Each construct in the first section was measured through a multi-item 5-point Likert scale. Each scale ranges from 1 = "strongly disagree" to 5 = "strongly agree", except the scales measuring the *quality expectation*, ranging from 1 = "much lower" or "very low" to 5 = "much higher" or "very high". *Contamination risk* scale is made of three items (Magnier et al., 2019; Argo et al., 2006), *perceived safety* scale of three items (Magnier et al., 2019), *quality expectations* of two items (Boulding and Kirmani, 1993), *functionality expectations* of three items (Magnier et al., 2019; Homburg et al., 2015), and *green perceived utility* of three items (Magnier et al., 2019; Chang, 2011). *Purchase intention* is assessed through three items (Bamberg, 2003; Gleim et al., 2013) and *willingness to pay* is assessed through two items (Magnier et al., 2019). Table 2 in the Appendix displays all the scales analyzed in this paper, with source, mean and standard deviation of each variable.

The second section includes questions about socio-demographic characteristics of respondents: gender (a dummy variable with 0 for male and 1 for female), age (from 1="18-24" to 6="over 65"), education (from 1="Middle school or lower" to 5="Doctorate"), and monthly household net income (from 1= "less than 1.500 €" to 4= "over 4.500 €").

## **4 Results**

### **4.1 Description of the sample**

From a demographic point of view, the sample is mostly made by young and highly-educated people. Actually, more than 50% of respondents are younger than 35 years old; 25% of respondents have a bachelor's degree and 34% have a master's degree. 36% of respondents are male and 64% are female. Around 24% of respondents declared a net monthly household net income lower than 1.500

euros, 42% between 1.500 and 3.000 euros, 19% between 3001 and 4.500, and 15% higher than 4.500 euros.

#### 4.2 Descriptive analysis

Figure 1 displays the assessment of *green perceived utility* for IS wood products (Figure 1a) and IS plastic products (Figure 1b). It can be noted that, for both products, more than 60% of respondents agree that these products protect the environment and can contribute to effectively reduce pollution and problems related to landfill saturation.

Concerning the *perceived risks* by consumers (Figure 2), the majority of respondents perceive both these products as not-risky: almost 90% of respondents do not consider them as contaminated, unsanitary, or dirty, regardless of the type of recycled material used – results for IS wood products are shown in Figure 2a, results for IS plastic products are shown in Figure 2b.

Table 1. Socio-demographic characteristics of the sample.

	Frequency (percentage)
Gender	
Male	445 (36.36%)
Female	779 (63.64%)
Age	
18-24	335 (27.37%)
25-34	380 (31.05%)
35-44	158 (12.91%)
45-54	150 (12.25%)
55-65	159 (12.99%)
over 65	42 (3.43%)
Educational level	
Middle school or lower	37 (3.02%)
High school	426 (34.80%)
Bachelor's degree	312 (25.49%)
Master's degree	421 (34.40%)
Doctorate	28 (2.29%)
Household net income	
< 1.500	291 (23.77%)

1.500 - 3.000	519 (42.40%)
3.000 - 4.500	232 (18.95%)
> 4.500	182 (14.87%)

Concerning the *perceived safety* (Figure 3), approximately 85% of respondents declared to perceive those products as not dangerous. Nonetheless, safety is perceived slightly higher in the case of IS plastic products – results for IS wood products are shown in Figure 3a, results for IS plastic products are shown in Figure 3b.

Concerning the *functionality expectations* (Figure 4), more than 90% of respondents think that IS products are capable of performing well, doing their job, and being functional. Even in this case, the perceived functionality is slightly higher in the case of IS plastic products – results for IS wood products are shown in Figure 4a, results for IS plastic products are shown in Figure 4b.

Concerning the *quality expectations*, it can be noted that almost 85% of consumers expect that the quality of IS products is equivalent to or higher than that of traditional products. Almost all respondents perceive the quality of these new products as acceptable or high (Figure 5).

Concerning the *purchase intention* (Figure 6), more than 60% of respondents state that they would consider buying IS plastic or IS wood products.

Finally, concerning the *willingness to pay* a premium price (Figure 7), more than 40% of respondents declared that they would pay a premium price for IS products, for both the types of product.

Figure 6. Results on purchase intention for IS wood products (a) and IS plastic products (b).

Figure 7. Results on willingness to pay for IS wood products (a) and IS plastic products (b).

## 5 Discussion and conclusion

This paper aims to analyze consumers' perception towards IS products, together with their purchase intention and willingness to pay a premium price for them. The theory of the decision-making process has been adopted, in order to study consumers' perception related to products with parts made of recycled wood or plastic (IS wood and plastic products), considering risks that might be perceived by consumers. Since the perceived risk is considered as a potential loss, it could have a negative impact on consumers' purchase intention and willingness to pay a premium price (Baxter et al., 2017; Featherman and Paul, 2003; White et al., 2015). In this paper, contamination and safety risks have been explored, together with the analysis of the performance risks and the study of the green perceived utility as a benefit.

In the literature, the existence of the perception of contamination has been demonstrated for several products. For instance, the packaging of a bottle of water is perceived as less shiny and clear (Laville and Taylor, 2017) or the recycled textile fiber is believed to have an unpleasant smell (Rucker, 2009). Nevertheless, this study shows that consumers do not perceive IS products as dangerous or dirty/unsanitary. Respondents also have good perceptions and very high expectations of the products' quality and functionality. This result is consistent with the results of Hamzaoui-Essoussi and Linton (2010) and Magnier et al. (2019).

Concerning the green perceived utility, respondents of this study believe that IS products can be useful and effective to protect the natural environment. This is an

important result because several studies demonstrate that the more consumers are concerned about the environment and aware of the utility of green products, the higher the likelihood they purchase them (Alhosseini Almodarresi et al., 2019; Choi and Kim, 2005; Kilbourne and Pickett, 2008; Laroche et al., 2001).

Results of this study show that consumers would like to purchase IS products and they would pay a premium price for them. According to the literature, consumers are more likely to purchase recycled products and are more willing to pay a premium price when they perceive a low risk of contamination or safety (Magnier et al., 2019; Michaud and Llerena, 2010), and when they have high quality and functionality expectations about the product (Baker and Crompton, 2000; Chang and Fong, 2010; Hamzaoui Essoussi and Linton, 2010; Magnier et al., 2019).

The results can be useful for companies and policymakers. Companies should take into account that, since consumers have good perceptions related to IS products and are willing to buy them, new markets for these products might exist. Hence, companies should devote attention to explore these new markets. In-depth research should be conducted on clustering (potential) customers of IS products. Since IS products can contribute to creating environmental benefits, policymakers could develop ad-hoc policies to support the development of IS products, such as incentives to companies producing them and customers buying them (Fraccascia et al., 2017; Tao et al., 2019).

Although this study considers several variables concerning risks and benefits related to IS production, it does not investigate the (potential) impact of these variables on the consumers' purchase intention of IS products, as well as the willingness to pay a premium price. Hence, future research is recommended to fill this gap.

## Appendix

Table 2 - Scales with source, mean, and standard deviation for each type of product.

CONSTRUCTS AND ITEMS	Source	Mean wood	Mean plastic	Std dev wood	Std dev plastic
Green perceived utility					
These products protect the environment.	(Magnier et al., 2019; Chang, 2011)	3.57	3.54	1.08	1.09
These products can effectively reduce pollution.		3.73	3.77	1.00	1.02
These products can reduce problems related to landfill saturation	Self-developed	3.64	3.77	1.05	1.06
Contamination Risk					
I believe these products are unsanitary	(Magnier et al., 2019; Argo et al., 2006)	2.00	1.86	1.12	1.12
I think these products are contaminated		1.90	1.78	1.01	1.01
In my opinion, these products are dirty		1.75	1.62	1.02	1.01
Perceived Safety					
I think these products are safe	(Magnier et al., 2019)	3.75	4	0.94	0.98
I think these products are benign		3.51	3.68	1.01	1.14
I think these products are harmless		3.66	3.90	1.06	1.10
Quality Expectations					
Compared to traditional products, I expect the quality of these products to be: much lower, lower, equivalent, higher, much higher	(Boulding and Kirmani, 1993)	2.96	3.05	0.67	0.63
I expect the quality of these products to be: very low, low, acceptable, high, very high		3.51	3.62	0.70	0.67
Functionality Expectations					
I expect these products will perform well	(Magnier et al., 2019; Homburg et al., 2015)	4.27	4.47	0.73	0.73
I expect these products are capable of doing their job		4.32	4.45	0.70	0.65
I expect these products are functional		4.36	4.56	0.65	0.63
Willingness to pay a premium price					
Compared to traditional products I am likely to pay more for these products	(Magnier et al.,	3.23	3.06	1.14	1.08

Compared to traditional products I am willing to pay a supplement for these products	2019)	3.23	3.05	1.12	1.10
<b>Purchase intention</b>					
I intend to buy these products in the future.	(Bamberg, 2003, Gleim et al., 2013)	3.74	3.90	0.86	0.80
I will try to buy these products in the future		3.85	3.99	0.82	0.77
I plan to buy these products in the future		3.67	3.84	0.87	0.83

### **Abstract**

Food waste is a global problem, affecting all areas of sustainability, that has already triggered various calls for actions via research, public, societal and private initiatives. The goal of this research was to analyse the impact of on-package food waste treatment claims on the consumer attitude and behavioural intentions toward the presented food company. A positive correlation between the communication of food waste measures and consumer attitude and behavioural intentions can motivate further activities against food waste.

A digital survey was structured and conducted with an online survey tool in order to measure the major constructs, regarding the attitude towards the company, the purchase

intention, and the willingness to pay premiums. All participants were first randomly presented a fictitious food product with a description about a food waste treatment claim and afterwards they completed the questionnaire. The answers of 256 participants have been analysed.

Food waste treatment claims were found to have a significant influence on the attitude towards the fictitious company in three out of four cases. The influence on the purchase intention was only measured to be significant in one case. On the contrary, we found a significant influence on the willingness to pay premiums for the products in all experimental conditions.

The results of this research demonstrated that descriptions, including the topic of food waste, can have a positive impact on consumers attitude and behavioural intentions. This offers empirical evidence that consumers see an additional benefit in buying products from companies that proactively engage in actions against food waste. Additionally, the coherence of sustainability strategies of companies was pointed out as a key element in creating competitive advantages.

**Paper type** – Academic Research Paper

## 1 Introduction

Food waste is a global problem that affects all of sustainability, generating negative environmental externalities (Campoy-Muñoz et al., 2017), with an annual global loss of three trillion dollars including social and environmental costs (Gustavsson et al., 2011). The issue of food waste has already triggered various calls for actions via research, public, societal and private initiatives (Aschemann-Witzel et al., 2017).

This study focuses on the processing and packaging stage of the food supply chain. Managers of food manufacturing companies apply different strategies to cope with food waste. The most common strategy is delivering potentially to-be-wasted food to non-profit organizations and food banks (Muriana, 2017). With consumers getting more aware of the impact of food production and consumption, as well as the climate change problem (Gadema & Oglethorpe, 2011), corporate social responsibility (CSR) has a crucial role in improving the reputation and trust among those consumers (Carroll & Shabana, 2010). CSR activities differentiate a company from the competition in the market (Vahdati et al., 2015), have the potential to influence consumer behaviour, and can lead to rewards from stakeholders (Hartmann, 2011).

To communicate CSR activities to consumers, companies mainly rely on the internet and the display in corporate reports (Wanderley et al., 2008). However, only a small segment of conscious consumers retrieves information from various sources to be highly informed about corporate activities. Other consumers rely on information at the point of sale (Walther et al., 2010). To reach their consumers at the moment of purchase (Chandon, 2013), companies can display information on food products depending on the type of packaging and label. It is an effective instrument to communicate with consumers (Stanton & Cook, 2019), can involve messages or claims (Biondi & Camanzi, 2020), and can lead to competitive advantages (Ballco et al., 2019). However, only a limited number of articles focus on the CSR information on packaged foods. One example is the study by Wei et al. (2018), which examines the effect of on-package CSR claims on the consumer perceptions of health benefits, taste, and attitude, as well as behavioural intentions toward the food company. Nevertheless, Willersinn et al. (2017) underline the importance of evaluating the perception of consumers towards food waste measures undertaken by companies.

Hartmann (2011) points out the lack of information for a clear answer on 'when, how and why' consumers are responding to CSR. Additional research is needed to better understand the impact of CSR information at the point of purchase on the food choice of consumers (Loose & Remaud, 2013).

The goal of this research is to analyse the impact of on-package food waste treatment claims on the consumer attitude and behavioural intentions toward the food company. Specifically, the following research question is investigated: To what extent do food waste treatment claims on packaged foods influence consumer behaviour? In this research, food waste treatment claims are statements on how companies deal with the issue of food waste. To answer the research question, the impact of food waste treatment claims on the consumer attitude toward the food company, the consumer purchase intention, and the willingness to pay a premium price for the product have been tested. To this aim, a survey has been conducted on 256 consumers between July and September 2020.

This research contributes to the academic literature in getting insights on consumer reactions towards the communication of several food waste measures, as well as to the academic literature on consumer insights by better understanding consumer perceptions of food waste measures.

Moreover, the practical contributions of this research help improving organizational decision making. Managers are expected to focus their environmental actions on areas where they can gain competitive advantage and base their strategies on solid justifications (Orsato, 2006). Richter and Bokelmann (2016) state that companies do not see the potential competitive advantage of differentiating themselves from the competition by food waste reduction in the production process. The findings of this study can help company managers to improve strategic decision making by analysing consumer perceptions and behaviours associated with corporate food waste activities.

## **2 Theoretical Framework**

### **2.1 Food waste**

Consumers have a large impact with their choices on the type of foods produced and the production methods, via supporting different products and brands (Grunert, 2011). Cecchini et al. (2018, p. 554) describe the post-modern consumer as driven by "more responsible and exigent buyer behaviour, increasingly providing attention to the 'mode of production' of food." In this study, the term "food waste" is used in compliance with the definition used by the High Level Panel of Experts (HLPE) on food security and nutrition (2014, p. 22): "Food loss and waste (FLW) refers to a decrease, at all stages of the food chain from harvest to consumption in mass, of food that was originally intended for human consumption, regardless of the cause."

### **2.2 Attitude towards the company**

The attitude of a consumer is the positive or negative feeling about an action in general and indicates the assessment of emotions and the interest or reluctance towards a specific idea or product (Kordnaeij et al., 2013). Therefore, attitude can be described as the cognitive and emotional overall assessment of a concept (Bem, 1970; Monirul & Han, 2012).

The spending patterns of many consumers show that they want brands to 'go green', believing in a better and healthier life for this and future generations (Yazdanifard & Mercy, 2011). If consumers can identify their own beliefs in the

actions of a company, this is expected to influence positive attitudes towards this company and resulting positive behaviours (Lech, 2013).

Regarding CSR, researchers already pointed out a positive relationship between the CSR initiatives and the attitude of consumers towards respective companies (Sen et al., 2006; Trudel & Cotte, 2009; Vahdati et al., 2015).

Based on these discussions, the following hypothesis was derived:

*H1. There is a positive relationship between food waste treatment claims on packaged foods and consumer attitudes towards the company.*

### **2.3 Purchase intention**

Prior studies had inconsistent findings regarding the relationship between CSR and financial outcomes for the companies. While some researchers found a weak or no relationship between CSR and financial outcome (Sen et al. 2006), others found the potential of proactive CSR - ethical and discretionary activities that exceed legal demands - to positively influence financial performance (Brown & Dacin, 1997; Kim, 2017). The study of Kim (2017) showed the positive intent of respondents to support and purchase from companies engaging in proactive CSR initiatives and Wei et al. (2018) stated a positive effect of on-product CSR claims on consumer purchase intentions.

Despite the inconsistent findings, CSR initiatives are expected to have the potential to change consumer buying behaviour, rewarding and/or punishing companies based on their responsible or irresponsible activities (Trudel & Cotte, 2009). Moreover, according to consumer inference-making theory, if a company is perceived as responsible by a customer, the positive inference of products or services are likely to lead to a purchase intention (Lech, 2013).

Vahdati et al. (2015) confirmed an indirect impact of CSR on consumer buying behaviour through the attitude towards the company in their study, while a direct impact of CSR on buying behaviour has been rejected. Empirical findings support the effect of attitude as a precursor to the formation of a corporate image, favourable behavioural intentions, and the establishment of relationships with stakeholders (Kim, 2017).

Based on these discussions, the following hypothesis was derived:

*H2. There is a positive relationship between food waste treatment claims on packaged foods and the consumers' purchase intention.*

## 2.4 Willingness to pay premiums

Today in western Europe, environmental-conscious consumers can actively transfer their beliefs through purchases of environmentally friendly products into corresponding actions reducing their environmental footprint (Moser, 2016). Even though White et al. (2012) showed that consumer purchasing behaviour does not have to correspond with positive attitudes towards certain food products, a positive willingness to pay for products with environmental, social, and ethical certifications has been approved in several studies (Cecchini et al., 2018; Loose & Remaud, 2013).

The results of Cecchini et al. (2018) point out that consumers are willing to pay a premium price (between 13 and 50%) for products with an environmental certification compared to similar products without such certification. Several studies pointed out an increased willingness to pay of consumers regarding CSR claims, sustainability labels or waste prevention labelling on food products (Del Giudice et al., 2016; Sammer and Wüstenhagen, 2006; Wei et al., 2018).

Based on these discussions, the following hypothesis was derived:

*H3. There is a positive relationship between food waste treatment claims on packaged foods and the willingness to pay a premium price for the product.*

Figure 1 shows the conceptual framework considered in the paper.

Figure 8 Conceptual framework

## 3 Methodology

This research was conducted via a structured survey distributed via online channels and online survey communities. The participants were randomly assigned to a questionnaire including a fictitious food product with a description about a food waste treatment claim out of one of the four management options

'prevention', 'preparing for re-use', 'recycling', and 'other recovery'. The description for the control group did not include a food waste treatment claim. The questionnaire is presented in Section 3.2. To formulate the food waste treatment claims, a pilot study was conducted, presented in Section 3.1.

### **3.1 Pilot study**

The waste hierarchy was applied for the pilot study in order to select a diverse set of strategies for treating food waste.<sup>1</sup> The participants were asked to rank different strategies out of the management options, according to how they would want a food manufacturing company to prioritize their actions against food waste. Additionally, participants were asked to list their five most frequently bought packaged groceries. This grocery was then used in the final questionnaire to present a fictitious food package with a fictitious company name and a randomly assigned food waste treatment claim. For the control group, a typical consumer service information was included instead of the food waste treatment claim.

The data of 52 participants of the pilot study was further analysed. The strategy out of the management option 'prevention' that was ranked highest was: "Preventing food waste through the application of eco-design (the systematic integration of environmental aspects into product design with the aim to improve the environmental performance of the product throughout its whole life cycle)." Out of the management option 'preparing for re-use', participants wanted food manufacturing companies to focus on: "Redistribution to people, re-using surplus food for human consumption for people affected by food poverty, through redistribution networks and food banks, or donations made to non-profit organizations." The strategy of the management option 'recycling' that was ranked highest was: "Recycling food waste by reprocessing food for human consumption (for example, making food products out of food waste)." These three strategies were further included in the final questionnaire.

---

<sup>1</sup> Strategies to tackle the issue of food waste are numerous. The food waste hierarchy was used in this research to select a diverse set of strategies for treating food waste as a food manufacturing company. One strategy out of each management option was selected for the final questionnaire to consider strategies that have a low similarity. Strategies referring to the management option 'disposal' were not considered as disposal represents the least desirable management option, since the biodegradable organic material of the food waste does not return to its original state (Fehr et al., 2002) and is therefore solely wasted.

The strategies found for 'other recovery' in academic literature were mostly focused on recovering energy from food waste (for example, through generating biofuel and bioenergy from food waste). Therefore, the food waste treatment claim about 'other recovery' was formulated accordingly.

Regarding the most frequently bought packaged groceries, the most stated grocery was "pasta" with 20 mentions followed by "cheese" (17 mentions). The food product "pasta" was included in the final questionnaire.

### **3.2 Questionnaire**

The aim of the questionnaire is to test the hypothesis regarding the three factors of 'attitude towards the company', 'purchase intention', and 'willingness to pay premiums'.

To present the food waste treatment claims, a fictitious food package was designed under the name "Pastolli", which is shown in Figure 2. The picture presented was the same in all versions of the questionnaire, only the description shown below all pictures were changed.

*Figure 9 Fictitious food product "Pastolli"*

To ensure comparability between the descriptions of the strategies for treating food waste in the questionnaire, they were all formulated following the same

structure. All strategies are based on the findings of the pilot study and formulated as CSR claims, as presented in Table 1. For the control group, a general description of the ingredients and the description of how to prepare the pasta was presented, formulated based on existing food product descriptions.

Table 6 Food waste treatment claims

Management option	Description used in the questionnaire
<i>Prevention</i>	<p><u>Pastolli</u></p> <p>Food waste is a global problem that affects all of us, generating high costs, negative environmental effects, as well as major social problems.</p> <p>At Pastolli, we minimize our food waste through the application of eco-design. This way, we design our products ecologically and directly integrate environmental aspects. Our aim is to improve the environmental performance of our products throughout its whole life cycle. We make our products more efficient, use fewer resources and generate less waste and emissions.</p> <p>Thank you for supporting our actions by choosing our products.</p>
<i>Preparing for re-use</i>	<p><u>Pastolli</u></p> <p>Food waste is a global problem that affects all of us, generating high costs, negative environmental effects, as well as major social problems.</p> <p>At Pastolli, surplus food does not go to waste. We redistribute our surplus food to people affected by food poverty, through redistribution networks and food banks, or donations made directly to non-profit organizations.</p> <p>Thank you for supporting our actions by choosing our products.</p>
<i>Recycling</i>	<p><u>Pastolli</u></p> <p>Food waste is a global problem that affects all of us, generating high costs, negative environmental effects, as well as major social problems.</p> <p>At Pastolli, surplus food does not go to waste. We reprocess our surplus food for human consumption. With our circular approach, we transform wastes or surplus ingredients, obtained during the manufacturing of other foods, into new food products under our high-quality standards. This way, we decrease the amount of food waste generated and improve our environmental performance.</p> <p>Thank you for supporting our actions by choosing our products.</p>

Management option	Description used in the questionnaire
<i>Other recovery</i>	<p><u>Pastolli</u></p> <p>Food waste is a global problem that affects all of us, generating high costs, negative environmental effects, as well as major social problems.</p> <p>At Pastolli, surplus food does not go to waste. We turn it into energy! The food waste gets treated in order to produce biofuel and bioenergy from it. Residues from biofuels production can be further used as soil fertilizers.</p> <p>Thank you for supporting our actions by choosing our products.</p>
<i>Control Group</i>	<p><u>Pastolli</u></p> <p>Pastolli spaghetti are made from durum wheat semolina from controlled production.</p> <p>To prepare the spaghetti, boil 80g per portion in 1 litre of boiling, slightly salted water (1 teaspoon = 5g of salt per 1 litre of water). After about 7 minutes, pour the spaghetti into a sieve and let it drain. Now just put it on a plate and serve with the sauce of your choice. Bon appetite!</p>

In the main part of the questionnaire, the participants were asked several questions to test the hypotheses. To assess the attitude toward the food company, three items from Kozup et al. (2003) were measured using a five-point Likert scale. The purchase intention was also assessed using three items from Kozup et al. (2003). The willingness to pay premiums was assessed using three items from Perrini et al. (2010) into the questionnaire. All items were previously included in a questionnaire by Wei et al. (2018) in a related field. Participants were asked to indicate the ease of understanding of the food waste treatment claim, using one item previously applied by Wei et al. (2018). All items were modified in wording or characteristics of the Likert-scale, to fit this research.

### 3.3 Analysis

To analyse the effects of the different food waste treatment claims on the "attitude towards the company", "purchase intention" and "willingness to pay premiums" of the participants, the method of Univariate Analysis of Covariance (ANCOVA) was conducted. To show direct comparisons between the groups, the Bonferroni post-hoc test was applied.

The factor analysis was used to uncover the underlying structure of the analysed concepts and the covariates. The internal reliability was then evaluated by calculating the Cronbach's alpha coefficient for each factor.

In the analysis, next to the demographic information (such as gender, age, ethnicity, income, and education), - following Wei et al. (2018) and based on prior studies by Raju et al. (2015), Chandon and Wansink (2007), Irmak et al. (2011) and Creyer (1997) - subjective nutrition knowledge, the nutrition involvement, diet restraint behaviour, the perception of the importance of a firm's CSR activities and the liking of food were used as covariates to incorporate their potential influence on the variables of interest and test the impact of food waste treatment claims.

## 4 Results

Participants were asked to indicate the ease of understanding of the respective description that was shown for each of the groups on a scale from 1 ("Very difficult") to 5 ("Very easy"). The highest mean indicating the understandability was calculated for the description of 'preparing for re-use' (mean=4,04), followed by 'other recovery' (mean=3,60), 'recycling' (mean=3,48), and 'prevention' (mean=3,35). The control group, which only included a basic product description and no food waste treatment claim, was the easiest for participants to understand (mean=4,09).

### 4.1 Demographics

The gender distribution was almost equal, with a total of 134 female and 122 male participants. The most important demographics measured can be seen in Table 2.

Table 7 Demographics

Measured value	Frequency	Percent
Age: Younger than 18	7	2,7
Age: Between 18 and 24	69	27,0
Age: Between 25 and 34	128	50,0
Age: Between 35 and 44	14	5,5

Age: Between 45 and 64	34	13,3
Age: 65 or older	4	1,6
Country of residency: Germany	217	84,8
Region of residency: DACH	235	91,8
Net income: < 1,000€	95	37,1
Net income: €1,000 - €1,500	51	19,9

## 4.2 Covariates

The covariates used in the questionnaire were all previously applied by other researchers and modified to fit this research. For assessing whether the modifications changed the functionality of the scales, the items were tested by means of exploratory factor analysis.

The Kaiser-Meyer-Olkin Measure of Sampling Adequacy ( $KMO=.824$ ) and the Bartlett test ( $\text{Chi-square}(190)=2316,384$ ,  $p<.001$ ) indicated that the variables are suitable for factor analysis. The principal component analysis with Varimax rotation was performed and the loadings of the different factors were in accordance with the previous studies. Cronbach's Alpha was further calculated for all covariates and was above 0,8 for all factors.

All covariates were further included in the Univariate Analysis of Covariance (ANCOVA) and the two-way ANOVA to test the four hypotheses.

### **4.3 Hypotheses testing**

The items used in the questionnaire to measure the attitude towards the company, consumer purchase intentions, and the willingness to pay premiums, were all taken from studies by Kozup et al. (2003), Perrini et al. (2010) and Wei et al. (2018) and modified to fit this research.

An exploratory factor analysis and the Kaiser-Meyer-Olkin Measure of Sampling Adequacy ( $KMO=.887$ ) and the Bartlett test (Chi-square (36) = 1580,739,  $p < .001$ ) indicated that the variables were suitable for factor analysis and the principal component analysis with Varimax rotation confirmed the factors in accordance with previous studies. The means of the four different groups with food waste treatment claims were always higher than the corresponding mean of the control group.

#### **4.3.1 Testing hypothesis 1: Attitude towards the company**

The first hypothesis was "There is a positive relationship between food waste treatment claims on packaged foods and consumer attitudes towards the company." The Cronbach's alpha coefficient indicated an internal reliability of 0,865.

The result of the ANCOVA showed a statistically significant difference between the groups in the test of between-subject effects after controlling for the included covariates.

Pairwise comparisons between the groups regarding 'attitude towards the company' pointed out a significant difference at the 0,05 level in the means of the control group and the group 'preparing for re-use', between the control group and the group 'recycling' and between the control group and the group 'other recovery'.

The positive relationship between food waste treatment claims on packaged foods and consumer attitudes towards the company was confirmed for the claims of three out of the four groups, except for the claim presented for the group 'preparing for re-use'. H1 was partially confirmed.

#### **4.3.2 Testing hypothesis 2: Purchase intention**

The second hypothesis was formulated as follows: "There is a positive relationship between food waste treatment claims on packaged foods and the

consumers' purchase intention." The internal reliability of the factor was tested using Cronbach's alpha coefficient, with a result of 0,862.

The ANCOVA showed a statistically significant difference between the groups in the test of between-subject effects after controlling for the included covariates.

The results for the comparisons between the groups with regard to 'purchase intention' pointed out a significant difference at the 0,05 level in the means of the control group and the group 'preparing for re-use'.

With only one out four food waste treatment claims resulting in a significant difference between the control group, H2 was rejected.

#### *4.3.3 Testing hypothesis 3: Willingness to pay premiums*

The third hypothesis was: "There is a positive relationship between food waste treatment claims on packaged foods and the willingness to pay a premium price for the product." The internal reliability of the factor was tested using Cronbach's alpha coefficient (Cronbach's alpha=0,896).

The factor 'willingness to pay premiums' met the homogeneity of variances assumption and was tested for normality with two tests and confirmed a normal distribution of the data.

While all calculated means decreased, comparing the means per group for the variables of 'purchase intention' and 'willingness to pay premiums', the means of the control group decreased most drastically for the dependent variable 'willingness to pay premiums'.

The result of the ANCOVA showed a statistically significant difference between the groups in the test of between-subject effects after controlling for the included covariates.

The pairwise comparisons between the groups regarding the variable of 'willingness to pay premiums', pointed out a significant difference at the 0,05 level in the means of the control group and the groups 'prevention', 'preparing for re-use', 'recycling' and 'other recovery'. Therefore, H3 was confirmed.

## **5 Discussion**

The global problem of food waste needs to be addressed simultaneously at all stages of the food supply chain. Increasing the understanding of the influences on consumer attitudes and behavioural intentions through the communication of

food waste measures was the goal of this study, wherefore three hypotheses were analysed.

### **5.1 Attitude towards the company**

The first hypothesis was formulated to analyse the impact of on-packaging food waste treatment claims on the attitude towards the company of the consumers.

Pairwise comparisons pointed out a significant difference between the control group and all groups except the group 'prevention'. This might have been impacted by the lower ease of understanding for the description of the group 'prevention'. With the lowest mean out of the four groups with food waste treatment claims, participants might have had struggles understanding the impact of the described solution and its impact on food waste.

The highest difference in means was measured between the control group and the group 'preparing for re-use'. It was again in line with the results of the ease of understanding. This was a very interesting finding, as a direct influence of the understandability of the claims on the level of influences was not mentioned in any of the cited literature but turned out to match the findings of this research.

With a significant influence of on-packaging food waste treatment claims on the attitude towards the company, the hypothesis was partially confirmed, and held true for statements regarding 'preparing for re-use', 'recycling' and 'other recovery'. The findings of this research are in line with prior studies by Sen et al. (2006), Trudel and Cotte (2009) and Vahdati et al. (2015), who pointed out the positive impact of various dimensions of CSR on the attitude of consumers. In their study, Vahdati et al. (2015) included social, environmental and moral aspects into CSR and approved the impact on the consumer attitude. The results of this research demonstrate that a distinction between different food waste treatment claims is crucial; accordingly, communication must be targeted to consumer groups and the topic of food waste cannot be generalized.

### **5.2 Purchase intention**

Prior studies have analysed and approved the influence of the attitude of consumers on their desires, intentions, and behaviour (Trudel & Cotte, 2009). Therefore, with a partially confirmed hypothesis about the influence of food waste

treatment claims on consumer attitudes, this was further expected to influence the behaviour of the consumers.

In the pairwise comparisons, the significant difference between the control group and the group 'preparing for re-use' was demonstrated as the only significant difference.

The level of purchase intention for the control group indicated a general buying intention of the participants, which can be a result of appealing packaging design or a tendency to give generally more positive answers. As a result, the differences between most groups with food waste treatment claims were not significant. The hypothesis of food waste treatment claims, in general, having a positive influence on the purchase behaviour of participants was rejected, but was approved for the group 'preparing for re-use'. In the study by Vahdati et al. (2015), a distinction between the direct and indirect impact of CSR on buying behaviour led to the approval only of the indirect impact through the attitude towards the company, which was also indicated in the results of this work. Other empirical studies by Jaafar et al. (2012), Kim (2017), and Trudel and Cotte (2011) underline the effect of the attitude towards a company as a precursor of behavioural intentions, such as purchase intention.

Jaafar et al. (2012) stated that to change the behaviour of consumers, the attitude should be changed first. Therefore, the analysed positive impact of food waste treatment claims on the attitude towards the company can have an impact on consumer buying behaviour in the future.

### **5.3 Willingness to pay premiums**

A comparison of the measured means for 'willingness to pay premiums' distinguished by groups showed a large difference to the means for purchase intention. According to the results of this research, participants in the control group were not willing to pay premiums for the presented food product, participants in the group 'prevention' were neither more nor less willing to pay premiums and the three other groups with food waste treatment claims were on average willing to pay premiums.

A significant difference between all groups with descriptions about food waste measures and the control group was presented in the results. These results indicated that participants in the control group did not see a benefit in paying more for this product compared to similar products. The presence of food waste

treatment claims in the description from all four groups significantly increased the willingness to pay of participants and showed the opinion of consumers that companies tackling the issue of food waste are worthy of financial support. This finding is in line with the work by Wei et al. (2018), where they approved the significant impact of on-package CSR claims on the willingness to pay premiums of consumers. This gave an indication that food waste treatment claims also might have a stronger impact on the general purchase intention of consumers as measured in this research, as the significant impact on the willingness to pay premiums for a product incorporates a preceding purchase intention.

## **6 Conclusion**

The aim of this study was to deepen the understanding of communicating measures taken by food manufacturing companies against the issue of food waste, on food packaging and how this influences the consumers at the point of sale.

Following the questionnaire, one issue arose from the feedback of participants. The packaging used for the fictitious food product in the questionnaire was, based on the looks on the picture, made from plastic, with no further information provided. Even though the issue of food waste was important for these participants, the plastic packaging of the presented food product was not appealing which negatively affected the answers given regarding the studied factors. Kotler and Keller (2006) indicated the importance of consistency to create and support a brand value that customers associate with a company. It has to be based on thoughts, feelings, images and beliefs that are in line with each other in order to achieve competitive advantages (Kotler & Keller, 2006). The results of this research might have been even more significant if the image of the fictitious food product would have complied with state-of-the-art eco-friendly food packaging.

One important aspect of this research that has to be taken into consideration is the applicability and the degree of sustainability of the different presented strategies. The participants of this survey were at no point informed about the degree of environmental sustainability of the presented measure against food waste. Moreover, not all solutions are always applicable for all companies.

The findings of this research can also lead to another sustainable impact. Consumers are responsible for the highest amount of food losses in the food

supply chain (Scherhauser et al., 2012). Food recovery at this stage could result in a worthless activity, as the food is highly spread across households with little quantity, which makes a recovery economically unfeasible (Muriana, 2017). Increasing the communication of the importance of the topic of food waste might have an educational impact on consumers. Most of the food waste at the domestic level is avoidable (Beretta et al., 2013) and creating awareness of food waste is a prerequisite for tackling this issue (Aschemann-Witzel et al., 2015).

The results of this study demonstrated the potential of the communication of actions against food waste to consumers, to positively influence consumer attitudes towards the company and behavioural intentions. Companies can create competitive advantages from tackling the issue of food waste and communicating their efforts to consumers. Rundh (2009) argues that companies should include customers in developing successful packaging designs, in order to result in an increased purchase intention and reinforcement of the brand name, for which this study can serve as a basis.

The finding of the measure of food donations as the food waste measure with the most significant impacts on the variables is in line with current food waste treatment measures of food manufacturing companies (Muriana, 2017).

To the best of our knowledge, there is a lack of research on consumer perceptions of food waste activities of food manufacturing companies. Most of the academic research focuses on the relationship between consumer perceptions and activities of retailers (Aschemann-Witzel et al., 2015; Hermsdorf et al., 2017; Topolansky Barbe et al., 2017).

Only a limited number of strategies for food waste treatment were taken into consideration for this research. Significant differences between the strategies were identified in this research, which underlines the importance of distinction between the various strategies and points out the need for future research regarding other strategies.

The selection of the food product pasta was based on a limited number of participants and only represented one type of food. Future research is needed to understand the role of the food product on the findings.

For future studies, also personal interviews, especially at the point of sale, would be of high relevance to understand the underlying reasoning. This could result in a better understanding of consumer behaviour regarding the information on food packaging, as this research was based on the assumption that consumers would read the whole description on a food package.

### **Abstract**

The concept of circular economy has recently gained prominence in the management research and the adoption of circular economy principles in companies has highlighted peculiar managerial practices that can be implemented in their business models. Existing research still falls short to describe in sufficient detail the enablers of these practices for a circular business model design. This issue is particularly interesting in the agri-food sector, and especially in rural areas, characterized by enormous sustainability challenges, including food production and waste, food packaging, transportation, consumer habits and behavior. The paper takes stock of this gap through the analysis of the enablers of managerial practices in a company that has designed its own circular business model and operating in the agri-food sector of a rural area. The case reveals interesting evidence in terms of relationships between enablers, managerial practices, and circular economy outcomes.

## 1 Introduction

The field of circular business models has recently emerged as a new one within the broader circular economy literature (Centobelli et al., 2020; Linder & Williander, 2017; Baldassare et al., 2017), with the aim to deepen the managerial practices that companies can implement in their business model to transform their linear business into a circular one (Bocken et al., 2019). Managerial practices represent the way top management, usually in charge of defining and modifying over time the strategy of the company, makes the transition to a new, circular, business model (Ünal et al., 2019). In the case of circular economy adoption in business models, for example, managerial practices can be related to the way companies use energy, materials, and resources, as well as how they reduce the environmental impacts of their activities. At the same time, companies can be required to maintain the properties of products, as well as of their components, while customers acting “mostly” as users, thus managerial practices can be related to the re-use or re-manufacturing of resources, as well as to maintenance activities (Tukker, 2015; Tukker & Tischner, 2006).

Although several studies have proliferated in the last years to deepen the transition of companies’ business model from linear to circular (Pieroni et al., 2019; Lüdeke-Freund et al., 2019; Garza-Reyes et al., 2019), much more theoretical and empirical effort is however needed to analyze what are the enablers of managerial practices for a circular business model design (Hussain & Malik, 2020; Ranta et al., 2018), intended as those factors that enable and encourage the implementation of circular economy-driven managerial practices in companies’ business model (Panwar & Niesten, 2020; De Jesus & Mendonça, 2018; European Commission, 2015). In this paper, we take stock of the research on the enablers and go into the detail of the factors that allow companies to implement managerial practices for circular economy adoption in their business model (Urbinati et al., 2021; Hussain & Malik, 2020).

The design of circular business models is particularly interesting to analyze from the point of view of the agri-food sector that is characterized by enormous sustainability and circular economy challenges, including food production and waste, food packaging, transportation, consumer habits, and behaviour (Testa et al., 2020). The relevance of the circular economy transition into the agri-food sector is due to the complexity characterizing this sector in terms of larger and differentiated nature of productions, the challenges of the deterioration and

shelf-life, the impact of weather and geographical condition, the need to guarantying safety and quality to the consumers, the commoditization of the productions (Lehmann et al., 2012). The focus on the agri-food industry is also relevant for what concerns the harmonization of development patterns between urban and rural areas, and it assumes a challenging meaning for this last one, where the primary sector plays a more critical role in terms of employment, infrastructures, market sophistication, and research orientation (Eurostat, 2021; Nicolosi et al., 2021).

Accordingly, a research avenue lies in the research stream of circular business models in the agri-food industry of a rural area, to better understand the enablers that allow agri-food companies in a such context to adopt circular economy principles in their business model (Barth et al., 2017). However, the debate on the enablers of managerial practices for a circular business model design in this sector of activity is still in its infancy and much more effort is required from a theoretical and a managerial perspective. To address this research gap, we leverage a single case study analysis of Fiusis, an innovative Italian company operating in the field of the energy production for agri-food systems and located in a small Apulian town in the South of Italy and awarded in 2019 as “the best business model in the rural area” by the European Commission.

The paper is organized as follows. After the Introduction, Section 2 presents the conceptual development of our study, i.e., a review of the existing research at the intersection between circular business models and the agri-food sector. Then, whereas Section 3 highlights the rationale of the methodology we used for the research, Section 4 points out the main results deriving from the empirical analysis. Finally, Section 5 summarizes the concluding remarks, including the main implications and limitations of the paper, as well as some avenues for future research.

## **2 Literature Background**

### ***2.1 Circular Economy Business Models: enablers of managerial practice***

Circular economy is an innovative industrial approach that has gained importance in the last decades, as the traditional “take, make, dispose”, linear, economic model, has become unable to manage the demand and supply balance in consumption of natural resources (Goyal et al., 2018). According to Mathews et

al. (2011), circular economy can be defined as a closed-loop system, characterized by (i) the reduction of the consumption of non-renewable sources and non-environmentally friendly raw materials; (ii) the reuse of the products and services, which have been specially designed for being reused; and (iii) the recycling of the waste products into new resources for further use and consumption in the same or other supply chains.

From a micro-level perspective, circular economy requires companies to reflect on changing their traditional business model into a new, circular, one, by significantly rethinking the anatomy of their business model, as well as their supply chain and supply chain's collaborations, and strategic positioning (Lüdeke-Freund et al., 2019; Choi, et al., 2018; Schoenherr & Talluri, 2012). In addition, as far as the value transfer is concerned, companies may leverage peculiar practices to share and promote their circular value proposition, such as a direct involvement of clients and customers in their activities or an extensive communication through different channels, such as in-store advertising, website, and sales personnel (Shao & Ünal, 2019; Linder & Williander, 2017). Again, relevant practices that could be adopted by companies for value capture, i.e., for gathering the value generated and converting it into revenues streams, cost savings and value preservation, are represented both by the pay-as-a-service mechanisms (Tukker, 2015; Williams, 2007), and the take-back systems or product-service systems (PSSs) (Kjaer et al., 2019).

While analyzing the managerial practices for a circular business model design, existing research has also paid the attention to the factors that can enable and encourage the implementation of these practices for the circular economy adoption in companies' business model (De Jesus & Mendonça, 2018; European Commission, 2015). Several enablers have been identified in the existing research that seem particularly promising, such as supply chain interactions (Albino et al., 2016), business model innovation (Antikainen & Valkokari, 2016), (green) technological innovations (Dangelico, 2016), values & culture, governmental policies (van Keulen & Kirchherr, 2021), and servitization & platformization (Konietzko et al., 2020; Ciulli et al., 2020), i.e., how firms can organize social and economic interactions through online platforms to achieve greater circularity, for example through dedicated sharing platforms (Fraccascia, 2020). Such enablers can support the design of circular business models in terms of, for example, supply chain contracts for reverse logistics and closed-loop supply chains (Govindan et al., 2015; Savaskan et al., 2004), industrial symbiosis (Chertow, 2000),

design for disassembly and recyclability (Boothroyd, 1994; Kuo et al., 2001), green product design and environmental innovation (Baumann et al., 2002), and innovation ecosystems (Del Vecchio, et al. 2020).

## ***2.2. Circular Economy in agri-food industry: challenges and opportunities***

Although the interesting research in the field of circular business models (Urbinati et al., 2017; Hussain & Malik, 2020; Ranta & Saari, 2019; Ranta et al., 2018), however, only limited progress has been accomplished so far regarding the enablers of managerial practices in circular business models in the agri-food sector, and especially in contexts of rural areas. Again, even though a high number of guidelines for governments and policymakers as enablers of circular economy are currently available (e.g., Ellen MacArthur Foundation, 2015), existing research still falls short to provide a systemic direction of how the enablers of managerial practices for a circular business model design can support companies into this aim and especially in rural areas (Lahane et al., 2020). Therefore, the aim of this paper is to increase knowledge and understanding about the enablers of circular economy-driven managerial practices experienced by agri-food companies in rural areas when adopting circular economy principles at the core of their business model.

In the agri-food sector, circular business models can play an important role both for decision makers and companies in supporting, the former, to develop new sustainable strategies and, the latter, to conduct their business responsibly (Muscio & Sisto, 2020). The relevance of the agri-food industry into the debate on sustainable growth and circular economy has been recently highlighted by several studies in terms of contribution to the preservation and enhancement of natural capital (Ciccullo et al., 2021; Pagotto & Halog, 2016). The transition of the agri-food sector towards the paradigm of circular economy has been enhanced by the larger adoption of advanced technologies, customer centric strategic approaches, as well as by the need to make sustainable the supply chains (Kumar et al., 2021) and it is recognized as a concrete opportunity for addressing the patterns of sustainable development in the rural areas as well as for the harmonisation and the reduction of the development gaps between urban and rural areas (Eurostat, 2021; Nicolosi et al., 2021). Furthermore, as argued by Jurgilevich et al. (2016), the food sector is characterized by growing population and increased demand for food, inefficient use of food resources and food distribution, and high levels of

wasted food. Especially in the agri-food sector, the main issues to be solved are related to reducing food waste and emissions in food production, including greenhouse gas emissions, recycling of food packaging materials and plastic, and cascading use of food products, including the use of fertilizing products, using them as inputs of new products (Cingiz & Wesseler, 2019; Borrello et al., 2017). In a recent study on circular economy in agricultural waste, Donner et al. (2021) have identified a critical set of success and risk factors that may support the design of circular business models for companies in the agri-food industry. These factors consist in technology and logistics, economic, financial, marketing, and organizational setting, institutional and legal frameworks, environmental, social, and cultural features. All these factors assume a more critical configuration in the context of rural areas, where the primary sector plays a more critical role in terms of employment, infrastructures, market sophistication, and research orientation (Eurostat, 2021; Nicolosi et al., 2021). In this context, the effectiveness of a circular economy adoption is largely depending by several features, including the cross-sectorial dependencies and intersections, the institutions and the larger community of stakeholders populating the area.

### **3. Methodology**

The paper adopts the methodology of a single case study as suitable investigative methodological approach for the analysis of a contemporary phenomenon in its natural setting (Yin, 1994, 2003), by leveraging on collection of data from various types of multiple sources (Eisenhardt, 1989). Consistently with the qualitative research approach described by Strauss and Corbin (1990) and Yin (1994, 2003), case study methodology has been preferred since the boundaries between the phenomenon and the context are not clear (Glaser and Strauss, 1967; Miles and Huberman, 1984).

The empirical context of the research has been identified on Fiusis, an innovative small Italian company operating in the field of the energy production in the agri-food sector and located in Calimera, a small Apulian town, in the South of Italy. The company counts 6 permanent employees operating in the energy plant, 10 permanents and 5 seasonal employees in pruning harvesting and transporting. The company has realized a small-scale power plant (1 MWe) for producing electricity exclusively from olive tree pruning. The plant consumes from 24 to 28 tons of pruning daily. Fiusis indeed is a critical and extreme case

(Eisenhardt, 1989; Yin, 1994) of an innovative company who challenged the opportunity to design a circular business model in attempting to close the loop in the agri-food sector in a rural area.

By benefiting from programs of public funds for the installation of new industrial plants and thanks to the national laws on the introduction of the produced energy in the national distribution system, Fiusis works in a supply chain populated by a largely distributed basis of suppliers (mainly for the woods, but also producers of tools, plants, and oil) and by two main customers, who are Fiusis itself, with the two plants for the production of energy and bio-pellet, and the national energy system.

Data collection and analysis were carried out using multiple data sources and ensuring triangulation of information (Eisenhardt, 1989). The combination of different investigative techniques has been embraced to reduce the bias of a single observation and to enhance data credibility (Patton, 1990). Data collection has been performed by integrating primary and secondary sources. About the first, several interviews and follow-ups have been conducted with the founder and CEO at Fiusis, the purchasing manager, and the responsible of the energy production plant.

All the gathered information has been integrated with data resulting from secondary sources and specifically the company's website and accounts on social networks, interviews and press releases available online, financial reports, and official documents related to the business competition in which the company has been awarded from the European Commission. We stopped interviewing, meeting people, and scrutinizing secondary sources, when the possibility for us to obtain additional new information was attained (thematic saturation), and further coding was no longer feasible (Fusch & Ness, 2015).

Finally, as suggested by Eisenhardt (1989), a further series of iterations between empirical data and literature review analysis has been conducted to identify the enablers of managerial practices for the circular business model design of Fiusis, as well as to better identify the theoretical foundations and implications of the research. The developed findings from the empirical analysis of the case have been discussed with the key informants for their final approval.

#### 4. Findings

Fiusis is an innovative company operating in the field of energy production from olive tree pruning and plantation removal. The company has started in 2010 by Marcello Piccinni, the founder and CEO. Fiusis works on a volume of 8.000 t/y and the coverage of an area of 10 kms. Fiusis is located in a rural area, traditionally vocated to the agriculture and characterized by the limited specialization of tertiary sector and the presence of urban areas of small dimensions. As highlighted during the interviews, the volume of the produced energy can satisfy the nightly need of electricity of the small town of Calimera. The innovativeness of Fiusis business model is clearly linked to the area. As highlighted during the interviews with the CEO, while the production of biomass energy was already diffused in the north of Italy and in other European countries, as they are characterized by high level of development, in the context of the province of Lecce it represents a meaningful innovation. As for the plant exclusively based on the olive tree pruning, the company has initially worked for assuring the procurement of this raw material. Despite its abundance in the area, at the beginning the number of farmers collaborating with Fiusis was very limited (only 12 in 2010).

Instead, the area is characterized by very small and fragmented farms with limited portions of fields. Currently, more than the 60% of the local farms of the area collaborates with Fiusis. In collecting pruning for Fiusis, farmers have the benefit of cleaned fields. This also allows to reduce the costs of cleaning and to reduce of a meaningful percentage the environmental pollution due to the burning. In the most recent years, the area has been interested by the emergence of Xylolla, which has impacted on the overall landscape and has enhanced the quantity of wood and pruning of olive tree available in the area. Despite this, the interviews with the company's founder and CEO have allowed us to comprehend how the most important challenge was to convince local farmers to abandon their well-established habits of burning branches in their fields. At this purpose, several meetings either with single local farmers or consortia have been promoted to illustrate them some scenarios of collaboration and mutual benefits.

Logistics and collection activities are also very critical in the Fiusis supply chain. Accordingly, after a first phase in which Fiusis collaborated with external contractors for the collection and harvesting of pruning, in 2014 Fiusis has created a "newco" (named Ligna). The activities of Ligna were aimed to perform a

new strategy of logistics' management and consisting in services of messaging and geo-localizations that are useful for the coordination of the supply chain, and that have a positive impact on the network of suppliers in terms of better organization of their single supplies, cultural spillovers, and cultural catching up. As highlighted during the interviews, the creation of Ligna has allowed to optimize the operational processes of the company. Accordingly, the company collects through Ligna the requests from the farmers by registering all the data necessary for both the traceability of the pruning and the effectiveness of the logistics.

In addition, as far as the new plant for producing the bio-pellet is concerned, also in this case, Fiusis leverages on the local farmers to work only olive wood. In addition, this plant is nurtured by the energy produced by the energy production plant of Fiusis and without the usage of chemicals that normally are used for producing pellet.

From the analysis of Fiusis' business model, it emerges how collaborations along the supply chain play a pivotal role to facilitate inter-organizational cooperation between the company and each stakeholder. The design of Fiusis' circular business model has indeed implied the design of a collaborations' network with some key actors operating in the same supply chain of Fiusis. This relevant aspect of the company's business model is deepened in the following section.

The analysis of Fiusis from the perspective of the enablers of managerial practices for a circular economy adoption in companies' business models can be summarized as in the following Table 1.

Table 1. enabling factors, the enabled managerial practices, and the circular economy outcomes characterizing the circular business model of the company.

<b>Enablers</b>	<b>Managerial practices</b>	<b>Circular economy outcomes</b>
National and supranational laws for the green energy production	Fiusis has implemented a production plant to produce biomass energy according to the national and supranational laws related to the green energy and CO <sub>2</sub> reduction	Image of a green and sustainable company with a higher commitment with the local community
Public funds for the installation of new industrial plants	Fiusis has accessed public programs supporting the development of new industrial plants	Lower direct investments by the company, fiscal benefits, and advantaged conditions for loans

Waste Management and Energy Efficiency	Fiusis value creation derives from the usage of pruning as raw material, the usage of energy produced for self-feeding, the attempt to use also the ashes resulting from the production for fertilizing fields	Value creation in coherence with the principles of circular economy and according to a strategic model that works for closing the loop and reintroduce equilibrium in the local ecosystem
Supply contracts with local farmers	Fiusis has developed a structured contractual system to have the raw material for producing energy. The recent introduction of the Ligna newco has allowed to structure the network of suppliers	A well-established network of suppliers that guarantees the raw materials by avoiding the problems of storage and management of the inbound flows of pruning.
Supply contracts with the national energy system	Fiusis introduces into the national distribution system all the energy exceeding the power of its plants for producing energy and bio-pellet	Certainty of the outbound flows with fixed economic conditions and access to a relatively protected market
Business and Technological Innovation	Fiusis continues to look for new entrepreneurial opportunities. Several innovations have been introduced during the last years, as initiatives to improve the competitiveness of company's core business, as in the case of Ligna, or to promote a diversification strategy, as realized with the new plant for producing the bio-pellet	Competitiveness and growth, higher employment rate, and larger value creation process

## 5 Conclusions

The present research was aimed to analyze the enablers of managerial practices in circular business models operating in the agri-food sector in the context of a rural area; an interesting research issue that has recently emerged in the existing fields of circular economy and circular business models. The paper has tackled this objective by leveraging a single case study analysis of Fiusis, a small company located in a rural area of the southern Italy operating in the field of the energy production from olive tree pruning and recently involved into the production of bio-pellet.

The anatomy of Fiusis business model reveals interesting evidence for the comprehension of the relationships between enablers, managerial practices, and

circular economy outcomes. First, the mechanisms of value creation, transfer, and capture in Fiusis are affected by the political and institutional environment, identifiable into the favorable policies that have allowed the creation of the company at the beginning of its story, but also standards for environmental safety that have made Fiusis able to reduce the CO<sub>2</sub> emissions in the atmosphere. Second, Fiusis has implemented core activities in the direction of a sustainable networking, affiliation of local farmers, traceability of their production, creation of a new culture of sustainability, and green behaviours into farmers and customers, as well as into the employees' mindset. Third, through the analysis of Fiusis circular business model and supply chain collaborations it is possible to identify several insights in terms of re-design of the traditional process of management of fields, change into the conception of waste usage for a new production process, and implementation of new forms of collaborations with a vast array of supply chain stakeholders. Finally, the case of Fiusis provides interesting evidence for the advancement of the academic debate in the field of circular economy, and especially at the intersection between circular business models, agri-food sector, and development of rural area.

The paper has of course some limitations that deserve a further examination. First, the paper does not analyze the barriers associated to the implementation of Fiusis managerial practices in its business models, but only the enablers that have pushed the company to design a circular business model. Another limitation is mostly related to the kind of the methodology we used for conducting the empirical analysis. Indeed, the single case study methodology does not allow for cross-case comparison or statistical generalizations. Other agri-food businesses who are adopting circular economy for a circular business model design could be investigated to reinforce the "analytical" generalization of the obtained results).

### Abstract

This paper addresses the topic of alternative financing for the cultural heritage sector, investigating equity crowdfunding as a potential means to increase financial resilience. Indeed, the allocation of funds to the cultural heritage sector has progressively decreased over the last fifteen years, making traditional financial models for cultural heritage no longer maintainable especially in times of crisis and economic downturn (Jelinčić and Šveb, 2021). As a result, both academics and practitioners have called for a higher degree of differentiation of sources of funding, that include also the exploration of crowdfunding as a promising funding means (Dalla Chiesa and Handke 2020; Rykkja *et al.*, 2020; Zhao and Shneor, 2020). However, this funding tool is just partially used in the cultural and creative sector, especially in its most innovative models such as equity crowdfunding (Massolution, 2015; Rykkja *et al.*, 2020). This paper aims to fill this research gap: it questions equity crowdfunding as a viable tool to finance cultural heritage interventions and explores the success factors and peculiarities of equity crowdfunding campaigns for cultural heritage. By means of a QCA -Qualitative Comparative Analysis, the research indicates that equity crowdfunding could raise considerable amounts of funds as those needed in heritage interventions. Moreover, it points out that equity crowdfunding campaigns for cultural heritage differ from traditional equity crowdfunding campaigns of other sectors, since it privileges signals related to emotional aspects and social and community values rather than those related to financial aspects.

## 1 Introduction

Over the last fifteen years, the allocation of funds to the cultural heritage sector has been gradually questioned (Jelinčić and Šveb, 2021), making the financing mechanisms for cultural heritage no longer sustainable. This issue has increased during the recent COVID-19 pandemic, adding new problems to traditional financial difficulties (FINPIEMONTE, 2020; Jelinčić and Šveb, 2021). As a result, both academics and practitioners have called for a higher degree of differentiation of sources of funding for the cultural heritage field. In this framework, crowdfunding has emerged as an innovative participatory way of financing, that could contribute to sustainability in the long term (Dalla Chiesa and Handke 2020; Zhao and Shneor, 2020). Although the cultural heritage sector is still reluctant to use it, crowdfunding has been considered a promising new way of financing cultural projects while at the same time promoting innovation (Rykkja *et al.*, 2020). The research on crowdfunding for cultural heritage has underlined several similarities with other sectors (Borin and Crepin, 2019; Rykkja *et al.*, 2020; Zhao and Shneor, 2020) and has pointed out that the community orientation of cultural heritage organizations could work as a strong catalyst for using crowdfunding initiatives (Tosatto, Cox, & Nguyen, 2019). However, most crowdfunding campaigns for cultural heritage (that are for the most using a donation or reward crowdfunding model) are collecting relatively small amount of money (De Voldere and Zeqo, 2017; Massolution, 2016) that are useful but not enough for often costly heritage interventions. Equity crowdfunding could represent an exception; in few cases, it has indeed proved a good means not only to raise considerable amounts of money for cultural heritage, but also lead to innovative and participatory models of cultural heritage governance and management. This research aims at investigating equity crowdfunding potential for cultural heritage, answering to the following research questions:

- What are the success factors for equity crowdfunding campaigns in the cultural heritage sector?
- What are the peculiarities of cultural heritage's equity crowdfunding compared to other sectors?

The paper is structured into five main sections. After this short introduction, a literature review on equity crowdfunding and crowdfunding for cultural heritage is carried out in section two. Section three presents the research design and methodology, while section four illustrates and discuss the results of the empirical

investigation. Section five presents some concluding remarks on the research and underlines the limitations and potential for future investigations.

## 2 Literature review

Over the last two decades, the cultural heritage sector has increasingly experienced a decrease of funding (Borin, Donato and Sinapi, 2017; Martin, 2010), that has pushed the organizations in this field to rethink their funding model and find new innovative funding streams that could ensure financing without compromising preservation and representation of cultural values. In this scenario, although cultural heritage professionals are still hesitant to use it, crowdfunding has emerged as new complementary method of financing (De Voldere e Zeqo, 2017; Massolution, 2015). Crowdfunding, described as a fundraising tool based on the online collection of small amounts of money from a wide number of people, has its roots in several fundraising campaigns for charity, political purposes, and arts (Kuppuswamy and Bayus, 2018; Ordanini *et al.*, 2011; Short *et al.*, 2017). The crowdfunding innovation consists mainly in the use of internet platforms as intermediaries that connect campaign's proposers with potential backers, notwithstanding their geographical distance (Ordanini *et al.*, 2011). Crowdfunding disrupts traditional financing mechanisms as it has the potential to call for the help of online communities leaving banks and traditional financing organisms outside the transaction. There are five main crowdfunding models (Giudici *et al.*, 2012; Harrison, 2013; Battisti *et al.*, 2020): donation-based, reward-based, royalty-based, lending-based, and equity-based crowdfunding. *Donation-based* crowdfunding is really similar to traditional fundraising in which the donors do not expect anything in return; whereas in *rewards-based* crowdfunding, rewards (such as free or discounted products or services) are offered in exchange for the donation. *Lending-based* crowdfunding is defined as crowdlending or peer-to-peer lending and works as a loan from the backers to the project proposers. In *royalty-based* crowdfunding a project is financed by the crowd in return for a share of the profits. Finally, *equity-based* crowdfunding is a form of crowd-investing in which the backers receive a percentage ownership in the company.

The research on crowdfunding has focused on the different aspects of this phenomenon, focusing also on the factors that might influence the success of a crowdfunding initiative (Gerber *et al.*, 2012; Zheng, Li and Xu, 2014). This stream of research has highlighted that donation, reward-based and peer-lending

crowdfunding campaigns mainly base their appeal on emotional and social/community aspects (Belleflamme, Lambert and Schwienbacher, 2014). The majority of these analyses do not consider the peculiarities of the equity crowdfunding. Indeed, research on equity crowdfunding is still considered at an initial stage (Lukkarinen et al., 2016). Nevertheless, so far equity crowdfunding investigations has peculiarities that are more related to an investing framework (Ahlers et al., 2015), where the backers are basically investors that could claim administrative and capital rights. As a result, equity crowdfunding is one of the most complex crowdfunding models, requiring *ad-hoc* legal schemes (investments are generally regulated by national securities exchange commissions; Cholakova and Clarysse, 2015) and agreements (Ahlers et al., 2015). The signals of potential success are mainly factors related to financial aspects, even if equity crowdfunding investors are often less experienced in investment, prone to herding behaviours and showing lack of due diligence (Block, Hornuf and Moritz, 2018). Emotional and social/community signals are considered significant but less important (Block, Hornuf and Moritz, 2018b; Wald, Holmesland and Efrat, 2019; Wuillaume, Jacquemir and Janssen, 2018 and 2019), whereas factors related to the quality and characteristics of financial investments are determining (Mochkabadi, and Volkmann, 2020). Several papers identify success factors and signals related to: *human capital*, interpreted as entrepreneurs and management education and experience (Ahlers et al., 2015; Vismara, 2016; Piva and Rossi-Lamastra, 2017; Nitani and Riding, 2017; Giga, 2017; Angerer et al., 2017); *equity retention*, considered as percentage of equity offered to investors (Ahlers et al., 2015; Vismara, 2016; Nitani and Riding, 2017); *social capital of the entrepreneurs*, defined as the number of social network contacts (Vismara, 2016; Nitani and Riding, 2017; Wald, Holmesland, Efrat, 2019); *validation of the project by third parties*, coming in the form of grants, intellectual property rights, professional investors as partners, product certification, social proof, prominent affiliates (Ralcheva and Roosenboom, 2016; Bapna, 2017); and last but not least, *active communication during the campaign* (Block et al., 2018).

There is however still a gap in the research on equity crowdfunding for specific sectors (Mochkadadi and Volkmann, 2018). Among these sectors, we can also include the cultural heritage sector, that has so far been kind of reluctant in using this crowdfunding model (Borin and Rossato, 2020; Massolution, 2015). This reluctance could be due to diverse factors: first, whereas equity crowdfunding in other sectors may be very profitable for investors, in cultural heritage the

prospective profits are rather unpredictable, and this may hinder the potential attractiveness of equity crowdfunding initiatives for cultural heritage (Borin and Rossato, 2020). Second, there might be concerns related to ownership, value preservation or governance issues.

However, the often-consistent amounts of money raised to equity crowdfunding could represent an interesting opportunity to deal with the inner traditional financial fragility of cultural heritage organizations (Grefe, 2010; Konrad, 2017; Perry and Beale, 2015; Tosatto, Cox, & Nguyen, 2019;). In addition, the typical community orientation of the cultural and creative sector (Konrad, 2015), the prevalence of small and medium size enterprises (Borin, Donato and Sinapi, 2017) or the desire for independence in the artistic production could work as a strong incentive in using this type of financing tool (Tosatto, J., Cox, J., & Nguyen, T. 2019). It seems therefore relevant to further investigate equity crowdfunding for cultural heritage and understanding its peculiarities and success factors, which is the aim of this research.

### **3 Research design and methodology**

In order to investigate the topic mentioned above, a qualitative empirical research was carried out on the signals/ factors of success at the basis of equity crowdfunding campaigns in the cultural heritage sector.

This study decided to focus on equity crowdfunding in France as this country seemed particularly relevant: not only because of its richness in cultural heritage (UNESCO, 2020) but also because it has been among the countries in which equity crowdfunding has been developing the most (Massolution, 2015). Moreover, French government has widely encouraged the development of blended finance models, for example supporting European initiatives such as the EIC - European Innovation Council or pushing for equity driven investments on cultural heritage.

The authors decided to use a QCA – Qualitative Comparative Analysis approach (Ragin, 1987). QCA is a research methodology aiming at investigating new phenomena and focusing on the theory of change. It is composed by six main steps: 1) Develop a theory of change; 2) identify cases of interest; 3) Develop a set of factors; 4) Score the factors; 5) Analyse the dataset; and 6) Interpret the findings and revise the Theory.

Since the geographical domain of the research was France, the case studies were selected in the most important French crowdfunding platform specialized in cultural heritage, which is *Dartagnans*. Over the last 10 years, in this platform five equity crowdfunding campaigns were launched, and all of them were successful, all dedicated to purchases or interventions on historical French castles. More specifically, these campaigns were related to the Castle of La Mothe Chandeniers (in Les Trois Moutiers), one campaign related to the Castle of Fort De L'Ebaupinay, and one to the Castle of Vibrac. These five equity crowdfunding campaigns constitute the research sample of the QCA analysis. In terms of key factors, they were selected according to the factors and signals identified in accordance with the ones highlighted in the literature review and divided in seven main domains: financial factors, equity retention factors, human capital factors, emotional factors, social-capital factors, factors related to active communication, and validation by third parties.

For each case study, the factors were scored according to a crisp set analysis (the score is always either '0' or '1' meaning absence or presence, respectively) using FsQCA, a specific software for QCA analysis. Finally, the results were critically analysed and referred to the initial research questions regarding the peculiarities and success factors of equity crowdfunding for cultural heritage, allowing the authors to get interesting insights on the topic.

#### **4 Results of the empirical research**

The results of this research reveal that equity crowdfunding could represent a viable source of external capital within the cultural heritage sector especially when a substantial amount of capital is needed.

Indeed, the findings of this analysis (Figure 1), show that all five campaigns were successful and able to raise even more than the targeted amount (75% or even 555% more). In this regard, the results of the theoretical model developed by Miglo (2016) show that entrepreneurs tend to choose equity crowdfunding if more substantial amount of capital is needed. Extending these results within the cultural heritage sector based on the findings of this research, can be argued that equity crowdfunding could be a sensible choice, outside the traditional finance, that can be pursued to raise considerable amount of funds needed to carry out preservation, restoration and/or enhancement works. Moreover, the choice of alternative sources of finance, such as equity crowdfunding, can be influenced by

factors like perceived lack of funding alternatives, which is the scenario that has been characterized the cultural heritage sector in the latter fifteen years (Brown et al., 2015).

*Figure 10 - Percentage of funded amount*  
(Source: authors' elaboration based on data from Dartagnans)

Furthermore, in order to identify the peculiarities of equity crowdfunding in the cultural heritage sector within the region of France, this study carried out a QCA - quantitative comparative analysis as explained above.

From the QCA's truth table and the intermediate solutions – Figure 2 - it can be stated that signals of potential success of equity crowdfunding campaigns within the cultural heritage sectors are mainly factors related to emotional signals. Indeed, each campaign included expression and images that encouraged the emotional component which seemed prevailing in comparison to other information provided. Starting from the motto used in all the campaigns where people were asked to contribute to the initiative as thanks to their donation, they could have been able to "*Devenez co-chatelain*", co-owners, of the Castle. Moreover, have been used images of volunteers taking active part of the castle's preservation and restoration and picture of them visiting the site, to show to the potential investor, what could have meant taking part of this initiative.

These results are in contrast with previous research that investigated equity crowdfunding success, as they identified to be the financial signals the key drivers (Block, Hornuf and Moritz, 2018). That difference could be because of the sector under analysis. Previous crowdfunding research within cultural heritage showed that a key factor of their success was the emotional and or social/community side

of it (Belleflamme, Lambert, and Schwienbacher, 2014) rather than the financial side.

Therefore, it can be concluded that equity crowdfunding initiatives for the cultural heritage sector differ from traditional equity crowdfunding campaign but are aligned with the main motivations that characterize crowdfunding campaigns for cultural and creative projects, such as their link with emotional aspects and social and community values typical of the cultural and creative sector.

## 5 Conclusions

This research aimed at investigating the success factors for equity crowdfunding campaigns in the cultural heritage sector and the peculiarities of cultural heritage's equity crowdfunding compared to other sectors.

From the literature review, it emerged that success factors in equity crowdfunding campaigns are generally identified mainly in financial factors such as shared information related to financial characteristics of the project, equity retention, with other significant but not determining factors represented by human capital signals, emotional signals, social capital signals, active communication factors, and validation by third parties.

Starting from these literature findings on factors and peculiarities of equity crowdfunding in general, this paper focus on the specific cultural heritage sector. It investigated successful campaigns of equity crowdfunding for cultural heritage, selected among the equity crowdfunding projects launched on the specialized website *Dartagnans* and analysed through a QCA methodology. The findings demonstrated that equity crowdfunding campaigns within the cultural heritage sector have been able to raise considerable amount of funds, thus representing a valid path to increase financial sustainability for this type of organizations. Moreover, results demonstrate that the traditional factors of success of equity crowdfunding campaigns are partially met also in those for cultural heritage, but the sector presents some peculiar characteristics. Indeed, within those signals, those related to emotional identification with the initiative and social and community values are more relevant, while financial factors or traditional equity retention information seems to have less importance.

The research contributes to the academic literature on the peculiarities of equity crowdfunding for specific subsectors and on the broader reflection on the opportunities of crowdfunding for the cultural heritage field. Furthermore, it could provide interesting insight to policy makers and managers who are interest in exploring new ways to increase the financial sustainability of their institution.

However, the limited research sample and geographical area of the campaigns call for further investigations based on a broader sample and international comparative approaches.

## **Transform Knowledge Assets into Reality: How the Purposeful Combination of Knowledge Activities Enables Organisations to Channelise the Knowledge Flow in Software Engineering Development**

---

### **Abstract**

**Purpose** — Knowledge Activities like acquiring, codifying, storing, maintaining, transferring and creating knowledge, can be seen as what constitutes Knowledge Management in an organisation. Executing knowledge activities should ideally come at no additional cost and blend well with the respective organisation's business. Being a highly knowledge-intensive discipline, software engineering becomes an interesting testbed for this approach. This study aims to identify existing connections between knowledge activities and some frequently used software team practices or measures, establish their relations and investigate their suitability as tools for implementing knowledge management.

**Methodology and approach** — In accordance with the research questions, this study used a qualitative research approach. Using a questionnaire, practitioners such as software developers and team leaders were asked to provide feedback on a set of previously selected team practices and measures typically used in software engineering projects and to assess their relation to the activities of acquiring, codifying, storing, maintaining, transferring and creating knowledge. The obtained results were analysed using frequency analysis and the comparison of summarised agreement vs. disagreement related to typical software development team practices and measures.

**Findings** — The results show that meetings and team processes like code reviews or pair programming come with intensive knowledge transfer while knowledge is acquired through activities involving client contact. New knowledge is created in a large number of team processes, often along with other knowledge activities. In addition, the inquiry revealed that the selection of team practices and measures are both relevant and considered important for managing knowledge in software teams. This indicated that

activities that are already part of the software engineering process in many organisations can be facilitated to trigger particular knowledge activities.

**Practical implications** — The study clearly shows the relevance of practices and measures well-accepted in software engineering for implementing knowledge management in software development teams. Based on a systematic analysis it establishes their correspondence with particular knowledge activities thus allowing practitioners to assess or create the prerequisites for knowledge creation in their teams along with existing workflows. Project and team leaders, and ultimately the whole organisation benefit from a tool enabling them to improve both flow and creation of knowledge within and between teams strengthening expertise and sustainability in the particularly knowledge-intensive software market.

## 1 Introduction

Due to the nature of what it produces and the work involved to create it the software industry had to find ways of dealing with knowledge at a time when knowledge management as a scientific discipline had not yet evolved. After theories on systematic knowledge creation and knowledge management, Nonaka's SECI model (Nonaka and Takeuchi, 1995) and first notions of knowledge activities (Pentland, 1995; Andersen, 1996) surfaced in the 1990s, blending practitioners' best practice and researchers' findings became possible. This led to considerable research focusing on the particularities of knowledge in software engineering as well as the introduction of some of the newly established terminology and methodologies such as knowledge transfer and storage. Some researchers focused on technology commonly used in the software industry like Wikis and issue trackers to support knowledge transfer, maintenance and storage (Dingsøyr and Conradi, 2002; C. Khalil and S. Khalil, 2019; Sungkur and Ramasawmy, 2014; Abdur *et al.* 2015). Others, like Dissanayake *et al.* (2013), conclude that knowledge management key concepts as described by Nonaka and Konno (1998), Nonaka, Toyama, and Byosièrè (2003), and Nonaka and von Krogh (2009) are already present in agile software development methodologies.

However, while the combination of knowledge management and software engineering as a field of interest for researchers has now been around for at least two decades, a separation between the two camps is still noticeable and calls for

a more holistic approach trying to connect knowledge management to existing elements of software development teams' work. This research aims to fill this gap by investigating a selection of software development team practices, measuring their relevance to team knowledge and establishing their relation to six knowledge activities as proposed by Heavin and Adam (2012) thus enabling software project leaders to more consciously involve the concept of knowledge when designing team processes.

The paper is organised as follows: In section 2 relevant existing research is reviewed, followed by two research questions. The research method used in this study is outlined in section 3 The results are presented in section 4 followed by the conclusion in section 5.

## **2 Literature Review**

### **2.1 Knowledge Creation**

The fundamental concepts of what is known today as Knowledge Management and Knowledge Creation have been created and further developed since the 1990s, and a vast amount of relevant research on how to implement KM in — usually large scale — enterprises exists (Nonaka, 1991; von Krogh, Ichijo, *et al.* 2000; Ichijo and Nonaka, 2008). Nonaka (1994), defines knowledge as 'justified true belief' held by individuals. In order to qualify as knowledge rather than just information a "clear understanding of information and their associated patterns" is an additional important requirement (Bierly *et al.* 2000, p. 600). Knowledge is also the actuality of skilful action and/or the potentiality of creating situations to permit (skilful) action (Nonaka and von Krogh, 2009).

Nonaka (1991) points out that there is a distinction between explicit and tacit knowledge. Tacit knowledge comprises information that is difficult to express, formalize or share. It resides within people and according to Stenmark (2000) it can neither be documented in a manual nor be explained in words to others. Hence this kind of knowledge requires involving the knowing one and transferring the knowledge via periods of practices where experiences are shared through actions. In other words, knowledge needs to be transmitted from person to person (Grover and Davenport, 2017). Nonaka and Toyama (2003) reinforce Stenmark's idea of tacit knowledge by stating that the only way to acquire tacit knowledge is through shared direct experience by spending time together.

Thereby, tacit knowledge often takes the form of narratives, analogies or metaphors in order to give insight into the 'why' and 'how' something is done the way it is (Holste and Fields, 2010). From a practical standpoint this means after writing down the narrative, it is read by another group of people in the company and should be discussed afterwards. The analysis of the narrative will help making better decisions in the future. However, the ability to amplify tacit knowledge is limited.

When focusing on an entrepreneurial environment, making tacit knowledge explicit carries the risk of losing sustainable competitive advantage. Tacit knowledge transformed to explicit and having left the original company may become industry best practice (Lubit, 2001). In opposition to tacit knowledge, explicit knowledge can be transmitted by using strings, i.e. interaction between physical objects, in the right circumstances (Collins, 2010). It can be codified and/or verbalized (Nonaka and Toyama, 2003; Grover and Davenport, 2017) and expressed by data numbers, formulas, pictures, manuals, patents (Holste and Fields, 2010). Both explicit and tacit knowledge can be passed on and converted using appropriate methods and with varying degrees of difficulty or required effort. The resulting four possible transitions — tacit-to-tacit (Socialisation), tacit-to-explicit (Externalisation), explicit-to-explicit (Combination) and explicit-to-tacit (Internalisation) are the pillars of the SECI model, according to which organisational knowledge creation evolves from a spiral out of continuously transforming and transferring explicit and tacit knowledge between individuals (Nonaka and Takeuchi, 1995).

Since the beginning of the SECI model's development, a broad academic debate has arisen, mainly around the distinctions between the different conversion processes, the relationship between the explicit and tacit levels and its possibilities related to cultural differences. The adoption and application of the SECI model is under continuous consideration and development (von Krogh, Nonaka, *et al.* 2012; C. S. Lee and Kelkar, 2013; Nezafati *et al.* 2009; Tee and S. S. Lee, 2013). KM practitioners soon learnt that a lot of important knowledge is not explicit. Only discussion, probing, reflection and conversion of tacit knowledge can bring out valuable explicit knowledge. The four conversion modes of tacit in tacit, tacit in explicit, explicit in explicit and explicit reversed in the form of new tacit knowledge constitute an approach to support the exchange and creation of knowledge. The SECI model is widely accepted but varying contents and perceptions regarding the importance of particular aspects of the knowledge

creation model exist, such as cultural aspects, the practical implications of the transformation of knowledge and the role of management (Kahrens and Früauff, 2018).

An important extension, the concept of Ba (Japanese for 'space'), introduced by Nonaka and Konno (1998) and Nonaka and Toyama (2005), stating that in order for the SECI model's transitions to take place an enabling context is necessary. The four pillars are complemented by four types of Ba: Originating Ba (face to face) for Socialisation, Interacting Ba (peer to peer) for Externalisation, Cyber Ba (group to group) for Combination and Exercising Ba (on the site) for Internalisation. The concept of Ba stresses how important relationships and interactions between peers are for the process of knowledge creation, and the environment needs to provide psychological safety and care (von Krogh, Ichijo, *et al.* 2000). Besides the already mentioned creation of the appropriate enabling Ba, fostering organisational knowledge creation can be supported by targeted management decisions. Knowledge transfer and knowledge creation best prosper in micro-communities of small to medium size and changing membership over the years, and sources of innovation, like e.g. R&D departments need to be organised (Ichijo and Nonaka, 2008) accordingly. Teece (2010) points out that in tech companies (e.g. Intel), innovation already originates from development and production without even the need for dedicated R&D departments.

Knowledge sharing, depending on the flow of information, plays a central role here. Inside an organisation, decentralised decision-making and reduced formalisation are preferred as they encourage initiative and participation (Saifi *et al.* 2016). When dealing with peers outside the respective organisation, similar principles apply. Building communities with them enables tacit knowledge sharing through co-experience and shared praxis (Sapir *et al.* 2016; von Krogh, Ichijo, *et al.* 2000; Nonaka and Toyama, 2005; Ichijo and Nonaka, 2008). While the SECI model starts from the point where individuals already carry knowledge to enter the knowledge creation spiral, the idea of distinguishing between embodied and not-yet embodied ('self-transcending') tacit knowledge is introduced in Scharmer (2001). Scharmer address the question for the driving force behind the knowledge spiral, stressing the importance of appropriate enabling contexts and the necessary conversational complexity in communication. In the future, the application and extension of the SECI model are expected to be leaner in structures and more digitised concerning knowledge creation and sharing (Kahrens and Früauff, 2018).

The SECI model has also been subject to criticism, a.o. for being too vague in its recommendations and its perception of both, tacit and explicit knowledge (Schreyögg and Geiger, 2003; Schreyögg and Geiger, 2004; Lin, 2010), also for being deeply rooted in Japanese culture and hence not sufficiently considering cultural differences as possible obstacles to its application (Andreeva and Ikhilchik, 2011). Nevertheless, this research will consider the basic concept of the SECI model when assessing typical meeting structures in software development projects to improve the exchange among team members and thereby increase learning and knowledge.

## **2.2 Knowledge Management in Software Development**

It is a common understanding that software engineering and development is a highly knowledge-intensive discipline, and various aspects of it have attracted the interest of researchers in knowledge management (Rus and Lindvall, 2002; Kavitha and Irfan, 2011; Vasanthapriyan *et al.* 2015; Shongwe, 2017). In terms of the taxonomy proposed by Earl (2001), knowledge management strategies are usually closely related to the technocratic schools for traditional software development and more to the behavioural schools for agile approaches (Bjørnson and Dingsøyr, 2008). Rus and Lindvall (2002) exemplify the need for knowledge management in software engineering by the different dimensions of knowledge involved in it:

- Process and product knowledge is concerned with how the development of a particular project should be approached.
- Domain knowledge is related to what a software system is developed for, like e.g. accounting or space shuttles.
- Technological knowledge includes programming languages, tools, libraries selected and used for implementation.
- Knowledge of local policies covers amongst others conventions existing in development teams.
- Also, it is important to know who the bearer of specific knowledge in the organisation is.

Hegde and Walia (2014) note that generally the different involved forms and dimensions of knowledge have a significant impact on the developers' creativity.

An early study based on 'lessons learnt' reports from eight software companies (Dingsøyr and Conradi, 2002) shows that employees are interested in this field

and also willing to invest in it, e.g. by developing supporting tools. From analysing knowledge flows involved when creating source code Sandhawalia and Dalcher (2010) conclude that the activities of knowledge creation, learning and reflection clearly play an important role in uncovering and reviewing mistakes and mismatches. Similarly, Ward and Aurum (2004) find that knowledge management helps appreciate the challenges and complexities inherent in software development with employees being able to identify activities related to knowledge management in their organisations. However, the same research also reveals that employees found the helpers, techniques and methodologies in use for the software development process inadequate to support the intended knowledge management.

A significant number of studies stresses the importance of software tool support. The use of knowledge repositories (e.g. Wikis, databases etc.) is considered a central element of knowledge management in software organisations (Dingsøyr and Conradi, 2002; C. Khalil and S. Khalil, 2019). However, this term is a bit misleading as persisted knowledge becomes *information* and needs to be transferred back to *knowledge* when consumed by others. Bjørnson and Dingsøyr (2008) confirm a tendency to over-emphasise the role of technology by finding that some software engineering organisations focus on storage and retrieval of knowledge at the cost of knowledge transfer, application and creation. In particular collaborative software tools already popular in software development environments, like issue trackers and the already mentioned Wikis, are useful, e.g. for externalisation of knowledge (Sungkur and Ramasawmy, 2014; Abdur *et al.* 2015).

Because of their strong reliance on team processes, agile methods already contain various elements of what is known from the SECI model as is shown in the mapping of agile practices to characteristics of Ba in Dissanayake *et al.* (2013). Similarly, Abdur *et al.* (2015) find processes and tools common in agile methods beneficial for knowledge creation. These findings are confirmed by an investigation in large French companies conducted by C. Khalil and S. Khalil (2019) who based on a theoretical model of knowledge management in agile environments and interviews with employees from 12 French companies conclude that agile practices contribute to the creation of a knowledge-intensive culture. But what makes agile methods so interesting from the knowledge management perspective is their team dynamics and the flow of information they bring along. These contribute to competitiveness and more or less come automatically in small

or medium-sized enterprises (Basri and O'Connor, 2011; Shongwe, 2017; Heavin and Adam, 2014). Even larger organisations can benefit from it since agile teams are usually kept small on purpose: e.g. Scrum recommends teams of three to nine people (Sutherland and Schwaber, 2010).

Elements fostering open discussion or collaboration have a strong influence on team knowledge. One is the Retrospective in Scrum where team members gather after each sprint reflecting on what did not go well in the finished iteration and which measures should be taken to prevent it from happening again (Viana *et al.* 2013). Similarly in projects based on the waterfall model lessons learnt meetings take place after milestones. Another example is Pair Programming where two developers share the same screen while composing source code together (Kavitha and Irfan, 2011).

### 2.3 Knowledge Activities

While knowledge clearly plays a crucial role in software engineering, still some measures are required in order to achieve or design a systematic process of knowledge creation. For this, researchers propose the definition of Knowledge Activities (KA) — transactions or manipulations of knowledge where the knowledge is the object, not the result (Jetter *et al.* 2006; Kraaijenbrink *et al.* 2006). The term Knowledge Activity is fairly generic, hence several different interpretations are in use. Table 1 provides a selection of variations to the concept.

Table 1: Variants to the concept of Knowledge Activities

Authors	Name	Activities
Holsapple and Joshi (2004)	Knowledge Manipulation Activities	Acquiring, Selecting, Internalising, Using, Externalising, Generating
Ward and Aurum (2004)	KM Activities	Application, Distribution, Organisation, Adaptation, Identification, Acquisition, Creation
Costa and Monteiro (2017)	Knowledge Management Processes	Acquisition, Storage, Codification, Sharing, Application, Creation
Kraaijenbrink <i>et al.</i> (2006)	Knowledge Activities	Elicitation, Codification, Detection, Assessment, Transfer (of knowledge), Transfer (of knowledge holder), Nurturing, Motivation
Heavin and Adam (2012)	Knowledge Activities	Acquire, Codify, Store, Maintain, Transfer, Create

Heavin and Adam (2012) derive a list of six Knowledge Activities — acquire, codify, store, maintain, transfer, create — from the definition provided by Holsapple and Joshi (2004) conducting an investigation of KA application in five Irish software SMEs finding a dominance of knowledge and an underrepresentation of knowledge creation (Heavin and Adam, 2012; Heavin and Adam, 2014). Ward and Aurum (2004) focus on seven separate activities — knowledge application, distribution, organisation, adaptation, identification, acquisition and creation — finding them used and evolving with technology, organisational culture and practises. In a subsequent study, the same group of researchers investigate how and whether all these activities are executed by looking at four projects in two software companies and linking them to typical project lifecycle stages: Requirements Gathering, Analysis & Design, Building & Development, Testing and Deployment (Aurum *et al.* 2008). Their findings indicate that while the KAs are executed, this often happens implicitly, i.e. without having been identified as KAs by developers. Although there clearly is a common understanding of the concept behind knowledge activities, there are differences in detail e.g. Costa and Monteiro (2017) refer to knowledge sharing and application instead of transferring and maintaining.

Hence it can be concluded that the concept of knowledge activities (or KM activities or knowledge management processes) is recognised as a relevant element in implementing knowledge management. To a far lesser extent, the question has been addressed which software development practices actually result in executing which KAs. Sungkur and Ramasawmy (2014) refer to such activities as building blocks for knowledge management processes to which technical tools are linked in order to show which aspects of knowledge management they support. In their survey on knowledge management in software engineering, Vasanthapriyan *et al.* (2015) go through the software development life cycle and analyse its stages for their relation to the teams' knowledge, while employees from small South African software companies comment on their experience regarding KAs in Shongwe (2017). Examples for such mappings, while not actually focused on, can be found in some other works, like Sandhawalia and Dalcher (2010) and Abdur *et al.* (2015).

Mapping of some team processes and measures to knowledge activities can be found as side products in some of the abovementioned studies, like e.g. Pair Programming, Daily Scrum, rotation/visit in Abdur *et al.* (2015), or design, test, implementation, document, development in Aurum *et al.* (2008). However, a

systematic analysis of how elements of software development workflows and management measures relate to knowledge activities would be of value to both researchers and practitioners, which is why this research is dedicated to this aspect.

## **2.4 Research Questions**

The purpose of this study was to develop a holistic concept of implementing knowledge activities in the context of software engineering organisation.

Therefore, the overarching research question for this qualitative exploratory study was:

**RQ1.** *Which knowledge activities are related to which team practices and measures?*

*A subordinate research question to support the analysis and interpretation of primary data was:*

**RQ2.** *How should team practices and measures be combined in order to support a mixture of knowledge activities suitable for effective knowledge management in software engineering organisations?*

## **3 Research Method**

### **3.1 Qualitative Research**

In accordance with the proposed research questions, this study used a qualitative research approach. Although such a kind of qualitative research allows for observing a phenomenon in-depth (Eisenhardt and Graebner, 2007) and case study research seems to be appropriate, the authors of this paper decided to take a broader view that is not bound to a single case organization.

Specific contextual problems are related to software development and delivery that create general challenges in relation to knowledge management in projects. In terms of complexity, these challenges are related to the complexity of software development projects consisting of complex interactions among project members internally and externally. Qualitative research methods are helpful to analyse abstract constructs of observable phenomenon (Creswell, 2014).

This study is concerned with analysing how knowledge activities and their structured and purposeful implementation benefit software engineering

organizations. The underlying assumptions of this research were based on a partially phenomenological stance. According to van Manen (2007), a context-sensitive form of interpretive inquiry, the phenomenology of practice, is well suited to serve practitioners who in their day-to-day practice may be unaware of the depths of people's experiences. By constructing the realities related to knowledge activities in developing and programming software solutions in projects with multiple perspectives this qualitative empirical method composed summaries of lived experience and asked a group of experts to assess these practices. Thereby, the underlying patterns and structures of meaning can be drawn when a central feature of the phenomenon is considered (van Manen, 2016). The interpretive findings of this research may serve as the foundation for future empirically conducted researches aiming to measure the degree to which knowledge activities applied in software engineering projects contribute to the organizational knowledge base.

### ***3.2 Sampling and data collection***

Several factors contribute to the success of knowledge management activities within organisations including the firm's objectives, the enabling conditions and the environment, the knowledge processes including the dialogue between individuals and the individual's experiences (Nonaka and von Krogh, 2009). The implication here is that knowledge activities are best examined within the context where they take place. A key advantage of qualitative research is that the researchers are free to choose from multiple sources while still incorporating one's know-how to extract understanding.

In this research, data was collected through questionnaires. The study population included managers, project managers, developers, and other experts involved in software development projects for internal organizational purposes or for external client-related purposes.

The sampling strategy for the data collection followed the principle of convenient purposive sampling that requires recruiting from a group or organisations with a close perspective on the research phenomenon of interest from a group or organization (Creswell, 2014). In the case of the questionnaire, the convenient purposive sampling took place by posting the questionnaire on online research platforms (SurveyCircle) and social media (LinkedIn) approaching special expert group related to software project management, agile

methodologies. Although convenience sampling strategies do not allow generalising the findings due to the unknown population, it plays a prominent role in the field of business and management (Bryman and Bell, 2007). The expectation was to reach 50 participants with a self-administrated internet-mediated questionnaire. Table 2 illustrates the composition of the participants.

Table 2: Composition of the participants

<b>Role</b>	<b>Team Lead</b>	<b>Developer</b>	<b>Architect</b>	<b>Other</b>	
	40.48%	30.95%	5.95%	22.62%	
<b>Organisation employees</b>	<b>1 ... 10</b>	<b>11 ... 50</b>	<b>51 ... 250</b>	<b>251 ... 500</b>	<b>over 500</b>
	10.71%	7.14%	30.36%	12.50%	39.29%
<b>Organisation core business</b>	<b>Standard Software</b>	<b>Individual Software</b>	<b>Products incl. software</b>	<b>Services incl. software</b>	<b>Others</b>
	3.57%	19.64%	26.79%	26.79%	23.21%

In this research, RQ1 and RQ2 served as a guide for the review of the questionnaire data which was analysed by frequency analysis and the comparison of summarised agreement vs. disagreement to statements related to typical software development team practices and measures.

## 4 Results and Interpretation

### 4.1 Various companies' approaches to software development

Through the questionnaire responses were obtained from practitioners working for companies of 5 different scales. The vast majority of these companies develop individual software, software as part of a service or software as part of a product. Almost all of them use some mixture of software development methodologies while a significantly smaller number focuses on a single dominant one (used by more than 75%). While still 45% use the waterfall model to some degree, a vast majority uses an agile methodology (58%) or a mix of agile and traditional (54%).

### 4.2 How Team Practices and Measures correspond with Knowledge Activities

In the questionnaire, practitioners were asked to 'tag' team practices and measures with knowledge activities executed or fostered by them. The result can be seen in figure 3 where the respective bar lengths indicate relevance.

Part 1: Meetings	Acquire	Codify	Store	Maintain	Transfer	Create
Daily standups	■	■	■	■	■	■
Recurring longer meetings	■	■	■	■	■	■
Client Meetings	■	■	■	■	■	■
Retrospectives	■	■	■	■	■	■
Part 2: Development	Acquire	Codify	Store	Maintain	Transfer	Create
Design software	■	■	■	■	■	■
Write Code	■	■	■	■	■	■
Code Reviews	■	■	■	■	■	■
Pair Programming	■	■	■	■	■	■
Test each others' features	■	■	■	■	■	■
Part 3: Planning	Acquire	Codify	Store	Maintain	Transfer	Create
Collaborative Release Planning	■	■	■	■	■	■
Epics/Stories Reviews	■	■	■	■	■	■
Joint estimate software features	■	■	■	■	■	■
Part 4: Organisation	Acquire	Codify	Store	Maintain	Transfer	Create
Bring in new staff	■	■	■	■	■	■

Informal exchange in the kitchen	■	■	■	■	■	■
Informal gathering after work	■	■	■	■	■	■
Part.in Open Source projects	■	■	■	■	■	■
Part. in cross-disciplinary exchange	■	■	■	■	■	■

Figure 3: Team practices and Knowledge Activities

Generally, knowledge activities were found to correspond with the 6 parts categorising practices and measures:

- The four kinds of meetings show relevance in maintaining and transferring knowledge while client meetings also help to acquire and create knowledge. Retrospectives even relate significantly to all knowledge activities with the only exception of acquiring knowledge.
- Development exhibits an emphasis on codifying, transferring and creating knowledge.
- Collaborative planning helps in transferring, also to a lesser degree maintaining and creating knowledge.
- Organisational measures leading to permanent or temporary changes in team composition emphasise knowledge transfer, acquisition and creation.
- Learning measures and documentation cover all 6 knowledge activities to different degrees.
- Informal exchange and participation in external activities are helpful for acquiring, transferring and creating knowledge.

The above results, in particular the findings displayed in figure 3, answer RQ1.

#### **4.3 Most effective Team Practices and Measures**

Finally, RQ2 asks how team practices and measures should be combined in order to achieve a mixture suitable for effective knowledge management in software engineering organisations. While figure 3 already gives a good indication of how particular activities can be fostered, some team practices and measures were found to be of particular value because of their high relevance for some specific knowledge activities, like onboarding and mentoring (acquire and transfer knowledge), team membership changes (transfer and create knowledge). Others are attractive because of their versatility, like contributing to documentation, Retrospectives and Pair Programming.

This indicates that for instance Retrospectives should take place because of their correspondence with 5 out of 6 knowledge activities. While they are usually compulsory for Scrum teams this is not the case for many others, hence introducing them and making sure they are always held could be helpful in this context. Pair programming can give a boost when needed, even if there are reasons not to use it by default. Finally, in general, teamwork is beneficial not only for knowledge transfer, ideally while making changes to the team composition from time to time.

Of course, it needs to be understood that just introducing the above will hardly trigger an automatism not requiring any further steering or management: once a tool's potential is understood it should be introduced and then applied in a purposeful way allowing it to fulfil its potential.

### **5 Discussion and Conclusion**

Based on the responses obtained from practitioners using an online questionnaire, team practices and measures were investigated on their relation to six knowledge activities. The clearness with which connections to knowledge activities were identified indicates their applicability as a tool for decision making by project leaders in software engineering.

Most of the practices and measures originate from agile software development methodologies and are widely in use in the software industry, even in organisations not considering themselves as 'agile'. This is significant because it shows that development teams will usually not need to start from scratch or

sacrifice productivity for the sake of knowledge management. On a side note, this also corresponds with other researchers' findings of agile software development methodologies being more suitable for knowledge management because of their focus on communication and collaboration (Dissanayake *et al.* 2013; Heavin and Adam, 2014; C. Khalil and S. Khalil, 2019).

The findings highlight some particular practices' and measures' versatility in terms of knowledge management indicating their potential to add value to software projects. Hence team leaders do not even need to rely on a large number of them in order to achieve the desired mixture of knowledge activities. An organisation does not have to be 'agile' in order to benefit from this: elements like Daily Scrums or Retrospectives either have their equivalents in traditional methodologies or can be easily integrated.

Software project work is frequently subject to enormous time pressure. Teams dealing with knowledge efficiently have an advantage here, while unfortunately systematic knowledge management usually does not promise immediate return on investment. This is why blending well with existing work procedures and not coming at an additional cost are critical requirements. Relying on commonly-used procedures with some direct value to the software development process while understanding their potential in knowledge management fills this gap.

These outcomes may already sound familiar to experienced practitioners, however, increased attention, a more substantiated understanding of processes and measures and their relationship to knowledge-related aspects can contribute significantly to more sustainable team development with little or no overhead.

Future research will continue exploring the application of knowledge management in software engineering by investigating the here presented team practices and measures on their importance and software teams' proficiency in applying them and how this relates to organisations' characteristics like scale or preferred development methodology.

### **Abstract**

The Blockchain potential in enabling and boosting business process innovation in the Healthcare industry is a hot topic. However, the realization of such a potential is hampered by two hindrances. First, healthcare business processes are inherently complex. This implies additional difficulties in managing and innovating them. Second, the digitalization trend has entailed relevant changes in the capabilities needed to manage and innovate business processes. Yet, to our best knowledge, such changes have not been empirically

investigated to understand context-specific factors in driving digital innovation. Accordingly, this research aims at figuring out which may be the main Business Process Management capabilities needed to carry on Blockchain-driven Healthcare business process innovation. To fill this gap, we developed two exploratory case studies in the healthcare sector – one for probing a case of incremental business process innovation (BPI) and another one for investigating a case of radical BPI. The cases focused on the business process redesign phase of the BPM lifecycle.

This working paper illustrates and discusses the preliminary results of the incremental BPI case, which concern an Italian project of Blockchain-driven innovation of the national drug logistics process. The findings suggest that the Process Portfolio Management, Process Data Governance, and Multi-purpose Process Design BPM capabilities should be prioritized. Furthermore, they highlight that a new BPM capability – Process Risk Assessment – may be strongly relevant in the healthcare context. These preliminary results integrate the BPM research stream and provide practitioners with actionable insights.

## 1 Introduction

The digitalization trend is increasingly challenging Business Process Management (BPM) (Baiyere et al., 2020; Lederer et al., 2017). In light of the innovation potential brought by digitalization, BPM can no longer be conceived only as the classic notion of reaction-based, problem-driven analysis and incremental enhancement of already adopted business process configuration (Dumas et al., 2018). Instead, it has to harness the generative capacity of the new digital-driven opportunities and the radical Business Process Innovation (BPI) it may enable (Berger et al., 2018; Eck et al., 2015; Kohlborn et al., 2014; Mendling et al., 2020; Tilson et al., 2010). Rosemann (2014) formalized this change in the ambidextrous BPM concept, described as the combination of "exploitative BPM" (i.e., the traditional BPM conception, which is associated with incremental BPI) and "explorative BPM" (i.e., the exploitation of digital-based opportunities to carry on radical BPI).

In the current digital technology landscape, Blockchain has been largely proffered as an enabler of incremental and radical innovation of inter-organisational business processes (Chang et al., 2019; Holotiuk et al. 2019; Mendling et al., 2018). Although the financial service industry had initially

monopolised the exploration of the Blockchain innovation potential (Swan, 2015), other industries, e.g., Insurance, Logistics, Agriculture and Food, Energy Management, have turned their attention on this topic (Al-Jaroodi et al., 2019). In this regard, Healthcare is getting the lion's share because Blockchain may tackle notorious issues that characterise this sector, such as data security and privacy (Esposito et al., 2018), lack of trust in sharing information among stakeholders (Tandon et al., 2020), supply control over cold chain interruption and drug counterfeiting and recall (Singh et al., 2020; Tseng et al., 2018), cross-institutional and cross-border data sharing (Omar et al., 2019).

Yet, while Blockchain may unfold and boost BPI in Healthcare ecosystems, harnessing its potential may be hampered by two hindrances. First, Healthcare business processes are complex because they: are knowledge-intensive; involve several heterogeneous business and medical functions; encompass medical practices that change and evolve over time; and are patient-dependent, i.e., each process instance exhibits specific – often unique – patterns/traces and highly variable control parameters (Antonacci et al., 2018; Reed et al., 2018). This complexity may make BPI harder to pursue because it entails not-to-underestimate difficulties in generating easy-to-interpret process models, analysing process performance and conformance, and orchestrating and coordinating concurrent processes and actors that use shared resources (Mans et al., 2015; Rebuge and Ferreira, 2012). However, most Management academics analysed drivers, limitations, and social and technical challenges of adopting Blockchain in Healthcare services (Khezzr et al., 2019; Pandey and Litoriya, 2020; Tandon et al., 2020; Tripathi et al., 2020). Thus, Blockchain-enabled BPI in Healthcare is a little-investigated topic.

Second, the changes brought by digitalization have deeply affected the capabilities needed to carry on BPM and to pursue BPI. This update concerns almost all the BPM capabilities (cf. de Bruin and Rosemann, 2007), particularly the cultural, individual, methodological, and Information Technology ones (Kerpedzhiev et al., 2021). This is not surprising, since digitalization is a socio-technical phenomenon involving a deep transformation in technological and behavioural aspects (Bockshecker et al., 2018). Yet, this shift in BPM capabilities has not been empirically investigated in depth and calls for further analysis in different contexts (Kerpedzhiev et al., 2021).

In light of digitalization, BPI in Healthcare is thus a worthwhile albeit challenging endeavour. Nonetheless, to the best of our knowledge, the BPM

capabilities needed to conduct Blockchain-enabled BPI are little known and largely unaddressed. Accordingly, we aim at answering the following Research Question:

*"What are the main BPM capabilities necessary to carry on Blockchain-driven Healthcare business process innovation?"*

In answering the Research Question, we focused on the business process redesign phase of the BPM lifecycle (Dumas et al., 2018). From a scientific perspective, this may contribute to the BPM research stream by pinpointing the main capabilities and challenges needed to innovate Healthcare business processes through Blockchain. In addition, it is an attempt to combine typical BPM approaches with empirical field work to advance the understanding of context-specific factors in driving digital innovation (Mendling et al., 2020). From a practitioner perspective, embedding the Healthcare ecosystem complexity in the technology-driven innovation initiative may be beneficial to a deeper exploitation of the Blockchain innovation potential. In doing so, the findings may provide managers with actionable insights on which BPM capabilities should be prioritised.

To pursue our research objective, we conducted two exploratory case studies in the Healthcare industry. The first one focused on the drug logistics process to investigate a scenario of incremental innovation, meant as improved data exchange integrity. The second one concerned the home care process to probe a scenario of radical innovation, intended as the development of unprecedented forms of process choreography hardly achievable by other technologies. This working paper focuses on the incremental innovation case study, expounding and discussing its preliminary results.

The remainder of this work is as follows: Section 2 illustrates the research design; Section 3 presents the results; Section 4 discusses them; Section 5 concludes the paper.

## **2 Research design**

Two exploratory, single-case studies were developed according to the guidelines by Pan and Tan (2011). The case study research method was chosen because it is suitable for studying a phenomenon in real-life settings when no control over behavioural events is required to the investigator(s), the phenomenon focuses on contemporary events, and when capturing the context

of the phenomenon is of utmost importance (Cavaye, 1996; Yin, 2013). The selected case type was exploratory because it fits the exploratory nature of our research question (Tellis, 1997). Furthermore, it is suitable for the situations in which an intervention or a phenomenon – the Blockchain-enabled BPI – has multiple, no clear outcomes (Baxter and Jack, 2008; Yin, 2013). The case design was single-case because our case studies are revelatory in nature, i.e., they investigate a rather unexplored phenomenon and aim at being an unprecedented source of insight on it (Yin, 2013). Indeed, the BPM capabilities for digital innovation have been more theorised rather than being actually explored. In addition, single cases may lead to a deeper understanding of the exploring subject (Dyer and Wilkins, 1991).

This working paper focuses only on one of the case studies, whose research design is detailed in the following. The case study investigated a national Italian project that aims at achieving incremental Blockchain-enabled BPI in a national drug logistics process. The objective of the project is to facilitate accurate information sharing regarding drug inventory across the national pharmaceutical supply chain to guarantee drug availability and compliance. The unit of analysis is thus the overall drug logistics process, including its innovation goals and its information and resource needs. We chose this project as an exploratory example of business process incremental innovation because carrying drug logistics out in the best possible way is critical to healthcare ecosystems for three reasons. First, it guarantees drug supply continuity to avoid supply starvation. Second, it is essential to preserve the quality of the drugs until their storage in their final destination. Third, it may cope with the well-known inefficiency of pharmaceutical supply chains (Papalexi et al., 2020).

The objectives of the case are to contextualize the project and to collect the necessary data to:

1. Model the drug logistics process before the Blockchain implementation, i.e., the as-is business process, and the re-designed process needed to introduce the Blockchain, i.e., the to-be business process.
2. Identify which BPM capabilities are needed to enable BPI through Blockchain.

The case data were collected by semi-structured interviews. The data collection started with a kick-off meeting with the Project Manager of the project to obtain an overview of the whole initiative and its objectives, phases, milestones, and challenges. During this meeting, the key informants were jointly identified

according to the following criteria: representativeness of the main project stakeholders; commitment to and sponsorship of the project; knowledge about the drug logistics process, the requirements according to which to re-design the process, and the resource and information needs. The interviews with the key informants (Table 1) were carried out until saturation, for a total of eighteen interviews. Further minor information exchange regarding additional details on quantitative aspects was arranged by additional video conferences and phone calls.

Table 8. Detail of the semi-structured interviews

Key informant	Timeframe
Project Manager	A first 2-hour meeting; a second 1-hour meeting
IT manager of the project	Two 2-hour meetings
International primary distributor	One 1.5-hour meeting
Two national primary distributors	Three 1-hour meetings per person
Supply Chain manager from three different regional purchasing bodies	One 1.5-hour meeting per person
One pharmacist from ten hospitals	One 1.5-hour meeting per person

The design and development of the question set followed the three steps recommended by McIntosh and Morse (2015). First, in line with the research question, the domain of the topic under investigation was defined and bound by analyzing the pertinent BPM and BPI literature and leveraging the authors' background, as suggested by Rabionet (2011). Second, in line with the case objectives, two categories were identified to develop the questions: "logistics process" and "BPM capabilities". The "logistics process" category includes all the main components of a business process, i.e., activities, relations among activities, resources, information flow, boundaries, and procedures (Dumas et al., 2018). The "BPM capabilities" category covers the five BPM capability clusters specified in the framework by Kerpedzhiev et al. (2021), i.e.: Strategic Alignment, Governance, Methods and Information Technology, People, Culture. For further detail on the BPM capabilities, please refer to the original manuscript. Third, the question stems were developed for both the categories. The questions were refined by a pilot test (Adams, 2015) conducted with the Project Manager. The interviews were

conducted from January to June 2021 and were recorded, transcribed, and enriched by field notes. The interview data were complemented by the analysis of project documentation and archival records. All the case data were arranged in a case archive (Yin, 2013).

The main case evidence was reviewed with the key informants. The case data were synthesized and coded into themes by the three-column approach by Saldaña (2015). The coding procedure was driven by the research question, with particular attention to informants' responsibilities, project drivers and objectives, Supply Chain configuration, and technological context (cf. Saldaña, 2015). The authors were split into two groups that concurrently carried out the coding procedure manually in two steps, which are detailed in the following:

- From raw data to preliminary codes. The chunks of raw data were analyzed to elicit the "preliminary codes". A preliminary code is the conceptual units representing the main concepts expressed by one or more consecutive sentences. This first step reduced the amount of data to manage by focusing on the most essential concepts expressed by the data.
- From preliminary codes to final codes. Based on a conceptual homogeneity criterion, the preliminary codes related to each question were gathered and synthesized into analytical categories (Schmidt, 2004), called "final codes". The final codes from each verbal interchange were compared to each other to remove any duplication.

After each step, the outcomes from the two groups were discussed jointly to reach consensus. The synthesized data were arranged according to the "logistics process" and "BPM capabilities" categories and steered the development and the discussion of the case findings.

### **3 Case study findings**

This section presents the preliminary case study results. In the first part (Section 3.1), it illustrates the drug supply chain in which the logistics process is put in place. In the second part (Section 3.2), it details the process incremental innovations that the Blockchain project aims at achieving. In the third part (Section 3.3), it expounds the most important BPM capabilities to enable the Blockchain-driven incremental innovation.

### 3.1 The drug supply chain

The supply chain is complex and illustrates different stakeholders:

- *Manufacturer.* The manufacturer purchases the drug raw materials (active ingredients) from the supplier and processes them in the manufacturing plant to produce the desired prescriptions. The produced drugs are then sold or delivered to the distributor, who further retails them to the downstream stakeholders.
- *Primary Distributor.* Primary distributors hold and distribute medicinal products to secondary distributors and to hospitals and territorial retailers, such as pharmacies, on behalf of manufacturers. Therefore, they do not have ownership of the medicinal products. They also offer a variety of specialized services such as specialty drug distribution, packing, and repackaging of drugs.
- *Secondary distributor.* Secondary distributors have ownership of the medicines they distribute. They purchase medicines from manufacturers and resell them to hospitals and territorial retailers, such as pharmacies.
- *Hospital System.* In Italy, the hospital system is managed centrally or in a decentralised manner depending on the region/area. In the first configuration, manufacturers and/or secondary distributors ship their products directly to a central hub. In this central logistics centre, shipments are broken down into smaller units, repackaged, stored, and then directly delivered to the hospital wards (Azzi et al. 2013). The hospital pharmacies have the role of validating ward requests, sharing information, etc. On the contrary, in the decentralised configuration, manufacturers and/or secondary distributors ship their products, through eventually intermediaries, directly to the hospitals' warehouses, which store the products until they were needed.
- *Pharmacy.* They purchase drugs from manufacturers and/or secondary distributors and sell them to end consumers (patients).
- *Patient.* The patient can be a part of the pharmaceutical supply chain as it buys the medicines directly from the pharmacy or it receives them during his hospitalization.
- *Drug Regulatory Authority.* The role of the drug regulatory authority includes checking and maintaining the quality, safety, efficacy, and availability of pharmaceutical products.

Fig 1 shows the structure of the pharmaceutical supply chain, highlighting both physical and information flows.

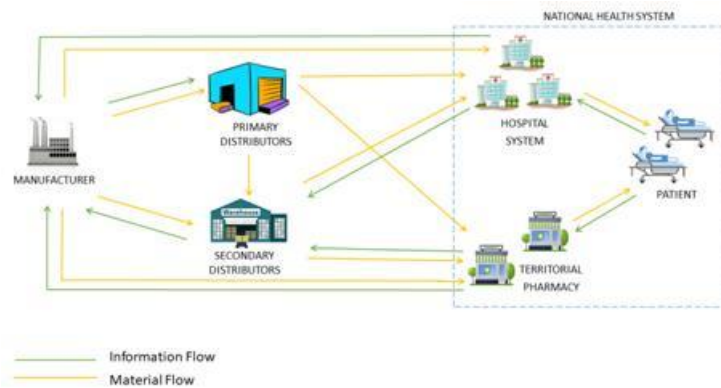

Figure 12. The drug logistics Supply Chain

More in detail, the downstream process begins with the doctor prescription based on the drug therapy defined for a specific patient. Such prescription is sent to the nurse, who verifies the drugs availability and administers the therapy to the patient in accordance with the prescription.

At fixed intervals and independently by the prescription, the nurse checks the drug inventory, manage drug's expiration dates, and quantify the drug needs. Based on the control, the nurse prepares a Refill Request (RR) to the hospital pharmacy or to the central hub, depending on the organizational model. The RR can be regular or urgent based on the in-stock situation. Once a RR is received and validated, it is processed by the warehouse workers and the related documentation prepared. The central warehouse outsources delivery to wards, while hospital pharmacies manage it in-house.

Based on the replenishment policy, the hospital pharmacy/central hub periodically prepares a Purchase Order (PO) to the manufacturer and/or the secondary distributor. The former assigns the PO management to the primary distributor, generally a third part, who prepares and packages medicinal products according to the PO and ships them to hospital warehouses and/or central hubs. The latter sells and ships medicinal products directly to the central hub/hospital pharmacy. Delivery is outsourced in both cases. The same process is followed by territorial pharmacies.

### 3.2 Use cases of Blockchain-driven process improvement

#### 3.2.1 Shipment traceability

The pharmaceutical supply chain is generally a cold chain, in which the temperature of the medicines should be maintained in a specified range throughout the journey (Sunny et al., 2020). Accordingly, such supply chain is inherently vulnerable to many critical points at various stages. Specifically, the temperature and humidity should be maintained both in the storage areas of the warehouse and during the transit as per the specifications. However, currently, the shipment is not monitored in real time and thus it is difficult to trace and certify the party who violated the specifications. As a consequence, any non-conformities may only be detected at the time of delivery or may not be detected at all. Figure 2 shows the as-is scenario. The actors are: distributor, carrier, and receiver.

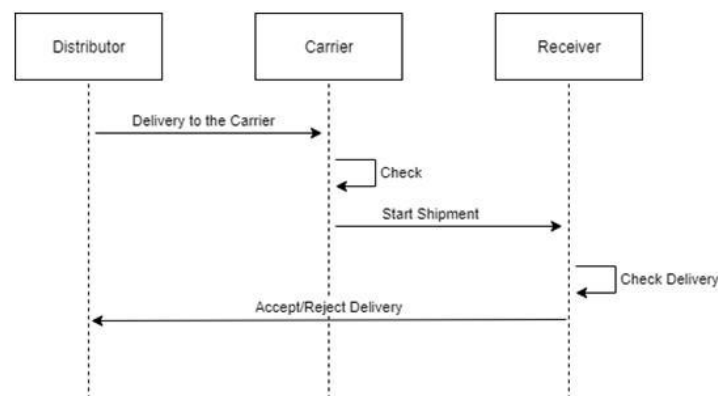

Figure 13. As-is scenario of drug shipment traceability

More in details, the distributor packages the drugs and delivers them to the carrier. The container is equipped with a data log that collects data on the status of the delivery (localisation, temperature). Before departure, the carrier checks the status of the truck's refrigerators to avoid nonconformities. Once delivered, the receiver verifies the accordance between the package, the purchase order, and the delivery note. He also checks the integrity of the package through the data recorded on the data log. In case of non-compliance, the shipment is refused. The combined use of an IOT sensor embedded in the container and a blockchain-

based logistics platform can enable a real-time monitoring of the shipment and allow to certify the responsibility of the actions. In Fig. 3, we present three different to-be scenarios, including a blockchain-based system, with and without temperature violations during the shipment. The main actors are: distributor, carrier, IOT sensor, blockchain-based logistics platform, and receiver.

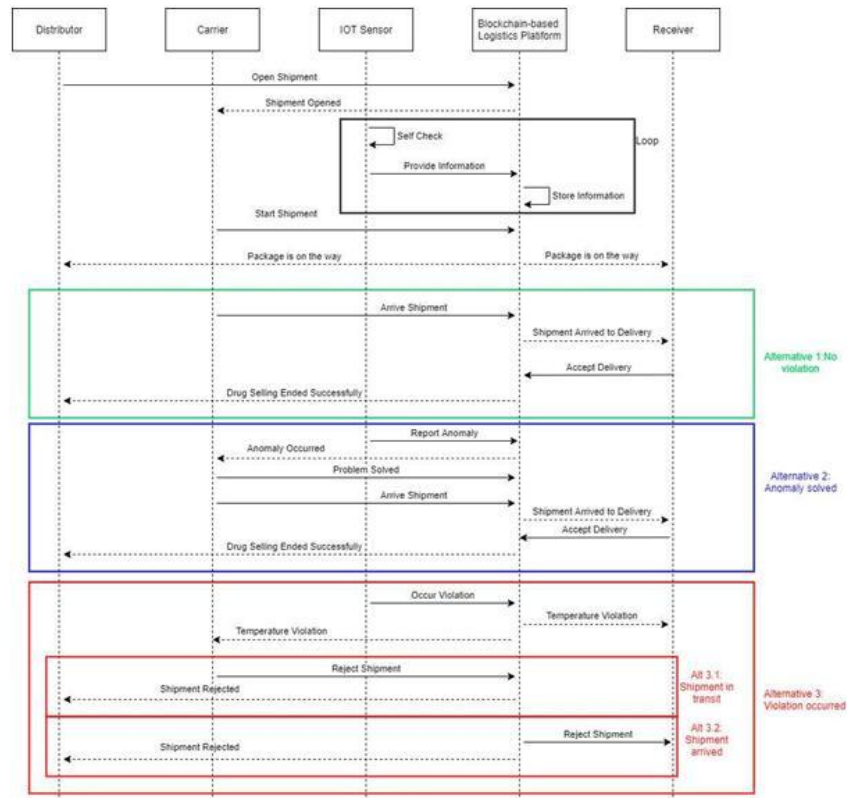

Figure 14. To-be scenarios of drug shipment traceability

Firstly, the distributor adds shipment information on the platform, including drugs to be delivered (e.g., type, lot number and expiration date, quantities, etc.), the place of departure and of delivery, the receiver, and shipment conditions (temperature, humidity, etc). Then, the IOT sensor starts to measure and record temperature and other parameters (geographic location, unexpected container opening, etc.) in real time and provides them to the platform, until the end of the ship. This enables to check whether the shipment conditions are in accordance

with the agreed terms during the transit of the container. At the same time, the carrier notifies to the platform the start of the shipment. If no violations have occurred (see alternative 1 in Figure 3), the shipment is accepted by the receiver. Alternatively, if any anomaly has occurred, the platform alerts the carrier, allowing him to solve the problem, before the arrival of the shipment (see alternative 2 in Figure 3). Finally, in case of any agreed parameters have been violated, the platform notifies the situation to the carrier or to the receiver (see alternatives 3.1 and 3.2 in Figure 3), and the shipment is aborted. In so doing, the system can allow the shipment to be stopped as soon as the violation occurs, without necessarily waiting for the end of the delivery.

### 3.2.2 Information sharing

The unavailability of medicines is a critical issue involving all actors in the pharmaceutical supply chain. This is aggravated by the current lack of information sharing on stock levels between them.

More in details, Figure 4 shows the as-is scenario with no information sharing between the actors upstream and downstream in the supply chain. In the first case, the main actors are: distributor, carrier, and receiver; while, in the second case, are central hub, carrier, and hospital ward.

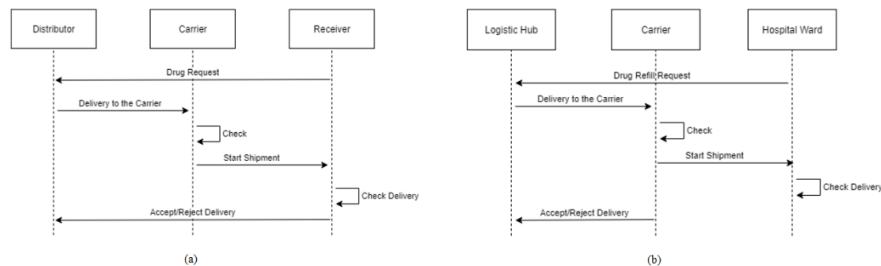

Figure 15. As-is scenario of drug information sharing

Once a PO or a RR is received, the package is prepared and delivered to the carrier, who will hand it over to the receiver (or hospital ward). At the end of the delivery, the receiver may accept or, in case of non-compliance, reject it. Up-to-date stock information are only used by the distributor or by the central hub to manage the warehouse and plan orders to the manufacturer.

The use of blockchain can enable the actors upstream and downstream in the supply chain to know the stock levels of products and their actual availability in

each area (regions or sub-regions), guaranteeing the privacy and anonymity of the information.

Figures 5 and 6 show the to-be scenarios, including a blockchain-based system, with information sharing between the actors upstream and downstream in the supply chain. The main actors are: manufacturers, distributors, central hubs, blockchain-based platform, hospital wards, and Drug Regulatory Authority.

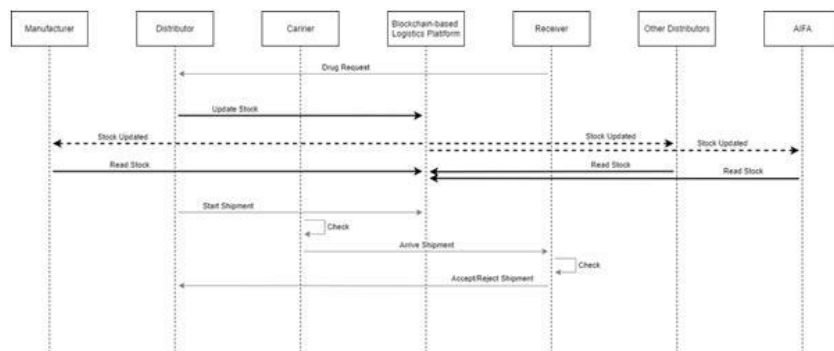

Figure 16. To-be scenario of drug information sharing among Supply Chain actors upstream

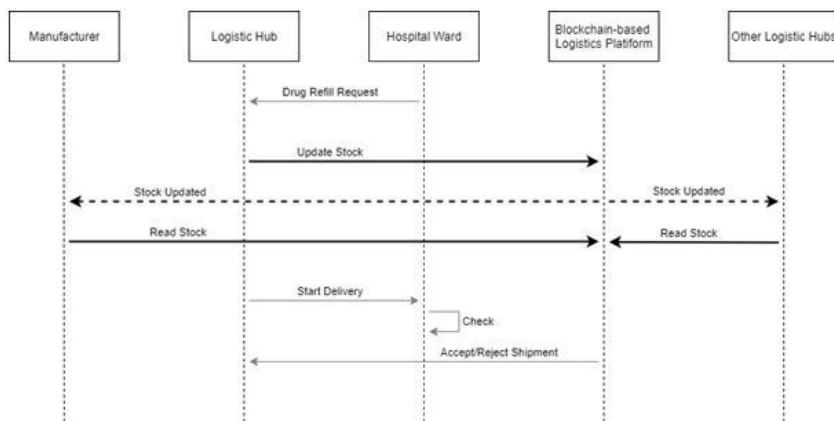

Figure 17. To-be scenario of drug information sharing among Supply Chain actors downstream

Once a PO or a RR is received, the package is prepared and delivered to the carrier. At the same time, stock updates are sent to the blockchain platform, which verifies that the required information are inserted on time by the

authorised actors. Then, such platform processes stock information, aggregated for example by geographical area, and shares it with the other actors in the supply chain. In so doing, as shown in Figure 5, upstream in the supply chain, both manufacturers and the drug regulatory authority can be able to see actual stock levels in the different areas, while distribution-side nodes can be able to see warehouse information (in terms of ID and distributor/logistic hub). On the contrary, as shown in Figure 6, downstream in the supply chain, central hubs can have visibility on the stock levels and on the availability of expiring drugs in the national territory. In this way, they can be able to better manage urgent situations or unexpected shortages. subsequently, as in the AS-IS scenario, the carrier delivers the package to the receiver/hospital ward, who verifies its quality and compliance with the order. In case of non-conformity, the delivery is refused.

### **3.3 Priority BPM capabilities**

The evidence obtained with the interviews highlights that 3 out of 5 capability clusters specified in the framework by Kerpedzhiev (2021) are of greater relevance in case of incremental BPI: Strategic Alignment, Governance, and Methods & Information Technology. Specifically, the first group of capabilities allowed to define the expected process improvements guaranteeing the lining up between the project goals and the aims of the involved organizations. These capabilities were particularly important in the process under analysis due to the high number and heterogeneity of the participating subjects (i.e., manufacturer, primary distributor, pharmacy, drug regulatory authority, etc.). Governance cluster capabilities led the actions of the project team during the process redesign activities through the definition of appropriate standards and guidelines. For example, the definition of privacy and cybersecurity guidelines prompted the devising of implementation logics of the blockchain-based system. Methods & Information Technology capabilities were also important, in particular for driving the most operative activities of the innovation implementation – e.g., specific requirements were identified for the integration of the existent IT systems with the new blockchain system since the presence of numerous different information systems.

The minor relevance of the two remaining clusters, People and Culture, appears to be related to the incremental nature of changes implemented, which are expected to slightly affect working practices and stakeholder relationships.

Analysing in detail each capability in the framework by Kerpedzhiev (2021), the preliminary results show that three capabilities – Process Portfolio Management, Process Data Governance, and Multi-Purpose Process Design – are of the greatest importance during the blockchain project under analysis. The Process Portfolio Management capability allowed to take into account effectively dependencies among inter and intra-organizational processes during the devising of the BPI. This element revealed to be crucial as the drug logistics process involves multiple functions and, most of all, several organizations which therefore imply the handling of many interactions. The evidence about Process Data Governance is related to both the process characteristics and the technology exploited. Indeed, the healthcare processes, and the drug logistics one is no exception, need to have very high reliability in the data produced and exploited. In parallel, blockchain-based systems can adequately meet this requirement but they require the definition of standards and guidelines for managing the process data, identifying the sources of data –for example in terms of actors – and the users of data. Multi-purpose process design capability revealed to be critical because it permitted to manage the process fragments in which the drug logistics process is divided and to obtain a unified process design, keeping into account the main decision points in the process and the operational needs of all subjects involved.

In addition to these three capabilities, the case study underlined a further essential element, the Process Risk Analysis. This capability, which appears to be quite overlooked by the framework of Kerpedzhiev (2021), was very useful because it allows to carry out an effective analysis of the main critical points for the correctness and cybersecurity of the data along the drug logistic process. The significance of Process Risk Analysis is linked to the nature of the blockchain technology, since it is usually employed to certify the correctness of the information, and the characteristics of the healthcare field, where the reliability of the information must be maximum given the potential serious side effects on patients.

#### **4 Discussion**

The project we analyzed exploited Blockchain to enable incremental BPI in the drug logistics process. The innovation did not require a significant process re-design. Indeed, the to-be processes show a re-design of the information flow only. Thus, the project intends to introduce Blockchain to enable new

functionalities (e.g. advanced traceability and information sharing) without entailing significant deep changes in the process flow.

In this regard, the risk assessment capability is of the utmost importance. This assessment should be carried out on the process events to figure out which data the Blockchain should certify to guarantee the requested performance, e.g., to assure that the right drug stocks are stored in the supply network or that the cold chain is not interrupted. Without this risk analysis, the selected event data may be less than necessary. This may jeopardize the achievement of the objective for which the Blockchain is developed. In other cases, the selected event data may be more than necessary. This may widen the scope of the Blockchain implementation, entailing additional unnecessary costs and managerial efforts.

The Process Portfolio Management capability is needed to prioritize the business processes to innovate. Indeed, the data that the Blockchain may certify are generated by different business sub-processes. These sub-processes should be correctly identified within the process portfolio according to the purpose of the Blockchain initiative. This process-driven approach is consistent with the well-acknowledged nature of the Information Systems implementation, which should be steered by process requirements and not by technological requirements (e.g., Arif et al., 2005).

The Process Data Governance capability should define standards and guidelines for data management. In particular, these standards should stress privacy and security aspects. Although Blockchain is largely proffered as a solution to privacy and security issues in information sharing, only a small set of blockchain platforms can actually cope with them (Zhang et al., 2019). These issues are even more felt in the Healthcare context because healthcare data include personal and private data that have to be correctly managed (Yüksel et al., 2017). Furthermore, for the Blockchain to work, information integration and interoperability among the stakeholders that participate in it must be guaranteed.

The Multi-purpose Process Design capability suggests leveraging process fragments to design business processes in a collaborative way (Kerpedzhiev et al., 2021). This is particularly relevant for healthcare ecosystems, in which business processes are often inter-organizational. In this context, the data that a Blockchain may certify are generated by several business processes. This certification may be conceived as a proxy business process built by means of different process fragments that are combined and integrated with each other by

the Blockchain. Without the Blockchain, it would be pretty challenging to reconstruct a single process instance referring to a unique process pattern.

## 5 Conclusions

This research aims at answering the following Research Question: "*What are the main BPM capabilities necessary to carry on Blockchain-driven Healthcare business process innovation?*". To do so, we developed two exploratory case studies in the healthcare industry. The cases investigated the re-design phase of the business process management lifecycle. This working paper presented the preliminary results from the first case. This case focused on the Blockchain-driven incremental innovation of the drug logistics process.

The results showed that the Process Portfolio Management, Process Data Governance, and Multi-purpose Process Design capabilities, defined in the BPM capability framework by Kerpedzhiev et al. (2021), should be prioritized over other BPM capabilities. In addition, we found that a new unprecedented capability, i.e., Process Risk Assessment, may be fundamental to enable Blockchain-enabled incremental BPI.

These outcomes may integrate the BPM research stream by responding to the call by Kerpedzhiev et al. (2021) to analyze which BPM capabilities may be relevant in specific contexts. In so doing, we did a first step in answering the call by Mendling et al. (2020), which stressed the need to combine typical BPM approaches and empirical field work to advance the understanding of context-specific factors in driving digital innovation. Furthermore, from a managerial perspective, our findings suggest prioritizing four specific BPM capabilities to conduct a Blockchain-driven incremental BPI initiative in the healthcare context.

However, this working paper is not free from limitations. First, it presents only the preliminary results of our research. Thus, further reflection on the outcomes is definitely needed. Second, the single case study may limit the external validity of our conclusions. Third, the detected capabilities cannot be interpreted as Critical Success Factors because we limited our inquiry to the re-design phase of the drug logistics process.

### Abstract

In the recent years, a new typology of innovation emerges in the global innovation literature: i.e., the Reverse Innovation. The term was introduced by Immelt, Govindarajan and Trimble (2009) to refer to innovations that are originated in emerging countries and later launched in advanced economies. This phenomenon has been mostly neglected by scholars and it misses a complete understanding of which are the potential drivers and obstacles. The aim of our work is to understand if and how cultural factors could impact the inversion of the flow, increasing or slowing the process. A cross-cultural approach to the Reverse Innovation is totally absent and could help scholars and managers in understanding how to implement it successfully, even in culturally distant context. The study focuses on two different types of barriers: cognitive - more relevant in the mature economies - and operational (in terms of infrastructure) - crucial in the emerging countries-. This theoretical paper presents six propositions, elaborated on the Hofstede's cultural dimensions of Power Distance, Individualism and Uncertainty Avoidance.

**Keywords** – Reverse Innovation; diffusion; process, cognitive barriers, operational barriers, culture; Hofstede

**Paper type** – Academic Research Paper

## 1 Introduction

Considering the uncertainty coming from the actual pandemic situation, the traditional innovation paradigms could change even faster than how we think. Thus, what if innovation comes from unexpected areas? Although innovation, in terms of product, service or process, is generally considered as costly, path dependent, and risky (Zanello, Fu, Mohnen, & Ventresca, 2016), nowadays it is no more a distinctive and exclusive feature of developed countries. Indeed, a new phenomenon is arising within the global innovation literature: Reverse Innovation (RI). The term was firstly introduced recently in 2009 by Immelt, Govindarajan and Trimble: while discussing about the GE handheld electrocardiogram device and the PC-based ultrasound machine, the authors proposed the term Reverse Innovation as “the opposite of the *glocalization* approach that many industrial goods manufacturers based in rich countries have employed for decades” (Immelt, Govindarajan, & Trimble, 2009, p. 3). According to the authors, indeed, the *glocalization* approach allows multinationals to create high performance product/service in and for their home market, and further spread them globally, adapting the innovation to the local context. By contrast, Reverse Innovation entails “creating fundamentally different products to meet the needs of people in these markets” (Govindarajan & Euchner, 2012, p. 13), without necessarily lowering the price. Surely, as the authors explain, affordability is a reality to face in emerging countries, since people will have a different purchasing power. Moreover, Reverse innovation, following an inverted flow of diffusion is not a necessity-driven strategy aimed at overcoming challenges and increasing competition, but rather it is a planned opportunity-based diffusion process. Thus, we consider the Reverse innovation as a process in contrast with the well-known Theory of the product life cycle Theory of Vernon, according to which firms flow internationally only in the third phase of the product’s life, i.e., the maturity (Vernon, 1966).

The focus on the emerging context as areas of origin for innovations is due to a change of perspective: nowadays, emerging economies have become the “hotbeds of innovation” (Petrick & Juntiwarakij, 2011, p. 24; Hadengue, de Marcellis-Warin, & Warin, 2017) in different sectors, from healthcare to transportation and “the new epicentre of global growth” (Shan & Khan, 2016, p. 1). This represents a serious challenge for western firms, to whom will be

demanding for a complete rethink of the innovative strategies (Petrick & Juntiwassarakij, 2011).

Although RI has several practical and empirical implications, the phenomenon, because of its newness, has not been deepened enough. In order to fill this gap, and provide useful insights, this theoretical paper adopts a cross-cultural approach, aimed to theoretically explore the role of national cultures in potentially inhibiting or incentivizing the diffusion of a Reverse Innovation by raising or lowering barriers to the process of moving an innovation from an emerging market to an advanced economy.

Specifically, our study focuses on two types of barriers that might be influenced by national cultural traits: (a) cognitive barriers, which may influence perceptions about Reverse Innovation and affect its diffusion; (b) operational barriers, which may either drive or inhibit initiative to promote RI diffusion. The first types of barriers may be particularly relevant in mature economies, since RIs from less advanced markets may be perceived as inferior and thus not easily accepted in some nations. The operational barriers, though, will be more impactful and challenging in the emerging, where lack of resources, infrastructure and entrepreneurial initiative could strongly discourage the inversion of the flow.

## **2 Literature review: the impact of culture on the traditional diffusion**

To the best of our knowledge, within the existing emerging literature of Reverse Innovation, it is completely missing a strand investigating the impact of culture (both in terms of national and organizational) on the inversion of the flow. Therefore, to fully understand this reversed flow, we referred to the established literature on the traditional diffusion process. The term “diffusion” expresses the process thanks to which innovations are used by different members of a social system over the time (Rogers, 2010; Zhang & Vorobeychik, 2019); while “innovation” indicate not only new technological product or service but also to “the spread of ideas and practises” (Zhang & Vorobeychik, 2019, p. 2)

Several studies have shown that, among different theoretical perspectives, such as those related to the nature of innovation (Rogers, 2010; Zanella, Fu, Mohnen, & Ventresca, 2016), relevant insights can come from institutional theory. This theory postulates that how an innovation diffuses in a market (Peres, Muller, & Mahajan, 2010) depends on three pillars, namely the cognitive pillar, the

regulatory pillar, and the normative pillar (Scott, 2007). The regulatory pillar, arising from economic studies, relies on sanctions and conformity, which act as guidelines. The normative pillar consists of organizational and individual behaviour model, which depends on what is socially expected for an institution. The third and last pillar is designed according to rules and beliefs at the individual level, that build the individual behaviour (Scott, 2007). Together, all these factors potentially influence the diffusion of an innovation, but the first pillar seems to be the most influential and relevant (Bruton, Ahlstrom, & Li, 2010). Indeed, scholars argued that cultural values deserve special attention for their role in the diffusion process (Takada & Jain, 1991; Zanello, Fu, Mohnen, & Ventresca, 2016; Yaveroglu & Donthu, 2002; He & Lee, 2020).

The previous mentioned scholars agreed on suggesting the extension of the classical diffusion models, such as the Bass model (Van den Bulte & Stremersch, 2004; Peres, Muller, & Mahajan, 2010) which studies the shape of the diffusion curve under certain starting conditions, or the agent-based model, which is essentially related to individual perceptions or user adoption behaviour (Desmarchelier & Fang, 2016; Zhang & Vorobeychik, 2019). Further, they argue that adopting a country-level perspective (Peres, Muller, & Mahajan, 2010; Desmarchelier & Fang, 2016) and including culture as an uncontrollable factor influencing innovation diffusion can expand our understanding of the phenomenon (Takada & Jain, 1991).

Scholars have focused specifically on various typology of cultural traits: some refers to cultural dimensions identified by Hofstede and have analysed how these traits are responsible for increasing or slowing the diffusion of innovation. Based on Hofstede's definition, we can define culture as "the collective programming of the mind that distinguishes the members of one group or category of people from others" (Hofstede, Hofstede, & Minkov, *Culture and organizations: software of the mind, intercultural cooperation and its importance for survival*, 2010, p. 6) and cultural dimensions as "an aspect of a culture that can be measured relative to other cultures" (Hofstede, 2011, p. 7). Others, for instance Takada et al. (1991), by means of Hall's concepts of high or low context, hypothesized and proved a country effect on the rate of adoption of consumer durable goods. According to the authors, in high context culture the rate of adoption is faster (Takada & Jain, 1991). Thus, several studies show how specific traits of national cultures affect the diffusion of innovation differently. For example, Dwyer (2005) shows how cultures that avoid uncertainty hinder the diffusion process of an innovation. In the same

vein, Tellis et al. (2003), Yaveroglu and Donthu (2002), and He and Lee (2020) show how uncertainty avoidance is negatively related to innovation diffusion in the early stage. In contrast with the previous, Desmarchelier and Fang (2016), in their simulations, demonstrate a positive influence of the uncertainty avoidance dimension on the cross-border diffusion rate of innovations. Further, Yaveroglu and Donthu (2002) and later He and Lee (2020) elaborate on this topic by investigating the role played by the dimensions of individualism and power distance on the early stage of innovation diffusion. Their results demonstrate that where there is high individualism and low power distance, there will be a high innovation rate (Yaveroglu & Donthu, 2002). Adopting a different approach, He and Lee (2020) explore how individualism and power distance impact on the speed of diffusion in the early stage: the first dimension is positively related, while the second is negatively related. In agreement with Van den Bulte and Stremersch (2004), individualism is shown to have a positive effect, while power distance a negative effect. In fact, the measures of individualism are also found to be correlated with the national innovation rate by Taylor and Wilson (2012). The authors, nonetheless, pointed out that different types of collectivism, such as patriotism, could enhance the innovation rate at national level "when it encourages society-wide efforts to develop scientific and technological solutions to national problems" (Taylor & Wilson, 2012, p. 245). According to Yaveroglu (2002), however uncertainty avoidance and power distance will both have a positive relationship in the post-initial stage of diffusion.

While the majority of scholars agree on the positive effect on individualism, Desmarchelier and Fang (2016) found out a negative influence of the dimension on the cross-border diffusion rate of innovations.

As showed above, although hugely discussed, different results are discussed in the extant literature: particularly, the most ambiguous dimension seems to be the uncertainty avoidance, which represent a challenge also in other strand of the literature. Nevertheless, these studies on the interaction between culture and innovation diffusion are entirely focused on the usual/traditional diffusion flows, where innovation starts in mature markets and then moves to the emerging. Meanwhile, studies aimed at exploring how culture can influence the diffusion of Reverse Innovation are still very few, generally the literature is still fragmented and almost based on anecdotal evidence (von Zedtwitz, Corsi, Sørberg, & Frega, 2015) and success stories (Hadengue, de Marcellis-Warin, & Warin, 2017). The cross-cultural approach to Reverse innovation is completely missing.

### **3 Methodology**

In order to theoretically explore how national culture affects the inversion of the flow in the diffusion process, we adopt a cross-cultural point of view, whose purpose is to empathize to which extent the Hofstede's dimensions of Power Distance, Uncertainty avoidance and Individualism could increase or lower the cognitive or operational barriers.

As mentioned before, generally the literature on Reverse Innovation is quite poor and there are just few researches studying the cultural effect on the inversion. Therefore, to reach our goal and to answer to our research question, we rely on the diffusion innovation literature to derive some theoretical propositions. We adopt a deductive reasoning, that starting from the existing literature allows us to build six propositions.

#### **3.1 The propositions**

We leverage the Hofstede's model (particularly the first three dimensions discussed above) to advance specific propositions concerning the cultural traits that can foster and discourage the acceptance of a Reverse Innovation. Firstly, we discuss how cognitive barriers could impact in the advanced economies; meaning how culture shapes the acceptance of these innovation in the host markets. Secondly, we examine the extent by which operational barriers work in the emerging economies, considering the Hofstede's dimensions as factors affecting the emergence of entrepreneurial initiative.

Regarding the Individualism dimension, main scholars agree on having a positive effect on the traditional diffusion (He & Lee, 2020; Yaveroglu & Donthu, 2002; Van den Bulte & Stremersch, 2004; Taylor & Wilson, 2012). However, the Individualism dimension, while boosting for personal creativity and promoting the generation of new ideas (Shane, 1993; Tian, Deng, Zhang, & Salmador, 2018), concerns mostly the individual and the personal achievement. Therefore, our first proposition states:

- P1: Advanced countries with high IDV will have a lower acceptance of RIs.

According to Hofstede, "high Power Distance nations are more autocratic, and individuals are more willing to accept differences in power and wealth" (Rinne, Steel, & Fairweather, 2012, p. 96). In the diffusion innovation literature, this dimension is found to have a negative relation: indeed, in high Power Distance

cultures, people feel superior to others and tend to reject opinions or suggestion from the outside. Our second proposition states:

- P2: Advanced countries with high PD will have lower acceptance of RIs.

The third and last dimension is Uncertainty avoidance, for which diverse results are reached in the diffusion innovation literature. Some authors prove a negative effect (Dwyer, Mesak, & Hsu, 2005; Tellis, Stremersch, & Yin, 2003; Yaveroglu & Donthu, 2002; He & Lee, 2020); while others a positive (Desmarchelier & Fang, 2016). In our opinion, within high uncertainty avoidance context, people will easily feel anxious about innovations' origins and quality. Thus, we formulate as follow the third proposition:

- P3: Advanced countries with high UA will have lower acceptance of RIs.

Thereafter, we consider operational barriers which may be relevant in emerging countries where innovations take advantage of less efficient infrastructures and resources. Thus, culture may play a relevant role in stimulating the entrepreneurial initiative to support the diffusion process or, on the contrary, in preventing the start of these initiatives. Accordingly, based on the Hofstede's model and on the innovation diffusion literature, we formulate three propositions for each cultural dimension considered.

Firstly, we assume that individualism push people to be free (Rinne, Steel, & Fairweather, 2012) and encourage the innovative initiative. Hence, our fourth proposition affirms:

- P4: Emerging countries with high IDV are more likely to spread RIs.

Regarding Power Distance, the typical strict hierarchy could hinder the diffusion. Consequently, we formulate the fifth proposition as follow:

- P5: Emerging countries with high PD are less likely to diffuse RIs.

Lastly, we focus on the Uncertainty avoidance: despite innovations represent always important challenges, launching an innovation from an emerging to an advanced economy represents an even more risky choice, due to all the potential conflict of rejection, the negative country of origin effect or even market share issues. Based on these assumptions, our last proposition is the following:

- P6: Emerging countries with high UA are more likely to inhibit the diffusion of RIs.

## 4 Conclusions and implications

One of the main issues concerning a Reverse Innovation is how it is perceived in the advanced markets: usually, people from the west are quite sceptical towards innovations coming from less advanced context, specially within the healthcare sector. This is due probably to the prejudice of emerging context having less capabilities and less resources, which brings people to think of dealing with second-rate products. Although the resources are still fewer if compared to the wealth of the advanced economies, their capabilities are quickly growing, challenging the advanced multinationals and firms. Indeed, innovations coming from the emerging context are not necessarily low-quality standard. Moreover, in this scenario, culture play an important role in shaping people perceptions and in facilitating the inversion of the flow.

This theoretical paper is intended to provide a starting point for future academic empirical study, and effectively test the elaborated propositions. This research aims to offer scholars and managers a conceptual framework to better understand how Reverse Innovation spreads across culturally distant countries.

In line with our goals, this work presents interesting implications from the theoretical point of view, enriching the fragmented literature related to Reverse Innovation and practical implications stemming from the possibility to successfully implement a Reverse Innovation. Concerning the latter, if innovations are coming from the emerging context and are also able to spread globally, there will be an increase in the innovations flowing around, with an expansion of the effective number of innovations working.

### **Abstract**

Experiences of cultural heritage and tourism have been enhanced by the development of digital technologies. In light of this, this paper focuses on the importance of immersive storytelling experiences to encourage visitors' engagement through VR and the evocative and emotional storytelling of events and contexts.

After an introduction to the best practices from Italy and abroad in recent years, the paper focuses on the VR immersive storytelling of the 1693 earthquake, which destroyed 70 cities in south-eastern Sicily. The survivors, revealing great resilience, soon rebuilt their cities. The well-known Baroque city of Noto, a UNESCO site since 2002, was rebuilt on another site, so abandoning the destroyed one (Noto Antica).

Through an immersive film in VR (25 min.), commissioned by the Noto Municipality, the last moments of the city are recounted, creating a "digital bridge" between generations to regain awareness of their ancient roots. The VR project stands out for its participatory production process involving a commission of experts and 3D casting of its modern citizens, and the tragic nature of the event, recounted through the emotional and evocative account of a recent earthquake and the solution adopted following the COVI-19 pandemic (in situ, on YouTube VR and Vimeo).

**Keywords** – Digital Storytelling, Virtual Reality Experience, Immersive Storytelling, Digital ethnoanthropology, 3D Historic Environmental reconstruction

**Paper type** – Practical Paper

## 1 Introduction

The diffusion of new technologies has given rise to the spread of information and improvement in quality as well as evolving the way people enjoy museums, culture and cities, by enhancing their experience, also in a mobile way (Ciasullo et al., 2016; Fernandez Vaz et al., 2018; Liang et al., 2017).

New technologies, which range from social media (Hays et al., 2013; Lund et al., 2018) to digital participatory platforms (Bonacini and Giaccone, 2018; Nisi et al., 2015) and serious games (Paliokas and Sylaiou, 2016; Sánchez Mateos 2018; Paliokas 2019; Bonacini and Giaccone, 2021) to virtual reality (VR) and to augmented reality (AR) technology (Atembe, 2015; Huang et al., 2016; Pietroni, 2012; Tussyadiah et al., 2018), are improving both cultural and tourist strategies and people's enjoyment of cultural opportunities such as museums, archaeological sites and art collections and, in general, culture. As they have created new cultural experiences for end-users enhancing their emotional aspect, they have become considered as a marketing tool for tourism (Huang et al., 2016; Li and Chen 2019).

AR and VR applications and experiences are among the most popular and innovative audience engagement solutions and their use has recently increased. Within the context of cultural and tourist attractions, organizations are searching for new ways to exploit the potential of these technologies to enhance the visitor's experience from home or in situ. While scholars are investigating how virtual and augmented installations are enhancing visitors' experiences and the impact they have on them (Errichello et al., 2019; Fernandez Vaz et al., 2018; Hopf et al., 2020; Tanasi, 2017), the COVI-19 pandemic has brought about incredible advances in the development of VR in the simulation of real-life experiences (Sarkady, Neuburger and Egger, 2021).

Within this framework, story-based narratives provide experiences which let users understand both cultural heritage and history thanks to more stimulating cognitive and emotional processes (Gabellone et al., 2017; Gabellone, 2020; Jung et al., 2016; Tussyadiah, Jung and tom Dieck, 2017; Tussyadiah et al., 2018). Digital storytelling has therefore been considered very useful in the enhancement and fruition of a cultural heritage and visitors' engagement (Alexander, 2017; Bonacini, 2020; Handler Miller, 2020; Schoenau et al. 2015).

In the light of this consideration, this paper focuses on the importance of VR storytelling experiences in Italy and abroad, to encourage visitors' engagement

not only through VR reconstructions (such as those tourism experiences literally exploited following the COVI-19 pandemic) but also on the evocative and emotional storytelling of events and contexts. In particular, after presenting some best practices (which have been extensively discussed in Bonacini 2020: 176-216), this paper focuses on the VR immersive storytelling movie of the 1693 earthquake in the Southern part of Sicily, focusing on Noto's last moments.

## 2 VR immersive storytelling

If the archaeological field is where scholars have demonstrated the greatest skills and competences in virtual reconstructions [by applying the *London Charter* (2006-2009) and the *Seville Charter* (2012) principles, regarding the application of scientific, transparent and verifiable methodologies], we agree with Gabellone's *active immersion* definition, achieved with VR viewers who are able to enter the virtualized environment in which the realism and the almost physical interaction with the 3D elements produces a natural and direct understanding of the architectural, figurative and spatial elements (2020: 125).

Many projects of immersive experiences can be cited, all dated to 2017, such as the *Domus Aurea Experience* in Rome; the *Jheronimus Bosch e Venezia* exhibition; *Nuragica* in Sassari. All these are strictly VR immersive experiences, but without a true, more involving storytelling, employing characters and/or narrating voices.

In recent years, in fact, increasing interest has brought about the creation of a real *immersive storytelling*, not limited to 3D reconstructions and music, but with a real script for digital characters with narrating voices. According to scholars, an immersive storytelling could be defined as:

*"Digital storytelling type based on a blurring of borders between fiction and reality. The putting into narrative is operated continuously and puts the user in a particular situation, in which the difference between the story told and the experienced reality becomes more and more tenuous. The narrative universe defines the experience in which the user is immersed"* (Brouillard, Loucopoulos, Dierickx, 2015: 37).

The descriptive style in a story, as Pietroni states, is less emotionally impactful than the narrative one; the storytelling itself, thanks to evocation and dramatization, has an enormously greater impact than description, able to *"create an emotional involvement and an expectation in the visitors, that throw a bridge between past and present"* (2019: 22).

This is the reason why we are going to describe some of the most important immersive storytelling experiences, useful to introduce the Noto VR movie.

## **2.1 An overview on immersive storytelling experiences**

Some projects deserve to be mentioned for their quality as benchmarks in the defined framework, based on mixing different techniques, such as traditional and stereoscopic filming, three-dimensional reconstructions, computer graphics, digital character animation.

### *2.1.1 Italian best practices*

The very first examples are those of *Apa* (2012) and *Ati* (2014) immersive storytelling projects (Guidazzoli, Liguori, Delli Ponti, 2012; Guidazzoli et al., 2014). Produced by the CNR of Rome, they are stereoscopic 3D movies, made in a cartoonish computer graphic style to connect, through immersive storytelling, the history of Northern Etruria (Bologna) with the Southern part of the region (Rome).

*Siracusa 3D reborn* (2013), realized in order to create a tourist attraction with a solid scientific base and a real tool for education and awareness for Syracusan citizens (Gabellone, Tanasi, Ferrari, 2014; Tanasi, 2017), and *Pompeii 3D Movie. A buried story* (2015), a real stereoscopic docudrama in full HD, on the last day of the Roman city (Gabellone 2020: 130-131), are stereoscopic documentaries in computer graphics created by a team of scholars, from Lecce-Catania CNR and other research centers. In *Pompeii 3D Movie*, the alternation of two external voices, one fictional, more narrative and evocative, one in a more documentary style, describe both the personal story of Abano, owner of the Villa dei Misteri, and the 3D urban archaeological landscape of Pompeii. Finally, the rain of pumice, ash and lapilli, covering everything, seems to pour directly on the user, creating the immersive experience. This human-centered narrative, in which Pompeii is just the background, offers an engaging experience in which the audience relates emotionally to the protagonist.

The narrative choice, featured in the immersive storytelling project *MARta Racconta. Storie Virtuali di tesori nascosti* (2013) created by the Lecce-Catania CNR for the Archaeological National Museum of Taranto (Giannotta, Gabellone, Dell'Aglio, 2014; Gabellone 2020: 193-205) alternates an evocative with a documentarist voice. The computer graphics animation makes use of modern urban landscape images while showcasing the Museum's precious exhibits.

The alternation of different narrative voices obtains the effect of a sort of emotional suspension in the user's direct engagement, which increases the suspense of the story itself.

The *Palazzo San Teodoro Experience* (2015), created by AppTripper, offers the visitor the opportunity to enjoy informative and narrative content, with 3D reconstructions of the 1700s architectural landscape, in the Naples so admired by the Grand Tour travellers and described by Alexander Dumas's voiceover (Errichello et al., 2019).

*L'Ara com'era project* (2016), created for Zetema by ETT Solutions, aimed at making the Mausoleum of Augustus accessible, by restoring in AR the original colours of the reliefs and offering a VR storytelling in Augustan times, carried out in a mix of live footage and 3D computer graphics reconstructions (Trunfio, Campana and Magnelli, 2020).

Since mid-2017, the *Teatro della Scala Virtual Experience* offers visitors a first-person immersive storytelling, in which the prima ballerina Nicoletta Manni lets the user discover the secret places behind the scenes of the Theater.

*Apud Cannas* (2017) is an immersive stereoscopic movie on the Battle of Canne in 216 BC, a real example of a cultural and scientific product becoming pure cinematography, thanks to stereoscopy and massive character computer animation (40,000 characters), in a real historical 3D re-enactment (Gabellone et al., 2017; Gabellone 2020: 181-191).

As a final example of mixed reality there is *Circo Maximo Experience* (2019), created for Zetema by GSNET Italia/Inglobe, which tells the story of the Circus in all its phases, up to the emotions aroused by the VR storytelling experience "A day at the Circus", by AppTripper, thanks to which the user becomes a witness of a chariot competition, perfectly rebuilt in computer graphics. The story is developed through a real script played by professional actors.

### 2.1.2 Best practices from abroad

In 2017, in collaboration with Samsung, the Museo Arqueológico Nacional in Madrid launched *Vive el Pasado*, an immersive digital animated virtual tour through Spanish history and the museum's collections, accompanied by an archaeologist as the digital storyteller (Sánchez Mateos 2018: 342).

For the *Modigliani exhibition* (2017-2018) the Tate Modern in London offered the *Modigliani VR - The Ocher Atelier* experience, a behind-the-scenes project in which the artist's last studio in Paris was recreated, through a meticulous 3D

reconstruction of the real apartment in all its details. Storytelling was an essential component: an external voiceover introduced the visitor, who personally met other protagonists in his life.

*Slav Epic VR* (2019-2020) at the National Palace Museum in Taiwan highlighted how useful immersive technologies can be in making works not currently on display accessible. Indeed, this is precisely the case of the immersive experience inside the epic narrative of *Slovanská epopej*, a cycle of 20 large canvases painted by the Czech Art Nouveau painter Alfons Mucha between 1910 and 1928, which have not been on display since 2016.

Another immersive digital storytelling experience of the highest quality within a painting is *Mona Lisa: Beyond the Glass*, within the *Leonardo da Vinci* exhibition (2019-2020). The immersive storytelling penetrates directly into the painting, transforming the experience into a *tête à tête avec la Joconde*, created to replace the real painting in the Louvre Museum. The story aims to reveal the woman's identity, her social status and additional details otherwise difficult to perceive (Rea 2019).

Finally, immersive storytelling productions, made both in computer graphics, virtual reconstructions and green screen filming, have new horizons to explore in the cultural, theatrical and cinematographic fields, as demonstrated by two projects, carried out by Dublin Trinity College: the stereoscopic VR movie *Faoladh* (2018), produced in collaboration with Google VR and TileFilms, revolving around the mythical repertoire of Irish stories, such as the werewolf Faoladh; *Virtual Play* (2019), a VR theatrical performance reinterpreting *Play* by Samuel Beckett with the virtual reproduction of real actors in action (vologram).

### **3 Noto. The day of fear (1693)**

#### **3.1 The historical contest: the 1693 earthquake**

On January 11th 1693 the *Val di Noto* region, in the South-east of Sicily, was struck by a major earthquake, around 20:30/21:00 local time (corresponding with today's 1.30 pm): according to the National Institute of Vulcanology (INGV) it had a maximum intensity of 11 on the Mercalli scale. The earthquake had been foretold by another strong shock on the 9th and by one on the 11th in the morning (corresponding with today's 9.30 am). Significant damage was reported everywhere but the 1.30 pm shock was devastating: nearly 70 urban centers were

partially or entirely destroyed and about 60,000 people died. Catania, the largest city, was the most seriously hit, losing 16,000 citizens out of an estimated population of 20,000. Among the destroyed cities, Noto Antica was seriously damaged, and after years of discussing where to rebuild the city, they decided to build a new town, abandoning Noto Antica. Following this event, the new city was founded, and new houses, palaces, churches and monasteries were built in a Late Baroque style. All 9 Late Baroque towns of Sicily, built after 1693, were included in the UNESCO WHL in 2005.

Few are the remains of the abandoned site of Noto Antica and little is known of its buildings: it was a late-medieval city, important from the Norman age and under subsequent dominations. In 1693, it was a rich city, embellished with numerous noble palaces, 56 churches, 11 convents and 8 monasteries; it was surrounded by walls and dominated by an imposing Castle, inhabited by over 12,000 inhabitants. Noto suffered 2,000 deaths, but between hunger, famine and pestilence after the earthquake, its population was soon reduced to 6,000 inhabitants. Today portions of the castle are visible, with the church of San Michele, and of the walls not to mention the desolating remains of churches and palaces which is why it has been called the "Sicilian Pompeii".

### ***3.2 The participatory production process and the ethnoanthropological 3D citizens reconstruction***

The project, assigned to AppTripper by the Municipality of Noto, was born from the idea of recreating the last moments of Noto Antica, seen through the eyes of the protagonists and based on historical and scientific references.

An important aspect of the project was that it should involve the participation of both the local scientific heritage community and Noto's living heritage community, in keeping with the Faro Convention.

A committee of experts was, in fact, established, including local historians and architects from the University of Palermo, volcanologists from INGV, archaeologists from the Superintendency of Syracuse and other experts in the field of fashion, costumes and furniture of the time. First the editorial project (a real research and pre-production book) was shared with the committee, then the screenplay, thus ensuring participation in the review and selection process of scenes to be digitally recreated (fig.1). They contributed also in providing data, scientific references, comparisons, each for their field (architecture, furniture, the

fashion of the time, reconstructions of ancient landscapes, music, even the majolica tiles on the floors and the pictures and weapons hanging on the walls) in order to guarantee the philological adherence for both the digital reconstruction of the urban landscape and the one of the citizens, from an historical and ethnoanthropological point of view.

The 3D modelling of some digital characters, through the rendering of the true faces of the citizens of today's Noto, was made through a "digital casting" of 130 volunteers (fig.2). There was a selection and digital reproduction of 30 people's faces, who can recognize themselves in those of the Captain of Justice, the Mayor, the Jesuit, the Prisoner (figg.3-4) or other characters from the crowd.

### **3.3 The VR immersive movie**

From a technical point of view, Unity3D engine with a real-time technology compatible with Oculus platform was used for the VR fruition; the content was created with animations, storytelling and visuals produced in FULL CGI 3D, with a 360° viewing angle.

The high performance visualization can scale up to 4K resolution, providing stronger levels of engagement. For less powerful and more user-friendly devices, converted and optimized versions of the movie are available, which are not immersive but can also work on smartphones, as long as they are equipped with an accelerometer and gyroscope (users can explore the scene even without the viewer).

The use of 3D advanced techniques, such as sculpting, mapping and matte painting, made it possible to obtain realistic and academically comprehensive results, while preserving their integration within the limits of mobile and wearable technology, thanks to an almost constant process of optimization.

In the texturing phase, all the urban and architectural elements have been reconstructed with a precise and evident note of general degradation (the city suffered much damage from the previous shocks), mixed with poor chromatic tones to simulate a veil of decadence, a suspension of the drama that is bearing down on people, buildings and objects.

With this approach, the user can see some structures, already damaged before the moment of the earthquake, in a general scenario documenting a widespread precariousness.

Furthermore, the use of mixed cinematographic techniques (depth fogging, particle dynamics, colour correction, light painting) has therefore made it possible to generate a kind of “virtual fresco” for each environment.

The result is 25 min. of an immersive movie, divided into a few scenes: the introduction starts in the dust (fig.5), capturing an already damaged city; the Captain of Justice in his house, almost impassive, while having lunch (fig.6); a meeting between the city authorities, inside the Church of San Michele, to whom the Mayor reads their agreed decision after the 9.30 shock (fig.7); a prisoner who sings a popular song, recalling when he was travelling by sea; a scene in which citizens try to convince the Carmelite friars to carry the Madonna’s statue out in a procession to obtain her intercession (fig.8); a terrible sermon by an old Jesuit, who announces a catastrophe in the style of Girolamo Savonarola (fig.9). Finally, the terrible 13.30 shock overwhelms everything and everyone, nullifying the history of the city and enveloping everything in dust, while a copy of the Laocon’s sculpture stands out, almost in a last desperate cry and proof of resilience (fig.10).

Special attention needs to be dedicated to the characters. In the movie, as described, after a digital casting selection, 20 people were selected and digitally replicated in 20 3D characters, who all have a real-life counterpart. Thanks to visual references and photos, the 3d models were rebuilt and painted with different techniques. The resulting character is thus far more realistic; the authors wanted to enhance the historical protagonists of the earthquake era with traits of real people (instead of procedurally generated by computer). This process is evocative of the underlying concept of the narrative: the resilience that overcomes the drama and events and emerges from the ruins of the centuries. Thanks to 3D technologies, it was therefore possible to faithfully reconstruct the faces and somatic features of the characters, who were then associated with really existing people, with their social rules, dressed in keeping with XVII century fashion, as agreed by the scientific committee, in order to obtain convincing, charismatic figures, endowed with complexity and personality.

In parallel, in the case of the Mayor, the Prisoner and the Jesuit, voice actors were also involved: the three mentioned characters were also able to express themselves vocally, thanks to facial animation and lipsync techniques (a particular type of animation by which the digital character imitates the movements of the lips and gives the impression of speaking and articulating sentences).

An external storyteller introduces the story in some scenes.

For many characters, motion capture integration (the reproduction of body movements achieved through the capture of real actors) was also used, so as to create the sensation of being in front of extremely more credible acting characters, increasing the emotional involvement and texture of the scenes in terms of storytelling and acting.

Some technical expedients used during the earthquake representation merit description. The use of light and the strong chromatic degradation convey the distressing narrative of the event. In accordance with scientific data, the animation of the earthquake and vibrations were carried out following two main techniques: creating an irregular deviation on the jolting plane and on the undulatory axis which was both continuous and unpredictable and the violence on collapse, which can be conveyed by the range of oscillation in all directions. A feeling of devastation, but at the same time of inexorability and the impossibility of escape, was therefore recreated. The computation of the collision, obtained by simulation, largely mimics seismic events though often an artistic intervention was necessary to enhance the experience, preventing buildings from collapsing in unison); the story of the earthquake becomes the protagonist with its own chromatic vestige, with its own visual unity, with a sequence that puts poor, unarmed humanity in the background, a victim in front of the monster so letting the event take over and overwhelm the viewer

#### **4 Conclusion**

In line with modern learning dynamics, the contemporary historical 3D re-enactment, which represents the final moment of a philological study, is presented to entice the visitor to know, to read, to study the same sources which inspire the reenactment (Gabellone 2020: 182-183).

In *Noto: The Day of Fear (1693)*, the last moments of the city are told, creating a "digital bridge" between generations to regain awareness of their ancient roots and the heritage communities which they all represent. The VR project is in fact remarkable for its participatory production process, involving local experts and citizens in rebuilding the last moment of Noto, and because it is the very first VR immersive movie telling, from an emotional and evocative storytelling, of a recent human tragedy, such as an earthquake.

The authors are sure that this is a new frontier of immersive and evocative storytelling. Thus it is possible to digitally reconnect distant generations with each

other, not only through the storytelling itself, but also by allowing a sort of digital transition of historical memory through digital characters.

### Abstract

Digital transformation creates opportunities through new digital technologies, but it also pressures organizations to change the working environment. Research from the last few decades has empirically documented resistance by individuals when organizations are changed. Surprisingly, far less has been reported about individuals resisting change in the context of digital transformation.

Using the Web of Science database, we conducted a structured literature review and identified that there is indeed a staggering amount of published research addressing digital transformation and resistance to change, separately. However, research that addresses these issues in combination is very limited. Therefore, this study aimed to provide a foundation for both future research and for practice concerning individual-level impediments within digital transformation processes and how these processes can be managed.

Our search method found 365 articles, which were further analysed using bibliographic methods. Subsequently, 20 relevant articles were identified, and a content analysis was performed. The meticulous analysis of extant literature revealed a strong emphasis on managerial issues within the transformation process. Remarkably, very few articles explicitly

focus on employees and rather address the influence of management over the employees when attempting to pursue digital transformation processes.

This study identified six managerial factors that link the individual level to the organizational level in digital transformation processes: beliefs and mindsets, preparedness and strategy framework, culture, competencies, communication, and management. The core articles explain how all these factors affect the resistance to change by individuals. Additionally, we offer a conceptual model providing a foundation for further theory development and guidance for practitioners aiming for a more agile digital transformation.

**Keywords** – Digital Transformation, Resistance to Change, Digitalization, Change Management, Structured Literature Review

**Paper type** – Academic Research Paper

## 1 Introduction

Digital transformation is a hot topic for researchers and practitioners alike (Sainger, 2018). A quick search on Google Scholar with the search text “digital transformation” yields a staggering 3.5 million hits. Since 2020, more than 60,000 articles have been published, thus indicating an overwhelming interest in the topic.

However, despite huge interest and the provision of new strategic opportunities through digital technologies, McKinsey (2016) has found that 70% of organizations going through a digital transformation process fail. Extant research also highlights the complexity of comprehensive digital transformation processes as they involve the transformation of many organizational dimensions, client interactions and business model innovations (Svadberg, Holand, & Breunig, 2019). Moreover, there are several overlapping terms in use (e.g., digitization, digitalization and digital transformation). Digital transformation is the most overarching term used, and digital transformation processes pressure organizations and leaders to change the organizational structure as well as the working environment in organizations to yield benefits from the adaptation of these technologies (Frick, Mirbabaie, Stieglitz, & Salomon, 2021). Furthermore, the transformation has both positive and negative impacts, thus making it more challenging to predict outcomes from the change process (Smith, 2018).

Change processes involve individuals in the organization (Coch & French Jr, 1994). However, little has been empirically documented to demonstrate how

individuals react to a digital transformation process in particular. This is puzzling, since a fundamental theme within the change management literature emphasizes an individual's resistance to change. Theories on resistance to change have developed over many years, and early sources document the resistance of Luddites to the technological adaptations of the early industrial age (Brynjolfsson & McAfee, 2016). The body of literature encompassing resistance to change related to technology adaptation amounts to an overwhelming 131,000 contributions. Nevertheless, to date, the relationship between an individual's resistance explicitly towards digital transformation processes has been less empirically documented.

Therefore, this study aimed to provide a foundation upon which a link between extant research on digital transformation and resistance to change can be established. In particular, we sought to identify extant research related to the individual level, as changes in the working practices of employees are a consequence of digital transformation endeavours. To provide this foundation, a structured literature review aided by bibliometric analysis was conducted to identify core articles upon which a content analysis could be performed in order to explore the following research question: *How can a structured literature review utilizing bibliometric analysis of current published scientific research contribute to identify and reduce individual-level impediments to digital transformation?*

Our structured literature review revealed that individual-level impediments to digital transformation are documented to a limited extent in extant research. Still, our search yielded 365 articles, which were subsequently reduced to a core canon of 20 articles providing a foundation for the improved understanding of an individual's reaction to digital transformation processes. Additionally, a structured overview of the existing literature addressing individual-level impediments to digital transformation processes is presented. Our analysis demonstrates that digital transformation affects individuals in the organization, including both managers and employees. Moreover, this study identified six managerial factors affecting an employee's response to digital transformation processes, and these factors function as a foundation upon which further theorization and guidelines for practitioners can be built. Furthermore, the relationships between the identified factors relating individual-level resistance to change and digital transformation processes are illustrated.

## 2 Theory

Since the literature addressing digital transformation and resistance to change is less integrated than anticipated, we will address these two topics by emphasizing how they have been treated at the individual level.

### 2.1 Digital transformation

Digital transformation concerns people and their adoption of digital technologies brought to an organization's business model, offerings, organizational structure and processes (Bloomberg, 2018). Vial (2019) has defined digital transformation as *"a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies"* (p. 121). This involves transformation of their key business operations, organizational structures, products and processes. The effects of the intended transformation can be observed at both the organizational level (Gregory, Keil, Muntermann, & Mähring, 2015) and the individual level (Lee, Sambamurthy, Lim, & Wei, 2015).

These types of complex transformations need strong management practices in order for them to be implemented in the organizations (Abdelaal, Khater, & Zaki, 2019). Therefore, management has to find ways to innovate with the new and emerging digital technologies, and strategies that embrace the use of digital transformation will have an increased likelihood of better operational performance (Hess, Matt, Benlian, & Wiesböck, 2016). In order for digital transformation to be successful, organizations have to take into consideration all factors that can set back or delay implementation of the process. By doing this, organizations can remain competitive, have operational efficiency and obtain improved organizational performance (Vial, 2019). Thus, it is assumed that a successful digital transformation process is linked to the organization's strategy, which shapes how the process is coordinated and prioritizes when digital technology is implemented through an integrated process (Hess, Matt, Benlian, & Wiesböck, 2016).

McAfee and Brynjolfsson (2016) have emphasized the importance of individuals within these strategic transformation processes. Moreover, they have highlighted that organizations should have employees with special competence in their field, acquired understanding and the ability to solve problems with high complexity (Hernaes, 2020). When routine tasks are automated, there is a greater need for

creativity and problem-solving competence, especially among managers (Schwarzmüller, Brosi, Duman, & Welp, 2018). New skills in analytics, design and technology as well as the identification of new roles that are more diverse and adaptive have been suggested as vital for success with digital transformation (Bughin, Catlin, Hirt, & Willmott, 2018). Kompas (2010) has stated that employees with high commitment will work passionately and provide maximum creativity so that they can ensure good performance of the organization. The importance of teamwork is also increased in such a transformation, since *"knowledge as a resource can only be developed and advanced together"* (p. 126); thus, these two elements are a prerequisite for digital transformation for individuals (Schwarzmüller, Brosi, Duman, & Welp, 2018). Additionally, research has documented how structural changes affect individuals, particularly related to new job descriptions or changed roles, and that the new role might have higher competence requirements (Schwarzmüller, Brosi, Duman, & Welp, 2018).

## **2.2 Resistance to change**

It is well documented that many attempts to implement technology, thereby changing organizations, fail as people naturally prefer to keep to what they know and feel familiar with, rather than to accept the unknown and therefore to accept innovation (Laumer, 2011). Thus, a determining factor often identified when organizations fail in their change efforts is the lack of employee commitment or individual-level resistance to change (Coch & French Jr, 1994). Resistance to change is a negative expression of stress or cynicism by employees caused by conflicting emotions and cognitions about the transformation (McKay, Kuntz, & Näswall, 2013).

### **2.2.1 Change management**

Change management seeks optimal adaptation primarily directed inward, toward the members of the organization implementing the change (Lauer, 2021). A radical shift in the norms of the organization requires active support of the employees by managers, as these norms are embedded in social structures and involve individual needs, ideas, experiences, emotions and characters (Armenakis, Harris, & Mossholder, 1993). Lewin (1995) has stated that organizations persist in a steady state until external forces, such as new disruptive technologies or stronger competition, push them to change. In response to this, the organization

pursues adaptation and change (Quoted in Swanson, Jin, Fawcett, & Fawcett (2017). If managers and their team have enough commitment to change, then they can influence both the change process and the outcomes of it. Furthermore, it is important that they encourage collaborative change (Swanson, Jin, Fawcett, & Fawcett, 2017).

McKay, Kuntz and Näswall (2013) have found that resistance to change comes from an experience of personal loss and that the loss is especially prevalent when it involves familiar routines that make the employees feel safe. Therefore, changes can trigger individual anxiety and subsequently affect further job stability and growth (Erwin, 2009). Resistance is also much more likely to happen when agreements and trust are broken (Ford, Ford, & D'Amelio, 2008; Kreitner, 1992). The lack of information, e.g., when managers are unable to express the need for change or be honest about the consequences of change, can lead to fear and uncertainty for the individuals involved (Bateh, Castaneda, & Farah, 2013). Moreover, Ford (2008) have emphasized the importance of relationships between individuals and communication within the organization as valued mechanisms to handle resistance to change.

Consequently, the extant literature highlights the importance of individual commitment, competence and trust, and it further emphasizes the managerial role of facilitation of information that fosters trust and a feeling of safety among the employees to succeed with the change process.

### **3 Methodology**

To address individual-level impediments to digital transformation, we decided to explore the extant published research through a structured literature review aided by a bibliometric analysis.

Initially, we experimented with different structured search term combinations. In order to identify research addressing both "digital transformation" and "resistance to change", we used the following search string in the Web of Science database on February, 15, 2021: "digital transformation" OR "digitalization" OR "digitization" OR "digi\* transformation" AND "change resistance" OR "resistance to change" OR "cognitive inertia" OR "change readiness" OR "change capacity" OR "change barriers" OR "resistance" OR "readiness" OR "barriers". This search identified 427 potential articles, which were subsequently reduced to 365 papers by only including full-text articles published in English prior to 2021.

Thereafter, all 365 articles were downloaded, and a database was created that could be analysed using VOSviewer bibliometric analysis software, with the aim of identifying articles that explicitly address the individual level. Different co-occurrence analyses were conducted using “all keywords” and “author keywords”. Keywords can create clusters that show how different terms are related and connected to other terms. Our search was then combined with the topic “individual”, and 72 potential articles were identified within the categories business and management. Subsequently, the abstracts of all 72 articles were read to assess the relevance of our sample to our ambition of identifying extant research addressing individual-level impediments to digital transformation.

Through this meticulous process, 20 core articles with the potential to inform our research ambition were identified, and a content analysis of this sample of articles was conducted. The core articles were read and analysed by two researchers independently. The articles were categorized and coded in Excel to ensure that the same variables were recorded in all articles and to enable a consistent format for article comparison. Finally, the results were compared; any discrepancies were discussed between two researchers to attain a higher objectivity in the selection procedure.

## **4 Findings**

### ***4.1 Descriptive analysis***

Extant research relating the two topics “digital transformation” and “change resistance” only account for 365 English full-text articles up until 2021; however, the number is increasing exponentially, indicating an increased interest and awareness of the relevance of the topic (Figure 1).

Figure 1: Bar-graph representation of publications per year (sample of 365)

Moreover, the core 20 articles were all published between 2018 and 2020, of which 75% of the articles were published in 2020. This corresponds with the exponential development we observed regarding the articles for our main search as well, and it also shows that there is a growing interest in this field. At the same time, this finding demonstrates that digital transformation in connection with resistance to change at the individual level has not been researched much but is beginning to receive more attention. However, 515,347 articles were identified by using the term "digi\*". This finding indicates that our 20 core articles only account for 0.0039% of all articles published on "digi"-related topics and that there is a huge potential for further research addressing the individual-level impediments to digital transformation. In general, the literature on digital transformation and resistance to change appears complicated and unstructured, and the number of empirical contributions is limited. Even though we first assumed that there was an astonishing amount of publications addressing these two topics, our structured search revealed that this was not the case for their combination.

#### 4.2 Bibliometric analysis

We conducted several different bibliometric analyses, such as co-occurrence analysis (Figure 2) using the VOSviewer software tool, to identify articles within our database of 365 articles addressing the individual level.

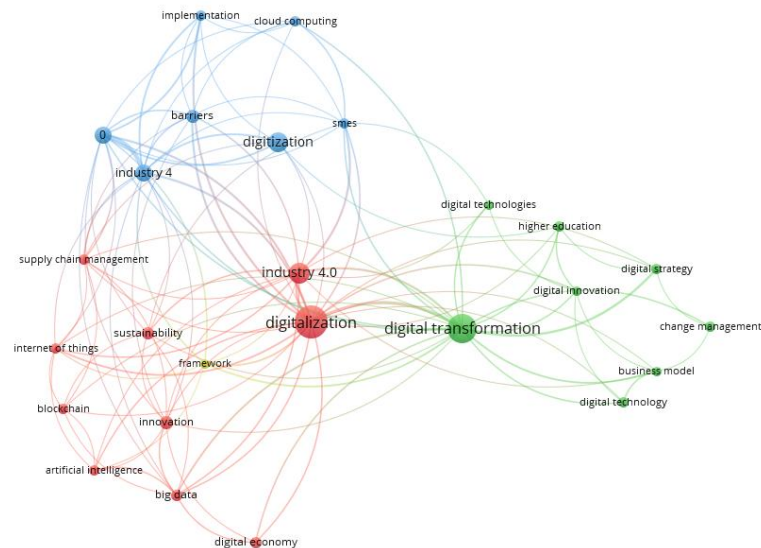

Figure 2: VOSviewer illustration of co-occurrence analysis with author keywords (5)

Our aim was to identify a cluster with connections between digital transformation and resistance to change at the individual level, but there were almost no keywords related to resistance to change in any of the clusters. The only keyword we found was “barriers” in the blue cluster, but nothing indicated whether this was a general barrier towards digital transformation or it was at an individual level. The other two clusters showed a clear technological focus rather than a change management perspective.

Consequently, our bibliometric analysis confirmed that there is only limited research that combines the two topics of digital transformation and resistance to change at an individual level. In total, only 1.44% of the research articles focused on digi\*-related fields (Figure 3). Furthermore, it was unspecified for industry; thus, many articles that were irrelevant for our research aim were included.

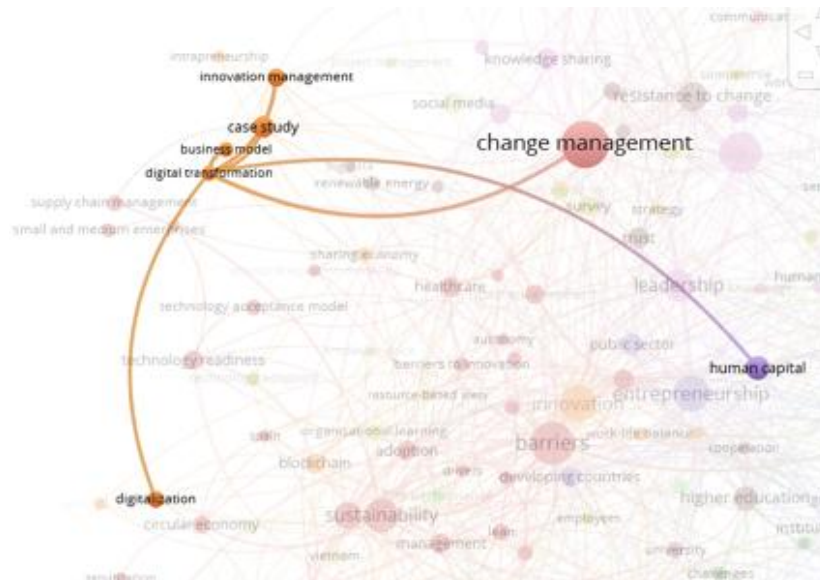

Figure 3: Close up of clusters in connection with *digi\**-related fields using author keywords (15 occurrences) from the VOSviewer illustration of co-occurrence analysis

The analysis identified a very limited intersection between the two topics. Subsequently, the relevance of 72 of our initial 365 articles was assessed. After a classification assessment, 20 articles were identified as relevant for further content analysis.

#### 4.3 Content analysis

Through content analysis, four articles were found to be irrelevant to our research question. Of the remaining 16 relevant articles, 9 of the articles used the term “digital transformation”, 5 of the articles used “digitalization”, 1 article used “digital innovations” and 1 article used “digital strategy”. After analysing the use of these terms, it was clear that “digital transformation” and “digitalization” are used interchangeably.

A pattern of factors emerged from this analysis. These were factors that specifically related individuals to the digital transformation process of the organizations. The topic addressed by all articles was related to management. Beyond that, 11 articles focused on preparedness and strategy framework, 8 articles addressed beliefs and mindsets, and 7, 6 and 5 articles referred to culture,

communication and competencies, respectively. Table 1 shows an overview of which factors are addressed in the various articles. The factors presented were addressed by a minimum of five articles, and all other factors addressed by fewer than five articles were left out, since they do not provide enough basis for comparison. Also excluded were general change process factors discussed in change resistance theory. The table additionally presents how these factors are related to individual-level impediments in connection with change resistance experienced due to digital transformation. Addressing individual-level impediments is important to improve the likelihood of an organization's success with digital transformation.

Table 9: Six factors relating digital transformation and individual-level impediments

Factor	Relationship to digital transformation (DT)	Individual-level impediments	References
<b>Management</b>	<ul style="list-style-type: none"> <li>- Allow employees to take risks</li> <li>- Management needs to adopt DT in order for employees to adopt DT</li> <li>- Identify additional opportunities offered by new technology</li> <li>- Assess their own beliefs about the changes they are leading</li> <li>- Job rotation</li> <li>- No hierarchy</li> </ul>	<ul style="list-style-type: none"> <li>- Affect employee's sense of security and trust</li> <li>- More encouraged</li> <li>- Affect employee's beliefs</li> <li>- Experience more digital readiness</li> </ul>	(Gfrerer, 2020; Trivedi, 2020; Schneider, 2020; El-Haddadeh, 2019; Solberg, 2020; Črešnar, 2020; Blštáková, 2020; Nasution, 2020; Meske, 2020; Peter, Kraft, & Lindeque, 2020; Bagrationi & Thurner, 2020; Christ-Brendemühl & Schaarschmidt, 2019; Tekic & Koroteev, 2019; Horváth & Szabó, 2019; Birkel, Veile, Müller, Hartmann, & Voigt, 2019; Hirte, 2018)
<b>Communication</b>	<ul style="list-style-type: none"> <li>- Communicate how DT will change their role both now and in the future</li> <li>- Let employees participate actively in the transformation</li> <li>- Platforms like online communication blogs, allowing free-flowing information, employees pose direct questions and suggestions to the management</li> </ul>	<ul style="list-style-type: none"> <li>- Feel valued</li> <li>- Being heard and included</li> <li>- Less uncertainty and role ambiguity</li> <li>- Know more about what's expected</li> <li>- Less resistance</li> </ul>	(Gfrerer, 2020; Schneider, 2020; Meske, 2020; Bagrationi & Thurner, 2020; Birkel, Veile, Müller, Hartmann, & Voigt, 2019; Hirte, 2018)
<b>Culture</b>	<ul style="list-style-type: none"> <li>- Develop a culture that constructively analyses, does</li> </ul>	<ul style="list-style-type: none"> <li>- Give more courage</li> <li>- More innovativeness</li> </ul>	(Gfrerer, 2020; El-Haddadeh, 2019; Črešnar,

	<ul style="list-style-type: none"> <li>- not conceal errors and where failure is not viewed negatively</li> <li>- Design thinking workshops or innovation sprints</li> </ul>	<ul style="list-style-type: none"> <li>- Individuals are more likely to adapt and implement new technology</li> <li>- More creativeness</li> <li>- Feel less likely to be replaced</li> </ul>	2020; Nasution, 2020; Bagrationi & Thurner, 2020; Horváth & Szabó, 2019; Birkel, Veile, Müller, Hartmann, & Voigt, 2019)
<b>Competencies</b>	<ul style="list-style-type: none"> <li>- Environment that appreciates the adoption and use of new technology</li> <li>- Bring in new important competencies or create a workforce with digital fluency</li> </ul>	<ul style="list-style-type: none"> <li>- Less overload and strain</li> <li>- Enhance performance and facilitate innovation</li> <li>- Interpersonal skills for collaboration</li> <li>- Strengthen the competence</li> <li>- Digital fluency</li> </ul>	(Gfrerer, 2020; El-Haddadeh, 2019; Nasution, 2020; Peter, Kraft, & Lindeque, 2020; Birkel, Veile, Müller, Hartmann, & Voigt, 2019)
<b>Beliefs and mindsets</b>	<ul style="list-style-type: none"> <li>- Create a digital mindset</li> <li>- Create shared thinking by collaboration and cross-hierarchical communication</li> <li>- Workshops that boost their self-image and confidence</li> </ul>	<ul style="list-style-type: none"> <li>- Believe in their personal abilities and become more confident</li> <li>- Personal growth and resources for personal growth</li> <li>- Lack of it can cause individuals to disengage and withdraw from DT initiatives</li> <li>- Feel less threatened and scared and more enthusiastic and curious</li> <li>- Less role ambiguity</li> <li>- More committed</li> </ul>	(Trivedi, 2020; Schneider, 2020; Solberg, 2020; Blštáková, 2020; Nasution, 2020; Meske, 2020; Bagrationi & Thurner, 2020; Christ-Brendemühl & Schaarschmidt, 2019)
<b>Preparedness &amp; strategy framework</b>	<ul style="list-style-type: none"> <li>- Form a common understanding of DT</li> <li>- Expertise centre equipped with technological knowledge</li> <li>- Provide a strategy for new problems due to DT</li> <li>- Assess employee's current abilities and not limit them to their current or previous jobs</li> </ul>	<ul style="list-style-type: none"> <li>- Feel like they are a part of the change</li> <li>- Sense of ownership</li> <li>- New technologies will be perceived as sustainable and be utilized successfully</li> </ul>	(Gfrerer, 2020; El-Haddadeh, 2019; Solberg, 2020; Črešnar, 2020; Blštáková, 2020; Meske, 2020; Peter, Kraft, & Lindeque, 2020; Bagrationi & Thurner, 2020; Christ-Brendemühl & Schaarschmidt, 2019; Tekic & Koroteev, 2019; Hirte, 2018)

## **5 Discussion**

Below we will discuss the six identified factors and explain how the individual-level impediments are linked to the organizational-level digital transformation process.

### **5.1 Management**

The content analysis identified literature addressing how managers play an essential role in the digital transformation of an organization (Nasution, 2020; Bagrationi & Thurner, 2020) because they act as role models for digital readiness among the employees (Gfrerer, 2020). Managers possess a strong understanding of the organization and have a lot of expertise; therefore, they can influence systems, processes and their employees. Their attitude and initiative impact and encourage change by allowing their employees to take risks (Hirte, 2018). Managers themselves are also individuals; therefore, the change process will also affect them and, like their employees, they can also be resistant towards change (Birkel, Veile, Müller, Hartmann, & Voigt, 2019; Peter, Kraft, & Lindeque, 2020).

Managers often adopt the concept of digital transformation, but they do not always support it wholeheartedly. The reasons for this might vary, but explanations offered include feeling an intense pressure to change (Tekic & Koroteev, 2019), fear of the unknown (Horváth & Szabó, 2019) and having enough knowledge (Hirte, 2018). They then tend to underestimate the sense of urgency of the digital transformation (Hirte, 2018), are more reluctant to change and show more resistance.

Digital transformation encompasses processes that can lead to role ambiguity and stress, causing resistance in the employees if not handled well by the managers (Christ-Brendemühl & Schaarschmidt, 2019). The digital transformation results in changed requirements for employees as well as the need for new competences (Birkel, Veile, Müller, Hartmann, & Voigt, 2019). These changes potentially result in fears in the employees like losing their jobs (Horváth & Szabó, 2019; Birkel, Veile, Müller, Hartmann, & Voigt, 2019). Knowing employees' perceptions and addressing their readiness becomes even more important for managers in a world where new digital technologies are used more frequently (Gfrerer, 2020). Managers need to have the necessary skills, experience and knowledge to control and support implementation of a digital transformation (Horváth & Szabó, 2019; Birkel, Veile, Müller, Hartmann, & Voigt, 2019).

## **5.2 Communication**

Resistance is connected to shortcomings in the interactions between individuals and the firm (Bagrationi & Thurner, 2020), and internal resistance will be the result of unclear or dishonest communication from the management to the employees (Birkel, Veile, Müller, Hartmann, & Voigt, 2019). Resistance is much more likely to occur when agreements and trust are broken; in addition, the lack of good communication leads to more fear and uncertainty (Bagrationi & Thurner, 2020; Christ-Brendemühl & Schaarschmidt, 2019).

The most crucial step for managers is to communicate decisions of symbolic importance that emphasize the organization's roots and preserve employees' identities, thereby addressing employees' emotions and feelings (Schneider, 2020). While actively interacting with their employees, the management will establish a feeling of security, and the changes will not be seen as occurring too rapidly (Hirte, 2018).

## **5.3 Culture**

With new technology, it is also important that the organization has a strong culture that supports change (Birkel, Veile, Müller, Hartmann, & Voigt, 2019). Since the organizational culture is so rooted in the daily practices, it can hinder employees from innovating and using new digital technologies effectively. This is because the culture can prevent the free flow of information across departments; therefore, it can become a significant barrier to form collaborations and creativity among employees in an organization undergoing a transformation.

An inadequate corporate culture contributes to a rise of additional risks in a transformation process (Birkel, Veile, Müller, Hartmann, & Voigt, 2019). A culture that constructively analyses and does not conceal errors should be developed within the organization, where failure is not viewed as wrong, so employees will not be afraid to contribute and adapt to new ideas.

## **5.4 Competencies**

Dynamic capabilities allow organizations to create, extend and modify their resource base to gain competitive advantages; in addition, they are essential for organizations to integrate and take advantage of digital technologies (Peter, Kraft, & Lindeque, 2020).

Nasution (2020) has found that an organization can either bring in new important competencies to the workplace or can create a workforce with digital fluency, where employees would be able to build their interpersonal skills for collaborating in ways that provide significance for organizations. Strong leadership promotes dynamic capabilities and is an important component of digital transformation processes that increase the performance of businesses in the digital age (Peter, Kraft, & Lindeque, 2020). With a focus on creating a strong workforce, the organization will be able to strengthen the competence they already have in many of their employees. With this workforce that has digital fluency, the employees will have a strong combination of skills, knowledge and resources to invest in a strong digital future (Nasution, 2020).

### **5.5 Beliefs and mindsets**

Bagrationi and Thurner (2020) have stated that the beliefs and mindsets the employees hold towards organizational change affect how successful the change process will be. The importance of changing the general mindset to a “digital” mindset, looking at new technologies with optimism and fully supporting the digital transformation are highlighted (Solberg, 2020; Trivedi, 2020; Tekic & Koroteev, 2019).

Solberg (2020) has discussed shared thinking and how it is an important tool for adapting the behaviour of employees with the vision and goals of the organization regarding digital transformation. It is important to have a change-oriented mindset and collaboration skills (Nasution, 2020). Lack of these characteristics can lead to poor and uncoordinated digital transformation, which in turn affects business performance.

A positive attitude is highlighted as a positive reinforcement of the digital mindset, while a negative attitude is related to employees feeling threatened and scared (Schneider, 2020; Blštáková, 2020; Bagrationi & Thurner, 2020; Christ-Brendemühl & Schaarschmidt, 2019). A positive view of the future will make it more likely that employees will embrace change and find a new role for themselves in the new environment (Bagrationi & Thurner, 2020).

### **5.6 Preparedness and strategy framework**

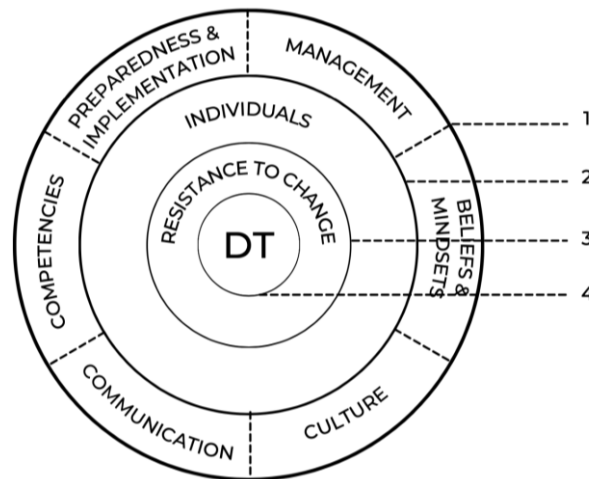

Raising awareness of a common understanding and collaborating to create a framework can be crucial for the potential application of digital transformation that organizations can achieve. The digital transformation is expected to have a significant impact on both the private and professional lives of individuals. Having a strategy that takes this into consideration is therefore crucial (Meske, 2020).

Introducing technologies alone will not be enough, and employees must be introduced to the new technologies and solutions so that they can be perceived as sustainable and utilized successfully (El-Haddadeh, 2019). The lack of a strategic focus in the digital transformation can result in a poorer transformation, implicating that there can be resistance to change, and the employees not understanding the scope of the digital transformation (Črešnar, 2020).

Therefore, it is crucial that managers assess both the current and potential abilities of their employees as they are related to the digital transformation; moreover, they should not limit these assessments to the current or previous jobs of their employees (Blštáková, 2020).

## **6 Conceptualization**

Through our analysis, we identified articles that have made it possible to distinguish between different factors that affect individuals and their resistance to the digital transformation process. These six identified factors include management, communication, culture, competencies, beliefs and mindsets, and preparedness and strategy framework. Figure 4 depicts the relationships between the six identified factors linking individual-level resistance to change and digital transformation processes.

*Figure 4: Relationships between the six identified factors connecting individuals and their resistance to the digital transformation process*

The six factors (1 on Fig. 4) will affect the individual and influence how individuals perceive change (2 on Fig. 4) when going through a digital transformation process. How these factors are handled will affect the perception of the individuals and help to determine how much resistance individuals might have in regard to the changes of the transformation process (3 on Fig. 4). The degree of resistance to change will consequently determine how agile and successful a digital transformation process is (4 on Fig. 4). Ultimately, these six factors will affect the likelihood that the digital transformation is successful. Of note, the focus is not on how resistance to change occurs but rather how to reduce and minimize resistance in individuals with respect to digital transformation. Organizations should create their own independent strategy customized to their employees and organization. It should focus solely on digital transformation and the factors presented. This will help managers navigate through the transformation process and create a common understanding, while reducing and preventing resistance. Therefore, the objective of Figure 4 is to provide an overview of the six factors and how they are related to an individual's resistance to change stemming from participation in digital transformation processes, thereby providing practitioners with an understanding of how these six factors can be handled to improve the likelihood of success with the digital

transformation endeavour by minimizing the potential for evoking resistance of individuals to change.

## 7 Conclusion

This study conducted a structured literature review of extant published research to address the question: How can a structured literature review utilizing bibliometric analysis of current published scientific research contribute to identify and reduce individual-level impediments to digital transformation. The aim of the study was to provide a foundation for future research as well as practical implications that would guide organizations and leaders on individual-level impediments to digital transformation.

This study revealed that surprisingly little empirical research has addressed individual-level impediments to digital transformation. In order to provide a foundation for more research, we identified six factors that link the individual-level resistance to change to the organizational-level digital transformation process. These six factors can improve the understanding of potential causes for individual-level resistance and provide practitioners with knowledge regarding how to strengthen the success of digital transformation processes through increased awareness of individual-level impediments. The results of this study will be of great practical value as a large percentage of digital transformation processes fail and these comprehensive changes affect all individuals within the organization, including both managers and employees.

### **Abstract**

With the diffusion of digitalization technologies that allow to analyze high volumes of operational data in real time, data-driven decision-making can now entail benefits on organizational performance not only at the strategic, but also at the operational level. However, little is known about the individual and organizational preconditions that make this approach possible on the shop-floor. Through a quantitative survey issued to 101 Italian auto supplier firms and regression models, this article investigates the antecedents of data-driven decision making at the micro- and meso-level, by analyzing the effect of involving production workers in continuous improvement, and moderating it with the skill gaps of Team Leaders and Supervisors. The results show that production workers' involvement has a positive impact on the adoption of data-driven decision-making at the plant level; notwithstanding, when Team Leaders suffer skill gaps, the effect becomes negative. Therefore, the involvement of production workers for the sense-making of operational data might be ineffective because of skill gaps in those who are in charge of recombining their context-dependent knowledge with data analysis to create knowledge and make operational decisions. The same results were not confirmed for Supervisors, suggesting a possible layering in favour of a central role of Team Leaders, yet to be tested with further qualitative empirical research. This study contributes to work organization and knowledge management literatures using the concept of organizational knowing cycle for operational decision-making, disentangling the roles of different organizational levels (production workers and first-line managers) in sense-making of, and knowledge creation from, the analysis of operational data. As such, this study positions the digital transformation as a "skill-biased technological and organizational change". In this vein, the present study has relevant implications for practitioners, too, as it highlights that specific operational employees' capabilities can limit the benefits of digitalization,

hindering the diffusion of data-driven decision-making. Recommendations are offered to HR managers and education policymakers, who are called to foster the diffusion of high-involvement managerial practices and promote an urgent upskilling of first-line managerial roles through ad-hoc education and training paths.

## 1 Introduction

With the advent of Industry 4.0, the increasing availability, volume and quality of operational data are generating high expectations about the impact of data-driven decision-making approaches on organizational performance. According to recent studies, firms that base their strategic or operational decisions on big data and analytics, rather than on intuition and experience, achieve superior performance (e.g., Brynjolfsson et al., 2011; McAfee et al., 2012). Especially if operations are well-structured, a data-driven approach to decision-making, enabled by digital technologies and data analytics software, can lead to operational performance at the shop-floor level (Flores-Garcia et al., 2019; Julmi, 2019).

However, the impact of digitalization is often analyzed under a pure technological perspective, despite wide evidences in literature that innovation needs to be approached considering organizational and managerial innovation too (Damanpour, 2014). Technological, organizational and managerial perspectives need to be analyzed together to capture the complex implications brought by the digitalization of manufacturing, using a socio-technical approach (e.g. Damanpour, 2014; Cagliano et al., 2019). The relationships between the use of digital technologies and change in organizational structures and decision-making management practices are still insufficiently explored in the literature (Cagliano et al. 2019; Mishra et al., 2017), and the micro-foundations concerning the changes induced by digital technologies in individual workers' capabilities and HRM practices are still an unexplored black box in literature (Appio et al., 2021). In this regard, research has focused on production workers and their complementarity with new information technologies (e.g., Helper, 2009), but not on their role in data-driven decision-making. Related to the use of data-driven

approaches, other studies have focused on the emerging high-skilled professions, such as data scientists and data engineers (e.g., Davenport and Patil, 2012; Carillo, 2017), but scant literature focus on what lies in the middle: Team Leaders and Supervisors, i.e. the first-line production managers who monitor and use production KPIs real-time data on a daily basis. With their interpersonal, informational and decisional roles in knowledge creation and decision making, they are in the position to play a key role for creating value in the age of digital transformation. However, they might not have the competencies required to adequately foster data-driven decision-making at the plant level, which would entail the urgent need to address these skill shortages to avoid that digitalization widen the so-called "middle-skills gap" (Kochan et al., 2012; Fuller et al., 2014). This article aims at exploring the adoption of data-driven operational decision-making through a Knowledge Management perspective, for which involved production workers and adequately skilled first-line managers are complementary in the sense-making and knowledge creation driven by big data collected and used in real time. Hence the research questions:

*RQ1: Is the involvement of production workers related to the adoption of data-driven approaches to decision-making?*

*RQ2: Do the skill gaps of first-line managers (Team Leaders and Supervisors) moderate the effect of production workers' involvement on the diffusion of data-driven decision-making?*

## **2 Theoretical framework**

Using a knowledge management perspective applied to literatures on high involvement management practices, this section aims at presenting the antecedents of data-driven decision making at the shop-floor level: the organizational knowing cycle leading to operational data-driven decision-making, the enabling roles of first-line managers, and the involvement of production workers in data-informed continuous improvement.

### **2.1 Operational data-driven decision-making: A Knowledge Management perspective**

Digital transformation is setting the ground for the bottom-up model envisaged by Nonaka (1994), in which 'those who create information are not top managers, but middle and lower managers'. Such decentralized decision-making

opens the way for the use of a Knowledge Management perspective on decision-making (Choo, 1996) not only for strategic, but also for operational, decision-making. The “organizational knowing cycle” (Choo, 1996) consist of sense-making, knowledge creation and decision-making. *Sense-making* is the action through which “things that have already happened” are made meaningful to the observant (Boland et al., 2008). Digital technologies have a huge impact on the sense-making of events happening on the shopfloor (failures, stoppages, slowdowns, etc.), as they enable a massive collection and analysis of data, entailing a more complex (though effective) understanding of which problems should or could be addressed (Verganti et al., 2020). First, operational data are transformed into information through sense-making; then, information is used in process innovation, which leads to creation of new knowledge (Nonaka, 1994). To transform information into process innovation and allow *knowledge creation*, a mix of tacit/implicit knowledge (personal knowledge that is difficult to formalize or communicate: experiential know-how, insights and intuition hard to express and formalize) and codified/explicit knowledge (formal knowledge that is transmitted between individuals and groups: formulas, rules, procedures, specifications and databases) – is required to be recombined (Nonaka, 1994). First-line employees can interpret, analyze, and communicate information (Helper, 2009), to integrate context-dependent and system-level knowledge into the knowledge extracted from big data. Last, following the knowledge creation, effective operational decisions can be taken effectively, with the final aim of operational action. Two different approaches to *decision-making* are identified: normative decision making – data-driven, analytical, conscious and sequential – and intuitive decision making – experiential, unconscious and holistic (Flores-Garcia et al., 2019). When events are well-structured (i.e. unambiguous and analyzable), data-driven decision making can be superior to intuition-driven decision making (Flores-Garcia et al., 2019; Julmi, 2019).

However, employees that benefit of visualization, simulation and interaction with digital technologies for their decision making will need knowledge, skills, and attitudes to embrace data-driven approaches (Dougherty and Dunne, 2012). Despite their importance for organizational performance, either team leaders’ and supervisors’ roles have been neglected in many studies concerning team effectiveness and operational performance (e.g. Inamizu et al., 2014; Ingvaldsen and Benders, 2016).

## **2.2 The roles of first-line managers in high-involvement work environments**

At the shop-floor level, the ability of handling production data and take operational decisions upon them is in charge of first-line managers such as Team Leaders and Supervisors. According to the definitions of Ingvaldsen and Benders (2016), for every five or six production workers there is a *hancho* (who we call Team Leader) leading the *han*, and for every two or three *hans* there is a *kumicho* (who we call Supervisor). Both Supervisors and Team Leaders are “lower-level managers responsible for operational control, maintaining day-to-day interaction with blue collar workers” (Ingvaldsen and Benders, 2016). Having to deal with operational control and monitoring, materials handling, and decision making, many first-line individual roles contain both managerial and supervisory elements (Lowe, 1993). Especially with lean production, many specialist functions have moved to the line, in order for supervisors to keep more managerial and strategic tasks as monitoring, informing, and making decisions. As such, supervisors and team leaders exhibit most of the ten roles of the managers identified by Mintzberg (1989). Supervisors, for example, are in charge of training workers for discipline, multi-skilling and continuous improvement (Ingvaldsen and Benders, 2016), and of performing managerial (“control and schedule” – Olivella, 2008) activities without working on the line: they manage workers’ vacancies, prepare statistical process control charts, revise standard operating procedures, acquire information about failures and give instructions to act accordingly (from the “group leader” job description of Inamizu et al., 2014). Also, they are in charge of creating a climate that encourages participation of production workers and continuous improvement (Forza, 1996).

Team leaders, on the other hand, are in charge of the micro-management of the line by responding to malfunctions, keeping the production flowing and facilitating kaizen activities; moreover, when a vacancy occurs, they substitute the production worker and join the line (Inamizu et al., 2014), a peculiarity for which they need to know the standard operating procedures as they were production workers. Team leaders have ‘primary responsibility of process improvement’, they set the work pace and the training activities (Olivella, 2008, citing Delbridge et al., 2000). Team leaders have also the “transformational leadership” role of facilitating team members’ creativity leveraging on their capabilities and team knowledge (Shibata 2001).

First-line managers are in charge of involving production workers, who collect the so-called "small data" (Lam et al., 2017), and perform a liaison role with data analysts, who are in charge of processing the big data coming from new digital technologies. Especially when knowledge has to be created from big data, volume can have a negative impact, but veracity a positive impact (Cappa et al., 2021), making it fundamental having them input properly by production workers in charge of documenting defects, breakdowns, line slowdowns. Indeed, data-driven decision making approaches are suitable for non-ambiguous and analyzable events (Flores-Garcia et al., 2019), that are enabled by the availability and quality of data (Pigni et al., 2016). In this vein, production management systems that formalize the involvement of production workers, such as lean production (Womack and Jones 1997), could have an advantage data-driven decision-making. In a continuous-improvement approach, big data – collected through sensors, materials tracking, machine vision and other digital technologies – can be the ground for better root-cause analyses carried out by Team Leaders and Supervisors in quality circles, kaizen weeks, or through suggestion systems through the involvement of production workers (Neirotti, 2018). Therefore, this involvement enables joint decision-making among production workers and their supervisors (Langfred, 2004), that has been defined as "participation in decision making" (Parker, 2003). However, despite the theoretical interest for investigating the effects of employee involvement and participation in decision-making on operational outcomes, the literature on this still needs to be expanded with more empirical studies (Boxall and Macky, 2009).

### **2.3 Conceptual framework**

Drawing from literature and field research, a visual representation of first-line managers' and production workers' tasks in the sense-making, knowledge creation and decision-making in a big data context is shown in Figure 1.

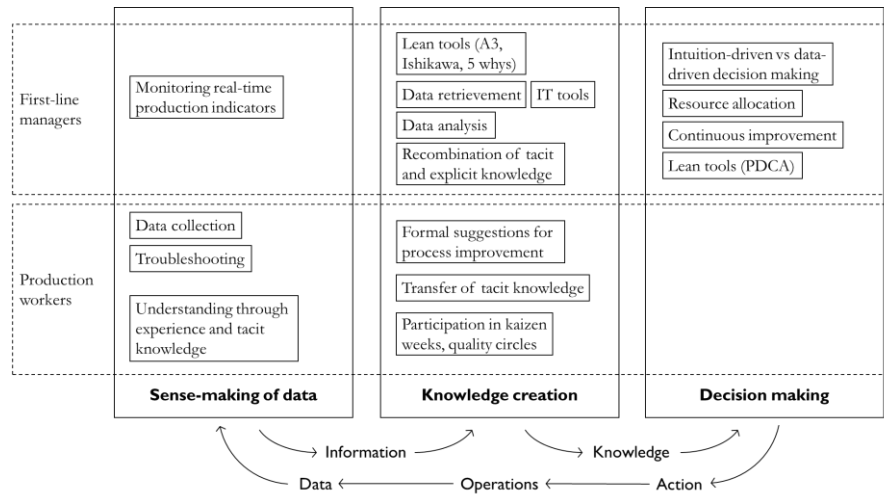

Figure 1. Conceptual framework

With a socio-technical approach (as suggested by Cagliano, 2019), the model considers technical aspects as digital *technologies* (to extract and analyze data) and the *organizational structure* (different hierarchical levels), and their relationship with social aspects as *people* (involved production workers and skilled first-line managers) and their *tasks* (data input, sense-making, knowledge creation and decision-making).

### 3 Research Methods

To address the research questions raised, this article adopts a quantitative method consisting of survey data collected in the Italian automotive suppliers' industry and analyzed by means of logistic regressions. Auto suppliers are exposed to international competition, which generates strong pressure on efficiency in the presence of product variety and innovation; these competitive pressures are transferred in turn to the supply chain, to which OEMs have long been making knowledge transfer of technology for the digitalization of production processes and lean practices characterized by continuous improvement, involvement of production workers, and a team-based work organization. Therefore, the automotive suppliers' industry is a suitable setting to study the joint involvement of first-line managers and workers in data-driven decision making.

### 3.1 Data collection

A multi-respondent survey was issued to HR, plant, and sales managers of Italian automotive supply firms between March 2019 and February 2020. Such sampling has been chosen empirically to guarantee appropriateness for this study. A total of 101 auto suppliers' plants participated in the survey, mainly SMEs operating as tier 1 (40%) and tier 2 (25%), constituting a sample representative of the population in terms of plant size, geographical region, and supply chain position. Response rates were 7% over the population and 20% over the sampling frame of firms, which allows generalizability with a 10% margin error. The questionnaire is comprehensive and contains – other than the queries strictly related to the research objective – questions to depict a complete and socio-technical overview of the digital transformation in these firms.

### 3.2 Data analysis

#### 3.2.1 Method

A logistic regression was used to determine the probability of using data-driven decision-making (DDDM) in a production plant using the involvement of production workers (PWI) and the skill gaps of Team Leaders and Supervisors as continuous predictors. The interactions between PWI and TL (model 3) and between PWI and SV (model 6) allow to test the complementarities hypothesized in the theoretical model (Figure 2).

Figure 2. Theoretical model

#### 3.2.2 Measures

Dependent variable:

- *Data-driven decision making* is a dummy variable that indicates whether the use of intuition and experience (0) or data (1) is

predominant in the decision making process, the other being still present but secondary.

Independent variables:

- *Skill gaps of production Team Leaders and Supervisors.* These two measures were computed using likert scales through which HR managers assessed these employees' adequate competencies to perform their specific tasks.
- *Involvement of production workers in continuous improvement* is a summated scale that takes into consideration organizational elements of participation of production workers in decision making related to corrective actions and changes to the process (continuous improvement). It incorporates transparency in data diffusion at the shop-floor level, that we needed to create as no other scale found in literature considers the participation of workers in monitoring data coming from sensorized equipment, yet. The five items, validated through a PCA with  $\alpha=0.8$ , are detailed in Table 1.

Table 10. Operationalization of the production workers' involvement variable

Variable	Operationalization
Formal lean production programs for the involvement of production workers in formal meetings (quality circles and kaizen weeks, see Olivella et al. 2008; Jin and Doolen 2014)	<ul style="list-style-type: none"> <li>• 0 if no</li> <li>• 1 if yes</li> </ul>
% of production workers who took part in the mentioned formal-lean meetings in the past six months	<ul style="list-style-type: none"> <li>• 0 if 0%</li> <li>• 1 if &gt;0%</li> </ul>
"Performance is continuously tracked and communicated, both formally and informally, to all staff (including production workers) using a range of visual management tools" (adapted from Bloom and Van Reenen, 2007, and Olivella et al., 2008: "work teams receive detailed information about quality, performance and accidents").	<ul style="list-style-type: none"> <li>• 0 if 1 or 2 or 3</li> <li>• 1 if 4 or 5</li> </ul>
% of production workers who carried out formal training activities on lean production methodologies and / or continuous improvement (see Olivella et al., 2008)	<ul style="list-style-type: none"> <li>• 0 if 0%</li> <li>• 1 if &gt;0%</li> </ul>
Formal program for collecting lean suggestions from production workers (see Olivella et al., 2008)	<ul style="list-style-type: none"> <li>• 0 if no</li> <li>• 1 if yes</li> </ul>

Control variables:

- *Firm Size* (number of employees in the plant) and *Employees Average Age*, to control for the plant workforce composition (e.g. long-standing workforce could have a bias in being more driven by their experience rather than by data);
- *Digitalization* is a summated scale that considers the main digital technologies used to collect data: (i) "sensors installed on equipment to continuously monitor work conditions and process parameters"; (ii) "tracking technologies for product components, e.g. RFID, bar codes, QR codes etc., to track location and status within the plant for logistic purposes"; (iii) "machine vision that allows the computer to inspect images used in metrology and other activities of process quality control";
- *Education level of Team Leaders* and *Education level of Supervisors* (0 = no title, 0.5 = high school diploma, 1 = degree or more) to ensure that the gap is not due by choices of hiring lower-educated workers driven by cost-saving reasons, but rather a characteristic nested in the institutional background of the labor market, generated by actual gaps between education and work.

## 4 Results

### 4.1 Descriptive statistics

Data-driven approaches to decision-making are adopted in the 54% of production plants. The more frequent educational level is the high school diploma for both Team Leaders (75%) and Supervisors (63%), followed by a university degree (21% Team Leaders, 33% Supervisors); these professions are done without a title in only 4% of the firms. However, the results show diffused skill gaps: 39% of firms report them for Team Leaders, 44% for Supervisors. Table 2 shows these and the rest of descriptive statistics concerning the measures used in the regressions.

Table 11. Descriptive statistics of the variables used in the regressions

Variable	Obs	Mean	Std. Dev.
DDDM (Data-Driven Decision-Making)	98	.541	.501
Firm Size (number of employees)	100	148.43	214.60
Employees Average Age	98	42.61	4.34
Digitalization	95	.589	.381
Sensorized equipment	96	.719	.452
Materials tracking	99	.556	.499
Machine vision	98	.510	.503
Educational level of Team Leaders	75	.587	.238
Educational level of Supervisors	76	.645	.269
Production Workers' Involvement (PWI)	88	.560	.372
Quality circles, kaizen weeks	96	.490	.503
PWs involved in lean meetings	95	.547	.500
Data diffused on shop floor	89	.629	.486
Lean training for PWs	96	.698	.462
Suggestion programs	96	.354	.481
Team Leaders' Skill Gaps (TL)	75	.387	.490
Supervisors' Skill Gaps (SV)	72	.444	.500

#### 4.2 Regression results

Table 3 shows the results of the three logistic regression models concerning Team Leaders: the involvement of production workers, alone, has a statistically significant positive effect on the use of data-driven decision-making (models 2 and 3), but the effect becomes strongly negative when Team Leaders show skill gaps (interaction in model 3). The results of the three models run using Supervisors' skill gaps and education level show the same result for what concerns the involvement of production workers, but the effect of the interaction is much lower and not statistically significant (Table 4).

## 5 Discussion

By providing empirical evidence on the importance of production workers' involvement and team leaders' capabilities as antecedents of shop-floor data-driven decision-making, the study provides the following relevant contributions

to work organization and knowledge management literatures, and valuable recommendations to practitioners (HR managers, education policymakers).

### ***5.1 Micro- and meso-level antecedents of data-driven decision-making***

From a socio-technical perspective, the results suggest that the propensity toward data-driven decision-making practices depend more on social (organizational and individual capabilities) variables than on technological variables. Indeed, the digitalization level does not show any relevant impact on the adoption of data-driven decision-making. On the other hand, being data-driven in digitalized production plants is possible when production workers are involved in data-informed continuous improvement, and their Team Leaders have no previous formal education skill gaps related to their jobs.

This article provides a contribution to Knowledge Management literature with empirical research on the exploitation of domain knowledge through data-driven approaches enabled by digital technologies. At the micro-level, it contributes to literatures of technological change, work organization and skills, confirming the importance of individual capabilities in exploiting new technologies and reinforcing the idea of digital transformation as a “skill-biased technological and organizational change” (Piva, 2005), for which an effective digitalization depends – in this case – on skilled team leaders. At the meso-level, a contribution to work organization literature is that Team Leaders seem not likely to be delayed, confirming the propositions of Ingvaldsen and Benders, 2016 and disconfirming prior literature on lean (e.g. Womack, 1990). The results, however, suggest that further studies – preferably qualitative, to investigate how and why this is the case – are needed to confirm whether this is also true for Supervisors, as their preparedness does not result fundamental in the data-driven transition. Also concerning organizational structure, when production workers are involved in continuous improvement, data-driven approaches are made possible. This can be explained through organizational and ecological knowledge management perspectives, focused on organizational design and interaction among individuals to facilitate knowledge processes. The empirical results can support the view for which production workers’ tacit knowledge and experience are fundamental in the sense-making of shopfloor data (Helper 2009), and that involving them could increase veracity of data and thus the propensity toward using them for operational decision-making.

Insisting on the importance of formal involvement of production workers in continuous improvement typical of lean production, this work contributes to the literature stream that explores the interplay between digitalization and lean practices (e.g., Buer et al., 2018; Pereira et al., 2019; Wang et al., 2016), suggesting that the introduction of formal lean programs could pave the way to data-driven decision-making. This work also contributes to literatures of High Involvement Management Practices by proposing a scale for measuring employee involvement in continuous improvement in digitalized environments that incorporates elements of production data transparency and availability to those of formal lean programs (quality circles, kaizen weeks, regular meetings, suggestion programs, training). The use of similar approaches could become a standard for studies concerning digitalization. Also, scales assessing perceived participation at the individual level (e.g. Kahnweiler and Thompson 2000; Delery and Gupta 2016) might be biased, as production workers could not be aware of which activities are part of continuous improvement initiatives. Therefore, computing this measure at the meso-level allows a better focus on work organizational practices.

Production workers' role in operational decision making can be empowered by increasing the exchange of information with team leaders and supervisors (Langfred, 2004). First-line managers, in turn, can facilitate continuous process improvement by fostering an "organizational climate where workers feel safe and obliged to contribute their knowledge and suggestions" (Ingvaldesen, citing Edmondson, 1999). Doing so, they can extract value from production workers and create knowledge by combining 'strategic, macro, universal information and hands-on, micro, specific information' (Nonaka, 1994: 32). This exposes first-line managers to new skill gaps, that arise due to changes in their managerial roles identified by Mintzberg (1989). They will need upskilling of interaction skills of teamwork, leadership, communication (interpersonal roles for sense-making); the "monitor" role to search – and the "disseminator" role for the recombination of – knowledge (informational roles for knowledge creation); and skills for – and attitudes towards – troubleshooting, continuous improvement, day-by-day and medium-term allocation of resources (decisional roles for decision-making).

## ***5.2 Implications for HR managers and education policymakers***

The results of this study show that such gaps in operational employees' capabilities can limit the benefits of digitalization. In particular, this confirms

previous studies according to which Team Leaders' skill gaps can lead to worse performance (Shibata 2001), updating them with skill gaps related to data-driven decision-making. In this vein, this article contributes to practice by showing the needs for a formal upskilling of specific job profiles to exploit the benefits of digitalization through data-driven approaches to decision making. Concerning implications for practitioners, this study could contribute to at least three categories: policymakers, universities, and secondary education systems.

Team Leaders' and Supervisors' activities are predominantly carried out with secondary-level education, and 89.8% of the firms in the sample envisage additional training after they take on their roles. This makes these jobs fall in the category of so-called "middle-skill jobs", i.e. those occupations that can be performed with a high-school diploma and additional training, but for which a degree is not usually needed (Holzer and Lerman, 2007). The "middle-skill jobs" category (Fuller, 2014) includes not only skilled technical jobs as IT technicians or quality and maintenance specialists, but also first-line and middle-line skilled blue-collar and managers (Osterman et al., 2011; Carnevale et al., 2013). For them, the digital transformation has been generating a demand for digital and interaction skills in the last decade, that is not being met, generating the so-called "middle-skills gap" (Kochan et al., 2012; Fuller, 2014). In the last decade, many studies showed how middle-skills gap have a huge impact on the productivity of advanced manufacturing countries (e.g. Fuller et al., 2014). Gaps in middle-skill jobs represent an increasingly urgent issue for the competitiveness of manufacturing industries (Kochan et al., 2012); in the US, 69% of HR executives stated that firms' performances are affected by a difficulty in attracting and retaining them (Fuller et al., 2014). Therefore, for HR managers, this work highlights the importance for operational roles to acquire, develop and retain the competencies required to create knowledge from big data and context-dependent knowledge.

From the educational point of view, the implications are two-fold: embrace a shift towards the "academization" (Bøje, 2012) of this category, requiring a university degree to perform it, or adapt secondary and post-secondary schools' curricula to match the new requirements. The first path, as graduates are increasingly available on the job market, is already being undertaken by companies to fill gaps in soft skills such as communication, leadership and reliability (Fuller, 2014). However, it represents an inefficiency in terms of over-education, and as such the second path might be more recommendable. For

example, there are curricula to become IT technician, programmer, electrician, robot operator, but no specific curricula – focused on lean production, basic statistics, team- and problem-based learning, etc. – are in place to become a first-line manager. These curricula could benefit from being designed to prepare the future team leaders for the “organizational knowing cycle” of sense-making, knowledge creation and decision-making. In this vein, (i) sense-making of data will require basics of statistics to interpret the data, team-based learning to develop interaction skills, and more humanities subjects, to develop communication and narrative skills; (ii) knowledge creation needs the interaction among – if not even integration of – technical schools, universities and firms for search of knowledge, and coaching systems like apprenticeships to exploit experiential learning cycle in recombining tacit knowledge and explicit knowledge; and (iii) decision making could find in workplace learning an accelerator of troubleshooting skill development, and in Challenge-Based Learning a method to develop problem solving and analytical decision-making (Colombiari and Neirotti, 2021).

This upskilling becomes crucial in this digital transition phase. However, Vocational Education and Training systems are not being able to keep the pace of technological innovation (Cedefop, 2018), therefore companies must keep insisting on developing the so-called “training academies” or “teaching factories” to fulfil the needs of future middle-skill “knowledge workers” (Mavrikios, 2013). On the other hand, with a progressive automation of operations, where the new “production workers” are machines, this upskilling of team leaders will acquire further importance, along with urgent reskilling plans (WEF, 2019) for production workers.

## **6 Conclusion**

In the last decades, management literature has largely stressed the importance of high involvement management practices and knowledge management for operational performance. More recently, practitioner literature has been stressing on the middle-skills gap issue – that involves also skilled blue collars and first-line production managers – being exasperated by digitalization and threatening the competitiveness of firms. Grounded in the knowledge-based theory of the firm, which interprets the knowledge creation for decision-making as a collaborative process integrating information coming from interpretation of data and context-

dependent knowledge, this article stresses the importance of taking both involvement of production workers and upskilling of team leaders into consideration as organizational enablers of data-driven decision-making. A main limitation of this study is that it is based on a single country and industry, therefore further research could compare and contrast these results in other institutional backgrounds and settings. The present work offers opportunities for further qualitative research aimed at characterizing specific skill gaps in sense-making, knowledge creation, and decision making in big data contexts, and explore ways to address them more punctually. This stream of further research could allow to address upskilling needs for team leaders and reskilling needs for production workers. Further considerations on employees' training practices, which can favor a stronger exploitation of digitalization, will be needed for an increasingly comprehensive theoretical and empirical understanding of the challenges and the benefits entailed by the adoption of new digital technologies.

### Abstract

How can firms leverage on digital technologies to improve their survival odds in an increasingly challenging and competitive environment? And what explains the differences observed in adoption timing and usage patterns? This paper resorts on the concept of resilience to justify the existence of different yet effective approaches to the digital transformation by contrasting the success stories of three Italian companies in the valves industry. The hypothesis underlying this study is that digital technologies aligned with the resilience level of the adopting organisation support an appropriate engagement with the external environment. The case studies of digital transformation examined in this paper point out three main findings. First, for all companies the digital transformation represents an evolutionary rather than a revolutionary process. Second, resilience has a continuous nature that increases with the coherent intensification of its underlying components. In each company a unique blend of resources and cognitive tools enable the design and the enactment of consistent routines and meta-routines. Third, digital technologies adoption patterns align with the resilience level of each company and with the organisation engagement with the external environment. When the resilience model focuses on the shift to a new equilibrium the adoption process is centrally governed, and organisational change is limited. In contrast, when the resilience model focuses on coping with continuous and unpredictable change the digital transformation involves more decentralised decision making and significant organisational change.

**Paper type** – Academic Research Paper

## 1 Introduction

The digital transformation is probably the most pervasive innovation in the last decades. Despite some concerns on the possible negative consequences for the mid- and low-skilled workforce, there is a widespread agreement on the importance of digital technologies in support of firm competitiveness and innovativeness (Brynjolfsson and McAfee, 2014; European Commission, 2019). However, systematic evidence on which conditions turn the adoption of digital technologies at the firm level into a successful growth path is still lacking. In addition, existing information suggests that adoption timing and mode, usage patterns, and impact on internal organisation widely vary across firms (Kiel *et al.*, 2017; Butollo *et al.*, 2018; Codara and Sgobbi, 2020; Götz and Jankowska, 2020). What justifies those differences? And how could firms leverage on digital technologies to improve their survival odds in an increasingly challenging and competitive environment? The empirical analysis in this paper supports the idea that the construct of resilience may help answering these questions. Defined as the capability to recover from a one-time shock or thrive under frequent, eventually continuous significant and unpredictable change, resilience is an enabling factor of survival and success in a turbulent environment (Manyena *et al.*, 2011). Based on a strong set of shared values, the resilient organisation develops a vision of the competitive environment, devises its role within this framework, and builds up and adapts a suitable set of routines to support the achievement of organisational targets. Resilience is therefore a powerful asset to navigate a complex external environment characterised by dynamic and unpredictable relationships between diverse players and forces (Ashmos *et al.*, 2000).

The hypothesis underlying this study is that successful firms configure digital technologies to reinforce their resilience and improve the probability of choosing a strategy that matches external complexity. The unique blend of resilience factors that characterises each company thus justifies variance in technology adoption and usage patterns.

This paper illustrates how resilience capability can explain the existence of different approaches to the digital transformation by contrasting the success stories of three Italian companies in the valves industry. We operationalise the construct of resilience based on Lengnick-Hall and Beck (2005), who frame resilience as a combination of cognitive, behavioural, and contextual factors.

The rest of the paper is organised as follows. Section 2 sets out the research hypothesis based on key suggestions from the literature on organisational resilience and complexity. Section 3 introduces the empirical methodology that drove the elaboration of the case studies reported in Section 4. Section 5 discusses the research findings and concludes.

## **2 Digital technologies, complexity, and resilience**

The diffusion of digital technologies has revived the debate on the relationship between organisations and their external environment. On the one hand, by increasing interconnectedness the digital transformation raises external complexity (Child and McGrath, 2001; Schroeder *et al.*, 2019). On the other one, digital technologies provide organisations with powerful tools to govern and adapt to external complexity (Tortorella *et al.*, 2021).

Past literature has shown how organisations, and firms in particular, can turn external complexity into an asset by actively selecting and shaping their task environment (Ashmos *et al.*, 2000; Daft, 2015) and even by leveraging on external complexity to exploit their distinctive capabilities (Aitken *et al.*, 2016). Decision makers' perception and interpretation of reality crucially shape engagement with external complexity because strategies and actions are undertaken based on representations and understanding of external complexity rather than objective measures (Boisot and Child, 1999). The richer the perception of the external environment, the more varied the representations held by decision makers, the higher the probability that purposive action taken by key organisational actors will actually match the features of the external environment.

A range of internal and external factors affect decision makers' interpretive processes, including interaction rules and power distribution among internal agents (Ashmos *et al.*, 2002; Accard, 2019), external collaborations (Schneider *et al.*, 2017), and environment segmentation (Child and Rodrigues, 2011). A comprehensive framework to connect all involved drivers and their interactions is provided by the construct of resilience. Lengnick-Hall and Beck (2005) identify resilience as the organisational feature that mediates between external complexity and organisational approaches to this complexity. According to the authors, organisational resilience results from the composition of interpretive capabilities (cognitive factors), routines and structures (behavioural factors), and resources (contextual factors). This model of organisational resilience allows for a

multi-faceted understanding of an organisation approach to external complexity. First, by disentangling the behavioural and the contextual dimensions of participation it stresses that routines and structure need enactment by properly endowed human resources. Second, by including among behavioural factors both current routines and the procedures to change current routines the model accounts for both the knowledge exploiting and the knowledge exploring mechanisms that take place within an organisation (March, 1991; Boisot and Child, 1999). Lengnick-Hall and Beck therefore suggest that resilience is more than the sum of its components. Resilience increases with the coherent growth of its underlying factors, which interact according to non-linear and non-strictly predictable patterns. The degree of organisational resilience can therefore be regarded as a proxy for internal complexity. The higher the resilience level, the wider the scale and the scope of change it can identify, select, and successfully master. Accordingly, more resilient organisations benefit from a higher probability to select an approach to external complexity that matches actual environment conditions (Lengnick-Hall and Beck, 2005; Lengnick-Hall et al., 2011).

The literature has identified in complexity reduction and complexity absorption two archetypal approaches to external complexity (Boisot and Child, 1999). Complexity reduction is appropriate when decision makers perceive a low degree of variety in the external environment and frame change as a shift from a no longer sustainable equilibrium to a new one. In this case, a simplified representation of the environment suffices to anticipate change and devise a strategy to achieve a new equilibrium. In contrast, when the external environment is perceived as highly variable and change is consistent and continuous complexity absorption is the most effective response to what Lengnick-Hall and Beck (2005) define as a robust transformation. A strategy based on complexity absorption requires the organisation to hold multiple (even conflicting) representations of its environment and redundant resources, which support a range of emergent routines and relations that provide strategical and operational flexibility under fluid conditions.

Complexity reduction and complexity absorption are typically presented as distinct, alternative approaches (Boisot and Child, 1999; Ashmos *et al.*, 2000; Walters and Bhuian, 2004). However, given the existence of multiple states for any system that represents the external environment of an organisation, whose complexity grows with the variety and the predictability of components and connections, a binary representation of the strategies available to face external

complexity may sound conceptually useful, yet unrealistic (Child and Rodrigues, 2011). Complexity reduction and complexity absorption may rather represent two extreme cases. The composition of the cognitive, behavioural, and contextual properties of an organisation contributes to defining different levels of resilience and therefore different degrees of complexity in context representation, viable strategies, and actual choices. Accordingly, real organisations position along a continuum that ranges from unique and stable representations of reality, corresponding to simplified strategies, to multiple and variable representations that support highly complex strategies. As the level of resilience increases, an organisation's ability to develop multiple representations of the environment and to foreshadow strategies and actions progressively gets more and more sophisticated. Complexity reduction may therefore represent the only perceived and feasible strategy for less resilient organisations, whereas more resilient ones can choose in a range that spans from complexity reduction to the maximum degree of complexity absorption they are able to deal with.

Our research hypothesis is that successful firms choose to compete in environments where their resilience level matches external complexity. In successful digital transformations we expect technology implementation and technology usage to reinforce cognitive, behavioural, and contextual factors, laying the foundations to raise the level of resilience of the organisation and therefore enabling the absorption of higher levels of complexity.

### **3 Methodology**

The relationship between digital technologies and resilience was explored by means of a case study approach. Based on in-depth analysis, case studies allow investigating a phenomenon within the peculiar environment it rises from. A case study approach is therefore particularly appropriate to appreciate organisational resilience, which cannot be separated from the environment and the people it originates from (Branicki *et al.*, 2019). More specifically, this study adopts a multi-case method (Lijphart, 1975) based on three comparable firms that recently adopted a bundle of digital technologies. The examined firms match on variables not central to the research hypothesis, including membership in the valves industry, a long familiarity with technological innovation, and an excellent capability to leverage on innovation in support of growth and economic performance. However, the sampled firms differ in resilience capability and digital

strategy, allowing for an assessment of the relationship between those dimensions.

Information collected during the case studies, which developed between late 2019 and early 2020, concerned two areas: the components of organisation resilience and the digital transformation projects. Lengnick-Hall and Beck (2005) stress that resilience capability at the organization level results from a unique blend of cognitive, behavioural, and contextual factors, each one can be further detailed in two elements. The cognitive dimension originates from a combination of organisational identity and constructive sensemaking. Organisational identity founds "on a strong sense of purpose, core values, a genuine vision, and a deliberate use of language" (Lengnick-Hall *et al.*, 2011, p.245). Strong organisational identity feeds high levels of motivation and encourage to face situations of crisis and change by mobilising all available resources in support of problem solving and action. Constructive sensemaking "relies on the language of the organization (i.e., its words, images, and stories) to construct meaning, describe situations, and imply both understanding and emotion." (Lengnick-Hall *et al.*, 2011, p.246). Constructive sensemaking, which reveals in situation-specific interpretations rather than plans and programmes, has to do with the guidelines rooted in the company's culture and shapes organisational propensity to innovation and change and the orientation towards external collaborations. Constructive sensemaking also has to do with power distribution, which delimitates what organisational units and which positions will have a voice in decision-making.

The behavioural dimension of organisational resilience, which turns cognitive properties into visible responses to uncertain situations, includes two components: the variety of the inventory of operational routines and the richness of functional habits that support the exploration of further courses of action and, consequently, the creative response to change. Both components are linked to internal variety and to the orientation of organisation design. On the one hand internal variety, which may be proxied by products diversification and by the heterogeneity of internal processes and organisation units, is proportional to the number and the diversity of operational routines and to the need for changing existing routines, due to higher probability of tensions and conflicts motivated by competition for the same (limited) resources (Größler *et al.*, 2006). On the other hand, the impact of organisational design on behavioural factors may arise by contrasting an organisation designed for efficiency to an organisation designed

for learning (Daft, 2015). The first model is characterised by a vertical structure based on strict hierarchy, centralised decision-making, and limited use of teamwork. In contrast, the learning organisation favours a horizontal structure characterised by more relaxed hierarchy, decentralised and participative decision-making, horizontal information flows, inter-functional work teams, and liaison roles. The stronger the orientation to a vertical organisation, the higher the formalisation of tasks and processes, the larger the number of detailed routines to manage day-by-day operations, and the stronger the resistance to change. The stronger the orientation to learning and the richer the internal connections, the more complex and varied the functional habits and, consequently, the creative response to change. Continuous Improvement and Total Quality Management provide examples of generative meta-routines that inform the behaviour of organisation members in horizontal organisations (Zamarian, 2010).

The third property of organizational resilience, contextual resilience, allows for integrating cognitive and behavioural resilience and includes social capital and resources network. "Deep social capital evolves from repeated, personal interactions between people and between organizations and is most effective when based on trust" (Lengnick-Hall and Beck, 2005, p.752). Consequently, the social capital of the observed companies was measured based on the use of practices aimed at enriching and deepening personnel relations, including high-performance work practices, training, personnel retention, and collaborative work. These practices impact not only human capital but also the social context of the organisation, therefore promoting the "ability of participants ... to subordinate individual goals and associated actions to collective goals and actions" and mutual trust which makes collaborative efforts possible. (Leana and Van Buren 1999). In a similar way, resource networks are assessed via the extension and the intensity of interdependent relationships with environmental agents (including suppliers, customers, research centres, and institutions).

The second set of variables examined in the case studies concerned the adoption of digital technologies. The interviews explored the contents of innovation programs, the degree of decentralisation in associated decision-making, employees' involvement, the solutions to monitor the progress of the innovation projects, and possible changes in organisational design. Thanks to significant differences among the examined companies, data in this area allow assessing the coherence between the nature of the involved technological

solutions, the adoption process, and the firm resilience capability as shaped by cognitive, behavioural, and contextual factors.

## **4 Three case studies**

All companies examined are highly internationalised family businesses based in an industrialised province of Northern Italy and operating in the valves industry. With a turnover of 9 billion euros and 30,000 employees in 2019, the taps and valves industry is an important sector of Italian manufacturing (Prometeia, 2019). The strength of Italian companies is witnessed by the high share of exports (65% of turnover in 2019), yet competition is fierce due both to the aggressiveness of low-cost producers from Far East countries, the more and more binding standards imposed by downstream clients such as oil and gas companies, and the raise of new application fields, as in the case of hydrogen valves.

This section reports how the examined companies – henceforth Company Alpha, Company Beta, and Company Gamma – explored unique paths to turn digital technologies into a tool for engaging with a complex external environment.

### **4.1 Firms characteristics**

As a preliminary step, Table 1 characterises the market and the organisation structure of the three companies, whose recent story witnesses the attempt to reposition in top market segments.

Company Alpha was founded in the 1970s as a branch of a taps and fittings parent company to produce make-to-stock steel ball valves and butterfly valves. In recent years, due to increasing price-based competition from Far East companies, Alpha entered the made-to-order market of valves for the oil and gas sector, where suppliers need to comply with the strict requirements imposed by large clients. In 2019 oil and gas valves represented 1% of produced volumes but accounted for 20% of turnover. The business of standard valves is still sustainable thanks to the value added by pre- and post-sales services, which allow for a price premium compared to products from low labour cost countries. The production of both standard and made-to-order valves include two main phases, allocated to separate job shops: highly automated fabrication and labour-intensive assembling and testing. Company Alpha employs about 90 employees and exports account for 45% of turnover.

Company Beta manufactures Liquefied Petroleum Gas (LPG) valves for multinational oil corporations and LPG cylinder producers. Founded in the 1950, Company Beta belongs to a vertically integrated corporate group that is world leader in equipment and components for gas control. Due to the increasing competitive pressure on lower market segments, Company Beta progressively focused on certified LPG valves, which secure higher margins but impose strict quality standards that require more sophisticated design and production processes.

Company Gamma was founded in the early 1980s and has since consolidated a reputation for producing made-to-stock and customised valves for utilities industries. The company subsequently expanded to valves for the automobile industry, to subcontracting and, in the last decade, to hydrogen valves. The latter move reflects the willingness to build on the company traditional strengths to reposition in a higher value-added yet more demanding and uncertain segment of the valves market to lessen the cost-based competition from mature products. Each product line corresponds to a business unit with dedicated sales, purchases, and quality control functions. R&D, support staff, and operations serve all business units. Company Gamma employs about 180 employees, including 40 R&D engineers.

#### **4.2 Sources of organisational resilience**

Table 2 reports the main differences and similarities in the cognitive, behavioural, and contextual properties of resilience at the three companies. Both Company Alpha, Beta, and Gamma display a high degree of coherence among the dimensions of organisation resilience identified by Lengnick-Hall and Beck (2005), with overall resilience growing from Company Alpha to Beta, and to Gamma.

Thanks to informal coordination and direct supervision Company Alpha can provide a flexible answer in case of limited change, whereas poor functional habits question the company resilience in front of more robust and continuous change. However, strong cohesion around the company values may enable a discontinuity, provided that modifications are sponsored by the CEO, supported by the parent company, and compatible with the existing social capital. In contrast, the higher resilience level allows Company Beta to face uncertainty by exploring change opportunities rather than exploiting already beaten roads.

Company Beta's resilience builds on a multidecade-long history of R&D and technical excellence in the LPG valves technology, on the parent company leadership in the field, on the capability to manage a high variety of products, processes, and customers, and on a consolidated focus on effectiveness and learning.

All resilience factors of Company Gamma reflect the founder's vision of the firm as a social community based on participation. If organisational identity builds on the innovativeness and the quality of products deriving from firm members' engagement, constructive sensemaking explicitly connects the company success to a technological performance rooted in participation. Thanks to intense vertical and horizontal communication, decentralised decision-making, and lean approach to manufacturing the company benefits from a wide repertoire of standard routines and meta-routines for continuous improvement and change management. In addition, Company Gamma has been developing appropriate internal and external resources to support engagement with an external environment perceived as complex and challenging. On the one hand the company social capital has been the target of sustained investments, on the other hand Company Gamma benefits from an extended network of R&D partners and consultants and from collaboration with clients that represent the state-of-the-art of technology in their application fields.

Table 1. Main characteristics of the surveyed companies

		<i>Company Alpha</i>	<i>Company Beta</i>	<i>Company Gamma</i>
Size [No. employees]		90	100	140
Foundation		1970s	1950s	1980s
Membership in an industrial group		Yes	Yes	No
Market	Traditional products	Water valves	LPG valves	Water valves, LPG valves
	New products	Oil & gas valves	Certified LPG valves	Hydrogen valves
Organisation	Organisation structure	Simple	Simple	Divisional
	Decision-making	Centralised	Partially decentralised	Selectively decentralised
	Managerial style	Family-style	Formal	Participative

#### **4.3 The investments in digital technologies**

Table 3 synthesises the feature of the investments in digital technologies recently undertaken by the observed companies. Table 3 outlines that, despite the differences in served markets, organisational structure, and resilience levels

recalled above, investment in digital technologies presents important commonalities across the three companies. First, all projects are promoted by top managers, with the agreement of the parent company in the case of subsidiary firms. Second, the common search for higher efficiency signals the competitive pressure in the industry. Third, all projects leverage digital technologies to integrate information from the operations in higher-level decision-making, as witnessed by the common introduction or upgrading of an MES system.

Table 2. Sources of organisational resilience of the surveyed companies

		<i>Company Alpha</i>	<i>Company Beta</i>	<i>Company Gamma</i>
Cognitive properties	Organisation identity	Family business – 3 <sup>rd</sup> generation Membership in an industrial corporation Lifelong employment International span, local roots Product quality and client service	Family business – 3 <sup>rd</sup> generation Membership in an industrial corporation Employees' wellbeing International span, local roots Product quality and client service	Family business – 1 <sup>st</sup> generation Lean production to raise participation Employees' wellbeing International span, local roots Product quality and client service
	Constructive sense-making	Technological excellence Success history "Familiar" management style	Technological excellence and innovation Success history Vertically integrated parent company	Technological excellence and innovation Success history Participation
Behavioural properties	Routine repertoire	Formalisation focused on operations	Formalisation extended to coordination	Focus on knowledge codification (lean production)
	Functional habits	Limited by focus on control	Focus on R&D and integration	Focus on learning and participation
Contextual properties	Social capital	Focus on trust Internal labour market	Focus on skills and training Internal/external labour market	Focus on skills and training Mainly internal labour market
	Resource network	Input commodities from global suppliers Informal support by parent company	Key inputs from internal suppliers Extended network of clients and R&D partners	Demanding clients Extended network of R&D partners and consultants

However, important differences also exist. The adoption of new digital technologies at Company Alpha had limited impact on resilience factors. Tasks and skills did not suffer significant alterations. No new position or organisational unit were created. In addition, the MES supports new decision processes only among managers. Internal change answers a need for increasing the efficiency of the existing processes rather than redefining and integrating the overall organisation design. The lack of radical structural changes and the persistence of

centralised control suggest that Company Alpha is using digital technologies to overcome the difficulties posed by increased competition and bounce back to a new equilibrium rather than to pursue continuous change.

In contrast, the digital transformation had a significant impact on resilience factors at Company Beta. Internal variety grew up with the institution of new positions and new organisational units to govern the technological change. Even if top management ruled adoption, implementation encouraged users' involvement and empowerment, also by means of training. In most cases the automation of manufacturing tasks lowered physical effort for operators and redesign jobs based on job enriching and job rotation. Company Beta uses new technologies to reposition in the higher segment of the market for LPG valves where it already operated. By enriching the cognitive, behavioural, and contextual dimensions of organisational resilience digital technologies create more suitable conditions to engage in continuous change according to a complexity absorption approach.

Table 3. Main feature of the investments in digital technologies

	<i>Company Alpha</i>	<i>Company Beta</i>	<i>Company Gamma</i>
Decision-maker	Company CEO and parent company top management	Company CEO and parent company top management	Company top management
Pursued targets	Efficiency increase; timely availability of shop-floor information	Efficiency increase; employees' wellbeing	Employees' wellbeing; efficiency increase
Adopted technologies	MES; automated warehouse	Integration between MES and ERP; highly automated assembly lines; collaborative robots	Integration between MES and ERP; integrated design and simulation software; 3D printers; machining centres with robotic loading and unloading
Innovation scope	Limited to involved processes	New positions in operations; new organizational units, including a change management unit	Company-wide support to the lean-production approach
Implementation strategy	Working group including managers of involved functions; external consultants; centralised management and limited user involvement; limited training for users	External consultants and technical support from engineering group subsidiary; key users early involvement; training for users	Launch of operative projects preceded by a taskforce to outline the overall vision; external consultants; implementation teams including key users from involved units; steering committee to supervise coherence among projects; training for users

Company Gamma shares with Company Beta the resort to digital technologies to absorb external complexity, which in this case is driven by entry in the highly innovative market segment of hydrogen valves. However, for Company Gamma the use of new technologies in search for greater efficiency and flexibility has been accompanied by an even stronger attention to expanding the workforce autonomy, reducing physical fatigue, and providing new tools and opportunities to involve all company employees in designing and implementing innovative solutions. We may therefore claim that the digital transformation further reinforces the already remarkable resilience level of Company Gamma and allows for the absorption of a high degree of external complexity.

## **5 Discussion and conclusions**

Based on interviews with managers and financial statements, the cases studied in this paper are successful examples of technological change. Our analysis points out three main empirical findings. First, for all companies the digital transformation represents an evolutionary rather than a revolutionary process. A habit of technological excellence rooted in market competition is still a powerful driver to adopt state-of-the-art solutions also in the knowledge economy.

Second, each company presents a unique blend of the factors that characterise an organisation resilience level. However, in the successful examples examined in this paper the combination of cognitive, behavioural, and contextual factors is not random. It rather composes a coherent picture of internal variety, where resources and cognitive tools enable the design and the enactment of consistent routines and meta-routines. Centralised government and reduced functional habits at Company Alpha suggest lower levels of resilience compared to the more structured and better endowed Company Beta, and even lower in comparison with participative Company Gamma. Our analysis consequently supports the intuition that resilience has a continuous rather than binary nature and that resilience increases with the coherent intensification of its underlying components.

Third, digital technologies adoption patterns align with the resilience level of each company and with the organisation engagement with the external environment. When the company resilience level is limited the adoption process is centrally governed and involves narrow organisation adjustments. In this case, exemplified by Company Alpha, technological change basically pursues a shift to

a new equilibrium. In contrast, when the company resilience allows for coping with continuous and unpredictable change the digital transformation involves more decentralised decision processes and significant organisational change. Company Beta and Company Gamma both aim at coping with environmental challenges by means of complexity absorption. However, whereas the former exploits large internal and external resources to reinforce its position in existing application fields, the latter leverages on structure and workforce flexibility to diversify in new markets. The continuous nature of resilience thus reflects into no clear-cut separation between complexity reduction and complexity absorption. Therefore, the proposed analysis supports our research hypothesis that successful firms configure digital technologies to reinforce their resilience and match external complexity.

### Abstract

In the last decade, the introduction of digital technologies has completely transformed the supply chain. Digital technologies have made the supply chain more efficient, reliable, and responsive. As a result, Digital Supply Chain (DSC) is now a major source of competitive advantage for firms. Significant resources are dedicated to manage, operate and control DSC and its performance. Performance Measurement System (PMS) is an integral part of any operation. Over the years, the role of PMS has evolved from merely measuring and reporting performance gaps to support managers in strategic decision making. PMS rely on a set of KPIs that a firm adopts as per its goals and needs. Different streams of literature have debated for and against the need for newer KPIs for measuring DSC performance. With the help of industry and academic experts, this study investigated the usefulness of existing KPIs in measuring DSC performance by collecting survey responses. A different set of experts were also interviewed to gain meaningful insights to contribute to the debate. The analysis of the responses confirms that the need for newer KPIs is not imminent. Another contribution of the study is to present a definition for DSC based on insights from the experts.

**Paper type** – Academic Research Paper / Practical Paper

## 1 Introduction

With the emergence of global procurement, manufacturing, and distribution, supply chain systems have become strategically important. During the last two decades, the focus has shifted from the factory level management of supply chains to enterprise-level management. These enterprise-level entities are often located in different corners of the globe but are closely connected/dependent on each other. This real-time integration of two or more physically apart entities is achieved by adopting digital technologies into the supply chain system. As a result of this adoption, supply chains become digitalized and are referred to as smart supply chain (Wu et al., 2016), supply chain 4.0 (Frederico et al., 2020) and Digital Supply Chain (DSC) (Büyüközkan & Göçer, 2018), including others. This study combines all these terms and refers to these interconnected supply chain as DSC. Studies have reported several benefits of DSC over the traditional supply chain, including higher customer satisfaction (Jiang & Zhao, 2014; Jonsson & Gunnarsson, 2005; Zhao & Jiang, 2013), operational efficiency (Lu et al., 2012; Sharma & Bhagwat, 2006; Zhao & Jiang, 2013), supplier relations (Ranganathan et al., 2011; Zhao & Jiang, 2013) and superior financial performance (Haoud & Hasnaoui, 2019; Youssef & El-Nakib, 2015).

On the one hand, the introduction of digital technologies makes the supply chain faster, efficient and more reliable. On the other hand, these introduce a higher level of complexity and variables into the system that need to be controlled and monitored. Chae (2009) argued that the Performance Measurement System (PMS) could help firms detect areas of problem and areas of improvement by identifying gaps between planning and execution. Over the years, the PMS has shifted its focus from merely measuring and reporting performance to participate and facilitate strategic decision-making (Nudurupati et al., 2021). These goals are achieved using different Key Performance Indicators (KPIs). These KPIs are used for *"assessing and controlling progress, highlighting achievements, enhancing understanding of key processes, identifying potential problems (e.g., bottlenecks), and providing insight into possible future actions, among others"* (Ahi & Searcy, 2015, p. 361). Researchers have argued that new complex systems will require more sophisticated KPIs to measure their performance (Cho et al., 2012; Mondragon et al., 2006; Ralston et al., 2015). Therefore there is a need to develop new KPIs for measuring DSC performance (Lima-Junior & Carpinetti, 2017; Rasool et al., 2021).

Previous studies have provided frameworks/guidelines to incorporate into DSC for better performance measurement and control (Dweekat et al., 2017; Marimin et al., 2017; Yadav et al., 2020). But surprisingly, the only study available that focused on developing KPIs for DSC was by (Sambasivan et al., 2009)). Since then, a lot has changed, and newer technologies have emerged and have become an integral part of the DSC system. Melnyk (2014) argued that it is vital for a firm to adopt an appropriate performance measuring method to record and report the system's performance, but this is not often the case. Recent literature emphasized the need for newer KPIs for DSC (Cho et al., 2012; Lima-Junior & Carpinetti, 2017; Mondragon et al., 2006; Ralston et al., 2015; Rasool et al., 2021). A different stream of literature used existing KPIs to measure DSC performance and demonstrated their appropriateness (Gilbert et al., 2017; Haoud & Hasnaoui, 2019; Llach & Alonso-Almeida, 2015; Youn et al., 2014; Youssef & El-Nakib, 2015). Given this background, this study investigates the capabilities of existing KPIs to measure DSC performance and if there is a need for newer KPIs. Such empirical testing will contribute to the current debate and identify future directions by improving the theoretical understanding of PMS used for DSC.

## **2 Theoretical background**

Historically, PMSs have received substantial attention from both academia and industry (Schleicher et al., 2018). Cascio (2012) estimated that over 90% of global firms have formal PMSs to control and monitor their performance. PMSs help firms in controlling, reporting, and correcting their performance to meet firm-level goals by highlighting the gap between planning and execution (Chae, 2009; Melnyk et al., 2014). One of the earliest attempt to systematize the performance measurement process was made by Flappe et al. (1996). The authors proposed a three-step method to develop and use a set of interconnected and consistent Performance Indicators (PIs) to cover all aspects of a business. Since then, the PMS has shifted its focus from merely measuring and reporting the performance to strategic decision making and implementation (Nudurupati et al., 2021). Therefore, the importance and reliance of firms on PMS have significantly increased. The researchers have proposed several methods to measure firm performance for financial and operational aspects (Hassan & Deraman, 2018). One important application of PMS is in supply chain management. Due to its importance, a plethora of this research is dedicated towards performance

measurement of supply chain systems that is synthesized in several literature reviews (Ahi & Searcy, 2015; Akyuz & Erkan, 2010; Duarte et al., 2011; Guersola et al., 2018; Rasool et al., 2021; Saleheen et al., 2018a).

Supply chain management refers to the process of managing suppliers, manufacturers, warehouses, and stores to produce and distribute goods in the right quantity, at the right location, at the right time to minimize system-wide costs while satisfying the service-level requirements (Simchi-Levi et al., 2000). In other words, it is the process that operates all activities of converting raw material into a finished product that satisfies the customer (Potoèan & Mulej, 2008). The increased customer expectations of faster delivery, higher quality and cheaper price have made it vital for firms to continuously improve, upgrade, and invest in their supply chain. Many of these efforts focus on making supply efficient, adaptive, and responsive by digitizing it. Studies have reported several financial (Di Vaio & Varriale, 2020; Korpela et al., 2017; Youssef & El-Nakib, 2015) and non-financial benefits (Haoud & Hasnaoui, 2019; Lu et al., 2012; Sharma & Bhagwat, 2006; Zhao & Jiang, 2013) of adopting digital technologies into a supply chain. But this digitalization is not straightforward. Researchers have cautioned that these technologies act as a double-edged sword and can harm firm efficiency and performance if not implemented and managed correctly (Hazen et al., 2014; Zhang et al., 2019).

To avoid the failures and benefit from digital technologies, their performance needs to be measured using the KPIs that can accurately record and report these newer capabilities (Ralston et al., 2015). Melnyk et al. (2014) argued that this is not the case in the majority of firms. The authors argued that even though the managers understand that they are operating under a new environment and need to develop newer KPIs, but often fail to act on it. Similarly, (Saleheen et al., 2018b) also pointed out the drawback of existing KPIs. They recommended developing newer KPIs that can capture the performance of today's supply chain. These arguments were also echoed by Rasool et al. (2021) in their recent literature review of digital supply chain performance KPIs. The authors emphasized the need to define new KPIs and validate the existing ones. The following section details the process adopted in this study to validate existing KPIs and propose new ones.

### 3 Methodology

The KPIs used in this study were obtained from a recent literature review of DSC performance metrics by Rasool et al. (2021). The authors reviewed the available scientific literature on DSC performance measurement and presented a list of 37 KPIs divided into four Balance Score Card perspectives. To the best of our knowledge, Rasool et al. (2021) is the only available study that synthesized the performance measurement literature on DSC and presented an exhaustive list of KPIs in use in academia. The authors noted that the frequency of adoption of these KPIs widely varied in the literature. Therefore, the authors recommended that before using these KPIs, these should be validated and further analyzed. In this study, the 37 KPIs were further analyzed by academic and industry experts to understand appropriateness and use. The following criteria were used to select the experts.

**Academic experts:** The digital supply chain literature is still in its infancy, and theory is evolving rapidly (Büyüközkan & Göçer, 2018). To ensure that the academic experts have the most recent information, only the experts having a PhD with at least two recent scientific publications (in the last three years) related to DSC were contacted. As a result, 86 academic experts meeting the initial set criteria were contacted via email.

**Industry experts:** Similarly, industry experts' minimum criteria included a college degree and work experience in the supply chain division at a managerial position. The profiles for industry experts were searched at LinkedIn using the keywords "digital supply chain" and "e-supply chain". A total of 515 experts meeting the criteria were contacted at LinkedIn.

The respondents were asked to participate in an online interview with the research team where possible or complete an online survey. Two reminders were sent to academic experts after the eighth and fifteen days of the first contact. No reminder was sent to industry experts due to restrictions from the LinkedIn platform. At the end of the period assigned to this phase of the study (2.5 months), eleven and thirty-three academic and industry experts filled the survey, respectively. Additionally, two academic and twelve industry experts joined the online interview with the researchers making an effective response rate of 9.6%. The average working experience for respondents was eight and fifteen years for academic and industry experts, respectively. The demographic location of the respondents varied greatly, with most respondents coming from the US (09),

Germany (06) and India (04). The interviews lasted between 35 to 55 minutes. In the online survey, the respondents were asked to rate the usefulness of each KPI collected from the literature. In addition, they were encouraged to propose additional KPIs that were not available on the list during the survey. An explanation of each KPI was also provided to remove ambiguity and difficulties in understanding the KPIs' purpose (The questionnaire sample is available at <https://tinyurl.com/DSCKPI>). While during the interviews, the experts were actively encouraged to elaborate on each KPIs usefulness and problems.

## **4 Data collection and processing**

### ***4.1 Expert interviews***

In the first phase of the semi-structured interviews, the interviewees were asked to define DSC and list the most important KPIs for DSC. This phase also investigated the opinion of the interviewees on the need for newer KPIs and how different KPIs will perform in the future. In the second phase of the interview, the interviewees were asked to list important KPIs from the provided list and discuss their usability and future. The definition and understanding of the DSC vary among the interviewees. Still, the ability to record and produce accurate (meta) data, transparency, seamless integration among stakeholders, and maximize utilization of human intelligence were common themes. The interviewees believed that in the next few years, the DSC would become the norm, and the use of digital tools such as Artificial Intelligence (AI), Machine Learning (ML) and Big Data (BD) will be as common as the use of email in today's environment. Expert 8 summarised this discussion by stating that the DSC will be a supply chain "with the capability to produce real-time information on demand, whenever it is needed, however, it is needed". Even though all experts were confident that DSC would become the new norm, expert 7 and expert 9 cautioned about overuse/misuse of the concept. Expert 9 pointed out several examples (shipping industry) where real-time information is not needed but are being pushed by industry leaders.

Similarly, expert seven was concerned about practitioners that fail to grasp the DSC concept and its potentials. Expert 7 commented, "it's not simply automating the supply chain, but it's also switching that over. So that where humans are involved, they're actually applying human insight and intelligence, and not just

using a human to insert the number and or go check metre or something like that". This insight highlighted the problem associated with digitalization, where digital technology is merely used to automate the task instead of using it to automate decision making.

This lack of understanding was also reflected in other questions; for example, when asked about the need to develop newer KPIs for the DSC, the academic experts emphasized that we already have sufficient KPIs. The industry experts believed that newer KPIs would be needed, and a hybrid system of old and new KPIs will prevail. However, the discussion revealed that the industry expects to keep on measuring the same KPIs, but the capabilities needed to measure these KPIs will evolve. For example, expert 12 said, "things like inventory, cycle time, and efficiency will always be important, but in future, we will be measuring them using different capabilities". This argument was in line with the academic experts who emphasized developing newer capabilities to measure the same KPIs instead of developing new KPIs. This approach was also visible while listing the most important KPIs for the traditional and DSC. Most of them listed KPIs related to customer satisfaction as the most important ones in both types of the supply chain. For example, expert 1 stated, "the purpose of the supply chain is to deliver ultimate customer experience in whatever shape or form. The supply chain is a business support function. Good supply chains save money, great supply chains make money, So you can only make money if your customers are happy". Surprisingly, the experts also emphasized the need for reducing the number of KPIs instead of developing new ones and encouraged researchers to merge several KPIs and measure them effectively with the help of digital technologies. Expert 2 commented, "It's not the volume. It's the critical data points, and that changes for every industry, every person, every company".

Similarly, expert 1 commented, "it's not how many times you measure it. It is how, where and why you measure it". These insights were in line with the suggestions of Melnyk et al. (2014) and Hazen et al. (2014), where authors recommended focusing on the quality of KPIs instead of quantity. One important thing that emerges is that even though experts believed that fewer KPIs should be used, they were quick to suggest additional KPIs particular to their own and industry. These insights partially disconfirm the need for DSC KPIs discussed in previous studies (Lima-Junior & Carpinetti, 2017; Rasool et al., 2021). The discussion with experts highlighted the problematic and complex nature of digitization. Even though all of them are certain that the supply chain will

become digitized soon, they are uncertain about what the future will look like and how this digitization will be achieved.

#### **4.2 Questionnaire responses**

The respondents were asked to select the important KPIs from the 37 KPIs proposed by (Rasool et al., 2021). During the interviews, the experts recommended reducing the number of KPIs by measuring only the most relevant. The survey respondents also confirmed this opinion by rating a limited number of KPIs as useful from the list. As a result, the 37 KPIs were divided into three categories depending on the frequency of selection. The KPIs selected by 80% or more respondents were categorized as very strongly recommended. Similarly, with selection rate between 60%-79% were categorized as strongly recommended. The KPIs with a selection rate between 40%-59% were categorized as recommended KPIs. There were no KPI with a selection rate of less than 40%. Table 1 presents the summary of these results. In contrast to the scientific literature, where more focus is placed on measuring the internal and financial performance of the digital supply chain (Rasool et al. 2021), the experts emphasized the focus should be on the customer and their satisfaction, not the firm and its performance.

In line with the insights from the interviews, where experts emphasized having fewer KPIs to make PMS efficient and less complex, the survey respondents also tend to agree on this. This can be deduced from Table 1, where 15 out of 37 KPIs tested fall under the recommended category, while only 07 are highly recommended.

### **5 Discussion**

The survey results and analysis of interview transcripts uncovered several insights useful for both industry and academia discussed in the following subsections.

#### **5.1 Academic contribution**

Headd & Saade (2008) and Podsakof et al. (2016) emphasized the importance of having an appropriate definition and argued that its absence could distort the results and impact negatively on theory building. However, the definition of the

DSC is still somewhat opaque, and experts had a different understanding of what is a DSC and what level of digitalization is required to call a supply chain digital. Several studies in the past have attempted to distinguish digital from traditional supply chain and proposed definitions (Büyüközkan & Göçer, 2018; Wei et al., 2019; Wu et al., 2016). These studies derived their inspiration from the academic literature and therefore have not received industry-wide acceptance. Based on the insights from the interviews, this study proposes the following definition. DSC is a seamlessly interconnected transparent supply chain, that independently performs decision support activities to minimize human input needs.

Another academic contribution of the study was answering the questions towards the needs for newer KPIs for DSC. The theory for supply chain performance measurement has been evolving for several decades. Saleheen et al. (2018a) reviewed the most prominent performance measurement systems available and categorized them into financial and non-financial systems. The authors argued that the top management needs financial KPIs to make strategic decisions while middle management requires operational KPIs to perform day to day activities. In contrast to the previous studies that emphasized the urgent need for developing newer KPIs for DSC (Lima-Junior & Carpinetti, 2017; Rasool et al., 2021), this study highlights that the need for newer KPIs is not as eminent as considered earlier. Instead, the focus should be shifted towards developing standardized systems and theories that can be employed across different interconnected entities to make DSC effective. The study also provided the evidence to support the argument proposed by Elrod et al. (2013) to reduce the number of KPIs used in PMS.

## **5.2 Practical contributions**

The fast-paced business environment has left managers busier than ever with fewer resources to spend on tasks, not directly contributing to profit generation. As a result, measuring the right performance indicators has become even more crucial in PMS success. The main contribution of this study for practitioners is the identification of highly recommended KPIs presented in Table 1. The Table presents the seven identified highly recommended KPIs that managers should focus on while deciding on what to measure. Another insight from the analysis was that KPIs related to customer satisfaction are the most important KPIs, not the ones measuring a firm's operational and financial performance, which is a

general practice and recommendation of the scientific literature (Rasool et al., 2021).

This study also concludes that more is not always better. Fewer well placed KPIs to measure critical business activities will produce better results than measuring every aspect of a business. This insight encourages managers to focus on only important aspects of a business. The study also highlights that there is no need to reinvent the wheel for managers when it comes to performance measurement. They already have appropriate KPIs that will be able to serve them well in the future as well. Instead, they should focus on developing a better understanding of the DSC capabilities and weaknesses and do not under or overestimate its value.

## **6 Conclusion and limitation**

In the last decade, the firms' reliance on sophisticated supply chain systems have significantly increased, and supply chain has become the main source of competitive advantage (Bi et al., 2010; Büyüközkan & Göçer, 2018). As a result, significant technological advancements were made to make supply chain systems digitalized in the last two decades. On the one hand, these technologies make the supply chain efficient, reliable, and responsive (Haoud & Hasnaoui, 2019; Zhao & Jiang, 2013). On the other hand, they make the system complex and sensitive (Rasool et al., 2021). This study investigated the usefulness of existing KPIs and the need for new indexes to measure the performance of this new and complex supply chain, commonly referred to as DSC. To this end, semi-structured interviews and survey questionnaires were conducted with both academia and industry experts. The interviews provided several insights, including the need for newer KPIs for DSC, which is overemphasized in literature. The experts believed that the existing KPIs would be sufficient with changes in performance measuring methods that arrive with the new supply chain. It was observed that understanding of DSC and its capabilities varied among the experts. To harmonize these differences, a definition for DSC was derived by synthesizing the interview transcripts. In the second phase, the 37 KPIs used in this study were divided into three categories, namely "very strongly recommended", "strongly recommended", and "recommended", by analyzing responses to the questionnaire. The categorization will help practitioners to identify important KPIs when limited resources can be dedicated to managing PMS. Lastly, contrary to general practice in literature where the emphasis is placed on internal and

financial performance. The analysis of both interview transcripts and questionnaire responses revealed that the KPIs associated with customers and their satisfaction are the most important ones.

This study is not without its limitations. First, although the recent literature review by Rasool et al. (2021) on performance KPIs is comprehensive may still have shortcomings. This might have prevented some KPIs to be included in the study for further analysis. Second, the selection criteria and database used for identifying experts have their limitations. It is acknowledged that the wider search may have included a more diverse selection of experts in the study. A larger number of interviewees would be useful in mitigating the interviewer biases during the semi-structured interviews. Also, more responses to the questionnaire would be useful in better classifying the KPIs into three proposed categories.

Table 14 Classification of KPIs

KPI	Academic		Industry		Combined		
	Responses	% Agreed	Responses	% Agreed	Responses	% Agreed	
Delivery reliability	10	91%	28	88%	38	88%	Very strongly recommended
Operational efficiency	9	82%	27	84%	36	84%	
Logistics cost	9	82%	27	84%	36	84%	
Firm innovativeness	8	73%	28	88%	36	84%	
On time delivery	8	73%	27	84%	35	81%	
Responsiveness to customers	8	73%	27	84%	35	81%	
Employee skills	8	73%	27	84%	35	81%	
Customer satisfaction	9	82%	25	78%	34	79%	Strongly recommended
Operational cost	9	82%	23	72%	32	74%	
Inventory level	5	45%	27	84%	32	74%	
System reliability	8	73%	24	75%	32	74%	
System flexibility	9	82%	22	69%	31	72%	
Information availability	8	73%	23	72%	31	72%	
Inventory cost	7	64%	23	72%	30	70%	
Cash cycle time	4	36%	25	78%	29	67%	
Data security	8	73%	21	66%	29	67%	
Return on investment	6	55%	22	69%	28	65%	
Production cost	6	55%	21	66%	27	63%	
Operational speed	7	64%	20	63%	27	63%	
Supplier relation	5	45%	21	66%	26	60%	
Resource utilization	6	55%	20	63%	26	60%	

Customer ease	5	45%	21	66%	26	60%	Recommended
Profit	5	45%	19	59%	24	56%	
Environmental cost	7	64%	17	53%	24	56%	
Employee satisfaction	3	27%	21	66%	24	56%	
Error cost	5	45%	18	56%	23	53%	
Production cycle time	4	36%	19	59%	23	53%	
Communication with supplier	7	64%	15	47%	22	51%	
Error rate	6	55%	15	47%	21	49%	
Responsiveness to supplier	3	27%	18	56%	21	49%	
Workplace safety	3	27%	18	56%	21	49%	
Sales	4	36%	17	53%	21	49%	
Market share	4	36%	16	50%	20	47%	
Labor cost	6	55%	13	41%	19	44%	
System ease of use	3	27%	15	47%	18	42%	
Data collection points	4	36%	13	41%	17	40%

### Abstract

In the digital age, organizations are built upon and rely on people and their technical skills, which are becoming an important source of competitive advantage. In this context, the role of Human Resources Management changes significantly, and this change has a direct impact on the governance of the company as well, thus configuring it as a Strategic Human Resource Management. It has the task of transmitting an innovative and cooperative corporate culture directly to the employees, helping them to develop a digital mind-set and new digital skills in line with the objectives of the business model.

This research aims to provide a qualitative analysis of the impact of Digital Transformation on Human Resources processes, to address organizational change, and on the development of appropriate transversal skills of individuals to incorporate and capitalize on innovations in the digital environment.

The research work was carried out using the methodology of the illustrative (and explanatory) case study, involving an Italian company that has witnessed a relevant digital transformation process in the last years.

Results show that Human Resources Management can (and must) have a guiding role in driving the organizational change through digitalization, particularly by incubating and accelerating digital innovations, while at the same time fostering the development of Digital Leadership.

**Keywords** – Digital Transformation, Case study, Digital Business Strategy, Digitalization capabilities, Digital leadership

**Paper type** – Academic Research Paper

## **1 Introduction and background**

In recent years we are witnessing a relevant Digital Transformation that will guarantee the future for companies, under the guidance of people (Braga, 2017). It is not a mere technological change, but it also represents the opportunity to rethink works and tasks, and to reinterpret values, through an innovative culture, while maintaining people at the very centre of business (El Sawy et al., 2016).

Digital Transformation is seen mainly as a cultural change that must take place both at an organizational and intra-organizational level and is a "Human and Business Transformation" with consequences on the organization of work and on the management of people (Rogers, 2016). It is important to understand, in a real context, how HR Managers deal with the process of managing and developing adequate transversal skills of human resources in line with a new innovative and cooperative corporate culture, in order to efficiently deal with digitization and guarantee that the internal organization obtains and maintains the qualified and well-motivated workforce in influencing the creation of corporate value.

The phenomenon of digitalization gives birth to a new era of corporate IT, in which technology is increasingly integrated into the company and where corporate IT moves from a legacy perspective to a digital one, suggesting that there is a need to develop a Digital Leadership (El Sawy et al., 2016). Digital Leadership skills must be nurtured to ensure integration between IT technologies and to seize new opportunities and realize them in a competitive advantage, but also to improve the Digital Business Strategy (DBS) on the development of agile and scalable digital operations and digital innovations (Sia et al. 2016).

In the digital age, organizations are built upon and rely on people and their technical skills, which are becoming an important source of competitive advantage (Hansen et al., 2011). In this context, the role of Human Resources (HR) Management changes significantly, leading the HR department to perform different functions that range across an organization, increasing their influence in the decision making process. This change has a direct impact on the governance of the company as well, thus configuring this process as a Strategic Human Resource Management (Oh et al., 2012; Annarelli et al., 2021).

HR Management has the task of transmitting an innovative and cooperative corporate culture directly to the employees, helping them to develop a digital mind-set and new digital skills in line with the objectives of the business model (Battistella et al., 2017; Rachinger et al., 2019).

## 2 Research aim and methodology

This research aims to provide a qualitative analysis of the impact of Digital Transformation on HR processes, to address organizational change, and on the development of appropriate transversal skills of individuals to incorporate and capitalize on innovations in the digital environment.

The following research questions were formulated accordingly to the research purpose detailed above:

*RQ1: How are people structured, in terms of digital mind-set and digitalization capabilities, in a digital context?*

*RQ2: How did internal processes and the HR function transform to meet the challenges posed by the development of a Digital Business Strategy?*

The research work was carried out using the methodology of the illustrative (and explanatory) case study (Yin, 1984; Eisenhardt, 1989) involving an Italian company that has witnessed a relevant digital transformation process since 2017: Telepass S.p.A.

For data collection, we defined an interview protocol in accordance to our framework of analysis (detailed in the next section). We interviewed various professionals who have been working for several years within the company. More in detail, the following figures were involved in the study:

- Chief of People and Organization Officer;
- Director of Product Development (R&D, innovation);
- HR Manager;
- Chief of Staff to the CEO;
- Smart Devices & Tolling Technologies Manager.

## 3 Theoretical framework of analysis

Given the strategic importance for companies to explore the opportunities represented by the intersection between business and technology, it is essential to analyse the impacts deriving from new technologies on the "people" component, that is, on the people who are called to the company, to apply and bring to life new development strategies (Camarinha-Mathos et al., 2017). To take full advantage of the opportunities offered by digital transformation, companies must in fact ask themselves whether the internal organization and its employees are really ready to face this challenge (Zangiacomi et al., 2020). If the company changes by exploiting the potential of digital more and more, HR functions must

also adapt to this change to accompany the transformation of skills and work behaviours. Thanks to new technologies, HR and Talent Management processes are evolving from centralized processes to something increasingly incorporated into daily work (Grover and Kohli, 2013).

This research aims to provide a qualitative analysis of the impact of Digital Transformation both on HR processes, to deal with organizational change, and on the development of adequate transversal skills of human resources to understand and capitalize on innovations in the digital environment. In other words, the study in question is structured on the analysis of two factors that are part of the same business system to ensure the creation of corporate value, or how HR is structured in terms of behaviours and skills in a digital context, and on the other hand, how the human resources management process is transformed to meet the challenges of Digital Business Strategy.

In order to answer the research questions, a framework was defined to highlight and represent the relationship between HR Management and its impact on company performance, in a context of organizational transformation (Jerez-Gómez, et al. 2019). Within this framework, we identified two main dimensions that characterize the digital transformation:

- *Ability to incubate and to accelerate emerging digital innovations:* companies must face the challenges of innovation to remain constantly at the forefront of technology and to keep in touch with customer needs (Sia et al. 2016);
- *Cultivating Leadership for Digital Transformation:* it is essential to articulate the Business Digital Strategy and to align the necessary investments in resources (O'Reilly and Tushman, 2004). Managers must understand the potential and challenges of technological innovation and have a shared vision of digitalization as a central element for business growth.

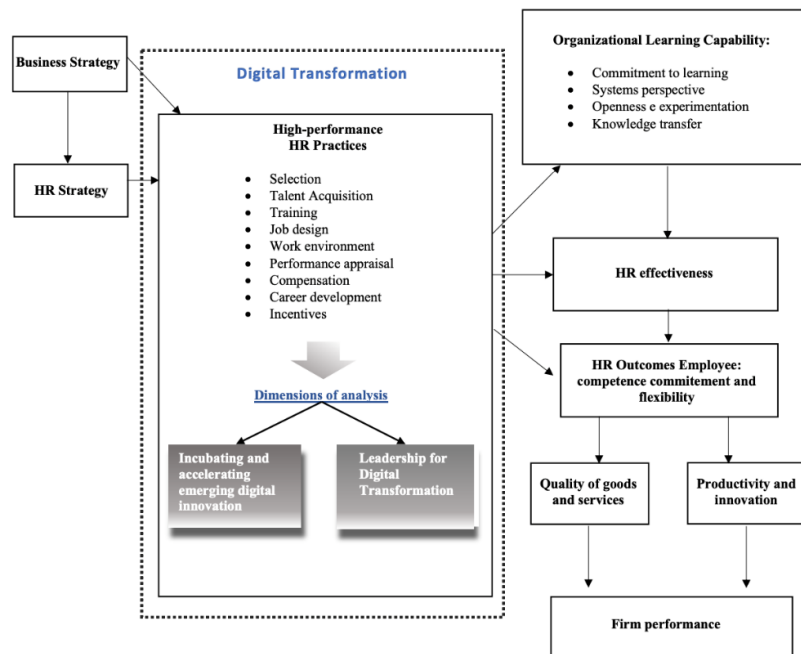

Figure 1. Dimensions identified in the context of Digital Transformation

To carry out an in-depth study, each dimension was detailed into sub-dimensions, which brought to the definition of the interview protocol. The analysis allowed us to evaluate the ability of the company to perceive the path towards digital transformation, and to develop a clear strategy to accompany employees and organizational structures in this new challenge, anticipating future needs in terms of skills, behaviours, tools and leadership as much as possible. Table 1 details the sub-dimensions of the framework.

Table 1. Sub-dimensions and variables of the research

Dimension	Sub-dimension	Variables
<b>Ability to incubate and to accelerate emerging digital innovations</b>	<b>Understanding digital transformation</b>	Research of technological trends and tendencies to interpret digital scenarios (Zangiacomi et al., 2020)
		New technologies to analyse, integrate data and change workflow (Zangiacomi et al., 2020)
		Extend the vision of digital processes to the entire organization (Zangiacomi et al., 2020)
		Use of digital analytical tools to read and interpret data (Zangiacomi et al., 2020)

Dimension	Sub-dimension	Variables
		Level of readiness of human resources to accept digital transformation (Zangiacomi et al., 2020)
		Propensity to collaborate with external sources of knowledge to accelerate innovation (Liao et al., 2017)
		Seeking expert support (Chief Digital Office) to efficiently invest in promising technologies (Sia et al., 2016)
	<b>Digital Maturity</b>	HRs' digital background and level of digital experience of the company (Zangiacomi et al., 2020)
		Adoption of modern information systems (e.g. mobile devices, machine-to-machine communication) to improve performance (Zangiacomi et al., 2020)
		Awareness of the increasing accessibility and usability of innovative technologies by employees (Zangiacomi et al., 2020)
		Level of integration between transversal skills and digitalization capabilities (Chryssolouris, 2013)
		Proactive involvement of human resources in the definition of procedures and qualifications for the adoption of new technologies (Bauer et al., 2018)
	<b>Knowledge Sharing</b>	Importance of sharing and disseminating practices for successful implementation of new technologies (Camarinha-Matos et al., 2017)
		Alignment between strategies and resources to allow the exploitation of potential synergies with suppliers and customers (Zangiacomi et al., 2020)
		Importance of partnerships with digital start-ups and companies (Zangiacomi et al., 2020)
		Exploitation of connections and data sharing practices with external networks (Bessant and Rush, 1995)
		Ability to promote the know-how on the experience of digital transformation (Zangiacomi et al., 2020)
<b>Cultivating Leadership for Digital Transformation</b>	<b>Investment in human capital</b>	Investments in training (Grover and Kohli, 2013)
		Readiness of high-potential resources, in terms of career advancement and taking on new responsibilities (Srai et al., 2016)
		Talent recruiting (Warner, 2019)
		Development of training paths for specialized skills to support digital transformation (Kache and Seuring, 2017)
		Ability to involve employees in the digital transformation and provide them with digital experience (El Sawy et al., 2016)
		Involvement of partners to outsource training for specific digital skills (El Sawy et al., 2016)
		Facilitation of training conditions, coherence between objectives and methodologies adopted (Senge, 1990)

Dimension	Sub-dimension	Variables
		Understanding training as a way to foster people's commitment (McClelland, 1985)
		Development of training initiatives in line with organizational needs (Senge, 1990)
	<b>Promote an innovative and cooperative culture</b>	Smart working attitude towards independent and flexible work (Bauer et al., 2018)
		Development and promotion of group-based activities (McDonough, 2000)
		Ability of the company to understand and emphasize with the personal sphere of employees to maintain and improve productivity (El Sawy et al., 2016)
		Investing in digital platforms for distance work (El Sawy et al., 2016)
		Technological support service (El Sawy et al., 2016)
		Availability of information (El Sawy et al., 2016)
		Encouraging a collaborative culture (McDonough, 2000)
	<b>Human Resources Management</b>	Job rotation frequency and speed in reallocating resources (Becker and Muendler, 2015)
		Awareness of the correct balance between talent acquisition and training of existing resources (Heavin and Power, 2018)
		Fostering motivation and commitment through promotions and career advancements (McClelland, 1985)

The research analysis model shows how the phenomenon of Digital Transformation entails the need to adapt both corporate work systems and digitalization capabilities and dynamic capabilities (Teece et al., 2016; Annarelli et al., 2021) to a new context.

The study is structured on the analysis of factors that are part of the same business system to ensure the creation of business value, because if well-developed these can act as enablers for a full exploitation of digital innovation. This is why we want to understand on the one hand how human resources are structured in terms of behaviours and skills in a digital context, and on the other hand how human resources management processes are transformed to respond to the challenges posed by Digital Business Strategy (Bharadwaj et al. 2013).

#### 4 Results and discussion

The case study company operates in the sector of urban and extra-urban mobility, and for about thirty years played (essentially) a monopolistic role with

only one type of substantially physical business, namely that of raising the bar at motorway toll booths. With the development of technology, the need arises to move the company from a low-tech legacy, made up of a single physical product, to a strong digitalization of services to guarantee more performing, agile and above all scalable solutions.

The Digital Transformation in the company started in 2017, when they began to diversify the business by introducing multiple services aimed at both the consumer market and B2B in digital form using a single mobile application.

To do this, it was necessary to start from the type of initial business and, once new technological assets were created, greater power was guaranteed on the mobility market and to undertake an internal change within the company, also addressing the outside world and creating new partnerships.

To quickly implement its strategy, the company has leveraged opportunities offered by the digital world by completely revisiting the processes of accession and subscription to services in a way that has now become "natively digital" both on the web and via their mobile application.

The key intuition of the Management was to take as a starting point their competitive advantage, namely that of having 6 million customers and knowing their movements by thoroughly investigating their mobility habits on the motorway. In this way, the company successfully establishes itself on a more general market which is that of mobility, which at this time cannot be separated from a digital evolution. The starting point of this strategy is precisely the collection of data, monitoring customers to obtain useful information and then offering services tailored to their needs.

Following, the analysis of the company's Digital Transformation will be structured in two sections, representing the main dimensions of the framework.

#### ***4.1 Incubating and accelerating digital innovations***

The Digital Transformation took place in terms of processes, organization and platform evolution. In particular, through technological evolution, Telepass has made all its services available to customers through a single access platform. This allowed to overcome the real challenge of Digital Transformation, namely that of enhancing the Data Warehouse with customer transactions and, therefore, using the available information assets in such a way as to be able to optimize the commercial approach based on artificial intelligence logic.

Following the change in business model and the possibility of selling new services to customers, it has become essential to exploit the information available in Telepass. Today the Marketing Clustering model is waning and that is why Telepass has transformed it into Event Driven Marketing, in which customer behaviours are analysed on a certain occasion to understand what their needs are in real time and provide, consequently, an immediate solution.

Data analysis requires increasingly powerful models and technologies due to their variety and volume, in order to provide useful information for business management. For this reason, the implementation of Big Data and Analytics is becoming such a relevant development area in Telepass that it can be considered a business critical capability.

For the above reasons, the company has built a Data Management Office structure that deals with the policy regarding data management and a Big Data structure that aggregates all customer data in a simple and rapid way in order to be able to develop (in compliance with privacy laws) further service initiatives.

For what concerns the pace in carrying out activities and processes, the management realized that the traditional way of handling IT projects was showing enormous limits. For this reason, it was necessary to define a new more flexible and agile development paradigm. When the time-to-market of innovations is long enough, when there is little room for flexibility and there is limited knowledge and/or visibility of what is going on until everything is finished, there is a natural aversion to innovation and a very strong break between IT and the rest of the company. Therefore, the company needed to switch to a more dynamic reality, and to a more dynamic approach in managing innovations. This, in turn, not only allowed a better management of innovative IT projects, but also reduced the "conceptual" distance and allowed a better integration of IT and technology throughout the whole company.

Another key aspect that enabled the company's Digital Transformation was to define new technological assets as "small bricks", giving the possibility to assemble new and customizable models of interaction with customers. This, in turn, allowed to implement an effective customer care and to define flexible (almost in real time) billing models.

## ***4.2 Cultivating Leadership for Digital Transformation***

Digital Transformation requires changes not only from the point of view of the development of new IT systems, digitized logistics and Big Data management, but also for the internal perspective.

The company is continuously encouraging managers to entrust their collaborators, to delegate responsibilities, fostering in this way individualism (in a positive perspective), and creativity. This does not mean giving up control obligations, but instead giving people the opportunity to express themselves, sometimes to dare in order to grow and therefore stimulating individual contributions, with the aim of creating a culture based on sharing in which managers act as mediators. Thanks to digital tools people are always more led by networks and not hierarchies, thus opening doors, eliminating barriers, supporting innovation and encouraging collaboration within and outside teams.

The digital and cultural change within Telepass affected also the development process of new skills and organizational capabilities. To this regard, the HR department started a thorough acquisition plan of new talents with digital hard skills so as to allow a rapid growth of IT capabilities. This, of course, has to be intended as complementary with training and internal skills development, in order to ensure a quicker construction of new digital capabilities at a company level.

The HR function of Telepass today believes that learning does not have to be necessarily guided, but must become a proactive effort, in which employees are leading their own skills development. The key role of the HR function is to create a positive and stimulating environment, which allows employees to gain insights into the digital world with greater freedom of learning and to have greater responsibility for their own professional growth. This, in turn, also ensures greater awareness of people's professional background and the development of self-learning skills.

Nonetheless, Telepass guarantees continuous growth paths for employees especially through on-the-job training initiatives, to develop new competences and handle more effectively unforeseen situations and problems. This training methodology is the most used within the company since it minimizes the gap between the training experience and the working reality, while maximizing the learning effectiveness.

As regards training for the development of new digital skills, this is mainly outsourced to external experts specialized in technological innovations. In this

way, it is possible to reduce personnel management costs and also decrease the workload for internal resources, that can be engaged in core business activities. One of the most effective training initiatives, according to HR, is to insert new talents in key projects in order to create heterogeneous teams, and in doing so they can foster both team spirit development and skills acquisition.

To encourage the increase of digital skills, two factors have been defined in Telepass:

- the selection, or the acquisition of skills from highly specialized external markets;
- the contamination, that is the creation of common spaces and the construction of integrated work groups made up of people with different skills and experiences.

The Company is working hard on the development of a common digital language, to be adopted in the organization at all levels, through digital contamination by up-to-date specialists on emerging innovations. This will also guarantee the entire organization a greater awareness of what it means to work in a digital way, which not only includes knowing how digital applications work, but also having the ability of human resources to experiment and manage errors along with feedback.

A challenge for the company, therefore, is to have the ability to manage talents capable of providing the necessary push for innovation. To this regards, the concept of Digital Leadership will have a profound impact on the organization. As a matter of facts, Digital Leadership is essential in fostering a close collaboration between people with different backgrounds (business and IT), belonging to different generations and, therefore, with heterogeneous points of view on possible "digital" evolutions in areas that have traditionally been less technology-driven.

## **5 Conclusions**

In recent years the company has been increasingly considered as a reference point for the many digital services that it delivers in a short time, thanks to the work that has carried out the IT function, especially in terms of speed in responding to customer needs and downsizing of technological assets.

The company also invested a lot on human capital for the development of digital skills and the digital mind-set. This favoured the transition from a much

more "paternalistic" approach, from an organizational point of view, to a setting where each employee, who is up-to-date on technological innovations, contributes with its knowledge to the professional and digital development of senior colleagues.

To cope with a dynamic and constantly changing world, the company did not invest in traditional forms of training, which is seen as an unnecessary and time-consuming activity. On the contrary, "on-the-job training" learning has been encouraged, with the awareness that more innovative ideas can rise spontaneously from this approach.

Following this method, the employee becomes not only a "learning worker", but an "agile self-learner", that is an individual willing to independently research the methods and contents to keep its skills and personal capabilities up to date. The individual is entrusted with the task, not only of organizing his own learning, but also of managing his own self-development through a process of change for which he is the main responsible. We thus go from being able to "learn" continuously to "learning to learn and unlearn" through a continuous evolution of their knowledge and skills.

The company has adopted the policy of collaboration, sharing and maximum responsibility for employees. This has allowed the company to innovate quickly and make all employees more accomplished and prepared for change: think exponentially, act quickly and know how to take risks.

This work contributes to the development of knowledge on the phenomenon of digital transformation, by investigating the guiding role that HR can and should have in driving organizational change through new digital business models.

Nevertheless, we must acknowledge that results are limited to a single case study. Future studies should involve a larger sample of cases, so as to allow for a generalization of results and a theory building effort.

### **Abstract**

The decommissioning of offshore Oil & Gas platforms, at the end of their life cycle, has been a very controversial topic in recent years. Moreover, the decommissioning complexity increases if we consider a shift towards a linear economy to a circular one. The latter pushes to innovate business models and re-configure the value chain activities in a sustainable way. Starting from these considerations, this work aims to identify a cost-benefit model suitable for evaluating sustainable business models of offshore platforms. After a literature review of different models for analysing maintenance and decommissioning Real Options (ROs), the Life-Cycle Cost-Benefit (LCCB) analysis has been selected as the most adequate managerial tool for evaluating and comparing the Net Present Value (NPV) of platforms compared the maintenance and decommissioning costs. The LCCB tool could aid the managers in the oil and gas industry to quantify the decommissioning and maintenance costs including capital expenditure (CapEx) and risk expenditure (RiskEx). In the future steps, to test the LCCB model, an empirical analysis could be carried out on a sample of organizations interested in the sustainable decommissioning of offshore platforms.

**Keywords** - offshore platform decommissioning, life-cycle cost-benefit (LCCB) analysis, Life cycle assessment, sustainable business model, Multi-Use Platforms at Sea (MUPS), circular economy

## 1 Introduction

In the last twenty years, the decommissioning of offshore oil and gas platforms at the end of their life cycle has been a very controversial and debated issue. The offshore industry expanded rapidly to currently number over 12,000 offshore installations globally (Ars and Rios, 2017). Offshore platforms are situated on the continental shelves of 53 countries, making offshore oil and gas production a major global industry (Parente et al., 2006). Several nations require the complete removal of obsolete structures, which presents substantial engineering challenges and requires incredibly expensive and labour-intensive. Therefore, the considerable decommissioning costs have led to a gradual change in international regulations considering a more flexible approach (Henrion et al., 2015). Consequently, economic considerations have influenced the decisions of the oil and gas companies, which are increasingly inclined to postpone the removal process according to economic and technical conjectures. Our main research questions were: *"Is there a cost-benefit model suitable for evaluating sustainable business models for offshore platforms?"* or rather: *"The eventual emerging analytic model is useful for an estimate the asset integrity in the Italian oil and gas industry?"* In particular, the adoption of Sustainable Business Models (SBMs), based on value creation (Nosratabadi et al., 2019) between the several actors involved as well as the environment and society, shed light on the possibility to reconfigure the value chain activities and reuse these structures to generate an opportunity from an economic, ecological and social perspective (Evans et al. 2017; Lozano, 2018). In this scenario, the offshore platforms (also known as Multi-Use Platforms at Sea, or MUPS) can represent an innovative solution to meet the growing pushes towards sustainability and circular economy. Likewise, MUPS represents a great opportunity for re-using or reconverting the end life structure, restricting the impacts on marine ecosystems as well as offering socio-economic benefits. In a MUPS scenario, some oil and gas platforms can be reconverted, a part of their structure can be used for activities related to a particular sector such as touristic-recreational, aquaculture (e.g., fish farming and shellfish farming), renewable energy, and hydrogen storage. However, these SBMs have not yet been assessed in the literature from a cost-benefit perspective and

the economic sustainability of these initiatives is still unclear. Based on these considerations, this work aims to evaluate the initiatives of reusing the offshore platforms in favour of SBMs in terms of cost-benefits analysis. The emerging cost/benefit model links with a broader framework of assets and infrastructures subjected to obsolescence or final removal (e.g., bridges, wind farms, marine turbines, and offshore platforms). To reach this goal, different models for analysing maintenance and decommissioning Real Options (ROs) have been analysed to identify the most adequate managerial tool for evaluating and comparing the Net Present Value (NPV).

## 2 Literature Review

### 2.1 The life cost benefit analysis

The theoretical fundamentals of the Life Cycle Cost-Benefit analysis start from its antecedents that were: the Life Cycle Cost analysis (LCC) and Life Cycle Assessment (LCA). In table 1 are summarized the main literature on this topic. Life Cycle Cost analysis (LCC) and LCA have major methodological differences (Norris, 2001). LCC compares the cost-effectiveness of alternative investments or business decisions from the perspective of an economic decision-maker such as a manufacturing firm or a consumer. LCA evaluates the relative environmental performance of alternative production systems for providing the same function. This environmental performance is assessed as holistically as possible, aiming to consider all important causally connected processes, all-important resources, and consumption flow. Life-Cycle Cost-benefit analysis is a term that is used in several different connections based on engineering knowledge, economic understanding, and mathematical experience. However, it refers in general to a tool, which may help to assess and estimate, a project or business proposal. Thoft-Christensen (2009) proposed a Life-cycle cost-benefit (LCCB) analysis for the bridges' building, but it also applies in designing maintenance strategies for other structures, as well as offshore platforms. The expected total LCCB of an infrastructure consists of the expected benefits for firms  $B_{\text{society}}$ , for the owners (agencies, private companies, etc.) of the infrastructure  $B_{\text{owner}}$ , for the users  $B_{\text{user}}$  and the expected benefits for the environment  $B_{\text{environment}}$  (Thoft-Christensen, 2012). The formula is as follows (1):

$$LCCB = B_{\text{society}} + B_{\text{owner}} + B_{\text{user}} + B_{\text{environment}} \quad (1)$$

Instead, it is more useful also to estimate the expected costs in the lifetime of the infrastructure rather than only the expected benefits. Equation 1 is then integrated with Equation 2. That is:

$$LCC = C_{society} + C_{owner} + C_{user} + C_{environment} \quad (2)$$

According to Thoft-Christensen (2012), the benefit terms as well as the cost terms in Equations (1) and (2) are clearly uncertain and must be modelled by stochastic variables or processes. The Life Cycle Assessment considers the environmental aspects and the Social Life Cycle Assessment the social ones, the LCC integrates the three layers of sustainability by considering its economic aspects (Andrews, 2009). The three types of LCC can be identified as follow: I) Conventional; II) Environmental and III) Social. The recent contributions on sustainable and circular business models (Joyce and Paquin, 2016; García-Muiña et al., 2020; Basile, 2021). offer a wide analysis of the three-layered considered applied to specific case studies. The conventional LCC is the most used type of LCC and is based on an economic evaluation that takes into consideration all the costs in the various phases of the Life Cycle of an asset. The environmental LCC analysis is considered the costs related to the Life Cycle of an asset, incurred by the stakeholders directly involved. Costs defined by external and situational factors with respect to the Life Cycle are also taken into consideration, to internalize them to the analysis. This latter was developed by a Working Group (Hunkeler et al., 2008) of SETAC (Society of Environmental Toxicology and Chemistry), which gave rise to the guidelines on the methodology of environmental LCC, in conjunction with the LCA. The social LCC differs from conventional and environmental LCC because it takes into consideration all the stakeholders not directly connected with the production system of a product or service. Neugebauer et al. (2016) proposed a Life Cycle Sustainability Assessment (LCSA) framework developed for assessing the sustainability performance of assets through Life cycle assessment (LCA), Life cycle costing (LCC), and Social Life Cycle Assessment (SLCA).

Table 1. The main existing literature on asset integrity management and life cycle cost benefit analysis

Authors	Focus	Main empirical evidence
Norris, (2001)	Integrating life cycle cost analysis and LCA	<i>"...standard methods of LCA can and have been tightly, logically, and practically integrated with standard methods for cost accounting, life cycle cost analysis, and scenario-based economic risk modeling. The result is an ability to take both economic and environmental performance- and their trade-off relationships into account in product / process design decision making"</i>
Thoft-Christensen, (2009)	Life-cycle cost-benefit (LCCB) analysis of bridges from a user and social point of view	<i>"The main purpose of this paper is to present and discuss some of these problems from a user and social point of view. A brief presentation of a preliminary study of the importance of including benefits in life-cycle cost-benefit analysis in management systems for bridges is shown. Benefits may be positive as well as negative from the user point of view. In the paper, negative benefits (user costs) are discussed in relation to the maintenance of concrete bridges"</i>
Snyder et al., (2009)	Ecological and economic cost-benefit analysis of offshore wind energy	<i>"...we discuss the costs and benefits of the offshore wind relative to onshore wind power and conventional electricity production. We review cost estimates for offshore wind power and compare these to estimates for onshore wind and conventional power"</i>
Santa-Cruz et al., (2011)	Maintenance and decommissioning real options models for life-cycle cost-benefit analysis of offshore platforms	<i>"Maintenance and decommissioning real options (RO) models are developed for life-cycle cost-benefit (LCCB) analysis of offshore platforms. Uncertainties about hydrocarbon prices, maintenance costs, environmental loading, structural capacity and damage due to deterioration are taken into consideration in the RO modelling. Expressions are derived for expected costs and benefits in terms of the availability function of the platform, which depends on the hazard and restoring functions, and on the annual probability of failure of the structure. Results show that the use of the net present value (NPV) approach can significantly underestimate the LCCB"</i>
Chandima Ratnayake et al., (2012)	Asset integrity management for sustainable industrial operations: measuring the performance	<i>"The main challenge for asset integrity management (AIM) is related to various aspects of its human dimension as apparent on organisational settings and associated cognitive dispensations. (...) The paper provides a review of AIM and a foundation for engineers and managers to analyse the general problem of managing PA' integrity to increase the sustainable value of an asset intensive business in a more holistic way"</i>

Thoft-Christensen, (2012)	Infrastructures and life-cycle cost-benefit analysis	<i>"Repair and/or failure of infrastructures will usually result in user costs greater than the repair or replacement costs of the infrastructure. For the society (and the users) it is therefore of great importance that maintenance or replacement of an infrastructure is performed in such a way that all costs are minimized not only the owners' cost"</i>
Kusumawardhani et al., (2016)	Asset integrity management: offshore installations challenges	<i>"The purpose of this paper is to identify the challenges facing asset integrity management(AIM) practices in the oil and gas industry, to continually develop AIM practices in organizations. (...) The paper identifies, analyses, and validates the challenges and factors that may impact the management of asset integrity on offshore installations. The challenges were discussed to develop an understanding of the root cause and thus aim to resolve underlying issues. (...) The identified challenges can be used by organizations to resolve underlying AIM challenges, improve their AIM strategy and obtain insights into current AIM practices in the petroleum industry"</i>
Neugebauer et al., (2016)	From Life Cycle Costing to Economic Life Cycle Assessment Introducing an Economic Impact Pathway	<i>"...Life cycle sustainability assessment (LCSA) framework has been developed for assessing the sustainability performance of products through Life cycle assessment (LCA), Life cycle costing (LCC), and Social life cycle assessment (SLCA). Yet, the focus of common economic assessments, by means of LCC, is still on financial costs"</i>
Lam et al., (2018)	Life-cycle cost-benefit analysis on sustainable food waste management: The case of Hong Kong International Airport	<i>"The aim of this study is to develop a Life-Cycle Cost-Benefit Analysis (LC-CBA) framework, through the integration of the life-cycle assessment (LCA) and cost-benefit analysis (CBA), to guide decision-making in sustainable food waste management"</i>
Animah et al., (2018)	Selection of the most suitable life extension strategy for ageing offshore assets using a life-cycle cost-benefit analysis approach	<i>"This paper presents a life-cycle cost-benefit analysis approach to identify the most suitable life extension strategy for ageing offshore assets by considering all the capital, installation, operational, maintenance and risk expenditures during the extended phase of operation. The potential of the proposed methodology is demonstrated through a case study involving a three-phase separator vessel which was constructed in the mid-1970s. The results from the application case indicate that the capital expenditure (CapEx) accounts for the largest portion of life cycle cost for the replacement strategy, while risk expenditure (RiskEx) is the major contributor to costs associated with life extension"</i>

Li et al., (2018)	Innovative energy islands: life-cycle cost-benefit analysis for battery energy storage.	<i>"We specifically put forward a life-cycle cost-benefit analysis model to evaluate the economics of battery storage systems used in small communities from a life-cycle perspective. In this research, we put forward a novel cost-benefit analysis model"</i>
Tang et al., (2019)	Risk identification and quantitative evaluation method for asset integrity management of offshore platform equipment and facilities	<i>"By analysing the disadvantages and shortcomings of the existing methods and adapting to the technology requirements of the Asset Integrity Management (AIM), a Streamline Failure Mode Effects and Criticality Analysis (SFMECA) was presented to achieve risk identification and quantitative evaluation based on the traditional FMECA and Borda scoring method"</i>
Nian et al., (2019)	Life cycle cost-benefit analysis of offshore wind energy under the climatic conditions in Southeast Asia—Setting the bottom-line for deployment	<i>"There is thus a need to evaluate the true benefits of offshore wind energy under the region's suboptimal climatic conditions. In response, this study employs the life cycle analysis approach to conduct a cost-benefit analysis of offshore wind energy in the context of Southeast Asia. Findings from study suggest that the cost of offshore wind energy remains high now for Southeast Asia"</i>
Giuffre et al., (2021)	Life-Cycle Costing Decision-Making Methodology and Urban Intersection Design: Modelling and Analysis for a Circular City.	<i>"The chapter presents a case study where the Life-Cycle Cost methodology is used to compare three alternative intersection projects based on their total life-cycle costs"</i>

## 2.2 Life cycle Management

The studies on life cycle cost (Fuller, 2010; Lam et al., 2018) integrate the Asset Integrity Management (AIM) contribution (Chandima Ratnayake et al., 2012; Kusumawardhani et al., 2016) into a holistic framework of Sustainable Life Cycle Management (SLCM). Generally, the Life Cycle Management (LCM) can be used to define, analyse and manage product-related information and activities towards continuous improvement along the product life cycle (Remmen et al., 2007). Sonnemann et al. (2015) state that Life cycle management is a concept applied in industrial and service sectors to improve products and services, while enhancing the overall sustainability performance of the firms and their value chains.

Fig. 1: Sustainable life cycle management framework  
Source: adapted from Remmen (2007).

The upper side of the SLCM framework has the following three blocks: 1) data, information and, models; 2) tools and techniques and 3) LCCB and AIM analysis. The lower side includes: 1) system and procedures; 2) life cycle thinking, the business case for sustainability and 3) corporate environmental and social responsibility.

### 3 LCCB analysis for evaluating the decommissioning of offshore platforms

The research methodology adopted is based on qualitative analysis and a descriptive approach (Blessing et al., 1998; Ezzy, 2013). Firstly, was carried out an analysis of the relevant academic literature (for the number of citations on Google Scholar, Scopus, and the Web of Science and for the quality of the academic Journals publishing the articles) on the asset integrity management and life cycle

cost-benefit analysis (see table 1 in appendix). The in-depth review (Rowley and Slack, 2004) mentioned above was useful in selecting the managerial tool that is the Life Cycle Cost-Benefit model (LCCB). Among the various conceptual models proposed in the literature on BMs, the LCCB was the one that best fits with the sustainable decommissioning of offshore platforms. The LCCB model, in fact, could be applied to SBM in the following industries: aquaculture (which includes fish farming and shellfish farming) (Troell et al., 2009); tourist-recreational activities (which includes hotel accommodation, water restaurant, a hub for recreation leisure and sports activities, high-experience events and naturalistic tourism, etc.); renewable energy (Elginöz and Bas, 2017); hydrogen storage (Hou, 2017); carbon capture utilization and storage (Yao et al., 2018); non-profit organizations. LCCB is the method used to calculate the economic cost and benefit (revenue streams) of the entire life cycle of a product or service, starting from the phases prior to production up to its final disposal, with the aim of minimizing production and maintenance costs. The LCCB method for offshore platforms makes it possible to relate the quantitative data related to decommissioning costs to acquire an overview of the maintenance cost to estimate the feasibility of the sustainable business. The goal is to achieve better economic sustainability of the business project that you want to implement, and if it is possible. Conducting an LCCB assessment of a platform helps predict the costs that potential companies must incur to start a new business, from securing the former oil and gas platforms to its disposal. The LCCB method enabling much more informed business decisions. For example, the assessment of the LCCB of an offshore platform also considers the maintenance that could be decisive for the purchase of certain raw materials or plans expenditures. The results of the LCCB allow companies to make smart investments: when deciding which resources to opt for, one must not only consider their price but the general cost that the adoption of those certain resources will have on the entire Cost of the Cycle Life of a specific asset. The formulation of lifecycle cost-benefit (LCCB) analysis applied to offshore platforms considers maintenance and decommissioning that is the Real Options<sup>1</sup> (ROs) for management along with the service lifetime. The platform structure is subjected to deterioration, and thus the probability of structural failure due to extreme environmental events evolves with time. Maintenance can be provided, depending on findings from future inspections,

---

<sup>1</sup> The RO models are based on the Black and Scholes formulation for financial options.

and management will have the option to provide maintenance or not. Asset integrity management is a great issue for the oil and gas industry. Usually, the management of oil and gas companies prefer to decommissioning the platform, due to the difficulty of estimate the costs for reconversion. The life cycle cost-benefit analysis involves comparing the costs to the benefits of a project and then deciding whether to go ahead with the reconversion options. The costs and benefits of the projects are quantified in monetary terms after adjusting for the time value of money. We can summarize the LCCB analysis in terms of Net Present Value (NPV) and benefit-cost ratio. The formula for Net Present Value (NPV) and benefit-cost ratio is the following:

$$NPV = \sum \text{Present Value of Future Benefits} - \sum \text{Present Value of Future Costs}$$

$$\text{Benefit-Cost Ratio} = \sum \text{Present Value of Future Benefits} / \sum \text{Present Value of Future Costs}$$

NPV expresses the future benefits of offshore reconversion business (artificial reef, renewable energy production, aquaculture, tourism and diving activities, etc). Furthermore, need to consider the present and future costs (decommissioning, maintenance, and reconversion cost).

To calculate the present value of future costs and benefits, we use the present value factor, which is  $1/(1+r)^n$ . Where  $r^1$  is the discount rate, and  $n$  is the number of years. The formula for calculating the present value is:

$$\text{Present Value of Future Benefits} = \text{Future Benefits} * \text{Present Value Factor}$$

$$\text{Present Value of Future Costs} = \text{Future Costs} * \text{Present Value Factor}$$

The Net Present Value can also be evaluated with the following equation:

$$NPV = \sum \text{Present Value of Future Benefits} - \sum \text{Present Value of Future Costs}$$

Therefore, if the Net Present Value (NPV) is positive, the project should be undertaken. If the NPV is negative, the project should not be undertaken. To calculate the Benefit-Cost Ratio, we consider the future benefits. and the present and future costs. After that, we calculate the present value of future costs and benefits. The benefit-cost ratio has the following formula:

$$\text{Benefit-Cost Ratio} = \sum \text{Present Value of Future Benefits} / \sum \text{Present Value of Future Costs}.$$

If the benefit-cost ratio is greater than 1, go ahead with the project. If the benefit-cost ratio is less than 1, you should not go ahead with the project.

<sup>1</sup> In general, the WACC can be calculated with the following formula:  $WACC = (E/V \times Re) + (V/D \times Rd \times (1 - Tc))$  where:  
 $E$ =Market value of the firm's equity;  $D$ =Market value of the firm's debt;  $V=E+D$ ;  $Re$ =Cost of equity;  $Rd$ =Cost of debt and  
 $Tc$ =Corporate tax rate.

#### **4 Implications, research limitations and future lines of research**

This work sheds light on the potentialities of the Life-Cycle Cost-Benefit (LCCB) analysis for evaluating and comparing the Net Present Value (NPV) of platforms compared to the maintenance and decommissioning costs. The LCCB tool could aid the managers in the oil and gas industry to quantify the decommissioning and maintenance costs including capital expenditure (CapEx) and risk expenditure (RiskEx). The results of the analysis highlight the great potential of the adoption of SBM from the oil and gas industry in favour of initiatives aimed at the re-use of offshore platforms. However, the importance of a clear and systems governance framework appears to be crucial to support the actors involved and the viability of these initiatives. In this sense, the study provides several insights for researchers and professionals in the oil and gas industry and in the governance field. In particular, the assessment of the LCCB tool could aid the managers in the oil and gas industry to quantify the decommissioning costs or estimate the maintenance costs for entrepreneurs who want to adopt SBMs for offshore platforms. Evaluating whether to start a particular business is very important for entrepreneurs especially for offshore oil and gas platforms. Using the LCCB method, firms can predict whether the ROI (Return of Investment) of a sustainable business is worth the investment they want to make. For an accurate ROI, one needs to consider the initial cost of decommissioning or reconversion of a platform, plus the future costs associated with it. Therefore, the LCCB model is useful to create a predictive and accurate budget for the total cost of the resources, for maintenance and decommissioning cost compared to prospective revenues. To define an accurate budget, firms must take into consideration: costs, revenues, and profit for the year.

In this sense, the purely investigative nature of the research does not allow us to generalize, although the insights that emerged from this first study on the subject can provide a foundation and useful stimulus for future theoretical and empirical studies, qualitative and quantitative. The main limitations of this contribution are related to the theoretical nature of the study. The literature review implies the complete reliance on previously published research and the availability of these studies using the method outlined in the search methodology (keywords, database) and the appropriateness of these studies with the criteria of the selection/exclusion procedure (coding). Therefore, in the future steps, the analysis of several international contexts could be carried out to broaden and

generalize the emerged findings (Lucas, 2003) and improving the validity and reliability of further inquiring (Golafshani, 2003). Also, in order to test the LCCB model, it could be useful to adopt an empirical analysis on a sample of stakeholders interested in the business feasibility of the three decommissioning ROs, that is, fish farming, hospitality, and hydrogen storage.

# Accelerating the Transition towards Sustainability through Green Innovations: an Integrated Framework to Support Business Models Evolution

---

Rosita Capurro

Department of Business and Economics  
University of Naples "Parthenope"  
Via Generale Parisi, Naples (NA), 80132, Italy

## Abstract

This paper proposes an integrated framework that aims to support firms in the transition towards sustainable business models by identify factors favouring the development of green innovations. The aim of this paper is to investigate the several endogenous pushes as well as external solicitations that involving the managerial decisions related to the investments in green innovations. Through a conceptual analysis, the study reviews the literature on business models, sustainability strategies and green innovations. By examining sustainability issues ranging from theory to practical application, the paper provides new insights and critical points by enriching the fragmented literature on green innovations and supporting the managers' commitment to implement successful sustainability strategies. Specifically, the integrated framework suggests implications for both academic and practitioners by shedding light on how firms could improve their ability to select the right strategic moves, at corporate and business level, in order to endorse sustainable investment in green innovation and therefore to improve sustainable paths of growth.

**Keywords** – Strategic management; Sustainability strategies; Sustainable business model; Green innovations; Green management

**Paper Type** - Academic Research Paper

## 1 Introduction

This paper focuses on the challenges that firms have to face for re-orienting their traditional business models towards sustainability (Geissdoerfer *et al.*, 2018; Fiorentino *et al.*, 2020; Bocken *et al.*, 2014). The increasingly relevant socio-environmental issues promote an evolution of business practices to comply – or even to anticipate - the expectations of several stakeholders (Freeman and

Dmytriiev, 2017; Vilanova *et al.*, 2009). In this transition, the broader vision of corporate social responsibility (CSR) approaches has made relevant the interplay among sustainability strategies, strategic management and green innovations for both scholars and practitioners (Taylor *et al.*, 2018; Garzella *et al.*, 2020).

Some studies argue that the formulation and implementation of green innovations is a critical success capability through which firms can pursue their sustainable aims by contributing to corporate communication for external actors (Evans *et al.*, 2017; Repo and Matschoss, 2020; Dangelico *et al.*, 2017). Other scholars claim that green innovations can greatly affect business success by increasing their value creation process (Chesbrough, 2007; Yang *et al.*, 2017). By developing green innovations, firms could gain new competitive advantages and create differentiation benefits with regard to socio-environmentally sensitive customers (Sellitto *et al.*, 2020; Ge *et al.*, 2018; Chen and Liu, 2019); moreover, these green innovative approaches could increase the firm's financial performance, reducing production costs and time to market and improving firms' process security (Qiu *et al.*, 2020; Tang *et al.*, 2018).

The calls for the implementation of new products and processes focusing on sustainability require strategic changes in operational process, governance practices, supply chains, and organizational structures (Du *et al.*, 2018; Fiorentino *et al.*, 2020). The development of green innovations involves the decision-making processes (Bocken *et al.*, 2018); managers should carefully analyse the decisions on green innovations alongside other traditional strategic investments by considering their impact on economic and financial dynamics as well as on medium-long term competitiveness (Saunila *et al.*, 2018; Lin *et al.*, 2019). In this sense, strategic management scholars captured the relevance of green innovations in corporate and business strategies (Soewarno *et al.*, 2019; Garzella *et al.*, 2020).

Despite these research advancements, there is a lack of integration across the several literature streams related to green innovations. Indeed, although scholars identify several endogenous pushes as well as external solicitations involving the managerial decisions related to green innovations (Qiu *et al.*, 2020; Chang, 2014), the academic debate concerning the factors affecting the successful development of green innovations is still fragmented (Albort-Morant *et al.*, 2017; Zhang *et al.*, 2020; de Jesus Pacheco *et al.*, 2017).

In order to bridge this gap, the aim of this paper is to advance an integrated framework on green innovations, useful to identify factors favouring their adoption and the transition towards sustainable business models.

Specifically, the study sets the following research questions: what are the main factors affecting the formulation and implementation of green innovations? how firms can embrace green innovations for accelerating the transition towards sustainable business models?

For developing this conceptual paper, first, we have reviewed the literature on business models, sustainability strategies, and green innovations. By the integration of the compatible elements of previous research, the study highlights the factors that sustain the formulation and implementation of green innovations underlining their integration in the firm's strategic planning process. In this way, we provide a comprehensive framework extending current studies and practices.

In particular, the paper is structured as follows. The next section provides the theoretical background. Section 3 analyses the factors that favour the adoption of green innovations. Section 4 advances a framework concerning the impact of the green innovations at corporate and business level in order to develop successful sustainability strategies. Finally, Section 5 summarizes the main contribution of the paper and provides implications and ideas for future research.

## **2 The literature review**

The broader vision of the CSR concept - seen as "the integration of social, ethical, and environmental concerns into the management criteria for corporate strategy" (Freeman *et al.*, 2010, p. 259) - has led firms to review their goals and objectives (Baumgartner, 2014). According to stakeholder and CSR approaches, an increasing number of firms have decided to integrate socio-environmental concerns into their strategic management and the value creation process (Porter and van der Linde, 1995).

The growing awareness of the crucial role of firms in the pursuit of sustainable paths has led to important development in doctrine and practice (Kiron *et al.*, 2017; Nave and Ferreira, 2019). The literature showed ample interest in whether and how firms could align their strategies to sustainability direction (Roy *et al.*, 2013). The need to pursue a "sustainable attitude" has swept away the traditional views about firms' competitiveness, survival and profitability (Vilanova *et al.*, 2009; Garzella *et al.*, 2020); the profit remains an essential element to pursue, but it

must be consistently balanced with equally important social and environmental purpose. This view opens opportunities for more integrated approaches to CSR. In this sense, some scholars argued that correct implementation of socio-environmental strategies can be considered is a critical variable for firms able to trigger new competitive dynamics (Porter and Van der Linde, 1995; Clarkson *et al.*, 2011; Garzella and Fiorentino, 2014). In particular, recent studies in the field of strategic management claim that the attention to socio-environmental issues can greatly affect business success by strengthening the strategic positioning in the firm-customers and firm-investors relationships (Garzella *et al.*, 2020; Capurro, 2020). In this stream of research, scholars developed the environmental social responsibility (ESR) as an autonomous research topic (Hart, 1995; McWilliams and Siegel, 2001, Devinney, 2009).

The transition to a green economy has opened new opportunities for firms by leading them to improve their business models (Engert and Baumgartner, 2016). This process has led several firms to re-orient their management processes in a perspective of sustainability (Schaltegger *et al.*, 2016; Llerena, and Wagner, 2012); firms progressively conform their strategic, organizational and governance models with the adoption of environmentally sustainable techniques, technologies and production processes to comply – or even anticipate - the expectations of several stakeholders (Freeman and Dmytriiev, 2017; Buysse and Verbeke, 2003). Thus, firms are shifting from a traditional business model to a sustainable one by integrating social, environmental and ethical principles into their value propositions (Fiorentino *et al.*, 2020).

The demand for continuous improvement in environmental, social, and governance (ESG) practices has led scholars to identify actions, decisions and practices that firms could embrace to become more sustainable (Bowen *et al.*, 2018; Burrit *et al.*, 2019). In this process, some studies in the field of strategy and sustainability management argue that the development of green innovations could be considered as key factor for firms to gaining new positions of competitive advantages and creating differentiation benefits (Farla *et al.*, 2012; Jacobsson and Bergek, 2011).

According to Bartlett and Trifilova (2010, p.2) green innovations can be defined as a "new products and processes which provide customer and business value but significantly decrease environmental impacts". Moreover, also the development a new business models can be green innovation (Schiederig *et al.*, 2012). The calls for support the implementation of products/services and/or the firm's business

model focusing on sustainability require new, or significantly improved, production processes, managerial models and institutional procedures (Song *et al.*, 2019; Markard *et al.*, 2012). Overall, the development of green innovations involves the decision-making processes transformations, including strategic changes in operational process, governance practices, supply chains, and organizational models (Lampikoski *et al.*, 2014). Moreover, implementing green innovations requires the availability of adequate tangible and intangible firm's resources; human and financial resources, as well as technological, organizational and management capabilities are assumed to implement green innovations (Kesidou and Demirel, 2012; Song *et al.*, 2019).

In order to support firms' transition toward sustainable business model, it is important to analyze, firstly, the several internal and external factors that favoring the development of green innovations.

### **3 The factors favouring the adoption of green innovations**

In business literature, a flourishing debate concerning the factors that favour the adoption of green innovations is established (Albort-Morant *et al.*, 2017; Weng and Lin, 2011; Cuerva *et al.*, 2014). Scholars identify several external and internal factors affecting the managerial decisions related to the selection and implementation of green innovations (Jun *et al.*, 2019; Engert and Baumgartner, 2016).

With reference to the external factors, the context peculiarities and the business sector characteristics push each firm to develop appropriate management processes and strategic tools to support their sustainable paths of growth (Schiederig *et al.*, 2012). In this scenario, several external pressures towards the adoption of green innovations can be linked to expectations of firm's stakeholders (Cai and Li, 2018; Lampikoski *et al.*, 2014).

Specifically, one of the most influential stakeholders is represented by the public administrations with which firms interface (Hojnik *et al.*, 2018). In addition to the introduction of compulsory regulations, the public bodies endorse the development of green innovations by offering fiscal or monetary benefits in order to obtain positive externalities connected to the socio-environmental sustainability (He *et al.*, 2018; Mazzanti, 2018).

Also, suppliers can press on their client firms to develop green innovations in line with those already adopted by themselves, or to implement their innovative

output (Yalabik and Fairchild, 2011; Guoyou *et al.*, 2013). Similarly, the firms embrace the green innovations to realize products/services in line with needs of customers more and more increasingly attentive to socio-environmental issues (Porter and Van der Linde, 1995). Firms should favour the design and management of green innovation by identifying new integration and coordination opportunities among their value chains and the value chains of external partners, both customers and suppliers (Garzella *et al.*, 2020; Capurro, 2019; Chesbrough, 2003); the greater the degree of integration and cooperation with other companies, the greater the likelihood of adopting eco-innovations (Hojnik *et al.*, 2018).

Moreover, financial intermediaries and investors can stimulate firms to adopt eco-innovations by showing a greater propensity to finance environmentally friendly investments (Aguilera-Caracuel and And Ortiz-de-Mandojana, 2013).

About internal factors, the possession of particular resources and capabilities are determinants to develop successful green innovations. In particular, the availability of tangible human and financial resources, and to the technological, organizational and management capabilities play a key role in the development of green innovations (Llerena, and Wagner, 2012).

Moreover, the diffusion of an organizational culture "sustainability oriented" can have a positive influence on the implementation of green innovations, both internally and externally (Garzella and Fiorentino, 2014). In the first case the top management could stimulate the development of green innovations by encouraging their employees; in this sense, top management efforts could be directed to promote incentive systems based on rewards to employees who develop new environmental ideas or programs to raise employee awareness on environmental issues (Garzella *et al.*, 2020). With reference to the effects on the firm's external, the green culture could favour the adoption of green innovations acting, for example, on image improvement, the firm's legitimacy, on to be a first mover, motivation of employees (Venturelli *et al.*, 2017). These aspects are relevant sources of competitive advantages (Porter and Kramer, 2006).

Overall, the development of green innovations can be motivated by environmental, competitive and economic concerns; like any investments, green innovations impact on consolidated production on actual and expected cost configurations and revenues, with consequences on economic and financial dynamics as well as on medium-long term competitiveness. In this sense, firms should develop a new business model that allows the implementation of

successful green innovations by analysing their impact on the overall firm's strategies, both at corporate and business level.

#### **4 The theoretical framework on green innovations**

The socio-environmental concerns call for new perspectives in the business models of firms. The crossover analysis on green innovations highlights their key role in strengthening the competitive positioning in the firms-stakeholders and in increasing the firm's social value. Based on the insights from literature review, we develop a framework useful to improve firms' sustainable paths of growth, analysing the impact of the green innovations development, with related benefits, into the system of the firm's strategies.

Specifically, strategic management scholars identified two main levels of strategies: the corporate level and the business level (Collis and Montgomery, 1997; Garzella and Fiorentino, 2013). The corporate level concerns the overall objective, scope and processes of firm to accomplish its goals and to fulfil stakeholder's expectations; the business level, instead, involves the achievement of new positions of competitive advantage on based of firm's strategic decisions (Galeotti and Garzella 2013). Moreover, the evolution of studies on the topic lets to recognize also an area related to "boundary zone", occurring activities and processes jointly controlled and influenced by many organizations through "linking" and bearing strategies (Garzella, 2000; Caputo et al., 2019; Capurro 2000; Garzella et al., 2020).

In order to reach the research aim, the framework is modelled on this categorization (Table 1). In this sense, our study provides a theoretical comprehensive framework that allows to capture the variety of strategic green actions and practices that can be connected into each level of the firm's strategies to facilitate the development of green innovations. Furthermore, we suggest the related benefits associated to the development of green innovations for firms supporting their decision-making process; the list of items is not intended to be a comprehensive one but represents a starting point to further and future improvements. Thus, firms can be guided in the transition towards sustainability by supporting an evolution of their business model evolution based on successful green innovations.

Table 1 – Implementing green innovations in the system of the firm's strategies

Level of strategy		Green innovations	
		Green actions	Benefits
<b>Corporate level:</b>			
Portfolio strategy	➤	Restructuring firm's portfolios business	➤ Increase exposure to high-value sustainable market positions
		Green business entry	➤ Reduction of risk exposure
		Pollutant business exit	➤ Efficient resource allocation
		Decisions on centralization/decentralization	➤ Increase corporate image
		Green strategic alliances	➤ Reduction of production
		Green synergies	➤ Increase firm's eco-efficiency
Financial strategy	➤	Implementation of processes in respect of biophysical environment	➤ Possibility of receiving capital at favourable conditions
		Green investments	➤ Less exposed to operational, legal and reputational risks
		Adoption of environmental, social and governance (ESG) practices	➤ More interest by investors and financial stakeholders
Social strategy	➤	Environmental impact reduction	➤ Increase firm's value
		Improve the living conditions of local communities.	➤ Increase social reputation
		Cooperative alliances with environmental organizations	➤ Increase corporate image
		Reduction of air pollution and climate change	➤ Green initiatives found and supports
		Improve waste and water management	➤ Green awards
		Development of greener business transports	➤ Social stakeholders' perception of environmental performance
		Green programs and communication of environmental actions to	

	community		
	➤ Reduction of environmental incidents		
	➤ Use of sustainable energy sources, replaceable resources, components and raw materials		
Organizational strategy	<ul style="list-style-type: none"> <li>➤ Promote incentive systems based on rewards to employees who develop new green ideas</li> <li>➤ Create organizational "green units" projects</li> <li>➤ Promote programs to raise employee awareness on socio-environmental issues</li> <li>➤ Improving the internal communication of sustainable actions to employees</li> </ul>	<ul style="list-style-type: none"> <li>➤ Positive impact on firm's routine</li> <li>➤ Positive impact on corporate culture</li> <li>➤ Positive feedback from employees</li> <li>➤ Shared and clear business objectives</li> <li>➤ Development new competences and capabilities</li> </ul>	
<b>Business level:</b>			
Competitive strategy	<ul style="list-style-type: none"> <li>➤ Environmentally friendly products/services,</li> <li>➤ Product offer for environmental conscious consumers</li> <li>➤ Introduction of recyclable packaging</li> <li>➤ Programs to educate consumers on environmental issues</li> <li>➤ Communication of firm's environmental actions to consumers</li> <li>➤ Environmental standards for suppliers selection</li> <li>➤ Reduction in consumptions of</li> </ul>	<ul style="list-style-type: none"> <li>➤ Competitive advantage by differentiation or by cost leadership options</li> <li>➤ Increase quality perception</li> <li>➤ Increase customer perception of environmental performance</li> <li>➤ Increase corporate image</li> <li>➤ Reduction of production costs</li> </ul>	

natural resources			
Boundary level:			
Linking and Bearing strategies	➤	Collaborative networks	➤ Increase firm's value
	➤	Green strategic alliances	➤ Improve business performance
	➤	Green partnerships	➤ Innovative green ideas
	➤	Green technological clusters	➤ Exploitation of new emerging technologies
	➤	Smart working	➤ Reduction of costs during the design and development of products
	➤	Collaboration with Research centers/Universities to solve general environmental problems	➤ Minimize the environmental impacts related to the overall supply chain.

The framework highlights that the development of green innovation affects the decision makers with regard to, for instance, products differentiation, increasing customer satisfaction, environmental regulations, sustainable incentives and/or technological progress; managers should carefully take decisions regarding, for example, the exit from pollutant business or the increase of eco-R&D investments in order to develop sustainable products, services, processes and initiatives focused on the social needs of people and on the environmental preservation (Peattie and Belz, 2010; Garzella et al., 2020; De Medeiros et al., 2014).

## 5 Conclusion

Our study categorizes internal and external factors that push firms to embrace green innovations in order to guide the decision makers to select the right strategic moves from the available ones. The advanced framework suggests, both at corporate and business level, relevant issues, strategies and actions, with related benefits, in order to improve firms' sustainable paths of growth, by managing at the same time, from a side, the relationship between the firms and the external environment and, from another side, a careful assessment of internal processes. Finally, the crossover analysis on green innovations highlights their key

role in strengthening the competitive positioning in the firms-customers and firms-investors relationships and in increasing the firm's social value.

By examining sustainability issues ranging from theory to practical application, the paper provides new insights and critical points by enriching the fragmented literature on green innovations and supporting the managers' commitment to implement successful sustainability strategies. Moreover, the integrated framework on green innovations provides guidance for both academic and managers offering a concrete response to corporate issues in terms of social and environmental responsibility.

Specifically, the study contributes to several literature streams such as strategic management, sustainability and innovation studies. Specifically, our contribution is relevant for strategic management studies because it proposes a crossover analysis on green innovations highlighting problems and limits related to their integration in the strategic planning process. With reference to sustainability literature stream the study proposes an in-depth analysis of factors, both internal and external, affecting the selection and implementation processes of green innovations. Moreover, with reference to innovation management, the framework provides a conceptual model able to identify sustainable ideas, goals and actions at corporate and business level that firms could embrace to maximize potentiality and reduce risks in implementing green innovations. Finally, the study suggests implications for practitioners to support an evolution of sustainable business models underling how firms could improve their ability to grasp external stimulus and therefore to endorse sustainable investments in green innovations.

### **Abstract**

The adoption of blockchain-based technologies for a sustainable agri-food sector is a recently developing area of inquiry. Blockchain technology promises to be a significant enabler of sustainability in the agri-food sector. However, there is still limited understanding on how the blockchain technology can promote agri-food sustainability, because its adoption is still in an early stage and the related literature is relatively limited.

This paper reviews and critically evaluates the available research with the aim to understand 1) how it is developing, 2) what are the main research foci, and 3) what future research directions are needed.

We analyzed a total of 31 studies extracted from the Scopus database using a structured literature review (SRL) methodology. We found evidence that the topic

is attracting a growing research interest and identified two main research areas: studies that focus on the technological components of blockchain with the aim to provide operational frameworks for blockchain-based food traceability, and studies that deepen the potential benefits, the challenges and the boundary conditions for blockchain adoption in the agri-food sector. Additionally, the coding analysis reveals that much of the reviewed studies are from the USA, the UK and India, and tend rely on the case study methodology.

To the best of our knowledge, there are very few review articles that describe the development of this research stream. The main limitations of this study are the sampling method (limited to a Scopus search) and the methodological approach employed to code and analyze the literature, which involves some degree of subjective interpretation.

**Keywords** — Blockchain, sustainability, supply chain, agri-food sector

**Paper type** – Academic Research Paper

## 1 Introduction

In the last few years, the agri-food sector has been facing many challenges concerning scarcity of natural resources, population growth and climate changes, and the need for food safety and quality (FAO, 2019).

The food chain needs to become more sustainable in order to improve consumers' trust and foster their purchase willingness (Feng et al., 2020).

In fact, the solution to address the food safety and quality concerns is to improve traceability transparency, security and integrity (Feng et al., 2020; Tsang et al., 2018; Helo and Hao, 2019; Banerjee et al., 2018; Li et al., 2020).

As ensuring food safety, quality, traceability along with post-harvest management are complex and intricate issues in the agri-food supply chain, food manufacturers have evinced interest to use blockchain with the existing Information and Communication Technologies (ICTs) i.e. Internet of Things (IoT), Radio Frequency Identification (RFID), cloud computing, machine learning, and artificial intelligence (Lehmann et al., 2012).

Blockchain is defined as "a digital, decentralized and distributed ledger in which transactions are logged and added in chronological order with the goal of creating permanent and tamper-proof records" (Treiblmaier, 2018). As such, blockchain is regarded as a promising technology that can help to build trust

mechanism for solving the transparency and security issues as no single party in the supply chain can alter existing information (Feng et al., 2020).

The literature suggests that the application of blockchain in the agri-food industry can improve process transparency and efficiency (Papa, 2017). In fact, blockchain technology can increase the levels of verification efficiencies and automation (Cole et al., 2019) and facilitates the digital traceability and authentication of food products throughout the entire supply chain suppliers to store shelves and finally to end consumers (Tijan et al., 2019).

In these last few years, studies on the implications of blockchain in agri-food sectors have increased, but there are still some limits to understanding how the blockchain can be used to improve the food traceability performance through the full information transparency and security dimension of food chains (Kim and Laskowski, 2017; Yiannas, 2018). Therefore, there is a need to understand how the blockchain is evolving within the context of agri-food.

Based on a structured literature review (SLR), this paper critically analyses the studies that specifically deal with the application of blockchain in the agri-food sector, provides an overview of the state of literature and outlines a future research agenda.

A SLR is a method for studying a corpus of scholarly literature, to develop insights, critical reflections and future research directions (Massaro et al., 2016).

This paper uses the SRL method to address the following interrelated research questions:

*RQ1. How is the literature on blockchain and sustainability in the agri-food sector developing?*

*RQ2: What are the main research foci?*

*RQ3. What future research directions are needed?*

The remainder of this paper is organized as follows. Section 2 explains the research methodology; Section 3 explores the results and discussion answer the first two research questions. Section 4 which concludes the paper presents our views on the future of blockchain and agri-food research, some closing remarks and the limitations of our research.

## **2 Research Methodology**

SLR methodology is applied to this research (Lombardi and Secundo, 2020; Kraus et al., 2020; Massaro et al., 2016; Petticrew and Roberts, 2006; Tranfield et

al., 2003) for understanding the role of the blockchain in the agri-food sector as an instrument for developing sustainability and traceability.

Following the methodological approach of previous works (Lombardi and Secundo, 2020; Massaro et al., 2016; Dumay and Cai, 2015; Dumay, 2014a; Dumay and Garanina, 2013; Guthrie et al., 2012), we have developed a multi-step review process to collect and analyze the studies on the topic of Blockchain in the agri-food sector.

The following sub-sections detail the steps we took to develop the structured literature review.

### ***2.1 The literature review protocol***

The first step of the review process starts to answer a question: why develop a literature review on blockchain and sustainability in the agri-food sector? In this regard, we have decided to analyze the existing academic literature on the topic of blockchain, because, to date, the review articles that examine the developments, the benefits and challenges connected with the adoption of blockchain in the agri-food field are very few.

The selection of the papers has been restricted to the studies that consider the blockchain as an enabler of sustainability and traceability in the agri-food sector. We selected the studies that featured the terms “blockchain” and “food” and “supply chain” in the title, abstract or keywords. Thus, we excluded from the review those studies that consider the blockchain technology in general terms and do not focus on the agri-food sector. We also narrowed the search to journal articles excluding book chapters, conference articles and editorials and notes. As a result of this search, we found 31 articles over the period 2019–2021. The 31 articles included in the SRL are marked with an asterisk in the References section.

The review process also implied the creation of a citation index and the definition of different categories in order to classify the selected papers. The indexation and categorization of the reviewed papers provides a useful understanding about the pathway followed by researchers.

### ***2.2 The literature review search process***

The second step of the review process involved selecting the database needed to collect the papers subjected to the structured review. Using the Scopus

database, we have selected 31 articles from internationally recognized academic journals that belong to several subject areas (according to Scopus classification) such as Business, management and accounting, Computer Sciences, Engineering, Decision Sciences, and Environmental sciences. The journals that have published the 31 papers included in the sample are the following:

Applied Economic Perspectives and Policy (2)  
British food journal (2)  
Computers in Industry (1)  
Decision Sciences (1)  
International Food and Agribusiness Management Review (1)  
International Journal of Industrial Engineering and Management (1)  
International Journal of Information Management (2)  
International Journal of Logistics Management (1)  
International Journal of Logistics Research and Applications (1)  
International Journal of Production Economics (1)  
International Journal of Production Research (1)  
International Journal of Scientific and Technology Research (1)  
International Journal on Food System Dynamics (1)  
Journal of Cleaner Production (5)  
Management decision (1)  
Production, Planning & Control (2)  
Quality - Access to Success (1)  
Quality Management Journal (1)  
Resource conservation and recycling (1)  
Supply Chain Management (2)  
Sustainability (1)  
Transportation Research Part E: Logistics and Transportation Review (1)

### **2.3 Analytical framework**

The third step consisted in developing the coding framework and categorizing the selected articles accordingly. Our coding framework is based, with some adaptations, on the coding categories developed by Lombardi and Secundo (2020), namely:

- Timing of publication: the evolution over time of the number of papers
- Geographic distribution of papers

- Author and citations analysis: number of citations of articles, citations per year (CPY)
- Research Method: the specification of the research method used in the reviewed studies
- Research Focus: the identification of the research areas emerging in the literature.

The results of this coding procedure will be analyzed in next section.

### 3 Results and discussion

In this section we answer the first two research questions: first, how is the literature on the blockchain and sustainability within the agri-food sector developing? and second, what are the main research foci?

#### 3.1 Timing of Publications

As said previously, we found 31 articles considering the period from 2019 to 2021. This indicates that the literature on blockchain in the agri-food sector is recent but it is growing rapidly, as shown in Figure 1, due to an increasing number of works published over the last two years.

We have decided to include the current year (2021) in the citation analysis, even if it is not yet concluded and we expect other papers to be published.

Figure 1 : Articles' evolution over time

### 3.2 Geographic Distribution of articles

In order to analyze the geographic distribution of the reviewed articles, we computed the number of articles and the number of citations per country (Fig. 2). Following Lombardi and Secundo (2020), we considered the involvement of a country (by university / research institution) in the articles' authorship and, when an article was co-authored by authors from different countries, each country received one point. As a result, we found that:

The top four countries in terms of number of articles are USA (7), India (7), Italy (7), UK (7), followed by China (6). 9 out of 16 countries have only one article, and 2 out 16 have two articles.

The top three countries in terms of citations are USA (210), India (182), and UK (171). These are also amongst the first countries in terms of scientific productivity.

Overall, these findings suggest that the existing studies are somewhat 'fragmented' among countries and that, to date, no country is truly specialized on the topic of blockchain adoption for agri-food sustainability, even though some countries are more prolific than others.

Figure 2: Geography of articles by number of items/citations per country

### 3.3 Articles citation analysis

The third step of the analysis shows the research impact of the sample articles based on the number of Scopus citations. We have chosen two different measures to classify the articles by their citation impact. First, we ranked the articles based on the absolute number of citations extracted from the Scopus database (Table 2).

Table 2. Top ten articles ranked by Scopus citations

Authors	Title	SCOPUS citations
Kamble S.S., Gunasekaran A., Gawankar, S.A. (2020)	Achieving sustainable performance in a data-driven agriculture supply chain: A review for research and applications	104
Behnke, K., Janssen, M.F.W.H.A (2020)	Boundary conditions for traceability in food supply chains using blockchain technology	93
Zhao, G., Liu, S., Lopez, C., Lu, H., Elgueta, S., Chen, H., Boshkoska, B.M. (2019)	Blockchain technology in agri-food value chain management: a synthesis of applications, challenges and future research directions	91
Bumblauskas, D., Mann, A., Dugan, B., Rittmer, J. (2020)	Blockchain use case in food distribution: Do you know where your food has been?	61
Feng H., Wang X., Duan Y., Zhang J., Zhang X. (2020)	Applying blockchain technology to improve agri-food traceability: A review of development methods, benefits and challenges	47
George R.V., Harsh H.O., Ray P., Babu A.K. (2019)	Food quality traceability prototype for restaurants using blockchain and food quality data index	40
Kumar A., Liu R., Shan Z. (2020)	Is Blockchain a Silver Bullet for Supply Chain Management? Technical Challenges and Research Opportunities	32
Kittipanya-ngam P., Tan K.H. (2020)	A framework for food supply chain digitalization: lessons from Thailand	30
Rogerson, M. and Parry, G.C. (2020)	Blockchain: case studies in food supply chain visibility	17
Yadav, V.S., Singha, A.R., Rautb, R.D., Govindarajanc, U.H. (2020)	Blockchain technology adoption barriers in the Indian agricultural supply chain: an integrated approach	15

However, as suggested by Dumay and Cai (2015), the problem with determining the research impact by the total number of citations is that older articles can accumulate more citations. For this reason, in order to counterbalance this trend, we also ranked articles using the number of citations per year (CPY).

As shown in Table 3, the results of our analysis remain almost unchanged. This is because, with some exceptions (George et al., 2019; Zhao et al., 2019), the articles with the highest number of citations were published in 2020, and the CPY is calculated as total citations divided by the number of years between the date of analysis and the date of publication (Massaro et al., 2015).

Table 3. Top ten articles ranked by citations per year (CPY)

Authors	Title	CPY
Kamble S.S., Gunasekaran A., Gawankar, S.A. (2020)	Achieving sustainable performance in a data-driven agriculture supply chain: A review for research and applications	104,00

### **3.4. Research method**

The articles were further categorized based on the research method into:

- Case study (13 articles)
- Empirical survey (6 articles)
- Literature review (5 articles)
- Conceptual framework (4 articles)
- Mathematical modeling (2 articles)
- Structural equation modelling (1 article)

As expected, we found many articles (13) based on case studies. The topic of blockchain adoption in the agri-food is a recently developing area of inquiry and the case study methodology is particularly suitable to describing, exploring, and understanding an emerging phenomenon in its real-life context. Next, we found six empirical surveys which are aimed at analyzing the benefits and the issues associated with the adoption of blockchain technologies from the perspective of food supply chain actors, consumers or blockchain experts (Aldrighetti et al., 2021; Kayikci et al., 2020; Rainero and Modarelli, 2021, Shew et al., 2021; Yadav et al., 2020).

Furthermore, we found five review articles (Ben-Daya et al. 2021; Feng et al., 2020; Kumar et al., 2020; Rana et al., 2021; Zhao et al., 2019). The relatively low number of literature reviews is not surprising given that the adoption of the blockchain technology in the agri-food sector is still in an early stage and that the related literature has grown only in recent years. Four articles (Casino et al., 2020; Collart and Canales, 2021; Guido et al., 2020; Dinesh Kumar, Manoj Kumar and Anandh, 2020) are based on a conceptual analysis of blockchain-based food traceability systems and one (Hew et al., 2020) uses the structural equation modelling to examine the intention of food supply chain actors to participate in a block-chain based food traceability system.

### **3.5 Research focus**

The last criterion of classification is the research focus of the sample articles. In order to identify the main emerging research areas, the authors performed a deep content analysis of the 31 papers. This process led to identifying two main research areas:

1. Studies that focus on the technical components of a blockchain-based food traceability system;
2. Studies that deeply analyze the potential benefits, the barriers and the boundaries conditions for blockchain adoption in the agri-food sector.

The first category is composed of (14) articles that provide operational frameworks for implementing a blockchain-based food traceability system. Overall, these studies show that the main advantages linked to the use of the blockchain compared to the traceability methods currently used concern: the absence of a third party responsible for controlling the logistics chain; greater transparency of data and information; shorter traceability times in the event of a food crisis; greater ability of the final customer to check the type and characteristics of the purchased product; greater economic security for primary producers thanks to the possibility of planning agricultural and cultural activities according to supply contracts stipulated before the start of activities (Guido et al., 2020). Pappa et al. (2018) conclude that the choice or adoption of integrated blockchain technologies is attributed to an electronic traceability system that has gained salience as a risk management tool to ensure food safety, food quality, and chain integrity.

The second category groups all studies (17) that have deeply analyzed the benefits, the barriers and the boundary conditions to the adoption of blockchain in the agri-food sector.

According to Tiscini et al. (2020), the potential benefits of the blockchain adoption in the agri-food industry can be summarized through four main drivers of sustainability:

1. Traceability
2. Labelling
3. Organic farming
4. Financial efficiency

With respect to point (1), the traceability is regarded as a driver to ensure the quality of food production through transparency and verifiability (Bastian et al., 2013).

With respect to point (2), it is argued that the blockchain allows for the disclosure of a huge amount of data and avoids labeling frauds through QR code (Tripoli and Schmidhuber, 2018).

With respect to point (3), the blockchain adoption is argued to enhance consumer trust regarding the organic farming, because customers and auditors

may be assured of farming processes in a more secure and efficient way (McCarty et al., 2016).

With respect to point (4), the blockchain has the potential to virtually remove the risks of fraud allowing transaction without trusted parties, as the system will certify and enable the payment. In turn, efficient transactions in agri-food supply chains would lead to greater financial inclusion and rural business development (Tripoli and Schmidhuber, 2018).

Further benefits identified in the literature include:

- Informational security

According to Puthal et al. (2018), Ølnes (2016), Conoscenti et al. (2016), the information stored in the blockchain technology is more reliable due to the consensus mechanism. Similarly, Tijan et al. (2019), state that Blockchain facilitates the digital traceability and authentication of food production throughout the entire supply chain from suppliers to store shelves and finally to end consumers. Feng et al. (2020) argue that the blockchain has a strong impact on the research and practice for agri-food product traceability.

- Improvement of trust between supply chain members

Blockchain can enhance trust and collaboration among supply chain partners (Tian, 2016). The blockchain allows the development of participated business model, in which stakeholders can be actively involved in the organization's decision-making process. Such engagement is more trustable, clear and rigorous, thanks to the technological features of the blockchain than other available modern technologies (Dal Mas et al., 2020). The information transparency obtained with the use of the blockchain becomes a strategic element to consolidate relations between company-customer and company-stakeholder and to create durable value over time (Mercuri et al., 2021).

- Sustainability and transparency of traceability management

Kshetri et al. (2018) argue that blockchain technology enables end-to-end traceability. It can meet the requirements for tracing the origin of products from farms to consumers.

As a result, the application of blockchain technology can build trust among stakeholders, which will allow them to gain insight into the entire supply chain (Feng et al., 2020). The application of blockchain can make significant contributions to effective sustainability and transparency of traceability management (Galvez et al., 2018; Hong et al., 2018; Chang et al., 2019). As stated by Mercuri et al. (2021), the lack of transparency and traceability in the agri-food

sector generates inefficiencies and poses future challenges for overcoming fraud attempts, pollution, human rights violations and many other inefficiencies. In an increasingly complex scenario, blockchain has the potential to increase the level of transparency, traceability and sustainability, through the use of a shared and decentralized database, in which information is immutably stored and encrypted, avoiding the problems of tampering and data forgery.

Nevertheless, the existing literature also points to several challenges that need to be addressed if the blockchain is to deliver the promised benefits. Specifically, the reviewed articles (e.g. Feng et al., 2020; Rana et al., 2021; Rogerson and Parry, 2020; Zhao et al., 2019) point to the following challenges for applying the blockchain technology in the agri-food supply chain: 1) technical challenges such as limited storage capacity, scalability and data processing issues (Tian 2016); 2) privacy leakage: the blockchain cannot ensure the transactional privacy because each transaction can be traced and every user identified by all participants to the network; 3) high cost problem: blockchain-based food traceability solutions may be very expensive (Lin and Liao, 2017) and complex blockchains such as blockchain-based agri-food supply chains may require a high computation power, which entails a higher energy consumption as well; 4) the human input element: errors and corruption in data entry are compounded in block-chain based systems because the technology's built-in trust mechanism may lead to accepting data unhesitatingly; 5) regulatory issues: there is a need to introduce a legal and regulatory framework to guide the blockchain application in the agri-food sector considering this issue from a global perspective; 6) lack of skills: there is still limited knowledge and skills about how blockchain can be used on behalf of agri-food value chain participants. Finally, the literature suggests that the blockchain technology will not fulfill its potential until the agri-food supply chains are fully digitized beforehand (Kayikci et al., 2020; Rogerson and Parry, 2020).

#### **4 Conclusions and future directions**

This paper aimed to critically review the available literature on blockchain in the agri-food sector. By employing a multi-step review process, 31 articles were selected, examined in order to determine their impact, and then classified according to their:

- Timing of publication
- Geographic distribution of papers

- Author and citations analysis
- Research Method
- Research Focus

In the first part of the paper we answered the RQ1: “How is the blockchain and sustainability literature within the agri-food sector developing?” and the RQ2: “What is the focus of the blockchain and sustainability within the agri-food sector?”.

In particular, we showed that in these last few years the literature on blockchain adoption in the agri-food sector 1) has rapidly grown with an increased scientific impact as measured by the number of Scopus citations, 2) is somewhat fragmented among countries even though some countries such as USA, the UK and India are more prolific than others; 3) has often employed the case study methodology; and 4) has focused on two main research areas: first, the impact of blockchain-based technologies on the agri-food product traceability mainly from a technical perspective, that is: many studies use the context of agri-food supply chain to discuss the technological components of blockchain and highlight the key design and implementation challenges mainly from a technical perspective; and second, the potential benefits, the barriers and the boundary conditions to blockchain adoption in the agri-food sector.

In response to RQ3: “What is the future of the blockchain and sustainability within the agri-food sector? we point out that the adoption of blockchain for the agri-food sustainability has not yet been fully investigated and that scholars should be committed to develop those areas not yet covered or underexplored by the existing research. Considering the findings of this article, the latter assertion has the following implications.

The first implication concerns the need to further increase the number of case study analyses examining the impact of blockchain on agri-food sustainability in real use cases. In particular, in the literature there are still few studies about the economic and organizational impact of the blockchain application in real agricultural supply chains. Many articles limit themselves to simulate the possible application of this disruptive technology. Therefore, further real case studies could be very useful to estimate actual costs, benefits and socio-organizational impacts.

Second, there is a shortage of studies that explore the actual propensity of the various participants in the agri-food supply chain to adopt the blockchain-based technologies and the key benefits and challenges they perceive with the use of

blockchain. Indeed, we found only a few articles that analyse the benefits and challenges of blockchain adoption from the perspective of agri-food supply chain actors (e.g. Hew et al., 2020; Saurabh and Dey, 2021). This research focus is particularly relevant because the openness of a blockchain based platform may involve the disclosure of confidential data and stakeholders in the supply chain may not be willing to do so.

Third, there is a need to increase studies on the impact of blockchain technology adoption on financial performance in the agri-food sector.

And fourth, we believe it interesting to study the impact of the blockchain technology under the framework of intellectual capital, considering that the blockchain can impact on the structural capital and relational capital. To the best of our knowledge, to date only a few studies have grasped this link (Ruzza et al., 2020).

Our study is not free of limitations. First, the selected articles descended from certain search criteria and thus results may vary according to different search criteria. Second, the chosen coding criteria cannot be considered an exhaustive framework for describing the adoption of blockchain technology research. Finally, as with all interpretative research, the findings are limited by the breadth and depth of the data analysed and by our interpretation of the results. Although the structured literature review method may be deemed more reliable than other traditional authorship literature reviews, researchers using the same method and dataset may come up with different conclusions.

### Abstract

The goal of the paper is to investigate about the impact of the crisis generated by Covid-19 on the Italian wine sector and how technological innovation has contributed to the going concern of Italian wineries.

As is well known, the slowdown in the national economies and, particularly, the dramatic reduction in the tourist flows, has affected the “ho.Re.Ca.” industry, that is strictly connected to the agri-food sector; but nevertheless, the latter managed to maintain good level of profitability both for its characteristic of satisfying unavoidable basic need and for the change in the eating habits of people, who now prepare and consume meals at their own home.

Some researches show that Italian wine sector suffered a drastic reduction in turnover growth rates during the months of lockdown (Paoloni, Cosentino, Dello Strologo, 2020), but they also argue that technological innovation has allowed to some wineries to overcome the crisis. In the wine sector, during the pandemic emergency, the e-commerce infrastructure has become the main success factor.

The questions that then arise are the following: “How does Covid-19 impact on the main financial results of Italian wineries? Have digital sales allowed revenues not to decrease, causing a change in the sales channel, or have not been able to replace the traditional buying experience? Is the present emergency an opportunity, instead of a threat, to make Italian wineries’ economic performance boost through e-commerce?”.

To test our thesis and to answer to the research questions, we set a data sample of Italian wineries and we collected, in addition to the main financial and economic ratios, before and after the pandemic emergency, some e-commerce indicators,. Applying descriptive statistical techniques to the data set, we found interesting results on the resilience of Italian wine sector and on its perspective growth.

## 1 Introduction

Winston Churchill said "some people regard private enterprise as a predatory tiger to be shot. Others look on it as a cow they can milk. Not enough people see it as a healthy horse, pulling a sturdy wagon". Despite the role of the business fabric and its socio-economic implications in the functioning of the world system, the Covid-19 health emergency spared no one and all sectors were affected by the necessary restrictions adopted, generating irreversible consequences.

One of the greatest consequences of Covid-19 for the Italian country and its economy is undoubtedly the impact of the total shutdown of the tourism sector. Due to the close correlation with tourism activities, the agri-food sector has also been affected by the crisis, particularly in a country like Italy, known and appreciated by tourists in terms of culinary values. Tourism is a complex supply chain involving many players. The supply side of the sector is highly fragmented and diverse, covering a wide range of activities and actors (OECD, 2020) such as service and information providers (online/offline), travel and tourism agencies, visitor attractions, accommodation, Food&Beverage suppliers and others (Korže, Škabar, 2020). The outlook for tourism in 2020 was downgraded several times during the pandemic; future uncertainties and lack of situational awareness generated extremely pessimistic scenarios for the future of the sector. During the first weeks of the pandemic the surveys conducted on European stock markets showed that out of a sample of 15 quoted tourism companies, the market cap fell dramatically due to the sharp drop in values. From February to March, the shock caused a contraction of -62.2%; Edreams Odigeo S.A., the Spanish giant tour operator, had seen a 71.1% fall in the time period 17 February to 19 March 2020. By July, the market cap decline had been reduced to 37.8%, still a very high figure explained by the inability to understand when the big chemical companies would get a vaccine that could counter the spread of the virus and give flow to the tourism channels again. The outlook at the end of the first half of 2020 foresaw consequences equivalent to three times those seen the 2008-2009 Global

Economic Crisis (UNWTO, 2020). In May, the international tourist number fell 98% compared to the same month of the previous year. There was a 96% decline in booking to Europe across all sub-regions over the period of January-May 2020 compared to the same period of 2019 (ETC, 2020). On a world scale, the shake-up seen in international tourism translated into a loss of 850 million to 1.1 billion international tourists, 910 billion to 1.2 trillion US\$ in export tourism revenues and a 100 to 120 million direct tourism jobs at risk (UNWTO, 2020a). Moreover, the entrepreneurial fabric of tourism presents characteristics that are not comfortable with negative events of this magnitude. Large multinational corporations operate alongside small companies (EC, 2020). In many tourism destinations, small tourism companies are numerically dominant (OECD, 2008), known as SMTEs in this sector (Small and medium sized tourism enterprises) (Beaver, 2005). SMEs are considered to be a cornerstone of the European economy, accounting for around 99% of all enterprises in the EU and two-thirds of total private sector employment (EC, 2020a). Globally, they provide 70% of jobs (ITC, 2020). The most of agribusiness in the wine sectors are Small and Medium Enterprises (SMEs); the sector is made up of a dense network of small businesses, that, even if they have a crucial role in the socio-economic context, taken individually are extremely vulnerable to economic crisis.

Although tourism has been at a standstill for months, the agri-food sector has shown some resilience due to the fact that what it offers is not only experience but also necessity. Some of these necessities have found expression through e-commerce that seems to be just the tool companies and consumers needed to deal with a situation where governments required minimal travel from home.

The drop in sales through traditional sales channels during Covid-19 has led to a boost in the digital wine business (OIV, 2020). In U.S. a two-month lockdown has sparked triple-digit growth in alcohol sales through e-commerce, alcohol delivery apps like Drizly and Vivino, and virtual tastings. Spirits were up 374 percent, while wine and beer were up 242 percent, respectively, as New York-based Nielsen reported in the June issue of Beverage Industry (Beverage Industry, 2020). The rise of e-commerce in spirits sales during Covid-19 has been confirmed by several industry professionals who have been impressed by the exponential growth curve of orders. Sara Goucher, Director Of Ecommerce at Molson Coors Beverage Company, declared that the company's 2020 online sales had grown 230% by November over the same 11-month period in the previous year, and by Thanksgiving about 50% of U.S. consumers were aware they could

buy beer online. While that figure may seem low, only 20% of consumers were aware of digital brew sales before the pandemic (Tiffany, 2021).

However, it must be acknowledged that Italian wineries have seen a drastic drop in turnover despite the development of the digital business model. In the first two months of 2020, there had been 10% growth in company results compared to the corresponding period of the previous year, while by the end of April, growth had shrunk to +1% compared to the first four months of 2019 (Paoloni, Cosentino, Dello Strologo, 2020). This contraction is mainly explained by two factors: the blockage of the "ho.Re.Ca" channel, which caused domestic and international orders to plummet, and, on the one hand, the propensity to consume and the characteristics of demand. Wine, in fact, is one of the products with the highest symbolic value, a cultural asset with social significance (Paoloni et al., 2020), and the state of emergency due to the pandemic has had a negative impact on consumption choices. A 30% drop sales of sparkling and semi-sparkling wines has been noted, and consumption has shifted towards lower-end wines (Paoloni, Cosentino, Dello Strologo, 2020). The result of the drop in turnover was not primarily dependent on volume but rather on value, demonstrating that wine is not only a commodity but a socio-cultural asset.

## **2 The growing impact of on-line activities in the wine sector**

As a result of this contraction, the business has had to adapt to the necessities of the moment by pursuing new strategies and companies have adopted digital channels as sales tools as much as possible. Other companies, however, have found themselves unprepared for this strategy, partly because digitalisation has not yet taken hold of the sector and partly because the wine sector involves a large number of SMEs that are used to working in the traditional manner, depending mainly on in-store sales and their physical retailers. Large companies use e-business faster than SMEs because for the latter access is often limited by several obstacles (Beynon - Davies et al., 2003), primarily due to the high initial costs and maintenance of web-based e-commerce sites. Nevertheless the gap between large companies and SMEs continues to exist, the recent growth of e-business is having a significant impact on entrepreneurs particularly for SMEs. E-commerce is also an important option for the survival and growth of small farms (EFS) (Brooksbank et al. 2003). The rate of growth and the use of e-business varies depending on the country, industry and firm size (Baourakis et al., 2002).

However, a growing number of studies have highlighted the potential of the Internet to help SMEs to be more competitive in the market. Digital channels offer several opportunities in terms of advertising, strategies and costs. In terms of advertising the lack of difference in the amount of space occupied by small and large companies online and the same freedom to adopt more Internet strategies are certainly an advantage for SMEs (Mason, Gos, 2015).

From a strategic point of view two main factors emerge: the possibility of implementing globalization strategies and networking with partners taking into account that the new risk factor for the competitiveness of SMEs is the reduction of costs for larger companies when entering (via the Internet) niche markets dominated by SMEs (Kleindl, 2000).

Regardless of the target group analysed in the business fabric certainly technological innovation has proved to be a bridge for some companies to cope with unforeseeable difficulties offering connection among market and consumers also during a pandemic emergency. Covid-19 accelerated a trend that has existed for a few years now: the increasing use of digital channels as a means of knowledge and consequent purchase. The tendency is recognised in several industry reports and confirmed by strategists and researchers who believe that consumers are increasingly turning to mobile devices to access the Internet and consequently purchase consumer and collectible products (Agnoli, Begalli, & Capitello, 2011; Dvorak, Ritsma, Lai, Strohmenger, & Pappafotopoulos, 2015). Though apparently limited to transactions, e-commerce owes its main success also (and most likely, above all) to the comfort of the global environment of electronic infrastructure (Colla, Lapoule, 2012); most probably, in fact, the global experience of website purchases is the most important factor for e-commerce (Corbitt, Thanasankit, Yi, 2003).

In the last ten years, the purchase experience had become increasingly melted to the consumption experience and characterized by value co-creation (Jaakkola, Helkkula, Aarikka-Stenroos, 2015); from this point of view, the idea of "serving" when assuming that this serving is mutual, seems to be one of the most important dimensions of experience (Tynan, McKechnie, & Hartley, 2014; Vargo & Lusch, 2017). In the Covid-19, buying online is not only the economic consequence of the shutdown, but it is also a social phenomenon, caused by the exigence of people to feel themselves part of a larger community, even if simply virtual.

This situation seems to be true for many kinds of products and even before the Covid era, it also concerned, in some countries, the wine sector (Fiore, Vrontis, Silvestri, Contò, 2016; Pelet, Lecat et Al., 2017). Previously wineries were already involved with the ICT's mainly in the field of tourism, i.e. trips and experiences focused on the knowledge of wineries and wines. In this type of tourism, market power consists in the use of information using ICT devices to satisfy customers' knowledge needs (Connolly and Olsen, 2000) although the progress of the Internet has brought new marketing opportunities for wineries that need to create and maintain websites in order to, among other objectives, achieve direct sales to customers, carry out direct marketing and promote wine tourism (Sellito, 2005). There are important benefits that digital channels offer to this sector, such as intra-industry interaction, improvement of the business image and brand presence, and the increase of visitors (Nowak, Newton, 2008).

Nevertheless Italy is consistently the most important producer of wine in the world, its supremacy didn't seem to affect, in the recent past, the world of wine e-commerce. Italian wineries have not kept pace with other countries in this matter by not sufficiently developing the correlation between wine and the Internet customers. Even though other countries are certainly more advanced than Italy in using e-commerce for selling and buying wine (Faraoni, Rialti, & Zollo, 2018), it is important to remember that experiences of failure in this business have also arisen in more developed countries (Cho, Bonn, & Kang, 2014; Gebauer & Ginsburg, 2010), giving evidence of the difficulty in designing, organizing, and implementing this kind of business model (Pelet et al., 2018). Several researchers such as Higgins et al. (2015) have shown that there have been efforts by wineries to integrate mobile and social media into their marketing strategies but that wine consumers are slow to accept and adopt the new marketing reality. Furthermore, they have demonstrated that the online wine buyer is an older, married man, with a high income. Thus it seems the online wine buyer is more likely to be a wine connoisseur. Despite access and comfort with technology, millennials, the largest portions of ICT users, are unlikely online buyers. The age factor is certainly not a plus for the wine sector in terms of e-commerce development and consumer attention.

Obviously, in addition to the opportunities offered by innovation, the main negative aspects holding back consumers from using e-commerce were identified: concerns about financial security, slow website navigation and insufficient product information.

However, Italy does not seem to be the only country that does not make much use of technological innovations in the wine sector. In Spain, another leading wine-producing country, after identifying the 101 wineries in Aragón and the 591 in La Rioja, a research was carried out to find out whether or not they had a website on the Internet. The research showed that 37.4% of the wineries analysed had a website. More than 70% of the pages reviewed are purely informative. In other words, they only use their websites to provide basic information about their products or business without trying to establish a relationship with the customer or to develop complementary businesses such as wine tourism. Finally, the presence of a small group of websites, less than 10%, which are clearly oriented towards the online sale of their products but without making any attempt to maintain relations with their customers or to offer them additional services (Mercedes Marzo-Navarro, Marta Pedraja-Iglesias, Lucia Vinzón, 2021).

It is therefore clear that it is not enough to have an e-commerce platform, but it is necessary to know how to use it according to the attitude and type of experience the wine consumer wants to have. Otherwise, it can be obsolete to have a digital channel. In wine and commerce, it is essential to execute a series of effective operations that require interactions between sellers and consumers/buyers that can only result from integrating the sales activity into a continuum of processes, considering information mapping, learning, searching, finding, comparing, choosing, and so on, in a global service flow (Bodini & Zanoli, 2011; Xu, Munson, & Zeng, 2017). It is common to identify cases of lack of strategic approach in digital channels where websites have not visibility and/or attractiveness given an adequate wine quality (Capitello, Agnoli, Begalli, & Codurri, 2014). Clearly, a famous wine (or a famous winery) is a huge attraction for a wine consumer/purchaser, however, a famous wine or winery is not sufficient to transform digital platforms into a successful wine-e-commerce site (Carpio & Lange, 2015; Pelet et al., 2018; Faraoni et al., 2018). Just as in the case of Spain, which we have mentioned above, one of the highest risks and common mistakes of wine e-commerce is the underestimation of experience as a system of activities, which are in turn an holistic sum of services which can be considered as outputs (wine assortment, information quality, purchase convenience, logistics flexibility, etc.) or processes (the integrated services of the global electronic environment). In conclusion, wine e-commerce is obviously a commercial activity (such as wine shops, supermarkets, and so on) but, moreover, its fundamentals go beyond the logic of a tool for selling the product, e-commerce is based on the

concept e-service and, consequently, immateriality, intellectuality, and knowledge (Allee, 2000).

Beyond the fact that ICT for wine producers is not as simple as it seems in terms of image and success strategies, it is also necessary to understand who is best equipped in the field.

In the field of technological innovation, the gap between large and medium-small businesses is still remarkable, as in the food industry SMEs was able to approach the “virtual” markets only after 2000s (Giustiniano, Fraticchi, 2002). Twenty years later, this gap has not been totally filled, because recent studies demonstrated that many important Italian wineries focused on e-commerce with a remarkable delay compared to companies in other sectors (Festa, Cuomo, Metallo, 2019). The limitations of economic, human and time resources mean that SMEs are putting e-commerce on the back burner and prioritising not innovation but their traditional forms of business.

### **3 The empirical evidence**

How much e-commerce has contributed to Italian wineries during the pandemic? Which player has been able to use it the most? We questioned whether the digital sales channel was able to deliver the same financial results as a normalised business scenario, although during our initial research we quickly realised that the answer was negative due to a number of inevitable ICT hurdles. The real question is: during Covid-19 has it been understood how e-commerce can be an added value for wineries? Despite the losses recorded, what has been the contribution of the digital channel on the results? What can e-commerce offer a company outside of sales?

It would seem that the lockdown has awakened the attention of SMEs Italian wineries as they have had to adapt to the needs of the moment and turn to another type of purchaser. In a study conducted by Trebicchieri, a business magazine in the Gamberorosso guide, it appears that in an interview with Roberto Bortolussi, founder of the Wine Marketing Italia community, the strategy for Italian wine companies has changed radically in just a few weeks. With exports and the “ho.Re.Ca” channel totally cancelled, companies have started to turn their attention to private individuals and, in particular, beginning to exploit social channels. In times of lockdown, smartphone use has skyrocketed, it has tripled. Wineries have done everything they can to make themselves known, from virtual

tastings to stories and posts on social media such as Instagram and Facebook. *"You have to tell your story. And especially for the small ones, it is important to put your face out there. Which means dedicating a little time each day to this activity, but with the awareness that, instead of reaching just one person met on the street (in the days when you could go out, ed.), in this way you can reach 10, 100, 1,000, 100,000 recipients all at once, directly from home,"* says Roberto Bortolussi. The director reveals how sales in his community tripled in just a few weeks after the lockdown, stating how incredible advantages are being recognised for many players, opening new doors and possibilities in the future for the Italian wine business. Through the digital sales channels many Italian SMEs were able to sell in one day a volume of bottles worth between 1,000 and 5,000 euros during the pandemic (TreBicchieri, 2020). The results are also cost-effective by offering companies a higher gross margin due to transport costs abroad and through other distribution channels.

The case of the Cinque Quinti winery in Cella del Monte, a very small business that has been active since 2015 and is run by five brothers, is proof of innovation and a reversal of the trend. This little reality represents an annual production of 22 thousand bottles that, before the emergency were mainly destined for the company's point of sale and "ho.Re.Ca" and reaching peaks of in-store sales equivalent to 100 bottles a day. The winery's channels had suddenly gone to zero but the company immediately turned to e-commerce where they had been present since 2017 but without much success. Great results have just been seen by understanding what are the necessary strategies of interaction and online communication with customers, offering a package "Wine-Box" at Easter, a pre-packaged box designed to introduce the different products and guide the customer in a real tasting with the aim of providing a repeatable experience for the consumer and bringing them closer to the company during the pandemic through digital channels. The e-commerce in the next 3 weeks has seen a growth of 5 times compared to the previous months. One of the owner of the winery recognised that future will probably go in this direction: less handshaking, more online communication. Another case is that of Cantine Rossella (220,000 bottles per year), whose debut in the world of online sales was a record: 3,000 bottles of Gutturino 2018 and the house's Ventesimato in just six hours (TreBicchieri, 2020).

Nowadays, an extraordinary situation such as the one we have experienced in recent months has changed the vision of many companies, opening their eyes to other fronts and new opportunities. Italian wine has recognised e-commerce as a

factor that can bring many advantages, not only in terms of new markets and turnover, but also in terms of costs, images and networking. Perhaps some Italian exceptions had already realised the potential; according to some researchers several Italian family-run wineries have already been using social media for a few years now, recognising the advantages there can be in terms of communication strategies and going beyond the concept of sales (Iaia, Scorrano, Fait, Cavallo, 2017). To date, the message has certainly been received by all.

Italy has been for year leader in the winery market in terms of production (volume and value creation), export and consume and the international wine market is, however, highly competitive, with emerging countries, such as Chile, South Africa and Argentina gaining increasing market shares (Morrison, Rabellotti, 2017). The challenge for the future supremacy of actual leaders' market is, therefore, ICT innovation, both for big companies and for SMEs.

To conclude our analysis, we apply a descriptive statistic, that takes into account the main economic and financial ratios of 18 Italian wineries in the periods before and after Covid-19, demonstrating that the pandemic was a hard blow to the wine sector. The results were obviously not as hoped for, but resilience was demonstrated thanks also to the use of new technologies that provided opportunities for reflection: advertising, network marketing, reduction of activity costs, and entry into a new profitable market. Italy's wine industry in lockdown has seen the new future.

In particular, to test the aforementioned hypotheses, we selected a sample of 18 larger Italian wineries.

The tool we used for the sampling was the Bureau Van Dijk database "AIDA". We chose The ATECO codes 110210 "Wine production".

We did not include in the sample the discarded companies because of the unavailability of 2020 balance sheet.

The companies selected have a revenue range from about euro 227 million to about euro 31 million.

For each company we collected the following data, using "AIDA":

- availability of financial statements at a date between December 31st 2018 and 31 December 2020;
- total revenues in the last available year and in previous 2 years;
- net profit in the last available year and in the previous 2 years;
- R.O.I. and R.O.S. in the last available year and in the previous 2 years.

Finally, we examined the web site of each company, and – if available – the Instagram page and the Facebook page and we observed the following information:

- possibility to buy via e-commerce;
- existence of on-line platforms used to sell wines.

We observed that almost all the companies are now experiencing on-line sales, both by e-commerce in their own web site and by Internet platforms, dedicated to wines (Vinicum, Drinks and Co., Callmewine, Diemme Vini, Tannico, Wineexpress, Vineria 43, Costaross, Zoona) or generally employed for on-line shopping (Amazon and Ebay). Only few companies don't use e-commerce.

We also observed that the biggest companies, using e-commerce, have experienced in 2020 an increase in revenues, demonstrating that the negative effects caused by pandemic in the tourism sector, can be balanced by the positive effects of on-line activities.

#### **4 Conclusions and implications for future research**

The current study contributes to emphasize the literature debate on the use of on-line commerce to improve the sales of wineries in pandemic times.

We believe the current study can open the way for new lines of research, concerning the financial and economic consequences of the e-commerce phenomenon.

The current research also presents numerous limitations. The sample is quite small and includes just companies whose 2020 balance sheet was available on AIDA. The sampling number of the companies is too small to give statistically significant results. The eventual multicollinearity between variables has not been detected.

We are confident this study represents a first step to develop studies about sectors in which Italy can confirm its excellence and, over all, to seize the opportunities that new technologies offer without underestimating the risks that they may hide.

### **Abstract**

In recent years, the European Commission (EC) has emphasized inclusive and sustainable governance policies, to offer solutions to the problems that arise in the relationship between science and society. With Horizon 2020's and transversal programs like the Science with and for Society (SwafS) a new approach to research and innovation is born: Responsible Research and Innovation (RRI).

One of the most critical challenges of the SwafS is "modeling and better understanding the dynamics of complex networks of innovation value chains and the openings they provide for RRI." The I AM RRI project responds to this call. In this paper we present an agent-based model in which innovation networks in the context of Additive Manufacturing are

created, evolve, and interact to spread RRI knowledge and practices throughout the system. Agents are characterized by specific knowledge domains, depending on the industry sector in which they operate, and seek to participate in innovation networks to define better or support an innovative idea. Moreover, their decisions are not only economic-based but are constrained by aspects of RRI. In our model three RRI keys identified by the EC are implemented in the model: public engagement, open access, and ethical thinking.

An initial set of experiments and analysis will be presented here to analyze the impact of agents' RRI knowledge and inclinations on their interactions and the economic, strategic, and social performance of the whole innovation system.

## 1 Introduction

The impressive progress in scientific research and innovation has led to an intensification of ethical, legal, and social issues concerning science and society's relationship. With the Horizon 2020 (European Commission, 2014a), the European Commission (EC) aims to spread a new approach that anticipates and assesses the potential implications and societal expectations of inclusive and sustainable design of research and innovation — Responsible Research and Innovation (RRI) (European Commission, 2012). RRI is the crucial action of the Horizon 2020 transversal program "Science with and for Society" (SwafS) (European Commission, 2020).

One of the most critical challenges of the SwafS program is "modeling and better understanding the dynamics of complex networks of innovation value chains and the openings they provide for RRI." Currently, the I AM RRI project – Webs of Innovation Value Chains of Additive Manufacturing under Consideration of RRI – responds to this call. Central in the I AM RRI project is developing a dynamic model to simulate and visualize the behavior of complex webs under various conditions. Such models can help researchers and practitioners grasp RRI practices' importance and provide evidence that can favor the adoption and dissemination of good practices, even promoting institutional change in Research Funding (RFO) and Research Performing Organizations (RPO).

In the recent years the concept of Responsible Innovation, which later officially became RRI, has become very popular in Europe (and beyond); this is also due to

the Horizon 2020 project's impetus, for which RRI is an essential theme. The Rome Declaration on RRI provides a precise definition: RRI is an "on-going process of aligning research and innovation with the values, needs and expectations of society" (European Commission, 2014b, p. 1).

Although there are still disagreements between academia and administration on the definition of RRI (Gianni, 2021), it seems clear that among the purposes of RRI practices, societal involvement plays an essential role (Gianni, 2021; Owen et al., 2012; Von Schomberg, 2013). Heterogeneity of stakeholders (understood as the presence of different points of view) is a critical feature in innovative adaptive processes (Stirling, 2007) to make good decisions (Stahl, 2013) and to ensure richer discussion (Flipse et al., 2013). Thus, an innovative project guided by RRI principles must be characterized by more significant heterogeneity of the working group. Kupper et al. (2015) translate this concept by formulating the process requirement of diversity and inclusion, measured in our model through the variable named heterogeneity.

In particular, in this paper we present an agent-based model called I AM RRI that simulates the creation, the evolution, and the interactions of innovation networks in Additive Manufacturing, highlighting diffusion of knowledge and RRI practices. The developed agent-based model starts from the existing agent-based model SKIN - Simulating Knowledge Dynamics in Innovation Networks - (Gilbert et al., 2007; Pyka et al., 2007) and enriches it with new elements and extensions. Our model is "double-industry" meaning that agents can belong to the Automotive Industry, the Biomedical applications industry, or both (this is the case of "broker" agents, able to be involved in Innovation Value Chains in both industries).

Agents' inclination to ethical and societal values is modeled through three endogenous variables representing three fundamental thematic areas in RRI identified by the European Commission (2012): public engagement, open-access, ethical thinking. These RRI characteristics influence agents' decisions, the IVCs' performance in which they participate, and their way of interacting with the environment and other actors. Furthermore, the model considers different types of actors (AM technology company, Supplier, Customer, Research Institution, OEM) assessed by Regulators and Standard Organizations according to RRI values and quality of innovation proposed. Each type of agent is characterized by a peculiar knowledge domain, from which it develops a fuzzy idea of innovation. Through cooperation and learning, an idea can be defined, developed, and

improved. Since the I AM RRI model aims to be a dynamic model we implemented the Innovation Value Chains (IVCs) and its evolution through different phases (Idea Generation and Product Development) each of them with a different duration and "final gate" stage.

The goal of the proposed model is twofold: strengthen the knowledge base for policy orientation in research and innovation and supporting the identification of strategic guidelines for policymakers and funding organizations able to manage innovation network dynamics and the implementation/diffusion of RRI principles. Some virtual experiments and their analysis and implications will be presented to analyze the impact of knowledge and RRI inclinations of agents on their interactions and the economic, strategic, and societal performances of the entire innovation system.

## **2 Methodology**

According to the literature about the development of computational models (Burton, 2004; Gilbert, 2007; Louie & Carley, 2008; Moss, 2008; Richiardi et al., 2006; Sargent, 2005), the methodology used to build up the I AM RRI SKIN ABM can be articulated in five main steps as depicted in Figure 1.

In the first step, the insights coming from the theoretical background analyzed in the preliminary phase of the I AM RRI project (not addressed in this paper) were translated into a conceptual model, reported and described in various deliverables, some of which soon available on the project web page. Furthermore, the SKIN model and its extensions represent another essential source of helpful inspiration to develop the structure of our model.

The second step, which regards the construction of the meta-model, helped us to define the building blocks of the ABM and a pseudo-code where micro-specifications of agents' behaviors are reported. In our case, the meta-model specifies the classes of agents, the rules of action and interactions among them, and the variables to be considered in future model simulations. Our meta-model has been developed starting from the conceptualization of the SKIN model. Still, it has been enriched by a new interpretation of the original building blocks and by new features devoted to increasing the representativeness of the model concerning the system under investigation.

The meta-model implementation requires the choice of an adequate software platform and the activity of code writing. The current version of the model,

described here, has been implemented using NetLogo 6.1.1. The implemented model was subjected to an internal analysis to verify consistency with the conceptual model and meta-model (step 4); the methodology, experiments, and results of the validation phase are described in detail in the following Section 4.

Currently, the model is at the beginning of the Validation phase, comparing the model's behavior to evidence in the literature. The project's future developments will deepen this last phase, using empirical data provided by the project's industrial partners.

*Figure 1 The methodology used to develop the AB model.*

### **3 The Agents During Simulation**

The model developed, coded in NetLogo using an ABM approach, originated as an extension of the already existing SKIN model (Ahrweiler, 2017; Gilbert et al., 2001, 2007; Pyka et al., 2007), and it is mainly focused on the study of IVCs, webs of IVCs and especially their openings for RRI. Additive Manufacturing was the basis for developing the model, given the characteristics of its innovation system, prone to the creation of webs of IVCs, and different from other traditional industries. Additive Manufacturing is also an industry that has only recently started to evolve; following innovative approaches to manufacturing, it is already valued at more than \$11 billion and growing (Wohlers Associates, 2020). However, the model is easily adaptable to other types of industries.

The I AM RRI SKIN model incorporates complexity, covering various stages of the IVC life, mainly: Idea Generation and Product Development. The development of the innovation process goes through phases in which the Capabilities (large

domains of knowledge), and the Abilities (applications in these domains) needed for an idea to be further developed, are not well defined. Therefore, cooperation among Agents and the creation of networks of IVCs is essential.

Moreover, unlike SKIN, from which I AM RRI SKIN derives, the innovation process develops through different ticks (simulation time unit), and is not obtained just in one model running cycle. Each IVC phase covers a defined number of running cycles, expressed as a result of the study conducted into the I AM RRI project.

The implemented IVC phases are, as mentioned above, mainly two:

- Idea generation (3 ticks);
- Product development (12 ticks).

This choice derives from the study of use-cases provided by partners of the I AM RRI project (reported in the Acknowledgments below) operating in the AM Automotive or Biomedical industry that ensure realism to the model. The main time-related assumption made by the project is that 1 tick equals 1 month. Additionally, as the main difference, in the I AM RRI SKIN, the agents' decisions and behaviors are not only price-related and cost-related, but time-related and especially RRI-related.

Each agent is equipped with three RRI state variables representing RRI inclinations that are translated into the model in the following three keys:

- Open Access;
- Public Engagement;
- Ethical Thinking.

These keys profoundly influence the decision-making process.

Other relatively minor extensions have been introduced to adapt the I AM RRI SKIN model to Automotive and Biomedical use-cases. A double-industry model has been built, in which six different types of Agents' breeds - particular typologies of Agent Set endowed with particular variables - interact between them also participating in more networks simultaneously. This implies that the agents in the model can belong to the Automotive industry, Biomedical applications industry, or both (this is the case of 'broker' agents, able to be involved in IVCs in both industries). The inter-relationships among the two Industries are assured by 'broker' agents and by the fact that agents in the I AM RRI SKIN model can belong to more than one network simultaneously. Identifying different types of agents, such as the duration of IVCs phases, comes from the

analysis of use-cases provided by partners of the AM RRI that cover two specializations of the AM Industry: Automotive & Biomedical.

The six types of agents' classes (breeds) are:

- AM-techs;
- Suppliers;
- Customers;
- OEMs;
- Research-institutions;
- Networks.

Other agents like the Funding Organisations, Regulators, and the Standard Organisations are modeled in terms of aggregated entities - in the current version of the model, Funding Organisations and Standard Organisations are modeled as environmental-global variables.

### **3.1 Idea Generation**

In the Idea Generation phase, the interaction mechanisms aim to create and improve an innovation idea. The start-project agents are the protagonists of this phase, searching for potential partners looking at prior experience and adequate agents' capabilities. A start-project initiates an IVC or a network since he does not possess all the capabilities needed to develop the Innovation Hypothesis (IH), and some of them are also unknown; therefore, the IH in this first phase has a fuzzy and undefined character.

Agents advertise their Capabilities through an advertisement so that the start-project agent can identify the best potential partners but preferring those of other breeds.

Therefore, the intersection of focal agent advertisement (who starts the project) and potential partner capabilities is assessed.

Other fundamental variables to be considered when searching for partners are their RRI inclinations; the weighted average of RRI values of each agent is a sort of signal considered in the search for suitable partners. The hypothesis at the basis of this computational choice depends on the evidence that a potential partner with high RRI values will be more visible to other agents and the focal.

Once the minimum number of partners has been reached, the start-project agent (also named "focal") can create an IVC/network by incurring a cost for the fine-tuning of the IH and the search for partners, while the participants will have

to pay a share of contributions to constitute the common fund (investment-capital). At this point, the RRI values of each member can be assessed and then averaged. This average is used to model the RRI value of the network agent and will be necessary for subsequent mechanisms of interaction with partners and exogenous agents. Members of a collective organization must have ethical values that conform to the collective values, so a diffusion and updating mechanism of RRI values among network participants is triggered, accounting for inertia to change.

The greater the distance between one's own RRI values and those of the network, the lower the RRI increment and the willingness to conform to the collective values. The agents of the I AM RRI model can be involved in more than one innovative network at the same time; therefore, following the literature (Sarkar et al., 2001), they must take into account all the projects in which they are involved (especially those with ethical values similar to their own) and not only the projects with higher RRI values. This aspect avoids the creation of a "cultural bias."

Finally, network members with sufficient economic resources can learn new knowledge from other partners through a learning and knowledge dissemination mechanism.

The intersection between the two phases represents a filter for networks that do not possess the regulatory bodies' ethical characteristics (ethical thinking). Networks that meet these constraints can access additional financial resources made available by funding bodies. The requirements of these funding bodies relate to the technical quality required by the IH and the RRI inclination.

Networks that do not achieve the level of ethical thinking mandated by regulatory bodies dissolve: network members terminate internal partnerships but keep their memory; the network agent disappears from the simulation environment.

### **3.2 Product Development**

Networks that pass the first next-gate can begin the Product Development phase, which lasts a minimum of 12 ticks.

At the beginning of this phase, networks may lose members who do not have sufficient financial resources to support the promotion cost of the RRI innovation idea. A member could also parasitically exploit the resources provided by the

network. Therefore, the more network resources available to support RRI values, the less effort required of members.

Agents may decide to publish in open access at this stage, taking into account their financial resources and inclination to open access. Each open access publication has a cost that reduces the financial resources of the agent. Once these thresholds are met, an element of randomness also intervenes, representing the various aspects of uncertainty associated with the process. This element of uncertainty is modeled through a Bernoullian variable with parameter  $p$  equal to the open-access value of the agent.

At the end of the Product Development phase, the mechanism of diffusion and updating of RRI values among network members is triggered and downstream of experiential learning, updating of expertise (taken from SKIN).

At the end of the second phase, the networks face the second gate. At this simulation point, the networks and their innovation ideas are evaluated by Regulators and Standardization Organizations. The former still evaluate the ethical thinking orientation of the networks, the latter evaluate the qualitative specifications of the innovation idea.

Networks with positive feedback during the gate-next-phase-3 evaluation can create RRI-focused start-ups that operate in the market or, alternatively, dissolve.

### **3.2 Learning and Outputs**

During the simulation, agents who have not been involved in any network try to increase their attractiveness by acquiring new knowledge through incremental search. As a result of financial availability, a new Capability is added to their Kene, representing the agent's knowledge base.

The Capabilities sought in this phase are part of the set of knowledge that characterizes the agent's typology (called "breed" in NetLogo language). When activated by the agent, the incremental research lasts three ticks, and after a new Capability has been acquired, the agent makes an advert to try to be selected by a focal agent. If not selected again, a new research session could be initiated according to the availability of financial resources.

The outputs are divided into three macro-areas of impact: social, economic, and strategic.

The system's economic performance is analyzed through the continuous evaluation of the average capital of the agents constituting the system and at the end of the simulation.

The strategic performance is evaluated through several indicators:

- The number of start-ups created;
- The average size of the networks;
- The number of agents involved in the networks or the percentage of agents involved;
- The percentage of surviving agents for each phase.

The result in social terms is estimated through a graph that expresses the time trend of the average of RRI values.

Another proxy for the analysis of simulation outputs is the number of open access publications made during the simulation. Obviously, at each time point in the simulation, the number of networks/IVCs relative to each phase and the total number of networks is provided.

#### **4 Experimental Design and Results**

Validation is the process of determining how well the implemented model corresponds to reality. Validation has always played an essential role in modeling issues (Conway et al., 1959), especially concerning computational models (Carley, 1996; Garcia et al., 2007). We could say that the biggest problem related to Validation is that there is no universally accepted approach. In the literature, there are many Validation techniques and the principles on which they are based, so it would be too expensive to use all the possible techniques (Xiang et al., 2005).

There are different validation levels depend on the availability of data, model, and research purpose. As suggested by Carley (1996), illustrative-theoretical models usually require a reduced level of Validation, while case-based models are more demanding in terms of validation because such models are used to give practical advice on some specific aspects.

Different levels of Validation identified by Carley are:

- Face validity;
- Parameter validity;
- Pattern validity;
- Process validity;
- Point validity;

- Distribution validity;
- Value validity.

The first four levels are more related to theoretical or illustrative models while others are more concerned with emulative models of reality. The I AM RRI SKIN model is not a purely theoretical (illustrative) model, but it is not a case-based model. Consequently, we expect to reach, an intermediate level of Validation.

Additionally, some data on Additive Manufacturing in the European market are available, thanks to the presence of industrial partners in the I AM RRI project; however, these data have not been processed sufficiently to be used for a process as complex as Validation. For this reason, we confirm at this stage our choice to only reach a low-intermediate level of Validation. Following the indications of Sargent (2005) and Law et al.(1996), there are different ways of to reach the intermediate levels of rigor approximating the Validation. In this paper, we focus primarily on the correspondence between existing RRI literature and the I AM RRI SKIN model's emerging behaviours.

Below, we report on two experiments whose results may have implications for the understanding and guidance of RRI practices, both at the managerial and governance levels. In addition to the experiments reported, further experiments necessary for Validation and internal Verification were conducted to ensure greater rigor to the model.

Finding a correspondence in the literature on how RRI practices impact innovations is not an easy task since "the impact appears to be elusive and difficult to measure" (Pansera et al., 2020, p. 402). In fact, "the RRI cannot be used as an evaluation tool since it does not have the material metrics to measure how responsible or positive or negative the impacts of innovation are but is a normative framework designed to influence the process of innovation" (Postal et al., 2020, p. 15). Thus, we can say that the RRI intervenes in the innovation process as a whole and indirectly on that process's product.

As Gonzales-Gemio et al. (2020) suggested, the performance of organizations that adopt RRI practices has benefits that can be seen in the long run, such as the acquisition of new knowledge. Another aspect reported in the literature is that RRI practices ensure greater inclusiveness and heterogeneity of working groups (Fitjar et al., 2019; Kupper et al., 2015; Van den Hoven, 2013) to reach better decisions (Stahl, 2013) and to ensure richer discussion (Flipse et al., 2013).

We can conclude that the introduction of RRI practices influences the innovation process and the actors involved in two ways:

1. Increased heterogeneity of actors involved in the innovation projects;
2. Increased knowledge base.

Having identified the impact of adopting RRI practices in innovation processes through the literature review, two experiments were conducted to validate the correspondence between the arguments reported in the literature and the I AM RRI SKIN model's behaviour. We ask then, "*if agents give more importance to RRI practices, select their partners considering RRI principles, will we observe an increase in the heterogeneity of actors involved in networks? Will the knowledge base also increase at the end of the simulation?*" The variable of interest is the threshold of the attractiveness of partners based on RRI values (RRI-attractiveness), while the output inserted are:

- *Average Heterogeneity of Networks*, where Network Heterogeneity is measured as the ratio of the number of different breeds within the Network to the total number of members.

$$Heterogeneity = \frac{\sum_{breed \in Network} breed}{number\ of\ partners} \quad (1)$$

- *Average Knowledge of Agent*. Starting from the Kene, the knowledge ( $k_i$ ) of the agent  $i$ , the average knowledge was modelled considering the length of the Capabilities vector. We could not use the expression for knowledge of the  $i$ -th agent used by Ahrweiler et al. (Ahrweiler et al., 2011, p. 227):

$$k_i = \sqrt{\sum_{j \in \{C\}_i} A_{ij} E_{ij}} \quad (2)$$

To be more explicit, in I AM RRI SKIN, Ability 6 is not "better" than Ability 3: we cannot use Abilities as a factor in a product that quantifies knowledge. Indeed, in the I AM RRI SKIN model the Abilities of the agents do not belong to an ordinal scale but represent the label of the capability in the broader knowledge domain. Thus, the knowledge of the  $i$ -th agent is represented by the number of Capabilities possessed by the agent. Finally, the Average Knowledge of the Agents participating in an innovative project can be represented as:

$$\bar{k} = \frac{1}{nFirms} \sum_{i \in \{partnering\ Firms\}} k_i \quad (3)$$

#### 4.1 Experiment 1

As mentioned, we use RRI-attractiveness as the input variable; all other independent variables were considered control variables and reported in Table 1.

**Table 1.** Control Variables Experiment 1

Numbers of Agents [value]		Firm's Variable [value]		Environmental Variable [value]	
nAM-tech	[200]	Attractiveness-threshold	[0.5]	Standard Organization	[5]
nSupplier	[200]	RRI-start-up-trigger	[0.5]	Funding	[50]
nResearch-inst.	[200]			Funding-RRI	[0.5]
		<i>Publish-open-access</i>		Funding-quality	[5]
nOEM	[200]	Economic-threshold	[50]	RRI-cost	[30]
nCustomer	[200]	RRI-open-access-thres.	[0.5]	Big-firm-percent	[10]
				Regulator	[0.5]

The input variable RRI-attractiveness, which expresses the weight given to RRI values in the partner selection process, has been divided into three ranges: low [0 0.3], medium [0.4 0.6], and high [0.7 1]. The value 1 indicates that the partner selection process is based exclusively on the compatibility of RRI values, while a value of 0 indicates that the selection of partners is based exclusively on the complementarity of the knowledge base.

The combination of variables used to design the experiments is systematized in Table 2.

Table 2. Experiment 1

Control Variables	Run	ticks	Input	output
See Table 1	300	30	RRI-attractiveness [0.2 0.5 0.8]	Average Heterogeneity of Networks

To investigate the issues outlined above, we first used some descriptive statistics concerning the average heterogeneity of the networks when varying the RRI-attractiveness factor. The results reported in Table 3 refer to the 30-th tick of the simulation. For each level of RRI-attractiveness [0.2, 0.5, 0.8], 300 runs were performed.

Table 3. Descriptive Statistics Experiment 1

Descriptive Statistics								
RRI-attractiveness	N	Mean	Std. Dev.	Std. Error	95% Confidence Interval for Mean		Min	Max
					Lower Bound	Upper Bound		
0.2	300	0.6553	0.02982	0.00172	0.6519	0.6587	0.57	0.74
0.5	300	0.6758	0.03027	0.00175	0.6724	0.6793	0.57	0.76
0.8	300	0.6909	0.03017	0.00174	0.6875	0.6944	0.60	0.77
Total	900	0.6740	0.03342	0.00111	0.6718	0.6762	0.57	0.77

The current literature search shows that an increase in the diffusion and importance given to RRI practices corresponds to an increase in heterogeneity within innovation systems. The I AM RRI SKIN model behaves as expected from the literature (Fitjar et al., 2019; Kupper et al., 2015; Van den Hoven, 2013). However, to assess a significant effect of the RRI-attractiveness factor on the dependent variable heterogeneity, a *One-way* ANOVA was used, the results of which are summarised in Table 4.

Table 4. Results of ANOVA for Experiment 1

ANOVA					
	Sum of Squares	df	Mean Square	F	Sig.
<b>Between Groups</b>	.192	2	.096	106.027	0.000 <sup>*</sup>
<b>Within Groups</b>	.812	897	.001		
<b>Total</b>	1.004	899			

As shown from Table 4, we can reject the null hypothesis  $H_0$  accepting a risk first kind  $\alpha=0.05$ . Thus, we can consider the influence of the RRI-attractiveness factor on network heterogeneity as significant.

In order to further deepen the analysis, Post-hoc tests (Tukey's HSD) were performed following the significance of the ANOVA, whose results are reported in Table 5.

Table 5. HSD Experiment 1

	(I) RRI attractive ness	(J) RRI attractiv eness	Mean Difference (I-J)	Std. Error	Sig.	95% Confidence Interval	
						Lower Bound	Upper Bound
<b>Tukey HSD</b>	0.2	0.5	-0.02053 <sup>*</sup>	0.0024	0.000	-0.0263	-0.0148
		0.8	-0.03563 <sup>*</sup>	0.0024	0.000	-0.0414	-0.0299
	0.5	0.2	0.02053 <sup>*</sup>	0.0024	0.000	0.0148	0.0263
		0.8	-0.01510 <sup>*</sup>	0.0024	0.000	-0.0209	-0.0093
	0.8	0.2	0.03563 <sup>*</sup>	0.0024	0.000	0.0299	0.0414
		0.5	0.01510 <sup>*</sup>	0.0024	0.000	0.0093	0.0209

\* The mean difference is significant at the 0.05 level.

These tests, performed two by two, offer us experimental evidence that the averages' difference is statistically significant. Therefore, observing that all three levels of RRI-attractiveness produce statistically significant effects, we can consider that this first subdivision into three ranges (low, medium, high) is acceptable.

#### 4.1 Experiment 2

The second experiment investigates the effect of a policy of selection of partners focused on the respect of RRI values, so the input variable remains the RRI-attractiveness. We try to establish whether an increase in this variable leads to an increase in the system's knowledge base. In this case, the variable of output is the Average Knowledge of the Agents described previously. Control variables are the same as in Experiment 1 (Table 1).

Again, the input variable RRI-attractiveness, which expresses the weight given to RRI values in the partner selection process, has been divided into three ranges: low [0 0.3], medium [0.4 0.6], and high [0.7 1]. The combination of variables used to design experiment 2 is systematized in Table 6.

Table 6. Experiment 2

Control Variables	Run	ticks	input	output
See Table 1	300	30	RRI-attractiveness [0.2 0.5 0.8]	Average Knowledge of the Agents

As mentioned, the existing literature indicates that an increase in RRI practices should increase agents' knowledge base. To test this hypothesis, a One-way ANOVA was used, setting the parameters as described above. As can be seen from the following Table 7, there is no experimental evidence to suggest that the effect of RRI-attractiveness input on agents' knowledge is significant.

Table 7. Results of ANOVA Experiment 2

ANOVA					
	Sum of Squares	df	Mean Square	F	Sig.
<b>Between Groups</b>	0.006	2	0.003	1.448	0.236
<b>Within Groups</b>	1.754	897	0.002		
<b>Total</b>	1.760	899			

At this point, the investigation did not stop. First, the code was modified so that the advertisements were formed only by the IH's Capabilities, as in SKIN (Pyka et al., 2007). This modifies the mechanism of partner selection and learning. However, even in this case, the ANOVA was not significant.

## 5 Conclusions

The proposed model focuses on RRI practices in the decision-making processes of various types of organizations by expanding the understanding of complex research and innovation networks.

I AM RRI SKIN constitutes a first attempt to create an auxiliary tool for institutional bodies and policymakers, assisting them in defining strategic guidelines for disseminating and encouraging RRI best practices. By modifying some model parameters, it is possible to investigate the impact of incentives on RRI practices and innovative performance regulation. Although the conceptual model is inspired by some use-cases provided by partners of the I AM RRI project operating in the AM Automotive or Biomedical industry, it is possible to set endogenous parameters adapting the simulation to different business and industrial contexts.

The validity of the proposed model has been tested through different simulation scenarios, the results of which demonstrate a correspondence between the I AM RRI SKIN artificial world and the existing RRI literature. Furthermore, the

proposed experiments demonstrate the model's use of the types of research questions that can be developed in the future and how to answer them.

The model offers an understanding of IVC networks and the potential of RRI practices and allows to simulate the processes of dissemination and knowledge creation. Based on some use-cases, the I AM RRI SKIN agents are characterized by well-defined knowledge domains found in the AM; however, in this way, the set of knowledge domains has limited numerosity that precludes the performance of exciting experiments. This aspect could be a limitation of the use-cases used, so it will be interesting to base future developments on different narratives and a deepening of those already available.

Finally, the link between RRI variables and the various components of the simulation environment will have to be further investigated using results from the literature and data produced by future workshops in the context of the I AM RRI project.

In this way, the RRI variables would depend more on the context and circumstances in which the organization operates, bringing the model even closer to empirical evidence. From this perspective, it would be interesting to reach the highest levels of the model validation process using empirical data to set the input parameters and compare the simulation results with the empirical evidence.

### Abstract

Knowledge Visualisation (KV) is a discipline that focuses on the collaborative use of interactive graphics to create, integrate and apply knowledge, to support the decision-making process, particularly in emergency contexts during the practice of People Management. This study is of an exploratory and confirmatory nature and helps us to understand how the use of KV has been implemented in complex organisations like university through an empirical analysis. Based on literature review and case study, it has been possible to highlight the role of KV in supporting the decision-making process, even during the COVID-19 pandemic.

The decision-maker that is interviewed displayed an awareness of the potential and importance of KV, which has been shown by their use of different tools and bodies with functions related to it.

**Paper type** –Practical Paper

## 1 Introduction

In recent years, the importance of exploiting and managing information and knowledge as a strategic resource for organisational growth and competitiveness has been recognised (Schiuma et al., 2012). Knowledge Visualisation is a very young research area that is increasing gaining attention because it examines the use of visual representations to improve knowledge management at all levels, including personal, interpersonal, team, organisational, inter-organisational and social. It focuses on creating images that can convey information about data (Henson and Johnson, 2005); in fact, the process of Knowledge Visualisation contains steps such as collection, interpretation, development of an understanding, organisation and planning. Through graphics, Knowledge Visualisation can transmit or apply knowledge, which includes methods and complex intuitions (Hornbæk, 2011). Many scholars have highlighted the importance of using diagrams, graphs, schemes, mind maps and social graphs captured in real-time (Berinato, 2016; Miah et al., 2017). Such visualisation tools can support management and evaluation knowledge within organisations by providing management means for translation, transfer, sharing, coding, creation and more general knowledge management for decision-making (Eppler, 2013). Visual representations of information and knowledge have been indicated as an essential dimension of modern knowledge management to support decision-making (Miah et al., 2017). Organisations have had to face the pandemic situation that is affecting the whole world, but Knowledge Visualisation could be seen as a support tool that the decision-maker can disseminate to manage the emergency. Hence, in this context, the decision-maker can use Knowledge Visualisation tools (images, maps, diagrams, etc.) to transform raw data and information into accessible forms of representations to extract information. On these premises, this research starts with an analysis of the literature about Knowledge Visualisation and its tools. It then focuses on the empirical analysis of a case study about the University of Catanzaro (Italy) as organisation that have strongly suffered the impact the virus. The aim of the research, with the help of interview university

decision-maker, is first to understand how Knowledge Visualisation is used in the context. Then, specifically, we want to understand, through the Knowledge Visualisation tools used, the impact of these tools on intra-organisational relations as an effect of the emergency.

## **2 Theoretical Framework**

### ***2.1 Knowledge Visualisation Tools***

The area of Knowledge Visualisation studies transferring knowledge through visualisation (Eppler & Burkhard, 2004; Cañas, 2005; Meyer, 2008; Yan, 2011). Eppler and Burkhard (2004) presented a widely accepted definition of knowledge visualisation, stating that it "is defined as a field that examines the use of visual representations to improve the creation and transfer of knowledge between at least two people. Knowledge visualisation thus designates all graphic means that can be used to construct and convey complex insights "(p.551). A corresponding field and predecessor of Knowledge Visualisation (KV) is Information Visualisation (IV), and both these fields are utilising our natural abilities to process visual representations successfully. This definition has allowed numerous scholars to discuss the difference between Knowledge Visualisation and Information Visualisation. The first forms of Information Visualisation were static or based on paper, such as a map or a drawing (Bertin, 1967; Tufte, 1997). However, the term Information Visualisation indicates "the use of interactive visual representations supported by the computer of abstract data to amplify cognition" (Card et al., 1999, p.2). Information Visualisation has the primary purpose of exploring large amounts of abstract data to gain new insights or make stored data more accessible. On the other hand, Knowledge Visualisation tends to improve the transfer and creation of knowledge between people by providing them with the means to express what they know. So, while Information Visualisation helps improve information retrieval, access and the presentation of large data sets, especially in the interaction between humans and computers, Knowledge Visualisation tends to increase knowledge-intensive communication between individuals, for example, by relating new insights to concepts already understood (Eppler et al., 2004). The primary goal of Knowledge Visualisation is to support knowledge creation and sharing processes. Burkhard (2005) compared Knowledge Management (KM) and Knowledge Visualisation and concluded that

both disciplines are intertwined in efforts towards knowledge creation and sharing. Knowledge Visualisation is classified as a component of KM, mainly because knowledge transfer is a key process in knowledge-intensive organisations (Burkhard, 2005). Burkhard proposed a model based on the intuition that knowledge cannot be directly transferred from one person to another. The recipients of the transferred knowledge must integrate it into their knowledge according to their individual background and experiences (Burkhard, 2005). According to Eppler (2013), Knowledge Visualisation refers to all graphic means that can be used to develop or mediate experiences, methods or skills. Starting with the first symbols, the visualisation tools have been designed to improve and enhance knowledge sharing and overcome the limits of time and space. Knowledge Visualisation encourages the creation and transfer of knowledge by providing users with an extended range of tools to express and share what they know. The Knowledge Visualisation framework includes all graphic means that can be used to build and convey complex insights. The transfer of visual knowledge is complex and challenging as the recipient's background can be distinguished. Visual formats need to be specific, but above all, they need to be consistent so that they can go beyond the details of any individual or group. To become knowledge, information must be processed, meaningful and integrated into the user's mental knowledge structure. In literature, Knowledge Visualisation tools are different; the most well-known ones are listed in table n°1.

Table n°1: Tools of Knowledge Visualisation

<b>Tools</b>	<b>Features</b>
Sketches	Simple drawings that help to visualise the key features and the main idea very quickly. They can be used in group reflections and communication processes as they make knowledge debatable. Additionally, they allow room for their own interpretations and thus stimulate creativity and keep the attention of a group fixed on the discussed object.
Diagrams	Schematic representations that are used to display, explore and explain relationships. They reduce complexity, make abstract concepts accessible and amplify cognition. Unlike sketches, they are precise and determined. Examples of the diagrams are bar-

	and pie charts, Gantt-, Fenn- or process diagrams.
Images	They represent reality but can also be artistic. They are able to address emotions and can inspire, motivate or energise the audience and thus are often used for advertisements (images are visual).
Objects	Amplify the effect of visual metaphors.
Knowledge Maps	Consist of two components: The context, which should be easy to understand for all users of the map, and project milestones are mapped within this context.
Concept Maps	Intended to represent meaningful relationships between concepts in the form of propositions
Interactive Visualisation	Computer-based interactive visualisations allow you to access, control, explore, combine and manipulate different types of complex data, information and knowledge. They also fascinate the recipients and enable interactive collaborations and thus help create new insights.

Source: Burkard, 2005; Eppler & Burkhard, 2007; Meyer, 2009

Knowledge Visualisation tools may include a sketch, diagram, map, images, physical model, an interactive visualisation (Meyer, 2008) and digitalisation may be helpful, too (Liao et al., 2012; Ursyn, 2015).

Starting with early symbols, visualisation tools have been designed to improve and enhance knowledge sharing and overcome limitations of time and space (Katuscakova et al., 2019).

To transfer and create knowledge efficiently, Burkhard (2005) proposes four types of perspectives (Figure n°1).

FUNCTION TYPE	KNOWLEDGE TYPE	RECIPIENT TYPE	VISUALIZATION TYPE
Coordination	Know-what	Individual	Sketch
Attention	Know-how	Group	Diagram
Recall	Know-why	Organization	Image
Motivation	Know-where	Network	Map
Elaboration	Know-who		Object
New Insight			Interactive Visualization
			Story

Figure n°1: The Knowledge Visualisation Framework  
Source: Our adaptation Burkhard, 2005 p. 251

The Function Perspective distinguishes six functions of visual representations that can be exploited. The functions of visualisations can be summarised as follows (Eppler & Burkhard, 2004): Coordination; Attention; Recall; Motivation; Elaboration; New Insights. The Knowledge Type Perspective aims to identify the type of knowledge that needs to be transferred. Five types of knowledge have been distinguished: Declarative knowledge (Know-what, e.g., facts); procedural knowledge (Know-how, e.g., processes); experimental knowledge (Know-why, e.g., causes); orientational knowledge (Know-where, e.g., knowledge sources); individual knowledge (Know-who, e.g., experts). The Recipient Type Perspective aims to identify the target group and the recipient's context, which can be an individual, a team, a whole organisation or a network of persons. Knowing the context and the recipient/audience's cognitive background is essential for finding the right visualisation method for the transfer of knowledge. The Visualisation Type Perspective structures the visualisation methods into seven main groups: sketches, diagrams, images, maps, objects, interactive visualisations, and stories (Burkhard, 2004). By using such a framework, organisations can optimise learning and improve the knowledge and skills of its employees.

### 3 Knowledge Visualisation in Emergency

The Knowledge Visualisation (KV) domain focuses on the collaborative use of interactive graphics to create, integrate, and apply knowledge (Hornbaek, 2011, p.6). Eppler (2008) highlighted the functional role of graphic representations for various knowledge management processes and that, in terms of future trends, KV will evolve with respect to new formats and new areas of application. The

emergency context in which we are currently living emphasises the use of different forms and the potential to combine various formats (such as diagrams, maps and metaphors) in a complementary way. That said, within the emergency management context, the use of knowledge visualisation significantly thematic, so that it can be used as a catalyst for creating, sharing, and transferring knowledge. Emergency management refers to the ability to deal with emergency tasks in all their phases and iterations, including mitigation, preparedness, response and recovery (see Figure n°2).

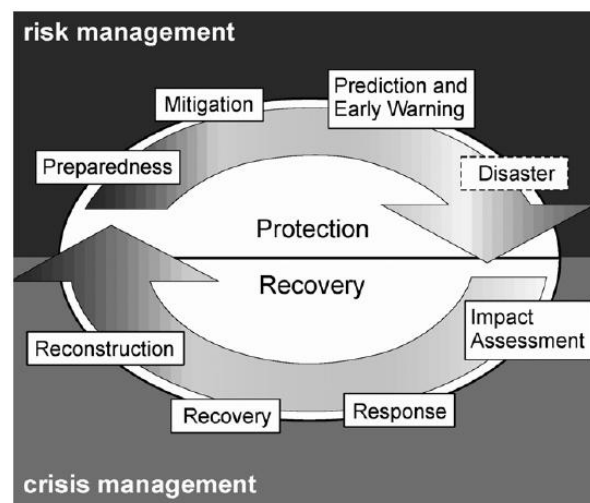

Figure n° 2: Disaster Management Cycle  
Source: National Drought Mitigation Center, University of Nebraska-Lincoln

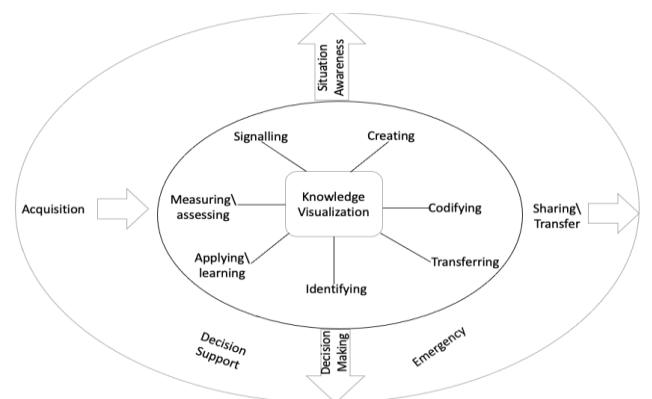

In the emergency era, the traditional ways to exchange and use knowledge among people are probably not sufficient anymore. To do this, each task requires many different types of information coming from several sources related to the emergency. Using mainly text and numbers instead of proper visualisations does not fit our knowledge society's requirements anymore (Burkhard, 2005) because they are complex and dynamic in nature. Such complexity is caused by the extensive, diverse and ever-changing factors involved in the problem, purpose, context and stakeholders. To be useful for the purpose, KV must satisfy different requirements:

1. It has to be able to capture and depict knowledge.
2. It has to relate these ideas to one another.

3. It has to be visual.
4. It has to support the process of knowledge integration among various people.
5. The visualisation has to be flexible, to be able to react to the changing of time.
6. It has to be communicable in the sense that the image can be communicated to others who have not been present during its creation process.

In Covid-19 era, the Organisation (WHO) has requested to take major steps to ensure safety, focusing indirectly on a decision-making process that is fast and appropriate—during and after the emergency.

Specifically, Burkhard (2005) tried to build a framework of KV, which should especially help decision-makers use and create visual representations of business processes. Despite improved awareness concerning the emergency, the emphasis on preparing for such emergencies is inadequate. This aspect is relevant because KV may reduce the cognitive load and enhance the processing abilities by visualising abstract relationships. To do this, they emphasise visual practices through the joint and iterative visualisation of facts, analysis, insights and experiences, and consequently improve the collaboration quality (Nicolini, 2007; White et al., 2007; Zhang, 2012). KV is a decision support system for decision-making in the emergency context. Emergency information is used to obtain situation awareness about a particular event, needs assessment and statistical analysis, while knowledge and experience are used to facilitate decision-making (Figure 3).

*Figure n° 3: The Use of Knowledge Visualisation*  
Source: our adaptation Zhang et al., 2002 and Eppler, 2007

### **3.1 Knowledge Visualisation and People Management**

KV has the potential to support knowledge transfer. The adoption of KV is much more than an effective means for strategists to provide structure to strategic problems because they facilitate knowledge creation and sharing (Kaplan, 2011).

The research reveals that this potential has been underused in the field of emergency management. Parry and Cowley (2015) identified critical aspects of KV how the decision problem. The decision management may involve relevant problem situations, physical surroundings, time, KV tasks and requirements and social and technological contexts.

During the decision-making process, decision-makers need to perceive the problem, gather relevant information, make the right judgment call and conduct a plan of action. In reality, the decision-makers encounter a variety of challenges, for example, how to gather relevant information in a timely and accurate manner, how to store, organise and manage the information efficiently so that the resources can be accessed and shared and how to reuse knowledge or experience to facilitate current decision making (Zhang et al., 2002).

The role of KV in supporting decision making (speed, appropriate, accuracy and completeness) has been considered in our research.

The decision-makers use of KV shows higher performance in terms of accuracy and decision speed (Lurie & Mason, 2007). Based on Eppler and Burkhard's (2007) study, Knowledge Visualisation is defined as the (collaborative) practice of graphically representing insights, experiences, gathered evidence and know-how to share knowledge, create new knowledge or apply knowledge to decision-making, problem-solving or planning. Visualisation shaping and presenting information in a more effective way facilitates better communication and supports sense-making (Al-Kassab, 2014).

The functions of KV in human resource management are: (1) coordination (coordinate the communication of workers); (2) attention (raise awareness and provide a focus for knowledge creation and transfer); (3) recall (improve memorability and thus foster the application of new knowledge); (4) motivation (energise human resources to engage in interpretation and explore the graphic); (5) elaboration (the process of visualising knowledge leads to further understanding and appreciation of concepts and ideas as one interacts with them); (6) new insights (knowledge visualisations can reveal previously hidden

connections and lead to sudden insights, experiences); (7) Furthermore, better the decision making and problem-solving. Diagrams, tables and maps are useful for representing precise and indexical information, both quantitatively and qualitatively, supporting decision-making by constraining the set of alternatives that one must consider during a decision-making activity and specifying paths and commonalities among different problem states within and information space (Parsons & Sedig, 2014). KV enables employees to re-construct, remember and apply insights gained through KV.

In this regard, KV may better aid the decision-making process by uncovering new insights that would otherwise have gone unnoticed from the analysis of datasets. Decision-makers need to be aware that KV can enhance knowledge processes and also bias them by constraining the attention to a limited set of alternatives, focusing the attention on the wrong variables or encouraging inaccurate comparisons (Al-Kassab, 2014).

KV investigates on the use of visualisation techniques to facilitate communication in knowledge-intense processes and to support the creation of new knowledge by using visual techniques in knowledge-intense processes and situations. It also explicates, shares or develops knowledge and supports the creation of visualisations for contents that constantly change, such as a process or complex project (Burkhard, 2006, p.4). The emerging field of KV examines the use of visual representations to improve knowledge management on all levels (personal, interpersonal, team, organisational, inter-organisational and societal). It designates all graphic means that can be used to construct, assess, measure, convey or apply knowledge (i.e., complex insights, experiences, methods, etc.). The decision-makers who employ Knowledge Visualisation aim to create, assess, reference or transfer insights, experiences, attitudes, values, expectations, perspectives, opinions and predictions, and they do this in a way that enables someone else to re-construct, remember, find or apply these insights correctly (Eppler, 2008). In addition, decision-makers often cannot rely on their own expertise alone. They need input from a wide spectrum of specialists and thus at times struggle to integrate knowledge from different sources and use it for idea generation, decision-making or planning. This factor is relevant because the visualisations may reduce the cognitive load and enhance the processing abilities by visualising abstract relationships. They allow us to externalise knowledge, for example, to share it with others or get an overview of the big picture of the field of interest (Tergan, 2006).

## 4 Methodology

The methodological approach implemented in this study is of a dual nature: exploratory and confirmatory. The exploratory nature aims to build the theoretical premises concerning knowledge visualisation, the use of knowledge visualisation in university and the operational and strategic capacity to support decision-making. This phase was not set up as a rigorous review of the literature but rather as a definition of a theoretical framework. Of a confirmatory nature, the second phase aims to understand the characteristics of the knowledge visualisation tools and practices in the case study. The case study identified in this study is public Italian University "Magna-Græcia" of Catanzaro (UMG), located in southern Italy, in the Calabria region, with a campus in Catanzaro. UMG was founded in 1998. The complex nature of the organisation subject to observation requires qualitative methodological approaches suitable for exploring the phenomena under investigation. Indeed, qualitative research allows researchers to generate data and theory that could not satisfactorily derive from existing data (Locke, 2001). Research based on case studies allows us to understand a wide variety of aspects of the investigated phenomenon better (Gerring, 2007; Vennesson, 2008). The case study structure is useful for deeply understanding an organisation in its context (Crowe et al., 2011, p. 1; Hyett et al., 2014). The use of the case brings out the characteristics of the phenomenon in the context.

Data analysis for research consists of three phases: (1) accumulation of data from different sources; (2) Identification of the organisational characteristic of the case study; (3) analysis of the COVID-19 response model.

The data used in this research come from various sources: analysis of university site; analysis of the adopted COVID-19 procedure manuals; interview with university decision-maker. During the interviews with the decision-makers, the experiences, opinions and all elements for the investigation of the phenomenon were collected. The researchers conducted the interviews with two decision-makers of university, who have functions specifically related to knowledge visualisation. The researchers conducted the interviews via video meetings. The interview lasted at least 40 minutes. Specifically, researchers interviewed the rector and the general manager.

The data collected during the interviews were integrated with an analysis of the university documents made available by the interviewees and published on the university websites.

The documents and data collected were analysed to answer the following questions:

*RQ1: Is Knowledge Visualisation (KV) used in the university?*

*RQ2: What is the impact of Knowledge Visualisation (KV) on intra-organisational relationships as an effect of the emergency?*

## 5 Results

This section provides the first results of how KV can be used to facilitate the transfer, creation, identification, and application of knowledge in the university context. Specifically, the following table aims to identify the different uses in this context proposed:

UMG
Knowledge creation Knowledge transfer Application of knowledge

*Source: own elaboration based on interviews*

Objects as visual metaphors are used by UMG for the transfer of knowledge because they are easily understandable and can serve this purpose. In addition, the brain can process them more easily. They facilitate the transfer of inter-functional knowledge between the various stakeholders (technical administrative staff; teaching staff; institutional organisations) with different professional backgrounds (UMG-General Manager). Another area of application of visualization in knowledge management is Knowledge Identification. The university use maps to provide an overview of various forms of knowledge sources to different expert stakeholders, project teams and other organisations (UMG-General Manager). Knowledge visualization can also help in the application of knowledge, through diagrams or interactive graphic frameworks and multidimensional scales. They appear to be maps of knowledge and visual metaphors that are particularly suited to this purpose as they make new material accessible through familiar structures.

The analysis of the area of application of the visualization offers a relationship at different levels (micro-meso-macro) within this university context:

	<b>UMG</b>
<b>Sender</b>	General Manager
<b>Recipient</b>	Institutional Members Professors staff Administrative - technical staff

Source: own elaboration based on interviews; our adaptation by El Sawy et al., 1997; Burkhard, 2005

The diversity of recipients has placed an emphasis on the fact that Knowledge Visualisation must be adapted to the preferences of the target audience (teaching staff, administrative staff, students, etc.) and as such implement the different types of KV.

Through the use of the different visualization applications, the goal is to understand the "Knowledge Type What":

UMG Knowledge Type What?
<b>Know-what</b> <b>Know-how</b> <b>Know-who</b>

Source: adaptation by Eppler, 2008; own elaboration based on interview

Below is the table with the KV applications used in the university before and after the start of the Covid-19 pandemic:

<b>Tools</b>	<b>UMG BEFORE THE PANDEMIC</b>	<b>UMG AFTER THE PANDEMIC</b>	<b>MOST USED</b>
Sketches	NO	NO	NO
Diagrams	YES	YES	YES
Images	YES	YES	YES
Objects	NO	NO	NO
Knowledge Maps	YES	YES	YES

Concept maps	YES	YES	YES
Interactive visualisation	YES	YES	YES

*Source: own elaboration based on interview*

Specifically, the integrated use of multiple tools such as diagrams, charts, schemes, mind maps and interactive visualisations were indicated by the interview as support during the decision-making process. In particular, Knowledge Visualization, in the pandemic era, has given us the possibility to homogenise knowledge and speed up choices (UMG-General Manager).

Particular emphasis has been placed on internal customers, actively involved in the design and construction of the visualization tools. The visualization tools have been evaluated very well in terms of performance and preferences by the internal customers themselves, and the analysis of the visual tools has shown that the different types of KV have a specific degree of usefulness depending on the activity.

Knowledge visualisations served to explain and answer questions about why and what-if. They can also inform multi-level coordinated decision-making to improve knowledge creation, identification and transfer. In this Universities, regarding Knowledge Visualization, various staff management levers have been active, such as: Training and Culture Activities organization in UMG. Furthermore, to date, a Model for Quality Management and a Strategic Plan for Emergency have been implemented in the university.

## 6 Conclusions

This study's results—of an exploratory and confirmatory nature—highlight significant findings in the field of Knowledge Visualisation (KV) studies in complex organisations. In particular, the study has focused its attention on universities understood as complex organisations. From the theoretical point of view, this research—starting with an overview of the main reference theories on KV—highlights that KV has been assuming a central role in the academic debate. The results of this research have allowed us to answer this study's research questions. The first result of the interview and the analysis of the documents show that KV is widely used in university. From the interview with the university decision-maker, we have found that KV supports the decision-making process and above all it

favours a quick transfer of knowledge to administrative staff and professors. The university decision-maker that were interviewed displayed an awareness of the potential and importance of Knowledge Visualisation. Awareness of the importance of KV in universities has also been shown by the use of different tools and organs with functions related to KV. KV tools have been implemented to create, transfer and apply knowledge. Therefore, KV tools allow for more efficient HRM and faster knowledge management. The tools have represented valid support in the COVID-19 emergency phase, especially in the management of Human Resource Management. Indeed, during this COVID-19 pandemic, university have increased their number of KV tools. In fact, UMG have made strategic plans to manage the pandemic available to their stakeholders (administrative staff, professors, students, etc.). The strategic plans made it possible to introduce the new KV tools into HRM organisations and practices.

## **7 Managerial implications**

This study represents one of the first reflections on a special topic that cannot be found in the literature or managerial practices. Therefore, this article aimed to contribute to the debate by considering the real situation that has emerged through this case study—the University of Catanzaro. Nevertheless, some evidence is visible. First of all, university manager showed awareness regarding the importance of KV for safety, especially in emergency time, and it seems that KV tools have largely been used in university. However, some other considerations are necessary. One implication is directly related to the real comprehension of KV regarding people involved in decision-making processes, by avoiding that the topic of KV is linked only to those who buy security services through contracts. In addition, to understand its real impacts, it is necessary to study how people in organisations act regarding KV by building sufficient awareness and also acquiring more knowledge, which we hope can be the next step of the investigation.

## Abstract

This paper is focused on the concept of visualization as a potential tool to foster knowledge translation. We investigate how using ad-hoc visual tools supports knowledge translation and knowledge transfer. The empirical case under analysis concerns the setup of a multi criteria decision-making model to analyse and select alternatives related to the factors that upgrade the lean production process quality, at a FCA Plant. Knowledge visualization can be interpreted as the interactional process where different players translate their know-how, share a framework and develop common ground to support decision-making.

## 1 Introduction

More and more organizations nowadays collaborate in order to achieve multifaceted outcomes through a joint knowledge effort. An increasing number of industries requires high levels of interconnection among actors of various types rather than being developed in isolation; demand various forms of common effort to manage increasing levels of complexity. Not surprisingly, then, studies on knowledge transfer represent a crucial domain within the broader topic of the management of knowledge in organizations.

Understanding the essence of knowledge transfer is far from simple, due to the lack of a unanimously accepted definition or clearly identified practices for transfer of knowledge. For the purposes of this study, we adhere to a definition able to depict the essence and processual nature of knowledge transfer (Christensen, 2003 in Liyanage et al.; 2009: 122):

*"Knowledge transfer is about identifying (accessible) knowledge that already exists, acquiring it and subsequently applying this knowledge to develop new ideas or enhance the existing ideas to make a process/action faster, better or safer than they would have otherwise been. So, basically knowledge transfer is not only about exploiting accessible resources, i.e. knowledge, but also about how to acquire and absorb it well to make things more efficient and effective".*

In the words of Liyanage et al. (2009: 124), "The process of knowledge transfer is not, per se, a mere transfer of knowledge [...] it requires an additional type of knowledge; the knowledge about how to transfer knowledge".

These reflections represent an important addendum to the literature on knowledge management, being able to provide more accounts on the possibility to effectively transfer knowledge in complex environments.

In recent years, two promising avenues of studies has dealt with the concept of knowledge translation (Simeone et al., 2017; 2018) and knowledge visualization (Gavrilova, 2017). Knowledge translation is required to contextualize the transfer from the source of knowledge to the receiver in a way that can be meaningful for him (Seaton, 2002).

Knowledge visualization is a process of looking at knowledge through the support of a visualizing tool in order to make clearer knowledge and supporting its sharing (Eppler, 2013).

This paper is focused on the concept of visualization as a potential tool to foster knowledge translation. We investigate how using *ad-hoc* visual tools supports knowledge translation and knowledge transfer (Eppler, 2013; Eppler and Burkhard, 2007).

The paper sets out as follows: initially, we review the literature on knowledge transfer and knowledge translation, adding the perspective of the visualization as a knowledge translation mechanism. We then analyse the methodology used for the empirical analysis. Finally, we present and discuss data from the empirical research before summarizing the main findings and conclusions.

## **2. Theoretical Background**

### ***2.1 The concept of knowledge between transfer and translation***

Knowledge transfer is a traditional field of research in the managerial literature, as witnessed by the growing number of articles trying to shed light on how organizations should foster knowledge to be more competitive (Liyanage et al., 2009; Holden and von Kortzfleisch, 2004; Chesbrough, 2003).

Different strategies and proposals to manage knowledge are strictly related to how to define the concept of knowledge itself. One of the main classifications refers to a dichotomy that defines knowledge in two ways. According to the first approach, the “cognitive” one, knowledge is assimilated to any resource management may control; in the second approach, social relationships are the ‘place’ where knowledge is found.

The cognitive model considers knowledge as an objective resource and treats it like information, something that may be codified and passed from one individual to another. It is admitted that knowledge is in the heads of individuals, but also that it may be taken, stored and passed on to others by means of ICT. The level of analysis is the individual; it is inside the individual that knowledge may be retrieved and spread among members of the organization. The concept of knowledge as an "entity" that may be codified, cumulated and stored has its roots in a Newtonian and mechanistic vision of the world (Myers, 1996). If knowledge is in the minds of individuals and may be explicitly represented through digital or mechanical devices, then its transfer takes place through tools and objects where knowledge is managed and memorized.

Alternately, the social-construction approach relies on the social relationship as a "moment" in which knowledge is created, according to a logic of clear sociological matrix. It finds its roots in organizational studies that may date back to the late 1980s and go into the matter of learning (Lave and Wenger, 1991). The value of this trend lies in shifting the debate from a technological viewpoint to a more managerial and organizational one that focuses on a role of human resources (Blackler et al., 1999). Knowing becomes practice: it is not essential to know what, but rather to know how. According to this line of research, knowledge transfer is strictly related to a dynamic process based on practices, interactions and negotiations.

In this sense, the concept of knowledge translation, defined "as a complex process riddled with negotiations" (Simeone et al., 2017), could be useful to support knowledge transfer in a social-construction perspective.

In the managerial literature, knowledge translation is typically associated with the concept of knowledge transfer (Simeone et al., 2017; Liyanage et al., 2009), and translation theory (Holden and von Kortzfleisch, 2004; Jacobson et al., 2004) is a way to explain knowledge transfer (Liyanage et al., 2009). According to Simeone et al. (2017: 3):

"Translating knowledge involves processing new knowledge, interpreting it according to the needs and interests of a specific organization and transforming it into forms that are more suitable for the specific organizational context of application. In this sense, translation is a highly applicable analogy to explore and understand the nature of knowledge transfer".

In this perspective, knowledge translation concerns the need to build up a process to produce new and more comprehensive knowledge. This perspective

tries to answer the need for a more complex environment, where a variety (in terms of technical domains, but also of language, nationality, etc.) of specialists cooperate to attain a specific aim.

According to Liyanage et al. (2009), knowledge translation is a dynamic process that involves different stages of knowledge transformation. As argued by Raven et al. (2011), "Translation is a concept originating from actor-network theory, denoting the transfer of objectives from one actor to other actors, thereby recruiting others into the network surrounding the primary actor". In this sense, it is a process where actors negotiate ideas, perspectives and meanings, and where different mechanisms could support the process in itself.

## ***2.2 Visualization as a tool for knowledge translation***

The knowledge translation perspective is related to the adoption of the boundary object concept, and Eppler (2013, p.9) stated: "They [boundary objects] have different meanings in different social or professional contexts, but their structure is common enough to more than one professional community to make them recognizable means of translation". Some scholars have adopted the concept of knowledge translation (Secundo et al. 2019, p.274) to observe that "when knowledge is transferred across very diverse contexts (e.g., from academia to industry), knowledge needs to be translated to still be interesting and relevant".

Knowledge visualization could be considered as a process where those involved try to facilitate typical knowledge management processes such as knowledge sharing, knowledge translation, and knowledge integration (Gavrilova, 2017; Eppler, 2013).

This paper uses Eppler's definition (2013, p.4):

"KV [Knowledge visualization] designates all (interactive) graphic means that can be used to develop or convey insights, experiences, methods, or skills [6, 7]. This definition implies that the realm of KV is not limited to computer-based images and that the main purpose of KV is to support the (inherently social) processes of creating and sharing knowledge with others."

At a general level, it is possible to argue that knowledge visualization is still in an embryonic stage as a managerial theory, notwithstanding recent contributions discussed by Gavrilova (2017). Eppler and Platts (2009) discussed the role of knowledge visualization in a strategic planning process, including the adoption of

different visualization tools at different steps of the process. The authors offered important reflections and tips about selecting the right visualization tool at each step. Unfortunately, there is no clear reference to Eppler's concept of knowledge visualization as a process.

This paper investigates knowledge visualization as a process supporting knowledge translation and knowledge transfer.

### **3 Methodology**

The empirical case under analysis concerns the set up of a multi criteria decision-making model to analyse and select alternatives related to the factors that upgrade the production process quality at a FCA Plant. As is common in literature, we selected a case study in which the phenomena of interest – in this case, the use of visualizations as knowledge translation mechanism in the automotive setting – were transparently observable. The case study provided a consistent, differentiated and information-rich setting for studying knowledge translation.

The case study origins within an innovative Ph.D. project with industrial characterization, launched in April 2019, which involves the involvement of a research group consisting of a Ph.D. student, two professors from the University of Sannio and two professors from foreign universities and the quality team at the FCA plant in Pratola Serra, project partner. This study used empirical material collected at FCA's Pratola Serra Plant, in Avellino, Italy. The Pratola Serra Plant has achieved in recent years several certifications and awards, but it has also experienced some problems and important organizational development in LPD processes.

Three data collection techniques have been used: internal document analysis, participant observation and semi-structured interviews. The documentary analysis made it possible to understand the nature and origin of the phenomenon of errors made by workers in the engine assembly phase, as well as the logic with which management faces the decision relating to the necessary actions for their resolution. Participant observation was used to explore organizational control report, management control reports for the definition of the most suitable multi-criteria model for the problem being analyzed. During her fieldwork, one of the authors spent two days a week for three months. Having free access to the Plant premises, she was able to make numerous formal and informal contacts and

become relatively familiar with the management. Finally, in-depth interviews with the management of FCA were the main source of data for this study (Canonico et al., 2017). Finally, several semi-structured interviews were conducted in particular with the World Class Manufacturing Plant coordinator, two manufacturing engineering managers (quality team members), the Plant quality manager, and the Pratola Serra plant manager. The interviews were based on an open, wide-ranging protocol provided one week before the first interview. The protocol aimed to stimulate interviewees' interest in this participative research process and to promote a narrative approach, crucial for the success of the interviews. In particular, the questionnaire included questions about:

Each interview was conducted by at least two authors of this paper to reduce interviewer bias (such as first-impression error, non-verbal influences or negative emphasis). The interviews lasted between 90 and 180 min. At the end of each interview, two authors 'in charge' reported, shared and discussed the outcomes of the interviews.

#### **4 Case Study**

The case study analyzes the visualization techniques used to support the construction of a multi-objective optimization mathematical model (Fattoruso et al. 2021) used to improve the selection of critical processes in an FCA plant. The goal of research project was, not to explain the mathematical approach of the portfolio problem used in FCA, but to analyze whether and how knowledge visualization activates different dynamics to support knowledge translation. To fit our framework, the analysis of the activities was articulated into four steps:

1. Definition and analysis of the decision problem;
2. Choice and explanation of portfolio optimization problem using ad hoc visualization tools;
3. Visualization tools to help the decision-maker to choose between alternatives;
4. Sharing the decision moment and common reflection for the final choice.

Visualization tools, in particular, are used to identify the critical process package that best meets the financial needs of the plant. The visualization techniques are used at different moments that characterize the decision-maker's choice process.

The first phase in which visualization techniques were used was following the definition of the objectives declared to be prevalent by the decision maker.

Following the definition of the decision problem, the best mathematical method was identified to support the decision maker in his choice process. The problem identified is the selection of a set of critical processes in which errors occur, taking into account the various financial resources that the company has available. To solve this problem, a multi-objective optimization problem is elaborated by the group of researchers. To make the researchers understand this model without showing the mathematical formulation, the researchers synthesized the mathematical formulation through graphs and images and showed them to the decision maker. This made it possible to involve the decision-maker in the process of building the mathematical model and to generate an initial exchange of knowledge between the parties involved in the decision-making process.

The second phase in which visualization tools were used was precisely in the moment of choosing between the various alternatives available to the decision maker. In particular, the decision-making problem proved to be particularly complex to make understood. For this reason, the alternatives were shown to the decision maker, through horizontal bar histograms (Figure 1). The histograms made it possible for the decision maker to have a clear picture of the composition of the most critical processes in the company and of those that showed a higher number of errors.

The use of visualization tools allowed the decision maker to translate the information obtained with the use of the mathematical model and share it with their team. This allowed the decision maker to choose the best alternative, reducing efforts as much as possible and obtaining a more effective and more shared choice process with the team.

Fig. 1 – Tabular representation vs horizontal bar histogram representation for 50% of financial resources available

The mathematical approaches used were particularly complex Riesz spaces or algebras (Cavallo, 2020), which are difficult for non-experts to understand. Ad hoc visualization tools were created to help the decision-maker to understand the mathematical approach and to simplify the choice between alternatives. For the multi-objective portfolio decision model, the definition of reference levels was envisaged to identify when a process could be considered optimal, tolerable and not tolerable based on the number and severity of errors. The research group therefore created ad hoc visualization tools to help the quality manager understand how the model worked and the reference levels that determined the critical points of the processes.

## **5 Discussion and concluding remarks**

Using the concept of knowledge translation introduced in the theoretical section, here we discuss visualization as a dynamic process able to foster knowledge translation (Liyanage et al., 2009). The context in which the decision-making model was developed was characterized by two very specific domains of knowledge that, in line with Grant's approach (1996), needed a very low degree of integration. The "mathematical" knowledge is fundamental to construct the model, but it does not need to be shared with the company. FCA engineers have highly specific knowledge of processes and portfolios, but this only partially needed to be shared with the mathematical experts. The main purpose of the knowledge visualization was therefore to create a "boundary object" (Eppler and Burkhard, 2007) between these two separate "worlds": a common point of reference to facilitate conversation around different domains (Spee and Jarzabkowski, 2009). This distance should not be bridged or shortened but simply respected. The process of knowledge visualization can therefore be interpreted as the "bridge," a tool that facilitates the communication (conversation) between the two worlds, which use different languages and need "common ground" to interact and understand each other.

In a context where the players are researchers and managers, this bridge could be sustained by translation mechanisms. Simeone et al. (2018) stated that, given the different objectives and languages in academic and industrial contexts, translation mechanisms between these two groups of stakeholders are needed to establish a common platform of communication. Visualization tools fostered knowledge translation among researchers and the quality manager, creating the

conditions for a dialogue between these two worlds (Canonico et al., 2020). These tools also enhanced managerial judgment by translating raw data and information into accessible forms to extract knowledge and selecting the “good” alternatives. The images of the critical points of the processes engaged those from heterogeneous backgrounds and enabled inputs from different actors, allowing a fruitful interaction.

In particular, the process of knowledge translation occurred when the visualization tools were used to share knowledge with other FCA engineers (quality team) and the plant manager. These tools helped to define the alternatives clearly, classifying and then prioritizing them. The team highlighted that the visualization tools were useful for assimilating new practices into the company. Visualization tools and knowledge translation embedded in both the researcher–quality manager relationship and collective reflection about the final choice were the keys to fostering knowledge sharing among the members of the team (academics and practitioners). Templates and ad hoc drawings of complex mathematical formulas helped to direct teamwork (Gavrilova et al., 2017), transfer and share insights and enable quality team members to apply these insights. They acted as facilitators, activating awareness and reactions in-group dynamics and supporting the social processes of sharing knowledge with others to make a decision about the upgrade of the production process.

Knowledge visualization, therefore, goes far beyond the visualization tools themselves (Eppler and Burkhard, 2007). It can be interpreted as the interactional process where different players translate their know-how, share a framework and develop common ground to support decision-making.

The main objective of this paper was to understand if and how, as part of a specific U-I collaboration initiative in the automotive sector, visualization can be interpreted as a mechanism for translating knowledge. Our empirical findings showed why and how knowledge visualization could be used to foster knowledge translation and sharing among individuals and from individuals to groups.

### **Abstract**

This article aims to implement a systematic review of the literature on e-learning in the academic context that includes the period from 2001 to 2020. We have chosen the 2000s as a starting point to implement this review because they represent the historical moment in which we are witnessing to the diffusion and implementation of e-learning in

universities. Although the flexible learning model via the Internet was introduced in the 1990s and only in the 2000s did these new technologies develop concretely within academic contexts.

The methodological approach adopted was quantitative. The work took place in three different phases. (1) The articles were found by inserting some keywords in the Web of Science (WoS) platform and covered a period from 2001 to 2020. (2) The selection of the articles took place through Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) by Moher et al. (2009). (3) The final data have been reported and represented in special graphs. Furthermore, the 2001-2020 analysis period was divided into four five-year sub-periods (2001-2005, 2006-2010, 2011-2015, 2016-2020), to analyze and explore the evolution of the problems identified during every subperiod.

From the first results found, using the WoS platform and the selection of articles implemented through PRISMA, two important issues emerged.

First, it emerged that the number of publications on e-learning has increased significantly in the last five years (about 50% of the total number of documents analyzed that appeared in 2016-2020), exceeding the number of 100 documents per year.

Secondly, from the in-depth analysis of the four five-year periods, a greater focus appears on the aspects related to technology during the first two sub-periods 2001-2005 and 2006-2021. On the contrary, in the subsequent two phases 2011-2015 and 2016-2020 there is greater attention to topics related to the learning content. All this was examined by comparing Fee's model (2009) with the sankey diagram.

This research could allow us to have a precise overview of the aspects studied and treated by researchers and academics in the field of e-learning in universities over the last twenty years.

**Paper type** – Academic Research Paper

## 1 Introduction

E-learning, or Electronic learning, is a system based on digital technologies capable of promoting the acquisition of knowledge and skills by users/students (Bernuy and Garcia, 2006; Hashim, and Tasir, 2014) and which allows to support and improve the learning process (Rodríguez et al, 2019), becoming a fundamental part of the learning experience of students in higher education (Ellis et al., 2009). Thus, most universities have created their own e-learning systems in order to offer Internet-based degree programs and provide online learning materials (Mohamed Sofiadin, 2014). During the last twenty years, many universities have combined traditional forms of classroom activities with those implemented online in blended learning mode (Hwang, and Arbaugh, 2006;

McKenzie, 2020). Recently, the health emergency resulting from the coronavirus pandemic (COVID-19) has forced universities around the world to suspend classroom teaching activities (Ali et al, 2020; García-Peñalvo et al, 2021), leading to a push towards distance and online learning (Ebner et al., 2020).

Yet e-learning in universities has spread in the academic context for some time. Indeed, although the term e-learning was coined between the 1980s (Moore, et al., 2011) and the late 1990s, distance education was developed in universities and organizations around the world, as early as the 1960s (Corbeil and Corbeil in Khan, and Ally, 2015; Harasim, in Weiss et al., 2006).

Six "generations" of Distance Education have spread on the basis of the type of Information and Communication Technology (ICT) used in universities (Kimani, 2019; Taylor, 2001). During the first two generations, before the invention of the Internet, distance learning was offered through two modes of communication channels (Corbeil and Corbeil in Khan, and Ally, 2015). Think of the correspondence courses developed during the late nineteenth century, marking the first generation (Cantoni et al., 2007; Ferri in Nacamulli, 2003; Kimani, 2019; Taylor, 2001). While around the sixties (second generation), the teaching activity is provided through video and audio tapes, radio, television and digital media (Esposito, and Mantese, 2003; Ferri in Nacamulli, 2003). E-learning is part of the history of distance learning, constituting the so-called the third generation (Parricchi, 2004). This type of training is based on two-way communication means, such as the internet or video-conferencing (Bates & Bates, 2005), which involves the creation of virtual environments of communication codes of a synchronous (live) or asynchronous nature (Bates, 1990; Ferri in Nacamulli, 2003; Taylor, 2001).

In the 90s we come to the advent of the fourth generation which was characterized by the adoption of a flexible learning model via the Internet (Taylor, 2001).

But with the launch of the fifth generation (in 2000) of distance education which is essentially a derivation of the fourth generation, we are witnessing the enrichment of the educational offer using the Internet and the Web (Taylor, 2001).

Within universities, the fourth phase began, only "potentially", in the nineties, in the sense that there was the availability of ICT systems to be able to deliver training via the Internet. But most educational and academic contexts implemented the use of these technologies in the following period, namely in 2000 (NCES, 2003; OECD, 2005). Thus, according to Taylor (2001), it has been found that many universities have activated the technologies of the fourth-

generation distance learning initiatives, only when those of the fifth generation had already emerged. This circumstance has had two fundamental consequences. (1) The lack of coincidence between the temporal demarcation of the different generations of distance education outlined and their real and effective application in the university context. (2) The 2000s stand as a real watershed compared to the previous phases, as they represent an important reference period for the evident use and diffusion of new technologies in university learning.

Finally, the sixth generation is the one that includes the delivery and support of educational activity through social media, student management systems, file transfer and storage services such as Dropbox, Google drive and one unit, mobile technologies, Resources Open Educational (OER) and Massive Open Online Courses (MOOCs). (Kimani, 2019).

If this "model of the generations", as defined by Taylor (2001), offers a brief reasoning on technological evolution in teaching, it highlights while we are facing the start of a seventh phase of change. Universities have had to reshape their strategies on their way of teaching following the pandemic situation that has raged since 2020. All this will increasingly require new forms of change in strategies in the academic context in terms of balance between face-to-face teaching and teaching at a distance. To contribute to this debate on the provision of e-learning activity in the academic context, during the period of COVID-19, several articles have been published (Almaiah, et al., 2020; Almanthari, et al., 2020; Kamal, et al, 2000; Kapasia, at al., 2020; Wan Hassan, et al., 2000; Zhu, 2020).

Therefore, it is necessary to better identify and clarify, through the adoption of an information database, how the development of these different phases has been implemented. This approach, in fact, would allow to acquire certain data, but also to grasp and understand the salient elements of this debate.

Based on these considerations, this paper aims to implement a systematic review of the literature on e-learning in the academic context that includes the period from 2001 to 2020. Specifically, the goal is to answer the following research question.

*RQ: Examine the evolution of e-learning issues in universities / higher education.*

As already anticipated, we have chosen the 2000s as a starting moment to implement this revision, within the model of the six generations of distance education (Kimani, 2019; Taylor, 2001), since they represent the historical moment

in which we are witnessing a diffusion and implementation of e-learning in universities.

The article was organized as follows. The methodology adopted will be presented in the next section. The remaining paragraphs will focus on the results achieved and the discussion of the same. The last section will illustrate the conclusions.

## **2 Methodology**

The methodological approach adopted was quantitative (Creswell, 2014). The work was carried out in three different phases.

(1) The articles were found through the inclusion of some keywords in the Web of Science (WoS) platform and covered a period ranging from 2001 to 2020, to collect publications on e-learning experiences in tertiary education.

We queried Web of Science (WoS) – initially developed by the Institute for Scientific Information (ISI) and currently managed by Clarivate Analytics – because it is one of the leading databases that allows you to explore the scientific production of scholars and covers more than 20,000 journals, conference proceedings and books. The quality of WoS information is often considered the highest, we have decided to focus exclusively on this database.

The query was built by observing the keywords: "e-learning" AND "university". First, the synonyms of "e-learning" were examined. Therefore, we included in the research: "distance", "online" and "blended" along with "learning" and "education". Furthermore, we checked the different spelling of the aforementioned terms: including both multi-word terms and those without hyphens. Next, we inserted the terms "university", "college" and the multi-word terms "higher education", "tertiary education" and "post-secondary education". As in the previous case, for both we considered the spelling of different terms with and without hyphens.

(2) The selection of the articles took place through Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) by Moher et al. (2009).

In Figure 1, the salient elements of the selection of articles are shown, based on PRISMA diagram.

The analysis covered a total number of original records of 2,074. Through a series of inclusions and exclusions of contributions, at the end of the process, 1,360 documents were received.

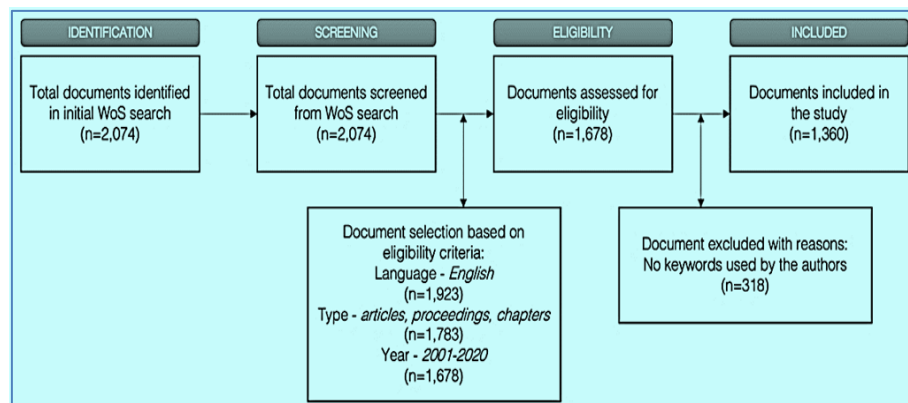

Figure 1. PRISMA flow diagram used in the study

(3) The final data were reported and represented by means of special graphs to crystallize and better identify the evolution on the various e-learning issues addressed over time. In this regard, the 2001-2020 analysis period has been divided into four five-year sub-periods (2001-2005, 2006-2010, 2011-2015, 2016-2020), to analyse in more detail the conceptual structure and explore the evolution of the issues identified over the periods. The topics were automatically tagged considering the most relevant term in each corresponding sector, observing the number of documents in which the terms are present.

### 3 Findings

We have tried to transpose the main results according to a double criterion: general and specific. In the first, we entered the general data found on the subject over the entire period 2001-2020. In the second, we tried to report the different topics on e-learning in universities treated by the authors by dividing the study survey into four sub-periods of five years.

(i) General analysis of the data. Figure 2 shows the year-wise cumulated distribution of documents published during 2001-2020. The number of documents that appeared in the last 20 years was, on average, 68 per year (with a standard deviation of  $\pm 52.40$  documents).

Noteworthy, due to the development of computer technology and the diffusion of the Internet in the field of Education, the number of publications significantly increased in the last five years (about 50% of the total number of

analysed documents appeared in 2016-2020), overcoming the number of 100 documents per year.

Figure 2. Growth and correlation of publications' production across 2001-2020.

This tendency in scientific production on e-learning in the academic context is likely to continue to increase considerably in the future. We must not forget that the universities, due to the COVID-19 pandemic, have predominantly introduced, as has happened in other areas, the technology to implement teaching activities.

From the dataset examined, throughout the investigation period, in table 1 it emerges that the publications relating to e-learning in the context of the most cited universities are those of Park (2009); López-Pérez et al. (2011); Ozkan and Koseler, (2009). The content of these contributions is linked to the concept of students' acceptance of new technologies and their perceptions. Instead, others analyze the practical implementation of e-learning systems (Graham et al., 2013; Bernard et al., 2014; Porter et al., 2014).

(ii) Specific analysis of the data. *We divided the overall study period (20 years) into four 5-year sub-periods (2001-2005, 2006-2010, 2011-2015, 2016-2020) to verify the topics covered by the authors. The label to each individual theme was automatically assigned.*

*In the first subperiod (2001-2005):* No. 34 publications were found. The number of topics covered is very limited. The leading themes consist of the concepts of

virtual university and computer-based education, while Internet-related issues are niche themes.

*In the second subperiod (2006-2010):* the total number of publications was 199 documents. Among the main topics of study emerge those connected to the organization of the infrastructures used in e-learning (e.g. learning management system, online learning environment). Interestingly, the use of acceptance models to assess the impact of distance learning appeared as a niche topic.

*In the third subperiod (2011-2016):* No. 458 published documents emerged. We are witnessing the shift of the fifth generation of distance learning towards a new phase with the reference to web 2.0 as a driving theme and the strengthening of education on the Internet and ICT.

*In the fourth subperiod (2016-2020):* No. 663 documents emerged. In this phase, the sixth generation of distance learning has been consolidated and a new one seems to appear. The meaning COVID-19 appears among the themes of the subperiod. Thus, it is evident that many institutions, due to the pandemic situation, have had to upgrade their ICT infrastructures and rethink their teaching / learning strategies. The core themes of the period were among others the use of Moodle (one of the most popular learning management systems) and the concept of MOOC.

## 4 Discussion

Taking up the main results obtained on the thematic evolution of e-learning in the academic field, we can make the following reflections.

(1) In Figure 3, a so-called sankey plot links the four analysed sub-periods (2001-2005, 2006-2010, 2011-2015, 2016-2020) revealing the paths of the different themes discussed in the literature. The extent of each flow connecting two themes graphically represents the magnitude of their conceptual nexus.

Although from the general descriptive analysis of these four phases as shown in figure 3, two main differences emerge that should be emphasized. Firstly, between the first, second and third phases there is a greater interest in the topics of e-learning on the part of researchers. Secondly, from the examination of the fourth phase there is a reduction in the topics covered in the publications on e-learning detected, compared to those exposed in the two previous periods. At the same time, in the last period (2016-2020) the contributions focus on certain e-learning issues, including a considerable number of articles published for each theme and leaving out some lines of study that had developed in previous moments (2006- 2010 and 2011-2015).

(2) According to a specific survey carried out by Fee (2009), e-learning systems are made up of three components which are: (a) technology, (b) learning content and (c) e-learning design (Gentile et al., 2020a; 2020b).

(a) The technological aspect considers the type of infrastructure used to transfer e-learning information (Ghiringhelli and Quacquarelli, in Nacamulli, 2003).

(b) the learning content, on the other hand, examines the type of teaching material and activities that are available in e-learning software (Al-Yahya, et al., 2015).

(c) The concept of learning / e-learning design is a learning process (MacLean and Scott, 2007) that allows to plan e-learning activities through an adequate use of resources and technologies (Brown and Voltz, 2005).

However, different models exist in the managerial literature on e-learning systems, such as the one developed by Ghavifekr et al (2012). Specifically, the authors state that this system is composed of four elements: planning, organization, guidance and monitoring. While according to Urh et al. (2015) the e-learning system is made up of five components: organization, planning, staff recruitment, guidance and control.

Figure 3. Thematic evolution across 2001-2020.

Instead, Henry (2001) believes that e-learning is made up of content, technology and services, in a holistic context. Within the first component, the author makes a further distinction between: generic content, classroom content and those published. In the field of technology, the second component includes: the technological infrastructures used, Learning Content Management Systems (LCMS), Learning Management Systems (LMS) and learning technologies. Inside the last component you can find the services relating to consultancy, support and design and construction.

More complex systems are those cited by Pahl, (2007) and by Khan (2005). In the first, three reference models are considered: Administration, Pedagogy and Technology.

In the second, an e-learning system is outlined which includes seven dimensions: Institutional; management; Technological; Pedagogical; Ethical; Interface Design, Resource Support and Evaluation. Within these two models of Pahl, (2007) and Khan (2005), there are further divisions that make the analysis more difficult to use for the purposes of our investigation.

We have selected the Fee model (2009) over the others listed for its display simplicity. In fact, it allowed us to have an overall overview of the topic in which the various studies, divided into three areas, can be examined on the basis of the content treated according to a logical criterion.

(3) Taking up the breakdown by thematic areas into four five-year subperiods as reported in the previous paragraph and the Fee model (2009) we selected through the use of the so-called sankey diagram (Figure 3). We verified which were the predominant themes, at internal of each of the subperiods identified, in this diagram, with respect to the three elements identified by Fee (2009): Technology; Learning content; Learning / e-learning design.

*First subperiod: 2001-2005.* The first lines of study that have developed on e-learning in the educational context can be traced back to the technology area of the Fee model (2009) in the context of that which appears in the sankey plot (figure 3) as Virtual University and Internet. Also in this period of time, some research begins to develop that focuses on the content of e-learning (Evaluation), even if the technological aspect is prevalent in this first moment.

According to Arbaugh (2001), the use of collaborative technologies, in the context of university e-learning, makes it possible to reduce social distance, as well as facilitate learning and student satisfaction.

*Second subperiod: 2006-2010.* In this new phase, as can be seen from figure 3, we are witnessing the presence of considerable and different topics treated on e-learning by researchers. Specifically, some of these themes have focused, according to the model of Fee (2009), on the technological aspect. As an example: Computer-Mediated Communication; Virtual Learning Environment; Online Learning Environment; Virtual University; Information Communication Technology; Information Technology; Learning Management System; Technology Acceptance Model.

According to Hwang, and Arbaugh, (2006) these web-based learning environments through blended courses seek to contribute to the nature of actual communicative behaviors and their resulting impact on knowledge acquisition.

Other research is related to the area of Learning content, analyzing, in particular: Learning Network; Collaborative Learning; Education; Evaluation; Perception; Internet Education. For example, Franceschi, et al. (2009) demonstrated that learning content of the virtual world on 3D is more suitable for effective collaboration and engagement of learners for e-learning than the text-based virtual learning environment (e.g., Blackboard, Moodle).

On the contrary, only one argument emerges attributable to the design of e-learning (Engineering). In this second phase, there is a greater interest of researchers in topics related to the technology area according to the Fee model (2009).

*Third subperiod: 2011-2015.* The publications on e-learning in this further period are very widespread, compared to the previous time, based on what emerges from figure 3. In fact, there is a lot of research that examines the technological aspect of e-learning according to the model outlined by Fee (2009) such as: E-learning System; Educational Technology; Information Communication Technology; Internet; Learning Management System; Web 2.0; Technology Acceptance Model. According to Ramayasa (2015), technology represents one of the success factors regarding the acceptance of E-Learning in Universities.

Other studies focus on the content of e-learning by addressing issues related to: Cloud Computing; Collaboration; College English Teaching; E-learning Readiness; Motivation; Online Course; Perception; Quality Management; Teaching Learning Strategy.

Thus, also Koutsabasis, et al. (2011), have shown that the provision of educational material through e-learning, specifically in asynchronous mode, is able to support the management of many types of information and content on

courses and generate student satisfaction. In this third phase there is a greater attention on the part of scholars to the content of e-learning.

*Fourth subperiod: 2016-2020.* In this last period of time, the contributions on e-learning that focused on the technological aspect, as identified in figure 3, were the following: E-learning System; Learning Management System; Educational Technology; Technology Acceptance Model. For example, the research by Alhabeeb and Rowley (2018) considers technological infrastructure as one of the Critical Success Factors (CSFs) associated with the adoption of e-learning.

Instead, the content of e-learning was studied for the following areas: College English Teaching; Student Satisfaction, Learning; MOOC; Moodle; Online Course. According to Nariman (2020), the learning content adopted by e-learning systems has a positive impact and generates high satisfaction for students.

Finally, the publications that have focused on e-learning design including the topics in figure 3 are: Community of Inquiries and Pedagogical Issue. Think of the research carried out by Renda dos Santos, and Okazaki, (2016). The authors tried to explain the factors that led to the adoption of e-learning by creating a specific design model called Decomposed Theory of Planned Behavior (DTPB).

Also, in this last period of time there is a preponderant focus of publications towards problems related to the content of e-learning.

## **5 Conclusions**

This article aimed to implement a systematic review of the literature on e-learning in the academic context during the period from 2001 to 2020. The stimulus to investigate this issue was dictated by the presence of the health emergency resulting from the coronavirus pandemic. (COVID-19) which has forced universities around the world to pervasively introduce and develop forms of distance and online learning (Ali et al, 2020; Ebner et al., 2020; García-Peñalvos et al, 2021). Yet the conduct of e-learning didactic activities is not new in academic contexts (Hwang, and Arbaugh, 2006; McKenzie, 2020; Mohamed Sofiadin, 2014). There were six "generations" of Distance Education that have spread over time based on the type of Information and Communication Technology (ICT) within universities (Kimani, 2019; Taylor, 2001).

But this research has been carried out since the 2000s, although already in the 90s we are witnessing the adoption of a flexible learning model via the Internet (Taylor, 2001). The answer to this depends on the fact that only during the 2000s

did most of the educational and academic contexts concretely introduce the new methods of distance learning (NCES, 2003; OECD, 2005).

At the same time, it would seem to be witnessing the task of a new generation of distance education: the seventh. As a result of the pandemic situation, universities have had to revise their strategies on their way of carrying out teaching activities.

To try to understand how this evolution on e-learning took place, we followed the following methodological approach. First, we entered some keywords in the Web of Science (WoS) platform to search for the articles on e-learning to be selected. Second, we selected items via Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) by Moher et al. (2009).

Finally, we divided the 2001-2020 analysis period into four five-year subperiods (2001-2005, 2006-2010, 2011-2015, 2016-2020), to better explore the evolution of the topic within each subperiod.

From the main results obtained, through the previously explained methodology, some fundamental questions emerge.

First, it should be noted that the number of publications on e-learning has significantly increased in the last five years (approximately 50% of the total number of documents analyzed that appeared in 2016-2020), exceeding the number of 100 documents per year. This trend in science production on e-learning in tertiary education is likely to continue to increase dramatically in the future, due to the SARS-CoV-2 pandemic.

Furthermore, from the in-depth analysis of the four five-year periods, a greater focus appears on the aspects related to technology during the first two subperiods 2001-2005 and 2006-2021.

On the contrary, in the subsequent two phases 2011-2015 and 2016-2020 there is greater attention to topics related to the learning content. All this was examined by comparing Fee's model (2009) with the sankey diagram (Figure 3).

Fee (2009) states that e-learning systems are made up of three components: Technology; Learning content; Learning / e-learning design.

The sankey diagram highlights the different fields of study on e-learning in the context of higher education that developed from 2001 to 2020 divided into the four sub-periods mentioned above. Thus, we tried to group the lines of investigation that emerged in the diagram of Figure 3 within the three aspects identified in the Fee model (2009).

Yet, this work will allow scholars to better understand in a theoretical key what has been the research carried out in the last twenty years on e-learning in the higher education system. Furthermore, it will allow academics to have a clear and comprehensive picture of what e-learning issues will be addressed in the future.

Also, from a practical point of view, this research could have positive implications, especially as regards the period 2016-2020. In fact, the contributions published in this period will be able to support concrete interventions in the use of technologies in teaching and learning, to better respond to the pandemic crisis.

But the main limitation of this study derives from not having reported and included further statistical data in the descriptive study of the results. But our main purpose, in this historical moment, was to implement a general verification of the existing contributions on e-learning in the field of higher education. The further step of our investigation will be to investigate these statistical criteria.

## Governance of Sustainable Greentech Value Chains

---

Inéz Labucay

Department of Economics  
University of Halle-Wittenberg  
Germany

### Abstract

The paper investigates structural shifts in an exemplary greentech sector, the value chain of semiconductors, between 1980 and 2018 with the aim in mind to uncover risks inherent in the configuration of the value chain. As this sector has seen an unprecedented transition from highly integrated device manufacturers to disintegrated modular value chains and is in the midst of a third wave of reintegration, it serves as a case in point to study potential risk sources based on patent data (WIPO's Patentscope). Tentative conclusions on a governance of these types of value chains are drawn which take into account the conflicting developments of digitization of manufacturing (industry 4.0) and the large-scale sustainability transition underway in most industrialized countries.

**Keywords** – sustainability, governance, Greentech, industry 5.0, patent analysis

**Paper type** – Academic Research Paper

### 1 Background and aim of the paper

The scaling down of production in companies worldwide due to a lack of semiconductor chips lasting well into June 2021 has prompted automotive companies to revert to reduced working hours and once more underscored the risk exposure of an industry with globally dispersed value chains (Tewari 2013). By enlarging their product range to include electric cars, automotive companies have (at least from a strategic perspective) begun to join other greentech industries (like, e. g., wind turbines, smart products) in their dependency on rare earth metals employed in sensors and in high efficiency magnets indispensable for most applications. Relatedly, the cumulative systems technology of semiconductors has contributed to both product innovations on an within-industry level, e. g., miniaturization of electronic circuits printed on silicon wafer chips (Hoeren 2016) built in computers, but also enabled follow-up innovations

for greentech applications in a variety of sectors (e. g., Smart City applications). The European Commission launched its industry 5.0 initiative earlier this year in an effort to reconcile sustainability (epitomized by the Circular Economy) with the promises of digitization of manufacturing inherent in industry 4.0 (European Commission, 2021). The current implementation of industry 4.0 however falls short of meeting the triple bottom line goals (Müller, Kiel, and Voigt, 2018; Nara et al., 2021) and the prospective large-scale digitization wave (Baldwin 2013) may compromise sustainability, e. g. through the digital rebound effect. The move towards digitized manufacturing platforms is a double-edged sword as it may exacerbate the already high energy usage of the manufacturing sector amounting to 38 % of global energy consumption (IEA 2017) and expected to exceed the emission share of the mobility sector in Germany within a few years (BMU 2020), increase product obsolescence and lead to higher resource consumption (Ford und Despeisse 2016). It has been argued that despite both industry 4.0 and environmentally-sustainable manufacturing being all but new technological paradigms, their interface might serve to underpin „a robust new industrial wave“ although their joint dynamics are still ill-understood (Sousa Jabbour, Jabbour, Foropon, and Godinho Filho, 2018, p. 19) contrasting with their relevance for manufacturing at large.

Semiconductors and high performance magnets are two examples where severe repercussions have occurred along the whole value chain in the past decade albeit for different reasons and with different consequences. In the case of magnets the fact that China represents a bottleneck for rare earth supply which is crucial for magnet production enabled it in 2010 to disrupt international rare earth supply by halting exports, a practice sanctioned by the WTO in 2014, once more demonstrating the global dependency on Chinese rare earths and the risk exposure of all related downstream sectors. Both the upstream and downstream end of the magnet value chain are fairly stable. On the contrary, in the case of semiconductors, supply disruptions in the automotive industry have been more recent (since 2020, due to the pandemic) but could be interpreted as a symptom of a more general reconfiguration of the value chain. After a first wave of vertical integration in the 1990s (Anzenbacher und Wagner 2020) power has been shifting from integrated device manufacturers (IDMs) like Intel to foundries and, increasingly, fabless firms specialised in design (Hall and Ziedonis 2001). Furthermore, the downstream end of the value chain formerly dominated by the bargaining power of automotive and electronics companies is in a state of

reconfiguration with chip producers like Dutch STM and TSMC (Taiwan), Samsung and Intel having begun to prioritize the gaming and entertainment sectors over automotive for the first time (Schmidt 2021; Schmidt et al. 2021). In both industries the role of patents is a decisive one as the core product itself as well as production processes are highly complex. Standardization is among the key processes through which complexity is reduced (Gereffi et al. 2005). The two cases are furthermore contrasting as to the degree of modularity (related to codification, particularly standardization in the model of Gereffi et al. 2005) with modularity high in case of semiconductors (with a highly disintegrated semiconductors industry challenging the business model of integrated conglomerates (Park et al. 2018) and low in case of magnets which, apart of mass produced all purpose-magnets, are highly customized.

Although uncertainty reduction arising from power asymmetries in value chains has been addressed before (Inomata 2017; Escaith 2017) and the power residing in either end of the value chain (e. g. power exerted by component manufacturers or large retailers) has been conceptualized as the ability to shape the risk-return profile of the industry (Gereffi 2011; Gereffi et al. 2005), value chain governance has neither been linked to the extant literature on risk exposure (or its counterpart resilience) (for an exception see Quoreshi and Stone 2019) nor to sustainability.

The aim of the paper is as follows: It proposes to establish a link between value chain risk (and how it can be reduced through codification), the different value chain governance types, and sustainability. The technological fields of high efficiency magnets and semiconductors are analyzed on a conceptual level which is followed by a more focused patent analysis of the case of semiconductors. These greentech sectors (categorized as greentech due to their importance for technologies such as wind energy and electromobility) have been chosen as they represent contrasting cases as regards the type of value chain governance with one rather stable but entailing high risk exposure for downstream firms (builder of high efficiency magnets) and one where market forces are in flux with new suppliers and customers from a wide set of industries entering the value chain thereby putting established business models under pressure and with risk originating upstream (suppliers of semiconductors). Also, within semiconductors, differences between the type of firms are taken account of, whether they be integrated device manufacturer (Hung et al. 2004), fabless firms, or foundries (Park et al. 2018) active in different value chain stages as will be explained in more

detail later on. The dynamics in semiconductors also extend to patenting which has gained added importance since the pro-patent shift in US legislation (1979-1995) (Hall/Zidonis 2001). In particular, the cases are used as a backdrop to the question if sustainability potential can be harnessed based on an antagonistic or conducive position of industry 4.0 vis à vis sustainability (Ford and Despeisse, 2016).

Sustainability goals are defined in line with the European Commission's Waste Framework Directive and the UN Sustainable Development Goals (SDGs), especially the goal of „ensuring sustainable consumption and production patterns“ (SDG 12) for which manufacturing is considered crucial not least through the reduction of waste and a better waste management (Kristoffersen, Blomsma, Mikalef, & Li, 2020). Despite its assumed instrumental role in making a sustainability transition, only one third of studies on the industry 4.0 sustainability link have been conducted in the manufacturing sector (Savastano et al. 2019; Min et al. 2019). Exploring the missing link between industry 4.0 and sustainability (epitomised by the Circular Economy) (Kristoffersen et al. 2020; Alcayaga et al. 2019) could contribute to better pinning down how the competitive landscape – in terms of market structure and value chain configuration - in rare earth based industries (e. g., semiconductor and magnet producers and their downstream industries) is likely to evolve.

Based on this, on an applied level, Governance strategies to safeguard against value chain risk are discussed, among them blockchain (which helps to reduce informational risks, Min 2019), standardization and closing the loop of global value chains (e. g., through increased Recycling and Reuse activities and cloud-based business models).

## **2 Conceptual background: value chains and risk exposure**

### ***2.1 Types of value chains in two exemplary rare earth industries***

Gereffi et al. 2005 differentiate between five governance types (and corresponding value chains) depending on concrete realizations of the following three parameters: complexity of transactions, ability to reduce uncertainty through codification and capabilities in the supplier base with the first two being discussed with reference to information related coordination costs.

The paper makes a point in stretching the reference frame of these three parameters to include tangible product and production process related traits, e. g. codification is related to modularized magnets in that their standardized set up would enable to bring down transaction costs of production and (hardly discussed so far) also of Recycling and Reuse. In the original Gereffi model standards (e. g., product and process standards) are mentioned as a means to bring down complexity and thereby facilitating transactions at low cost. For magnets, a too high degree of variation of their set-up have been identified as a hindrance to Recycling and Reuse (Binnemans et al. 2013). In both types of value chains, the interplay between organizational setup (value chain configuration) and traits of the technologies/products on the one hand and consequences for risk governance on the other (chapter 2.2) is particularly addressed.

#### *2.1.1 Value chains in high performance magnets*

Machacek and Fold 2018 characterize the rare earth industry as an opaque industry which is why the “ability to codify” (the second parameter of Gereffi et al. 2005) in their view is considered crucial in engineering the outcomes of global value chain participation. The “ability to codify” pertains to standardization and, more generally, Intellectual Property Rights (IPR) protection which also includes patents. In the early stages of the value chain of high efficiency magnets for instance, where metals are turned into magnet alloy powders (Bast et al. 2012), the efficient allocation of IPR, particularly patents and standards, is of high significance (European Commission 2014). Furthermore, the lack of standardization of the geometry of magnets (which are often glued to each other) as well as the variety of magnet composition prevents their reuse (Binnemans et al. 2013) and thereby hampers the sustainability transition (Markard, Raven, and Truffer, 2012) of the sectors involved. The downstream section of the value chain, pertaining to intermediate and final goods, has been most often analyzed from a value chain risk perspective (Wagner and Neshat 2012), however, magnet producers face exposure to value chain risks particularly upstream, in the materials’ sourcing stage due to a high concentration of suppliers.

Fifarek and Veloso 2010 show that innovation (proxied by patent output) tends to be more clustered in magnet industries than in the comparatively less complex catalysts which are also manufactured from rare earths. Despite the increasing global reach of value chains, innovation activities in magnets became more pronouncedly clustered after China became the market leader in rare earths in

1990 – mirroring the fact that magnet production is dependent on knowledge spillovers along the value chain stages which leads to inventors and producers having to locate as closely as possible (Fifarek and Veloso 2010).

### 2.1.2 Value chains in semiconductors

The value chain of semiconductors consists of a series of production stages which can be technically separated and allow for a disintegration of the value chain: starting with the design, followed by the production of the silicon wafers, the production of the mask (the celluloid filaments carrying the electronic circuits), the assembly of both elements in fabrication (transferral of the circuits in the mask to the wafer by way of etching into its surface), the assembly of transistors, diodes and integrated circuits and the testing of the end product, the finalized semiconductor (Grinberg 2016; Malerba und Nelson 2011).

Besides the classical, highly integrated semiconductor conglomerates like Intel and Texas Instruments (US), Toshiba, Matsushita Electric, Hitachi (Japan) and Samsung (Korea) (integrated device manufacturers) which span large parts of the value chain from design to fabrication, to packaging and testing (Hung et al. 2004) two hybrid types have emerged each covering only a fraction of the value chain: fabless firms (design only) which are highly technology intensive (Park et al. 2018) and foundries (fabrication only) offering high end manufacturing to the former two (Hall and Ziedonis 2001) (Figure 5).

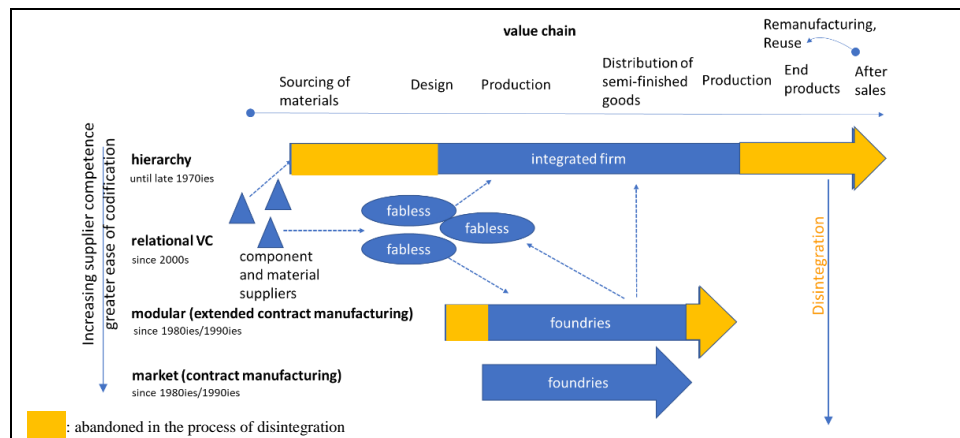

Figure 5: Global value chain evolution in the semiconductors industry  
Source: own representation (systematization of Value Chain (VC) types based on Gereffi et al. 2005)

Semiconductor contract manufacturing offered by foundries, and, to a limited degree, by integrated device manufacturers, has given rise to a high market concentration in the supply stage (Florea 2013). The emergence of a split model of design-only firms (fabless firms) and fabrication-only firms (foundries) now coexisting with classical large-scale manufacturers can be traced back to an upgrading of supplier capabilities (Gereffi et al. 2005) particularly of technological capability related to standardized product platforms in the case of fabless firms (Park et al. 2018) and a shift to modularity in the case of foundries. The needed upgrading of supplier skills was driven by market demand (consumer electronics since 1970s and wireless communication and video gaming since 1980s and 1990s) which, unlike the PC era with the long-lived Intel standard, necessitated customized instead of standardized chips (Adams et al. 2013). The resulting fabless firms as suppliers of on-demand customized chips have experienced a high exposure to hold up by their intermediate users as the low barriers allowed the latter to tap into suppliers' knowledge and finally create their own chips (Adams et al. 2013). The patent analysis of the semiconductors industry for 1980-2018 (section 3) will come back to this by looking whether a higher risk exposure as a result of the structural shifts in the value chain can be verified by using two patent indicators.

The ability to codify (e. g., by means of interface standards) facilitates modularity (e. g. market modularity in arms-length relationships and technical modularity, i. e. pertaining to design, see Ernst 2005) and has enabled a large-scale disintegration of the semiconductor industry. Modularization also contributed to sustained scale economies despite an increasing vertical disintegration of the value chain (Malerba und Nelson 2011). The Taiwanese semiconductor industry (with its own "Silicon Valley", the cluster Hsinchu Science-Based Industrial Park) has seen a steep rise in both foundries and fabless firms since the 1980ies driven by, among other factors, a decrease in development costs and short technology cycles which prompts their categorization as distinct industries by Hung et al. 2004. However, there are signs of the pendulum swinging back, some authors stress the need for tighter coordination when complexity levels become too high to be counteracted by codification which puts a limit to modularization and market coordination (Dibiaggio 2007) and in turn calls for higher degrees of integration in the semiconductor industry (Ernst 2005).

This is equivalent to saying that the governance modes of fabless firms and foundries are in need of being more tightly integrated or coordinated or else that

there may be a renaissance of integrated equipment manufacturers. Prior research has pointed to a relationship between structural shifts (modularization and miniaturization which contributed to a vertical disintegration giving rise to fabless firms) and scientific firm output with foundries more active in patenting and fabless firms publishing more scientific articles (Pellens und Della Malva 2018).

Technology related factors impacting on value chain configuration to be taken into account besides integration are modularization and systems-on-a-chip design with the latter enabling reuse of designs (Dibiaggio 2007) and miniaturization (Hoeren 2016). As both the complexity of transactions and the ability to codify impact on modularity levels, the model of Gereffi et al. 2005 should be a suitable backdrop for analyzing the risk exposure of this exemplary greentech value chain in more detail in what follows.

## ***2.2 Risk exposure in value chains: measures***

Originating in ecological studies (Adger 2006), value chain risk studies in an economic context have addressed resilience and robustness of local value chains (Quoreshi and Stone 2019). Transaction risks proliferate in long and lean value chains (Peck 2005) dominated by few suppliers (Wagner and Bode 2006) in which trading costs (including informational ones) accumulate. The main industries analyzed in prior resilience studies however have been outside greentech, namely chemistry, automotive, pharmaceuticals (Enyinda and Szmerekovsky 2008) and machinery and electronics (Peck 2005; Svensson 2000).

China holds a de factor monopoly on rare earths, estimations range between 67% and 85 % of worldwide heavy rare earth production being concentrated in China which is also the biggest magnet producer (Glöser-Chahoud, Tercero Espinoza 2015, referring to Du, Graedel 2011; Keilhacker & Minner 2017).

For fabless firms specialized in the design stage of the value chain, it is critical to tap in to diverse sources of design related knowledge and, at the same time, to orchestrate the interplay of modules which may become an additional source of uncertainty (Dibiaggio 2007), or, in other words, a driver of value chain risk. Value chain risk also emanates from the structure of the value chain, e. g., from being trapped in contracts with less productive partners (Cantner et al. 2019).

### 3 Patent analysis

#### 3.1 *Measurement of risk exposure based on patent data*

Patent analyses on technologies have been conducted from different angles, e. g. as a means to identify technological sub-trajectories (Kalthaus 2017) and to uncover technological trends as mirrored in patent maps and patent networks (Abbas et al. 2014; Lizin et al. 2013). From the viewpoint of this paper, prior work is of interest which has used patent indicators as a means to identify the developmental stage of a technological innovation system (Berg et al. 2019), particularly as a means to measure sharp intrusion of technologies into established fields (Porter et al. 2019). This can lead to disruptive innovation as radical shifts to new trajectories (Dosi & Nelson 2010) which destroy established governance modes and leads to a repositioning of value chains, e. g. between fabless firms and foundries and, potentially, back to integrated device manufacturers. In what follows, a closer look at the semiconductors value chain is taken, entailing an attempt at measuring shifts in technological fields which are interpreted as entailing risk for established technological fields (uncertainty in the model of Gereffi et al. 2005) by means of a patent indicator.

##### 3.1.1 *Three crucial time spans in semiconductors*

In the semiconductor industry, patent licensing, particularly by integrated device manufacturers, fabless design firms and IP vendors which license designs to the former, is a major source of revenue (Florea 2013). Figure 6 shows the development in granted patents for the top four countries accumulating most of the patents granted in semiconductors in the period 1980-2018.

Almost half of all patents during this period have been granted to Japanese inventors (395.000), followed by the United States (183.986), the Republic of Korea (148.988) and, with a considerable lag, China (54.688). Notable is the recent surge in the number of granted Chinese patents (green line in Figure 6) the quality of which may be lower though compared to its peer economies.

Figure 6: Semiconductor patent grants by country of origin 1990-2018, equivalent count<sup>1</sup>, top 4 patentees only

Source: retrieved from WIPO Statistics Database of World Intellectual Property Organization (WIPO) 2020, 17th June 2021, technology class nr. 8 (World Intellectual Property Organization (WIPO) 2019)

As Boeing und Mueller 2016 have shown (for PCT applications through which countries seek international protection), the steep increase in Chinese patents has been achieved at the expense of patent quality when only foreign and no self-citations of patents are considered. 30 % of the surge in Chinese patenting has been traced back to the policy of grant based patent subsidies initiated between 1999 and 2007 resulting in lower quality patents with narrow claims (Dang und Motohashi 2015).

A more detailed analysis of PCT patents (now looking at applications) is conducted in what follows for three crucial periods in the history of semiconductors:

1. **1980-1994** – Pro-patent shift: This is the era of the pro-patent shift, marked by the 1984 Semiconductor Chip Protection Act (SCPA) which protected the mask work, i. e., the pattern formed by the circuits on the silicon wafer, and the 1994 Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) agreement (Hoeren 2016; Hall und Ziedonis 2001). TRIPS as a multilateral IP system subject to the WTO dispute settlement mechanism grants extended protection to all types of means to create that pattern (topographies) besides through masks (Hoeren 2016) and grants protection against trade secret theft and

<sup>1</sup> Equivalent count means that „an application filed at a regional IP office is counted multiple times according to the number of its members. This method applies to all regional offices where the filing has an immediate legal effect in all member states“, (WIPO 2021).

compulsory licensing for semiconductors (Semiconductor Industry Association November 2020). The end of the period coincides with the founding of a formal industry association of fabless companies, the Fabless Semiconductor Association in 1994 which suggests a fair amount of stabilization of the fabless governance model (which had existed mainly in the US since the 1950ies whereas Japan invested in IDMs (Hoeren 2016)

2. **1995-2009** – Disintegration: During the 1990ies, the market for semiconductors became substantially more diversified including, after consumer electronics and PCs, gaming and, in the 2000s, communicative platforms in automobiles which necessitated more customized chips and decoupled the manufacturing and design ends of the value chain (Adams et al. 2013) which further fuelled both the entrance of fabless firms and of foundries
3. **2010-2018** – Reintegration (?): Increasingly, modularization contributes to product and technological complexity, bringing the need for coordination back in to semiconductors (Dibiaggio 2007)

During the whole time period 1980-2018, a total 153.710 PCT patents have been applied for at WIPO (the time span is pruned to the year 2018 due to patents pending for a maximum duration of 18 months before being granted).

Three independent searches on WIPO's Patentscope for PCT patent applications have then be conducted (17<sup>th</sup> June 2021) using the search strings included in the Appendix A which cover the three time periods, 1980-1994, 1995-2009 and 2010-2018. The aim is to find out, if these periods, marked by regime shifts in patenting (first period), market structure shifts (second and third period) and shifts in the market power of suppliers and the composition of the demand side (second and third period) are characterized by different levels of exposure to risk induced by the intrusion of other technologies into the core technological category. First, an overview of the prevalent technological categories in the three time periods is provided (Figure 7). Overall, 144.798 PCT patents applications have been registered at WIPO in semiconductors between 1980 and 2018. Summing up patent numbers across technological fields (IPC codes) results in 257.041 PCT patent applications where the difference stems from the fact that patents are filed in multiple IPC codes. Patent applications have increased in all three time spans in all technological categories (IPC codes) from 5748 applications in the first, to 93.550 in the second and 157.743 in the third time span. The biggest increase has

understandably been in the core category of semiconductors, H01L (a separate scale is indicated for this in Figure 7 due to the large difference in application numbers to the other categories), with a particularly steep rise beginning within the first time span (1980-1994) and lasting into the second time span (1995-2009) reflecting at least in part the repercussions of the pro-patent shift happening during these 15 years and culminating in the TRIPS agreement in 1994, and, to a lesser degree, between the second and the third time span (2010-2018).

Figure 7: Patent applications 1980-2018 in semiconductors

### 3.1.2 Patent indicators as a measure of risk exposure

In what follows, based on two patent indicators developed by Berg et al. 2019 (which build on the technology cycle of Anderson und Tushman 1990), it is investigated for the three time spans if the market structure and market power shifts described at the beginning of this section have affected the composition of technological trajectories.

It is argued that as patent applications (being the nearest indicator of creative inventions) are published ahead of their being granted and can therefore leave a trace in semiconductors as an innovation system in that they spur further inventive activity and therefore can be considered a good representation of early signs of changes in innovation dynamics (and risk exposure). The indicators are defined as follows:

<p>The <b>Patent Trajectory Indicator</b> of year <math>t</math> is defined as</p> $PT_t = \frac{M_t}{\sum_{i=1}^N P_{i,t}}$ $= \frac{\text{number of applied IPC codes in year } t}{\text{sum of total patent applications in year } t}$
<p>The <b>Category Concentration Indicator</b> of technology category 1 and year <math>t</math> is defined as</p> $CC_{c1,t} = \frac{\sum_{i=1}^N P_{i,c1,t}}{\sum_{i=1}^N \sum_{c=1}^M P_{i,c,t}}$ $= \frac{\text{number of patent applications in tech category } c1 \text{ and year } t}{\text{number of patent applications in all tech categories in year } t}$

Figure 8: Two patent indicators for tracking technology development

Source: own representation based on Berg et al. 2019

Legend:

$i = i_1, i_2, \dots, i_N$  : Identification number of patent,  $N$  is the number of patents

$t = t_1, t_2, \dots, t_q$  : application year,  $q$  is the number of years

$c = c_1, c_2, \dots, c_M$  : technology category (proxied by IPC code),  $M$  is the number of applied WIPO technological categories

The first indicator, the Patent Trajectory Indicator ( $PT_t$ ) allows to analyze the breadth of the innovation system measured by the number of technological categories divided by the number of patent family applications in a given year with a decline in the indicator pointing at a stabilization of the TIS around a dominant technological category.

The Category Concentration Indicator ( $CC_t$ ) sheds light on how concentrated the TIS is on one technology category which dominates the sample of a given year ( $CC_t > 50\%$  together with a negatively trending  $PT_t$ -Indicator), or, on the contrary, if it is quite dispersed with new trajectories beginning to take shape and to crowd out the dominant technological category. A high degree of dispersion ( $CC_t < 50\%$  for all technology categories and years) together with a varying linear trend of the  $PT_t$ -Indicator can be interpreted as the TIS being in an era of ferment with technology categories not yet fully consolidated possibly marking the beginning of a new technology cycle. This is equivalent of saying that the era of ferment is characterized by externalities. These externalities can be positive: a good example of this is the co-development of mainframe computers and transistors in the 1950ies and minicomputers and integrated circuits in the 1960ies which propelled the further development of their respective industries of origin, the computer and semiconductor industries (Malerba et al. 2006). However, negative externalities arise in the form of market-stealing as a consequence of product market rivalry (Bloom et al. 2013). In the above mentioned case, alleged market-stealing (copying by Japanese chip producers) ended an era of generous cross-licensing between US and Japanese semiconductor and electronics firms and led into what became known as the chip war in the 1960ies (Hoeren 2016).

A positively trending  $PT_t$ -Indicator together with a share of the dominant technology category of more than 50 % ( $CC_t > 50\%$ ) indicate that more remote technological categories begin to invade the core trajectory of the innovation system (era of discontinuity) (Berg et al. 2019). While this may bring in knowledge from outside the system, it can also be a sign of eroding of knowledge boundaries between users and suppliers, endangering established IP positions of suppliers as users incorporate increasing shares of the semiconductor design specific knowledge (Adams et al. 2013) and threaten the competitive edge of suppliers.

The indicators have been calculated for the ten most often occurring IPC patent codes in semiconductors and have been retrieved 25<sup>th</sup> June 2021 from WIPO's

Patentscope (for search string see Appendix A). The results are as follows (Figure 9 and Appendix B): The clear negative trend of the  $P_t$ -Indicator between 1980 and 1994 combined with the dominance (>50 %) of technology category of Electricity which accumulated around 80 % of patent applications indicates that this has been an era of dominance of the central technology, H01L: Semiconductor devices, which is part of Electricity. In the following two time periods, the  $P_t$ -Indicator starts with a slightly negative slope but plateaus off already between 2000 and 2009 (in the second half of the middle period) and ultimately is almost flat between 2010 and 2018. Patents filed in Mechanical engineering are non-existent in the latter two periods and filings in Performing Operations and Transporting wane away since 2004. Thus, the field consolidates around the three remaining technological fields Physics, Electricity and Chemistry since 2010 with Electricity still the dominant category. Neither of the technology cycle phases in semiconductors can therefore be categorized as being in an era of ferment with the competitive edge at stake. However, the fact that the  $P_t$ -Indicator (which is a measure of breadth of the innovation system) is declining substantially, the consolidation around the focal technology appears to be coming to an end which (should the indicator turn out to become positive) would be the beginning of an era of discontinuity with new fields intruding into the core field of semiconductors. This will prospectively be applications from Chemistry and Physics which have both begun to accumulate more patent applications in the course of the last two periods. Chemistry, for instance, has been reaching around 10 % of applications since 2011. This, however, is an open ended development which needs further confirmation as to its long-term stamina.

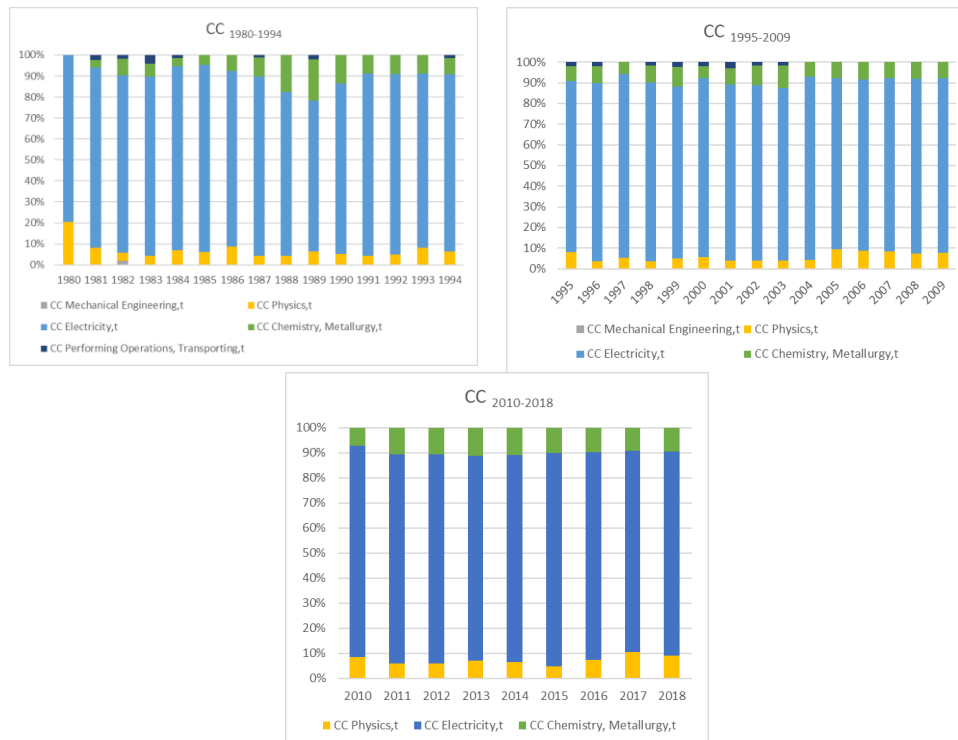

Figure 9: Patent indicators in semiconductors for three time spans in comparison

#### 4 Governance of the semiconductor value chain

Value chain governance types (in the definition of Gereffi et al. 2005) have been outlined for semiconductors based on patent data. However, governance of value chains may be understood from an applied angle as a set of measures taken to mitigate risk in the value chain. Given space constraints, a range of measures pertaining to sustainability and industry 4.0 shall be outlined.

Although the Re-Use of magnets from car motors is technically feasible with a net positive outcome according to ecological life cycle assessments they are rarely reused due to a lack of standardization of the rotor design (Walachowicz et al., 2014). Electric motors, for instance, are rarely re-used although it is mandatory to explore how a modular set up of these may contribute to prolonging their life-span, provided that the quality and performance requirements are clearly laid down so as to make them eligible for the same or a similar use (Wehrspohn 2017). A combination of standardized components and a modular design of

assembly would help to bring down risks associated with the spare parts business and maintenance contracts and to better align the design of products and service portfolios (Schneider et al. 2016) thereby increasing Re-use and Recycling quota. However, the question remains how materials' origin and composition and the feasibility of recycling methods for RE intensive industries can be ascertained in a timely and efficient manner by both legislators and industry (Schlegel & Rockland 2018). The case of industry 4.0 is an example of a process discontinuity which offers process variants potentially enabling „order-of-magnitude improvements in the cost or quality of the product“ (Anderson und Tushman 1990, p. 607), e. g. in combination with blockchains. Blockchains (which helps to reduce informational risks, Min 2019), standardization of the setup of chips which allows to curb the existing high degrees of complexity as well as closing the loop of global value chains (e. g., through increased Recycling and Reuse activities and cloud-based business models) would help semiconductors to reduce the level of risk in their value chain.

## **5 Results and discussion**

To conclude, a general configuration of the value chain caused by a sharp intrusion of competing technologies could not be ascertained. However, although electronics applications are still the dominant technology category, the rise in the  $P_t$ -Indicator (as a measure of technological breadth) which has started off negative but plateaued off in the course of the last 18 years, could point to the fact that the phase of retention around the focal technology applications in Electronics is coming to an end and that an era of discontinuity in which this dominant technology category could be destroyed (from applications stemming from Physics and Chemistry) may be imminent.

The technology cycle of Anderson und Tushman 1990 has been combined with a model of value chain governance of Gereffi et al. 2005 in this paper. The development of PCT patent applications in the three time spans has been tracked based on WIPO's Patentscope database. In addition, two patent indicators have been calculated based on PCT applications. These indicators have originally been developed as a means to track technology footprints (emerging and declining technologies) in technological innovation systems (Berg et al. 2019) but have been applied in this paper as a measure of the degree of resilience of an exemplary innovation system, semiconductors. Limitations of the indicator

employed translate also to the application in the context of this paper, e. g. the fact that the choice of technology categories (IPC codes) and the selection of the time period are critical for the results obtained (Berg et al. 2019). The patent search only included the most basic IPC code, H01L, but could have been enlarged by a combined keyword and IPC code search enlarged by further codes. The last time span is shorter than the other two (8 years) and the further development cannot be foreseen with any degree of certainty.

Alternative measures could have been used to measure the exposure to risk based on patents, e. g., Lee et al. 2016 have established that a low connectivity of the patent portfolios of Japanese firms particularly in electronics and robotics has insulated the Japanese economy in technologies critical to make a digital transition in the context of industry 4.0. Patent citations mirror knowledge networks and have been used to describe the evolution of knowledge in the design hierarchy of wind energy (Huenteler et al. 2016) which could also be related to uncertainty and risk. The measures applied here however, to the best of the author's knowledge, have not been used as a measure of risk exposure of sectors critical for the sustainability transition, like semiconductors, as they originally stem from a technology emergence background.

It has been contended that the private sector's SDG performance is more objectively investigated by means of patent data than by employing more elusive measures mirrored in reporting (van der Waal et al. 2021). This is in line with the tech mining approach which mandates combining analyses of scientific literature and patent analyses with the aim to trace technological trends in an informative, reproducible and efficient manner (Porter et al., 2019, Lizin et al. 2013). This paper has suggested an approach aimed at measuring the degree to which an innovation system like semiconductors is prone to value chain risk by means of patent indicators.

### **Abstract**

Social Innovation (SI) is a configuration of social practices prompted collectively and intentionally by multiple stakeholders in a specific ecosystem to solve problems that would be not effectively solvable through traditional approaches or practices by transforming the social and economic settings. Despite the literature around SI ecosystems has grown considerably in the latest years, what makes an ecosystem facilitator for transformative SI remains unexplored, especially in specific contexts and geographies, such as developing and emerging countries, where structural, cultural, relational, and power conditions differ from those of more powerful stakeholders enacting the SI initiative. Our research aims to fill such a gap by investigating the combination of characteristics - stemming from Stakeholder Theory and Knowledge Management - that enables local stakeholders'

autonomy in developing and emerging coffee-producing countries to increase the impacts of SI initiatives. We adopt a configurational approach through fuzzy set Qualitative Comparative Analysis on 18 projects of SI undertaken by coffee MNEs, NGOs, and institutions to favor an egalitarian value co-creation among local coffee farmers. That entails that farmers overcome being just the projects' target to become the catalysts of local social, economic and environmental initiatives for change ultimately. We demonstrate that stakeholder empowerment, cooperative strategic posture, knowledge transfer, and local knowledge exchange are necessary conditions within the ecosystem for creating local autonomy as antecedent for transformative SI. Our novelty resides in suggesting a combination of characteristics that represents a virtuous process changing the rhetoric of firm-centric view based on stakeholder dependence to move to lower-power stakeholders' interdependence and collaboration through a reconfiguration of relationships, advancing fresh perspectives on stakeholder and knowledge management thinking applied to SI literature. Eventually, we also propose practical ways to deal with the imbalance in stakeholder power, which the literature identifies as a factor that might limit the SI's actual transformation and effectiveness locally.

## 1 Introduction

Social innovation (SI) is a highly fragmented practice that can be explained through various theoretical angles and involves multiple groups of stakeholders with different levels of power and expectations (Moulaert et al., 2017). SI is intended as a new configuration of social practices prompted collectively and intentionally by a constellation of stakeholders in a certain environment to solve problems that would be not effectively solvable through traditional approaches or practices (Cajaiba- Santana, 2014; Howaldt and Schwarz, 2010). Rethinking and reconfiguring resources, relationships and knowledge are two mainstream actions of SI, aiming to find new methods for accomplishing social goals such as innovation sources and new key strategic partners for developing projects of social interest (Chesbrough, 2006; Herrera, 2015; MacCallum et al., 2009; Mirvis & Googins, 2006; Mulgan, 2006). The context in which SI happens needs to be supportive of the transformative mechanisms behind social innovation. Scholars and practitioners commonly define such a context as an ecosystem (EU Commission, 2015) or enabling ecosystem (Terstriep et al., 2020; Biggeri et al., 2017; OECD-LEED, 2016).

The word ecosystem itself – defined by the Oxford dictionary as “all the plants and living creatures in a particular area considered in relation to their physical environment” – reflects those characteristics of interaction and interconnection, which are common to any SI initiative. In the SI field, an ecosystem is formed by the multiplicity of stakeholders involved in the initiative, their power, their relationships, the elements affecting their interactions as well as any other condition impacting on the processes and the outcomes of SI (Terstriep et al., 2020; Bloom and Dees, 2008). Therefore, the ecosystem framework perspective best fits the study of the transforming nature of social innovation. It gives the idea of continuous interaction among stakeholders and interconnection between stakeholders and the environment, allowing movements and transformation in the structural conditions (Carayannis et al., 2018). An ecosystem needs a combination of enabling and empowering elements to allow SI to grow effectively and transformative (Terstriep et al., 2020).

Even though the literature around SI ecosystems has grown considerably in the latest years in the attempt to formulate adequate responses to social, economic, and environmental issues through a broader conceptualization of innovation (Domanski et al., 2020; Ziegler, 2017), which combination of enabling elements makes an ecosystem a facilitator for transformative SI remains unexplored, especially in certain contexts, such as developing and emerging countries (Sept, 2020; Terstriep et al., 2020; Voorberg et al., 2015; Rüede and Lurtz, 2012; Murray et al., 2010).

Our research aims at filling such a gap by investigating which combination of characteristics—stemming from Stakeholder Theory and Knowledge Management—makes an ecosystem capable of facilitating transformative SI initiatives conducted in coffee developing and emerging countries, where smallholder farmers (coffee owners and producers) struggle with economic, social and environmental issues. In the context of our research, we define transformative SI as initiatives that, despite being prompted by the multinational enterprises (MNEs, in our case coffee roasters) together with other partners such as global and local NGOs and institutions in a logic of support to local coffee farmers’ well-being and coffee sustainability, are undertaken to favor an egalitarian value co-creation among local coffee farmers. The egalitarian logic – opposite to a traditional paternalistic narrative (Civera et al., 2019) – entails that farmers are not merely the objects of the SI initiatives but rather the initiatives aim at turning them into partners and co-designers of further local SI projects (Candelo et al., 2019; Civera et al., 2019;

Candelo et al., 2018). In other words, transformative SI means reconfiguring stakeholder relationships to increase farmers' autonomous decision-making so that they can become the catalysts themselves of local SI with a strong motivation to cooperate and develop participation in their own ecosystem, to foster their local community well-being and independence as well as to reach business sustainability.

Our study aligns with previous research positing that innovative and transformative solutions within SI in complex scenarios need to be investigated through a multidisciplinary and interactive perspective (Scott et al. 2017; Woodside, 2012; Mitleton-Kelly, 2006).

That is why we observe the phenomenon under study through the theoretical lenses of Stakeholder Theory (ST) and Knowledge Management (KM). Those best interpret such kind of transformation in an ecosystem, in terms of relational drivers for redesigning fair, balanced, and trustful relationships (Mirvis et al., 2016; Mirvis et al., 2012; Cajaiba-Santana, 2014; Greenwood and Van Buren III, 2010; Howaldt and Schwarz, 2010) and critical mechanisms of transfer and exchange of knowledge that can help to solve problems, developing new ideas or implementing new practices or policies (Cummings, 2004).

From our theoretical analysis, we outline key constructs within ST and KM – which the literature considers relevant to allow effective social transformations – that we summarize into five enabling characteristics (also named initial variables): stakeholder empowerment; cooperative strategic posture; knowledge transfer; local knowledge exchange; engagement to digital transformation. Those characteristics can be developed to a certain degree and implemented in a specific combination, impacting differently on the local autonomy of farmers for transformative SI, which is the outcome that we aim at testing.

To investigate the degree and combination of those characteristics, we analyzed 18 carefully selected SI initiatives, which involve multiple stakeholders of the coffee supply chain in various developing and emerging countries to enhance local autonomy for transforming the traditional SI nature and outcomes in a twofold way. First, we collected data and information through primary and secondary sources, tested each characteristic's degree of development within the cases through thematic analysis, and evaluated each enabling characteristic per each SI initiative. Second, we adopted a configurational methodological approach by performing fuzzy set Qualitative Comparative Analysis (QCA) (Woodside, 2010; Ragin, 2009; Drass and Ragin, 1992).

The reasons why we focus on such a specific context are threefold. First, since social innovation is 'often highly contingent and context-sensitive' (Nicholls et al., 2015, p. 22), contextualization helps identify key mechanisms for improving the impacts of SI. Second, developing and emerging contexts are full of paradoxes, especially in terms of stakeholder power and culture. Studying a possible enabling ecosystem for SI in those contexts can contribute to overcoming the issue of stakeholder power, limiting SI effectiveness (Sept, 2020; Lannon & Walsh, 2019; Nicholls and Ziegler, 2015; Moulaert et al., 2007). Third, within SI practices, analyzing how to progress the autonomy of lower-power stakeholders who have always been underestimated (Dawkins, 2014; 2015) can be a way to establish a change of mindset and adopt a new perspective of social transformation. Such a change of mindset can be challenging and fruitfully applied in developing and emerging contexts, where we are used to witnessing a traditional firm centric-view through which firms tend to impose social changes through SI initiatives involving powerful stakeholders. This attitude needs a rethinking that might open new challenges for lower-power stakeholders not to be the passive actors of SI projects anymore but to become active co-operators and catalysts for a greater SI impact (Jamali and Mirshak, 2007; Civera et al, 2019; Khavul and Bruton, 2013; Muthuri et al. 2012).

## **2 Social Innovation from a Stakeholder Theory perspective**

The essential argument of Stakeholder Theory (Freeman, 1984) is the conceptualization of organizations and stakeholders as entities entangled in a complex ecosystem of relationships. What makes ST a breakthrough approach in the rhetoric of business is the acceptance of harmonization, cooperation, and joint-ness of interest among various categories of stakeholders (Strand and Freeman, 2015), versus considering conflicts and competition as the main forces governing an ecosystem through a firm-based perspective (Porter, 2008). According to stakeholder scholars, a firm centric view based on transactions might overlook key factors, mechanisms, stakeholder identities, and needs that can enable higher stakeholder participation, proactive actions, and increase the impacts of value co-creation (Bridoux and Stoelhorst, 2016; Den Hond and de Bakker, 2007; Rowley and Moldoveanu, 2003). That is why fresh perspectives on stakeholder thinking posit that looking at stakeholder relationships only from the more powerful stakeholders' perspective (such as the MNE) might overlook the

possibility of valuable collaborations for broader scopes with those groups of stakeholders that have always been considered to be less legitimate and less powerful (Derry, 2012). Therefore, ST scholars posit that power and responsibilities should be spread among stakeholders at multiple levels to encourage joint value creation and higher creative outcomes of SI (Civera and Freeman, 2019; Dawkins, 2014; 2015; Freeman et al., 2010; Jamali and Mirshak, 2007).

Such a perspective fits with the key objectives of SI, which rely upon collaborative engagement and the creative reconfiguration of social relationships within ecosystems for solving social issues (Chesbrough, 2006; MacCallum et al., 2009; Mirvis & Googins, 2006). Therefore, ST can support Social Innovation in a twofold manner.

First, the issue of stakeholder power remains a huge barrier limiting the effectiveness of SI initiatives, because it prevents collaborative engagement (Montiel et al., 2012; Moulaert et al., 2007; Nicholls and Ziegler, 2015). This is particularly true when MNEs establish relationships with stakeholders in contexts that can favor the spread of unfair practices, such as powerless communities in developing and emerging countries where the MNE sources key resources for its business. In this specific case, it is most likely that the relationships between the company and the vulnerable stakeholders are unbalanced and merely based on dependency. To this end, latest ST research has applied the empowerment construct to lower-power and vulnerable stakeholders operating in developing and emerging contexts to increase their independent participation in social and business initiatives (Civera et al., 2019). Stakeholder empowerment (SE) has been conceptualized as a step-by-step process aiming to provide stakeholders with the right tools and knowledge to create awareness and influence over their decisions (Dawkins, 2014; 2015), increase their moral standing, their autonomous voices and their proactive participation to social and economic initiatives (Dawkins, 2015; Freeman et al., 2010; McVea and Freeman 2005). Empowerment goes from the mere economic support to vulnerable communities to the strengthening of lower-power stakeholders' business mindset, the organizational structures of their businesses to operate independently and the establishment of social and sustainable approaches to adopt locally (Civera et al., 2019; Crane and Ruebottom, 2003; Fassin et al., 2017; Kumar and Pansari, 2016).

Second, empowerment is understood as the main antecedent of the cooperative strategic posture needed to effectively reconfigure stakeholder

relationships and responsibilities for enabling stakeholders' participation in SI (Desai, 2018; Shams, 2016). Developing a local cooperative strategic posture (CSP) (Strand and Freeman, 2015; Enright & Bourns, 2010) entails that vulnerable and lower-power stakeholders are empowered enough first to establish fair and trustful relationships (Greenwood and Van Buren III, 2010; Phillips, 1997). That means that stakeholders must perceive that the more powerful actors involved in the SI ecosystem act to meet their needs and rights legitimately without opportunistic behavior and through fair and transparent information-sharing mechanisms, communication, and two-way dialogue (Greenwood and Van Buren III, 2010). Then, empowerment and trust might lead stakeholders to be engaged with both the SI ecosystem actors and their own local communities and resources. Despite being a multi-faceted construct, engagement is, in this context, defined as a process of positive stakeholder involvement (Greenwood, 2007) that is the result of continuous powerful stakeholders' commitment to lower-power and vulnerable stakeholders so that the latter develop consent, commitment, alignment to the organizations' values and are inclined to cooperate through a collaborative mentality (Freeman et al., 2010).

Spreading power and favoring cooperative strategic posture can contribute to redesign relationships in an interdependent way (Freeman et al., 2010). The idea is that once power is redistributed (thanks to the efforts of virtuous organizations within the SI project) and relationships among stakeholders redesigned in a fairer way, responsibility shifts to categories of stakeholders that were previously considered lower-power, vulnerable and dependent, creating a fertile ground for further actions to boost the transformative impacts of SI.

### **3 Social Innovation from a Knowledge Management perspective**

Knowledge Management (KM) scholars agree that establishing knowledge-based relationships through knowledge transfer (KT), local knowledge exchange (LKE) and engagement to digital transformation (EDT) can enhance mutual learning interactions and the chance for co-creating value in the interest of social, economic and environmental outcomes within SI (Wood and Bischoff, 2019; Jali et al., 2017; Avelino et al., 2015; MacCallum et al., 2009; Peloza and Falkenberg, 2009; Usoro et al., 2007).

Knowledge Management is a set of valuable ways to collect the knowledge accumulated in an ecosystem in its path of technological, social, environmental

and business strategies using procedures that allow, at any time, to retrieve it, review it and update it dynamically (Davenport and Prusak, 1998). KM success depends on ensuring that both explicit and implicit knowledge are detected and developed (Frappaolo, 2008). That happens to the extent to which the dimensions of the intangible assets (human, organizational and relational capital) interact in synergy (Janz and Prasarnphanich, 2003). In recent decades, awareness has grown that a large part of an ecosystem's development depends on its intangible factors: the creativity, unpredictability, and emotional intelligence of human capital (Lazovic, 2012). Continuous learning processes based on localization, "cross-fertilization" between different experiences and categories of stakeholders create new skills and make the existing ones evolve, increasing the chances to spread SI in the ecosystem (Dahiyat, 2021).

The management of innovation, starting from the 90s, ceased to be exclusively a rigid and engineeristic process, to coordinate and enhance the knowledge heritage toward complexity and development (du Plessis, 2007). The valorization of knowledge is achieved only when knowledge sharing occurs between people within an ecosystem (Cabrera et al., 2006; Wang and Noe, 2010). If we refer to the local communities of vulnerable and lower-power stakeholders in developing and emerging countries, this can happen because of knowledge transfer, which is defined as the act of moving the knowledge among different entities or organizations (Szulanski et al., 2004). According to Wang and Neo (2010), sharing knowledge can support intra-stakeholder collaboration to solve problems, develop new ideas, or implement new projects (Cummings, 2004). However, it does not deliver results if stakeholders are not keen to absorb the new knowledge (through knowledge transfer from more powerful actors), to look for extra information, inputs and learning, that is knowledge-seeking. Such a process is defined as knowledge exchange and implies both the intention (as a starting point) and the act of sharing knowledge as well as the act of seeking new knowledge for creating innovative solutions.

Clearly, in a context of lower-power and vulnerable stakeholders, the presence of an empowering culture favors, even more than within an organization, a knowledge enhancement culture and motivation, in a virtuous circle (Caniëls et al., 2017). It has already been demonstrated in various contexts that digital innovation within KM practices can boost such a virtuous circle when it is accompanied by a high engagement and cooperative strategic posture of all

stakeholders involved in the digitalization strategy (Candelo et al., 2021; Troise and Camilleri, 2021).

In this sense, KM makes technology, culture, business, and social processes collaborate on an equal basis: new technologies offer the opportunity to increase interactions between people within an ecosystem while at the same time allowing to reach many interlocutors and to accelerate the processes of sharing new ideas and information. Therefore, even though the interactions between the social layer of SI and the role of technology are very complex to detect (Meijer and Bolívar, 2016), digitalization strategies and technological transformations can be considered social actors boosting active participation and multi-stakeholder inclusion in social change (Kar et al., 2019; Bock, 2016; Townsend et al., 2015). Digital transformation can impact the way stakeholders interact in the ecosystem and make decisions by favouring: faster communication through an interactive dialogue; sharing of good practices; transparency and trustful relationships; the possibility to develop new capabilities through faster local knowledge contamination (Jafari-Sadeghi et al, 2021; Tödtling and Trippel, 2018).

Our literature review points out that specific characteristics within ST and KM–stakeholder empowerment (SE); cooperative strategic posture (CSP); knowledge transfer (KT); local knowledge exchange (LKE); engagement to digital transformation (EDT)–might be pivotal to create an enabling ecosystem that favors transformative SI. Here our research question raises: which combination of those characteristics makes an ecosystem facilitator of transformative SI?

#### **4 Research context**

Our research focuses on lower-power and vulnerable stakeholders who are, on the one hand, smallholder farmers, owners of key resources in the complex supply chain of coffee (Hwarng et al., 2005) and, on the other hand, suffer from a given situation of inequality linked to their geographical context (Mongelli and Rullani, 2017) – in this specific case developing and emerging countries.

In those countries, commonly, such a group of stakeholders is characterized by: low income (Ahen, 2017); inequality in business power (Dawkins, 2014; 2015); vulnerability and unfairness in relationships with other stakeholders, even local (Candelo et al., 2018; Dawkins, 2015); lower power in decision making (Dawkins, 2015); incapacity to replicate business rules and models on the local territory and exert influence (Greenwood & Van Buren III, 2010); marginalized and vulnerable

conditions (Derry, 2012); poorer structural condition (Mena et al., 2010); lower access to basic needs (Mena et al., 2010) and sometimes denied human rights (Mena et al., 2010); inability to autonomously develop whatever they think is valuable; impossibility to transform ideas into a successful business, social, and environmental practices (Greenwood & Van Buren III, 2010).

## 5 Method

To explore the simultaneous combination of characteristics that makes an ecosystem facilitator of transformative SI, we used fuzzy set/Qualitative Comparative Analysis (fsQCA) as our main method. Fuzzy-set QCA is a research paradigm (Mellewigt et al., 2018) that suits our investigation in three ways.

First, it strengthens new knowledge generation from a continuous dialogue between theory and case studies and favors learning processes among different theoretical perspectives applied to SI.

Second, it goes beyond the mere cause-effect statistical analyses by focusing on a joint causal system that allows interaction effects among each characteristic within a case and permits to study complex and new phenomena within an ecosystem that is constantly evolving (Woodside, 2012). FsQCA allows to simultaneously explore, based on asymmetric linkages (Ragin, 2009), all the possible interactions between a set of initial variables (in our case 'characteristics') of the phenomena under investigation and the relevant outcome (in our case 'local autonomy for transformative SI'). Essentially, fsQCA focuses on combined effects of causal conditions (initial variables), because it assumes causation to be complex, intertwined, and holistic.

Third, it is ideally applicable to a small-to-medium number of cases (Woodside and Baxter, 2013; Woodside, 2010), requiring familiarity to exploratory investigations (Trueb, 2013).

We used Podsakoff et al. (2012) list of principles for correcting estimated values to minimize common method bias.

We adopted a grounded theory approach (Charmaz, 2014; Corbin and Strauss, 1990). We worked separately, made independent judgments on the case studies, and then agreed to evaluate each characteristic in a final set of discussions.

### **5.1 Sample and Data Collection**

Our sample of case studies consists of 18 SI projects that focus on enhancing local farmers and their families' livelihood conditions, their knowledge on coffee-producing methods and sustainable practices, their capacity to establish local and global relationships of value with the overall outcome of increasing their decision-making power for autonomous business and social choices and for designing SI initiatives locally. These projects are enacted by coffee MNEs and their Foundations; global and local Non-Governmental Organizations (NGOs); global and local research institutes and Foundations; Country Regional Governments; International Coffee Organization (ICO); field project officers operating in the following countries: Brazil; India, Tanzania, Ethiopia; Uganda; Haiti and Dominica Republic; Colombia; Trifinio; Indonesia; Peru; Vietnam.

We have selected the SI projects that, to date, have already concluded at least their initial phase, producing measurable results. Furthermore, we have been guided by the Secretary of the International Coffee Organization during several interviews conducted between January and April 2016 (identification phase), who supported us in the identification of the coffee SI projects that could be global benchmarks in illustrating the characteristics of enabling ecosystems for transformative SI.

To develop the case studies, we collected data respecting triangulation (Yin, 2013) and gathered information from multiple sources of complementary evidence, including the systematic literature review, semi-structured interviews (Bernard, 1988) with 30 main stakeholders involved in the SI projects, and content analysis of reports of each project.

First, the literature review allowed us to detect the five enabling characteristics used as the configurational analysis variables, whose degrees for evaluation will be described in the next section.

Second, the semi-structured interviews were conducted both face-to-face and through virtual meeting platforms with the following stakeholders: MNE 1 chief sustainability manager; MNE 1 chief sustainability manager's collaborator 1; MNE 1 chief sustainability manager's collaborator 2; MNE 2 corporate affairs director; MNE 1 green coffee purchasing manager; Secretary at the MNE 1's Foundation; Secretary of the ICO (International Coffee Organization); project manager at the global NGO 1 in Haiti and Dominican Republic; project manager at the global NGO 2 in Uganda; project manager at the global NGO 3 in Brazil; consultant at

the global NGO 4 in Germany; project manager at the local NGO 5 in Colombia; project manager at the local NGO 6 in India; project manager at the local NGO 7 in Ethiopia; project manager at the local NGO 8 in Indonesia; project manager at the local NGO 9 in Vietnam; project manager at the global foundation 1 in Peru; member of the Regional Government in Peru; representative of the local coffee research institute in Tanzania; eleven (11) field project officers of the MNE 1 in all countries.

Interviews were based on a questionnaire containing open questions addressed to first discuss the content and the main aims of the SI initiative. Second, to investigate each initiative against the five enabling characteristics outlined by the literature. In particular, interviewees were asked to describe in detail: the enacted process of stakeholder empowerment and its stage of development locally (SE); the evaluation of stakeholder engagement and the detection of trustful relationships to favor cooperation locally (CSP); the capacity to move knowledge from the more powerful stakeholders to the local farmers (KT); the ability to exchange knowledge by sharing, seeking and generating new sources of innovation and information locally (LKE); the degree of local digital implementation and contamination, as well as the local autonomous usage and understanding of technology for designing innovative solutions in the economic, social and environmental sphere (EDT).

To follow the procedures of grounded theory, each researcher independently cross-interviewed each participant in a reiterative process (i.e. both researcher 1 and 2 personally interviewed MNE 1 chief sustainability manager on different occasions). Some key stakeholders were interviewed at least twice to monitor the projects' evolution during its different phases. A total of 58 interviews were conducted, recorded and transcribed *verbatim* and kept secure in a folder of the researchers' laptops.

Eventually, we consulted available descriptive documents and reports and impact evaluations of each project.

All data and information were gathered on multiple occasions over a time span of about five years, starting in January 2016.

Table 1 reports the full description of each SI project included in our sample regarding the country where the SI initiative is undertaken and project purpose.

Table 1: Sample description

<b>Projects of social innovation</b>	<b>Country</b>	<b>Description</b>
Coffee resilience	Brazil - Minas Gerais	The project aims at contributing to the increase of incomes of small scale coffee farmers in Southern of Minas Gerais through the quality market access adding value and increasing the resilience of their production systems to climate change.
Sustainable coffee production - Brazil	Brazil - Lambari	The project aims training on good agricultural practices; improving coffee quality; improving techniques to face climate change; improving organizational skills; implementing the "Farmer Field School" Methods; Providing soil analyses services; Quality Contest.
Sustainable coffee production - India	India - Sakleshpur and Mudigere	The project aims at improving the living conditions of the smallholder households through the production of sustainable coffee. Empowering the MAS company which ensures the delivering of services and supporting programmes for its members.
Supporting youth in coffee producing regions	India - Calcutta	The project "EveryOne" aims at combatting child mortality; support to a project in favour of marginalised youth in Calcutta
Sustainable coffee production I phase - Tanzania	Tanzania - Kilimanjaro	The project aims at improving the production systems of 5,000 coffee farmer households in Tanzania within 3 years in order to maximize income, cash flow, asset growth, food security and nutrition in a sustainable way
Sustainable coffee production II phase - Tanzania	Tanzania - Kilimanjaro	The project aims at setting up of 28 Farmer Field Schools; setting up of producers' companies trading coffee; product and quality management; saving programs alternative to loans
Coffee Farmer Alliance in Tanzania	Usa River/ Mbeya, Tanzania	The project aims at giving technical assistance to farmers through the Coffee and Climate Methodology; providing support to existing organisations (Shiviwaka and Tanzania Coffee Farmers Alliance) and to intergenerational and gender challenges; providing support to the development of relationships with other local actors
Ethiopia C.A.F.E.	Ethiopia - Amaro and Amhara	The project aims at improving coffee producing techniques and management skills; improving the product quality through sustainable techniques, aimed also at coping with climate change; improving gender balance within families and empowering women in the household management; in partnership with Slow Food working on food security through crop diversification
Technology transformation for coffee	Colombia	The project aims at establishing the IT infrastructure to guarantee that high speed internet allows constant interaction among local and foreign stakeholders, engagement of young generations for facilitating the emergence of creative solutions, exchange of technical skills needed by different teams and exchange of real time feedbacks on smart agricultural practices as well as access to a central database of technical information

Carcafé - Colombia - Meta	Colombia	The project aims at enhancing product quality and quality consistency through training sessions and investments in infrastructures and in reserach and development to sequence the Arabica coffee genoma in order to enhance the coffee quality to cope with climate change and disease and infection of plants as well as increase the antioxidant effects of coffe.
Sustainable Coffee Program - Uganda	Uganda	The project aims at strengthening the implementation of the national coffee strategy, supporting financially farming households with holistic and innovative strategies that will make a long-term and sustainable impact on the productivity and quality of Uganda's coffee.
Building Coffee Farmers Alliances - Uganda	Uganda - Kasese	The project aims at supporting and consolidating the activities already implemented by the existing Producers organizations; supporting the coffee re-planting initiative; supporting the organizations in the relations with financial institutions
Café Hispanola	Haiti and Dominican Republic	The project aims at improving coffee productivity and empowering smallholder farmers, especially women. It is addressefd to transfer agricultural know-how and promote cooperation as well as improve the coffee purchasing and selling systems.
Verdad y Vida	Guatemala - San Lucas Chiacal, San Cristóbal Verapaz	The project aims at supporting the production of coffee by a group a 20 indigenous women victims of the past civil conflict. It aims at enhancing their technical (e.g. organic fertilizers), organizational and administrative capacities.
Coffee development - Trifinio	Trifinio (Guatemala-Honduras-El Salvador)	The project aims at developing managerial skills; technical assistance to farmers through the Coffee and Climate methodology; supporting thr managing of intergenerational and gender changes; developing relations with other local actors and projects.
Promoting Organized Farmers	Peru	The project aims at increasing the flow of income to improved livelihoods of smallholder farmers in the provinces of Lamas, Moyobamba y Rioja in the department of San Martin, Peru.
Strengthening the smallholder Robusta sector in Sumatra	Indonesia	The project aims at collecting, consolidating and disseminating best practices for adaptation in the project regions. The coffee farmers take part in hands-on training activities, assisting them to find strategies which suit their needs. Coffee farmers have access to an online platform, the c&c toolbox
Coffee environmental sustainability	Dak Lak- Vietnam	The projetc aims at improving production techniques efficiency in order to reduce the carbon foot print amd enhance the environmental practices through training on climate change

## **5.2 Description and evaluation of variables**

Using the systematic literature review, we constructed initial characteristics to operationalize the constructs within ST and KM relating to our research question. As the two initial variables to clarify ST and its constructs applied to SI we will use stakeholder empowerment (SE) and cooperative strategic posture (CSP). As the three initial variables to clarify KM and its constructs applied to SI, we will use knowledge transfer (KT); local knowledge exchange (LKE) and engagement to digital transformation (EDT). Each enabling characteristic was evaluated according to a 1-5 Likert scale ranking the absence (1), low, medium, high or full (5) presence, development or implementation of each characteristic.

For SE, the more advanced the empowerment actions (5 on the Likert scale), the higher the chance for the SI initiative to favor cooperation. Otherwise, when empowerment actions are addressed just to cover local basic needs (1 on the Likert scale), the project is considered to be paternalistic rather than transformative.

For CSP, the higher the local farmers' trust and engagement both to the project and other local and international social and business actors, the greater the cooperative strategic posture they can develop to cooperate locally (5). Otherwise, the lower the engagement and the trust, the lower the chances of developing the cooperative strategic posture needed (1).

The more the training is tailored to local farmers' needs for KT, the more effective the transfer of knowledge (5). Otherwise, the mere knowledge assessment among existing and potential partners of the project reflects just an initial intention of transferring knowledge (1).

For LKE, the more effective sharing of knowledge, the higher the chances of the local proliferation of knowledge sharing behaviors (5). Otherwise, the local knowledge awareness reflects a situation where local farmers might want to seek knowledge but do not implement knowledge-sharing behavior yet (1).

For EDT, the higher the presence of solid partnerships and innovation of local services, the greater the engagement to digital transformation (5). Otherwise, the lower the capacity to partner and contaminate local stakeholders and institutions digitally, the lower the engagement to digital transformation (1).

### **5.3 Fuzzy set calibration**

Before running fsQCA, a calibration process was conducted to transform the original Likert scale into a continuous value range from 0 to 1 (Ragin, 2009; Woodside, 2010). This includes identifying breakpoints that allow the option to assign membership of set cases. All the enabling characteristics were converted into fuzzy set continuous values (Fiss, 2011) by applying the 'direct calibration method' approach to coding (Ragin, 2009). This method relies on identifying specific anchors for each attribute. The anchors were chosen based on a technical (relying on percentiles distribution related to the sample properties) and qualitative (relying on theoretical expertise and qualitative knowledge) assessment (Greckhamer, 2015).

Specifically, in order to simplify the analysis without losing model significance, our original shades through the Likert scale were transformed into a final scale of five categories: 0.95 (corresponds to 5: fully present/developed/implemented), 0.76 (corresponds to 4: highly present/developed/implemented), 0.5 (corresponds to 3: the point of maximum ambiguity where we considered it equally probable to represent a low or high development of that condition), 0.25 (corresponds to 2: low presence/development/implementation); and 0.05 (corresponds to 1: not present/developed/implemented).

For the outcome 'local autonomy for transformative SI' we employed a fuzzy logic, assuming three degrees of the outcome: high, medium, and low. High means that the project has succeeded in generating local autonomy of decision-making, and the farmers have already implemented some local social and business cooperation initiatives. Medium means that the project has partially succeeded in creating local autonomy of decision-making but mostly for autonomous decisions regarding the business (for instance, farmers deciding to start local tourism activities with few social and environmental impacts). Low means that the project has succeeded in supporting the local activities and societies, but the farmers' autonomy of decision making has not been reached; instead, it is being early discussed. Therefore, by adopting the same 'direct calibration method' as before, projects showing high outcome have been evaluated with 0.95; those projects showing a medium outcome achievement are evaluated with 0.5; those projects showing a low outcome achievement are evaluated 0.05. In Tables 2 and 3, the initial values and the fuzzy set scales for each enabling characteristic and the outcome are presented.

Table 2. Initial values and fuzzy set calibration - characteristics

		<b>SE</b>	<b>CSP</b>	<b>KT</b>	<b>LKE</b>	<b>EDT</b>
<b>Original Likert values</b>	<b>Calibration</b>					
1	0,05	Addressing basic needs and upholding human rights	Absence of trust, no engagement	Knowledge assessment among potential partners	Knowledge awakeness	Absence of partnerships, no digital contamination, no product and service innovation
2	0,25	Sustaining income	Low trust, low engagement	Traditional training	Knowledge seeking	Weak partnerships, low digital contamination, poor product and service innovation
3	0,5	Enhancing business and negotiation skills	Initial trust, low engagement	Supporting structures and infrastructures locally	Knowledge sharing intention	Infancy of partnerships, medium digital contamination, low innovation of products and services
4	0,75	Supporting business creation and entrepreneurial innovation	Trustful relationships and initial engagement	Favouring a culture of openness and accessibility of information	Intention to encourage knowledge sharing	Strong partnerships, initial digital contamination, initial innovation of products and services
5	0,95	Strengthening of governance and creation of organizational structures to favour cooperation	Trustful and long term relationships and effective engagement	Training tailored on local needs	Knowledge sharing behaviours	Strong partnerships, high digital contamination, full products and services innovation

Table 3. Initial values and fuzzy set calibration – outcome

<b>Original Likert values</b>	<b>Calibration</b>	<b>Outcome: local autonomy for TSI</b>
low	0,05	Local autonomy is in its discussion and initial phase
medium	0,5	Medium local autonomy with business orientation
high	0,95	High local autonomy for transformative SI for social, environmental and economic impacts

## 6 Data analysis and results

First, we analyzed all collected data through ATLAS.ti, a software for qualitative analysis, data management, and coding. By following the principles of thematic analysis, ATLAS.ti supported our investigation in confirming the enabling characteristics, highlighting the emergence and frequency of keywords that identify the characteristics in all the degrees of implementation per each considered SI initiative, and confirming if the outcome of each project was high, medium, or low. We conducted axial coding (Eisenhardt, 1989; Strauss and Corbin, 1998) and double-checked the keywords that emerged from our theoretical understanding. Keywords emerged from the analysis of the lexicon adopted in primary and secondary sources. According to the grounded theory approach, we personally ranked the degree of implementation or development of each characteristic based on a previously agreed keyword building system for qualitative evaluation, corresponding to the literature background.

One example of keywords building and coding is when respondents described the SI project against stakeholder empowerment as: *"In this initiative we act as a sort of business incubator, supporting the creation of the organizational structure for farmers' cooperative and we design training courses to farmers around the mechanism of governance, in order to support their greater autonomy"* (Project Manager at NGO 3), which we coded as "strengthening of governance and creation of organizational structures to favor cooperation" (fuzzy calibrated 0.95), therefore illustrated as "high SE".

This phase ended with a collaborative discussion among the researchers for agreeing on the evaluation of each enabling characteristic per each SI project as well as on the evaluation of the outcome (high, medium, low) of each project (See appendix 1 for the data set already fuzzy calibrated). It resulted that 6 projects out of 18 reached a high outcome, 9 out of 18 reached a medium outcome, 3 out of 18 reached a low outcome.

Second, we performed the fsQCA through the software fsqca 3.0 based on the theoretical background of Drass and Ragin (1992), by employing a combination of intermediate and complex solutions (in our case they coincided) including all counterfactuals related to core and complementary characteristics (Greckhamer, 2015).

We set a consistency threshold of 0.90 for necessary and sufficient conditions to ensure high model reliability and robustness and, according to Schneider and

Wagemann (2010), we conducted the analysis separately. We found 4 initial variables to be individually necessary and sufficient for reaching the set outcome (local autonomy for transformative SI), as reported in table 4 below: SE; CSP; KT; LKE.

Our analysis suggests that necessary conditions greatly affect the outcome, as the absence of one of these characteristics will prevent SI initiatives from having a high outcome, reaching, in our case, the absence of local autonomy for transformative SI.

Table 4: Analysis of necessary conditions

Analysis of Necessary Conditions		
Outcome variable: Out		
Conditions tested:		
	Consistency	Coverage
SE	0.956522	0.736059
~SE	0.309179	0.703297
CSP	0.963285	0.710114
~CSP	0.252174	0.659091
KT	0.944928	0.638381
~KT	0.197101	0.761194
LKE	0.963285	0.805982
~LKE	0.389372	0.715808
EDT	0.761353	0.975248
~EDT	0.620290	0.647177

As for the remaining characteristic, we obtained a 'Truth Table Algorithm' to highlight configurations of conditions that were subsets of the outcome from those that were not. This evaluation was made using the measure of set-theoretic consistency reported in the consistency row and we selected only the potential configurations falling under the consistency 1.

The final exploration consisted of the Truth Table analysis on the remaining characteristic that was not necessary (EDT), which combined with the other 4 necessary conditions covers 76% of the sample in reaching a high value of the outcome. Using standard analysis to derive intermediate and complex solutions (Ragin, 2009), we observed whether the condition of each initial characteristic contributed to the outcome when the characteristic was either present or absent. As stated, we only selected the configurations with a raw consistency greater than 0.9 to improve our model's robustness (Ragin, 2009).

We, therefore, obtained a final complex solution that included the configuration of the necessary conditions with EDT, as per the following:

$$SE * CSP * KT * LKE * EDT \leq \text{High Out}$$

Table 5: Complex solution

Model: Out = f(EDT) Algorithm: Quine-McCluskey  --- COMPLEX SOLUTION --- frequency cutoff: 4 consistency cutoff: 0.975248			
	raw coverage	unique coverage	consistency
EDT	0.761353	0.761353	0.975248
solution coverage: 0.761353			
solution consistency: 0.975248			

In this solution, we can observe that high stakeholder empowerment combined simultaneously with high cooperative strategic posture, high knowledge transfer and high local knowledge development is a necessary and sufficient configuration for reaching the outcome. If one of the characteristics is missing, there is no outcome. EDT is not a necessary condition, only sufficient, but combined with the other 4 covers 76% of the sample. Having EDT is not necessary for creating a high outcome.

### 7 Discussion

Our results show that four out of five characteristics identified through the literature of ST and KM applied to SI need to be necessarily present and interlinked in the ecosystem in order to make it a facilitator of transformative SI by creating local farmers’ autonomy. Those are: high stakeholder empowerment; high cooperative strategic posture; high knowledge transfer; high local knowledge exchange.

This result suggests that ST and KM constructs are intertwined in a virtuous process that begins with stakeholder empowerment to enhance local knowledge exchange and, in this way, creates the conditions for further empowerment and mutual learning interactions within the groups of local stakeholders and more powerful ones, confirming what KM scholars posit (Wood and Bischoff, 2019; Jali

et al., 2017; Avelino et al., 2015; MacCallum et al., 2009; Peloza and Falkenberg, 2009; Usoro et al., 2007). We confirmed that in a context of lower-power and vulnerable stakeholders, the presence of an empowering culture favours, even more than within an organization, a knowledge enhancement culture and motivation in a virtuous circle (Caniëls et al., 2017). This highlights that for an ecosystem to develop and be a facilitator for social change, it needs to rely upon diverse intangible factors for reconfiguring relationships (Bridoux and Stoelhorst, 2016; Civera et al., 2019; Freeman et al., 2010; Lazovic, 2012). We confirm that "cross-fertilization" between different experiences and categories of stakeholders create new skills and make the existing ones evolve, increasing the chances to spread SI in the ecosystem (Dahiyat, 2021).

Our results strengthened the interrelationship between Stakeholder Theory (ST) and Knowledge Management (KM), in explaining and interpreting the transformations happening in a SI ecosystem, in terms of both relational drivers for redesigning relationships (Mirvis et al., 2016; Mirvis et al., 2012; Cajaiba-Santana, 2014; Greenwood and Van Buren III, 2010; Howaldt and Schwarz, 2010) and outlines that those relationships are key for transferring and exchanging knowledge that can help solving problems, developing new ideas, or implementing new practices or policies (Cummings, 2004).

Our final complex solution points out that, for being a facilitator of transformative SI and creating local autonomy, an ecosystem of stakeholders carrying out initiatives of SI needs to combine the 4 necessary characteristics with engagement to digital transformation (EDT), demonstrating a successful outcome with this combination in 76% of our cases. Such a complex solution suggests that all the characteristics identified in the literature need to be enacted simultaneously and together in an interlinked evolutionary path toward transformative SI.

Most of our projects show an advanced stakeholder empowerment strategy, with initiatives to support business creation and entrepreneurial innovation, strengthen governance, and create organizational structures to favor cooperation. For instance, the "Sustainable coffee production" initiative in India entails supporting local stakeholders for developing and strengthening the MAS company - an organization for technical and commercial services to its producing members. This strategic choice within the SI initiative reflects the will of MNEs, NGOs, and institutions to increase local stakeholders' independent decision

making and influence over their decisions and participation (Civera et al., 2019; Dawkins, 2014; 2015).

In an interdependent and virtuous circle, high stakeholder empowerment becomes the antecedent for collaborative engagement within SI initiatives (Desai, 2018; Montiel et al., 2012; Moulaert et al., 2007; Nicholls and Ziegler, 2015; Shams, 2016). Indeed, the CSP characteristic was evaluated high in 15 projects out of 18, meaning that empowerment was key for facilitating the spread of trustful relationships both in the community and among all powerful and powerless actors of the ecosystem, as reported by the literature (Greenwood and Van Buren III, 2010; Phillips, 1997). Our respondents pointed out that their positive involvement in the projects through on site visits and constant dialogue with local stakeholders was fundamental to create local stakeholder engagement, a sense of affiliation (confirming Freeman et al., 2010; Greenwood, 2007) and the culture to absorb knowledge and replicate it locally (Cabrera et al., 2006; Caniëls et al., 2017; Wang and Noe, 2010).

Therefore, most of our SI initiatives were evaluated with a high knowledge transfer capacity, meaning that the more powerful stakeholder groups were engaged in passing knowledge to local stakeholders by favoring a culture of openness and accessibility of information and tailoring local training needs (Dahiyat, 2021). For instance, our respondents highlighted that within the sustainable coffee production SI initiatives in Tanzania, 30 farmers' field schools were set up with a dual intent. First, to provide ad-hoc technical training on the local environmental and sustainable issues to maintain and increase the coffee quality. Second, to advise on how to set up financial saving programs alternative to loans, given the local financial threat relating to farmers' massive use of loans.

The high effective knowledge transfer appeared to have facilitated a high local knowledge exchange, as emerged by the literature (Wang and Neo (2010), by spreading key tailored knowledge and making local stakeholders more empowered and inclined to collaborate for seeking new knowledge and sharing it. This process increased the chances for developing new ideas and implementing new projects (Cummings, 2004).

Thanks to the "Training the Trainers" program within the SI initiative in Haiti and the Dominican Republic, whose aim was to train farmers on becoming trainers themselves, some groups of farmers started autonomously local training to other farmers to improve the adaptation of their production to climate change.

Our findings show that EDT is the least impacting characteristic on the outcome. One explanation could be that in the analyzed SI initiatives, farmers have just recently developed the virtuous circle proposed by ST and KM, and now they are seeking to increase its impact through digitalization, which is very complex to achieve (Meijer and Bolívar, 2016). Eventually, although EDT is a non-necessary but sufficient condition within our complex solution, its inclusion in the configuration can boost active participation and multi-stakeholder inclusion in social change (Kar et al., 2019; Bock, 2016; Townsend et al., 2015).

Both Colombian SI projects, which fall under the successful pathway of facilitating ecosystems for transformative SI, see coffee-growers proactively taking part in collective local social and economic initiatives to strengthen the area's coffee sector and participate in educational processes and technical advisory. Local farmers have autonomously created working groups intending to strengthen and share educational processes, thanks to a higher level of ICT adoption and the possibility to access training remotely. Furthermore, these groups have formed local citizens' online communities to attract younger generations to the plantations to include them in technical and social processes to improve crop cultivation.

## **8 Conclusion, social and practical implications, limitations**

In this study, we demonstrated that a specific combination of characteristics drawn from ST and KM literature can make an ecosystem capable of facilitating the rise of transformative SI in developing and emerging contexts. In outlining the successful pathway for enabling ecosystems, we discovered that high stakeholder empowerment, high cooperative strategic posture, high knowledge transfer, high local knowledge exchange are necessary conditions within the ecosystem for obtaining a transformative outcome of SI, such as local autonomy of farmers that will allow them to take independent actions locally and increase the impact of SI. We demonstrated that such necessary conditions are interlinked and happen simultaneously in a virtuous circle and that if any one of them is missing in the ecosystem, the SI initiative will not have chances to reach the expected outcome (local autonomy for transformative SI).

From a theoretical standpoint, we proved that a multidisciplinary and interactive perspective best fits the studies on SI in complex ecosystems (Scott et al. 2017; Woodside, 2012; Mitleton-Kelly 2006) and could represent an effective

response to an open issue in Social Innovation research, that is the absence of theoretical and empirical studies investigating what makes an ecosystem enabler of SI in a transformative way (Terstriep et al., 2020).

In filling such a gap, our study also brings some novelty to the SI literature through the adoption of a configurational methodology by suggesting a combination of characteristics that can turn a firm-centric view based on stakeholder dependence into an egalitarian perspective of lower-power stakeholders' interdependence and collaboration, confirming fresh perspectives on stakeholder thinking (Bridoux and Stoelhorst, 2016; Civera and Freeman, 2019; Dawkins, 2014; 2015; Freeman et al., 2010; Greenwood and Van Buren III, 2010; Jamali and Mirshak, 2007; McVea and Freeman 2005; Strand and Freeman, 2015).

In terms of social implications, by examining the combination of characteristics within an enabling ecosystem for SI, we advanced some arguments around the issue of stakeholder power within SI initiatives in developing and emerging countries, which is identified by the literature as a factor limiting the SI effectiveness locally (Sept, 2020; Lannon & Walsh, 2019; Nicholls and Ziegler, 2015; Moulaert et al., 2007). We demonstrated that enhancing the autonomy of lower-power stakeholders can be a way to initiate the process toward that change of mindset to adopt a new perspective of social transformation, which might, eventually, include the engagement to digital transformation as a social factor to boost the outcomes of transformative SI, only when and if the virtuous process (combination of the necessary characteristics) is activated.

Therefore, from a practical standpoint, we suggest to social innovation practitioners (MNEs, NGOs, local and global institutions) to draw a process based on the following:

- Local farmers' empowerment through the creation and strengthening of organizational structures and governance;
- Establishment of constant two-way communication among all actors involved and strengthening of their local presence;
- Co-designing of training activities for farmers that is tailored on local needs and favor replication;
- Supervision of the behaviors enacted by farmers locally to share the knowledge acquired to keep track of the outcomes;
- Establishing partnerships with local service providers to enhance the digital contamination of knowledge and providing online training

activities to foster new habits of knowledge seeking and sharing, where possible.

Eventually, our study suffers from the limitation of analyzing the issue from the perspective of powerful stakeholders who were the catalysts of the examined SI initiatives. Therefore, avenues for further research open as for the investigation of the topic by involving the targets of such SI initiatives through field research in developing and emerging countries directly with local stakeholders.

### **Abstract**

This paper aims to investigate the relationship of stakeholder with the value flow of business model for sustainability. Specifically, it links the topic of stakeholder theory to the value flow perspective of a business model for sustainability, namely: value intention, value proposition, value creation, value delivery, and value capture.

The research methodology is a multiple case study in three Italian B-corporations, where we analyse the stakeholder groups engaged by the company and how they relation with, interact or intervene in the value flow of business models for sustainability.

Main findings are the following. The value intention of the entrepreneur is influenced by society and the environment. The stakeholder that influences value proposition are the employees that suggest innovations and the government by changing regulations. A sustainable value creation is a multi-stakeholder issue, whose aim is to stimulate the balanced exploitation of natural resources at the local level and to limit the social and environmental impacts. Other organizations as the members of the associations or networks to which the company belongs influence the promotional activities of the product or service that increase consumer awareness towards the company's commitment to sustainable development. Companies are committed to having a positive impact on society and the natural environment, so that they as stakeholders could partially capture the value deriving from the business activity.

The research aims at contributing to the knowledge on business models for sustainability by looking for relationships with stakeholders that could be replied by other companies.

The paper contribution is a stakeholder value flow framework of business models for sustainability that categorizes the stakeholders in the specific value flow step. The framework can facilitate a systematic and deeper analysis of stakeholder influences. Moreover, the stakeholder value flow framework can be used to map from the company point of view the most significant relationship and to help companies to inspire and facilitate the stakeholder engagement for business models for sustainability in the future.

## 1 Introduction

The growing environmental problems, due to the increase in temperature, population and the consequent consumption of resources, led the United Nations in 2018 to issue a plan that represents a call to action and aims to achieve 17 Sustainable Development Goals (United Nations, 2018). Sustainable development requires the integration of environmental and social issues into the decisions that determine economic and social development, both by the public and private sectors (WCED, 1987). Companies have a great power on the economy and life in general and therefore, sustainable development is not possible without sustainable business development (Schaltegger et al., 2012). However, current economic system is linked to a concept of growth, which is reinforcing the depletion and scarcity of resources.

Since sustainable development requires moving towards a sustainable economy, involving entire systems is necessary to implement a significant change in the scope of the business (Bocken et al., 2014; Boons et al., 2013). Indeed, according to Stubbs (2019), sustainability is increasingly becoming a changing behaviour, and less a technical challenge, because the types of approaches to sustainable innovation are shifting from internally oriented, incremental and focused on efficiency to more radical and systemic (Adams et al., 2016). Generally, business model research is focused on the relationship between the company and its customers and do not take into account that all organizations depend on exchanges with other systems to survive (Scott, 1998). The interactions of companies with their external environment, including stakeholders, represent a fundamental topic for the discussion on business models and especially business models for sustainability (Velter et al., 2020). Companies have to consider not only

the interests of customers, but must adopt a multi-stakeholder perspective at system level (e.g., Evans et al., 2017; Lüdeke-Freund et al., 2016; Schaltegger et al., 2016) to create economic, social and ecological value. In fact, sustainability problems can be solved by reinforcing the participation with competences and resources by different people and organizations and therefore necessitates multi-stakeholder collaboration (Hörisch et al., 2014).

This is even more true if we consider the value flow perspective of a business model. While business model research is focused on the creation of value for customers in exchange for economic value for the business, a sustainable perspective requires a different perspective as the traditional “view of value creation results in a separation of stakeholders into those who receive value and those who contribute to creating it” (Freudenreich et al., 2020; p. 3). Therefore, this paper takes in consideration all the stakeholders that are placed in the value flow with their multi-directional influences.

While current research focuses only on value creation, this paper takes in consideration the perspective of the entire value flow, consisting of: value intention, value proposition, value creation, value delivery, and value capture (Barth et al., 2017; Bocken et al., 2014; Short et al., 2014).

The stakeholder theory sees organizations at the centre of a network of stakeholders that can influence or be influenced by the organization's objectives (Freeman, 2010). For this reason, the stakeholder theory gives a multidirectional connotation to the value flow of a business model for sustainability (i.e., value intention, value proposition, value creation, value delivery and value capture) and its stakeholders (Freudenreich et al., 2020). Thus, this work combines the whole value flow perspective and the stakeholder theory, to address the following research questions: 1) Which stakeholders relate to the business model for sustainability? 2) How do stakeholders relate to the value flow of the business model for sustainability?

This paper provides a stakeholder value flow framework derived from key characteristics of both business model and stakeholder theory. The framework depicts the relationships between the stakeholders and the value flow of business model for sustainability. As a first step towards closing the research gap, this paper examines the whole value flow from a stakeholder theory perspective. Stakeholder theory proposes that value creation is a collaborative effort in relationships, ideally benefitting the focal business and all its stakeholders (Freeman, 2010). This corresponds to the idea of multi-directional relationships

and supports an in-depth analysis of what types of value a stakeholder relationship creates with whom and for whom.

This paper is structured as follows. First, there is an explanation of the main concepts coming from previous literature. Secondly, the methodology is exposed. Then, the results and the contributions follow.

## **2 Theoretical background**

### ***2.1 Stakeholder theory to solve business and sustainability issue***

The term stakeholder first appeared in 1963 in opposition to the notion that shareholders are the only group that management must refer to (Parmar et al., 2010). A stakeholder can be defined as "any group or individual that can influence or be influenced by the achievement of the organization's goals" (Freeman, 1984; p. 46), while for Dunham et al. (2006; p. 25), it represents "a group that the company needs to exist, particularly customers, suppliers, employees, shareholders, and communities."

In a context characterized by high levels of uncertainty and change (as organizations are), stakeholder theory arose to address three business-related and interrelated problems. Specifically, it seeks to understand: 1) how value is created and exchanged, 2) what are the connections between capitalism and ethics, 3) and how managers should think about management to better create value and explicitly link business and ethics.

To effectively address these issues, stakeholder theory proposes to adopt as a unit of analysis the relationships (unilateral, bilateral, or even multiparty) between a firm and its stakeholders (Parmar et al., 2010). From this perspective, it is possible to manage and shape these relationships to create as much value as possible to distribute to stakeholders (Freeman, 1984) and to rethink problems so that the needs of a broad group of stakeholders are addressed (Harrison, et al., 2010).

Additionally, from a moral perspective (Post et al., 2002; Sisodia et al., 2007) effectively managing stakeholder relationships helps businesses survive and prosper in capitalist systems by assessing potential damages and benefits to broad groups and individuals (Phillips, 2003).

Similarities with sustainability emerge from these early concepts related to stakeholder theory, regarding for example: the purpose of business that must go

beyond maximizing short-term shareholder value; the interconnection and conflict between ethical and business issues; and the consideration of a long-term perspective that allows for the creation of stakeholder value now, without compromising the ability to create value in the long term (Hörisch et al., 2014).

Thus, corporate sustainability (understood as a vision) and sustainability management (understood as a general approach to corporate sustainability) challenge companies to engage with stakeholders on a multitude of contemporary social and ecological issues (Hörisch et al., 2014).

The United Nations Sustainable Development Goals (SDGs) include multi-stakeholder partnerships as one of the key goals (United Nation, 2018).

Stakeholder relation has thus been recognized in academia, practice, and policy as a key factor in advancing organizational sustainability (Bäckstrand, 2006; Cazeri et al., 2018; Onkila, 2011). Therefore, several scholars emphasize the need to move from the bare stakeholder management to interacting with a broad range of stakeholders to embed sustainability within organizational practices (Le Roux and Pretorius, 2016; Rhodes et al., 2014; Sloan, 2009).

This because the literature argues that stakeholder relations and interaction with organizations allow for the sharing of resources and knowledge to solve complex environmental and social problems (Fadeeva, 2005; Gray and Purdy, 2018). In addition to a technical exchange that is focused on a specific project and does not affect other units, Vildåsen and Havenvid (2018) identified two other stakeholder interactions for corporate sustainability: cooperation, in which the organization and the stakeholder engage in working together and develop mutual long-term goals; and networking, in which an organization systematically interacts with more than two stakeholders together in joint initiatives (Vildåsen and Havenvid, 2018). The latter stage of interaction has the highest potential for improving sustainability performance (Vildåsen and Havenvid, 2018).

However, stakeholder interaction such as cooperation and collaboration, can go beyond the practice of sustainability to become the foundation of the organization-stakeholder relationship in which organizations integrate intra- or inter-organizational activities (Fobbe and Hilletofth, 2021). Furthermore, the importance of stakeholders to interact with is dynamic and could change depending on the approach to solving sustainability problems (Hall and Wagner, 2012; Mitchell et al., 1997).

The tool that allows organizations to keep track (even if partially) of these stakeholder relationships for sustainability and beyond, is the business model.

Actually, some scholars such as Breuer and Lüdeke-Freund, (2017), Freudenreich et al., (2020), Kujala and Korhonen, (2017) have proposed not only to consider stakeholder interaction as part of sustainability practices, but to implement stakeholder interaction as part of business models.

While stakeholders are recognized as a central element in these sustainability-oriented business models (Bocken et al., 2013; Freudenreich et al., 2020; Stubbs and Cocklin, 2008), the role and function of stakeholders remain vague (Fobbe and Hilletoft, 2020).

## **2.2 Integrating stakeholder theory into sustainable business model**

Traditionally, the business model has been viewed as a tool available to companies useful to describe the logic by which an organization creates, delivers, and captures value (Osterwalder and Pigneur, 2010). The firm - centric view of the business model has since been overcome by Zott and Amit (2011), who view it "as a system of interdependent activities that transcends the focal firm and extends beyond its boundaries. The system of activities allows the firm, in concert with its partners, to create value and also to appropriate a share of that value (Zott and Amit, 2011; p. 216). The same authors call this concept the "networked nature of value creation," claiming that "value creation through business models involves a more complex and interconnected set of relationships and activities among multiple actors" (Zott and Amit, 2011; p.1031). These concepts broaden in the case of business models for sustainability.

One of the definitions of a business model for sustainability sees it as a simplified representation of the elements, the interrelationship between these elements, and the interactions with its stakeholders that an organizational unit uses to create, deliver, capture, and exchange sustainable value for, and in collaboration with, a wide range of stakeholders (Geissdoerfer et al., 2016).

Thus, while for the traditional business model the creation of value occurs together with all stakeholders, in business model for sustainability the concept of completes by adding the exchange of value between the company and its stakeholders. Furthermore, the notion of business model for sustainability "builds on the business model concept and combines it with the important concepts of stakeholder management (Donaldson and Preston, 1995; Freeman, 1984; Post et al., 2002), sustainable value creation (Short et al., 2012), a long-term perspective" (Geissdoerfer et al., 2016; p.2).

Since stakeholder theory is linked to the concept of sustainability (Hörisch et al., 2014), it can be applied to business models for sustainability and can add several points to the discussion, as indicated by Freudenreich et al. (2020). First, it is recognized that company relationships are the basis of value creation. Therefore, it is impossible to make a business model work without solid relationships with stakeholders. Secondly, the creation of value through the business model takes on a multi-directional and multi-actor connotation around a common purpose oriented towards sustainability.

Therefore, value is no longer a one-way flow between the company and its customers, but it is created by joint actions and formal and informal alliances with stakeholders who are both recipients and creators of value (Beattie and Smith, 2013; Freudenreich et al., 2020). Several authors have depicted the value flow in business models by considering value proposition, value creation and delivery, and value capture (Bocken et al., 2014; Short et al., 2014). To these Barth et. al (2017) added value intention.

### **3 Research design**

To address the research question, a systematic review of the literature on business models for sustainability was conducted. The literature was furtherly investigated by considering the two main aspects of this discussion: stakeholders and value flow. Specifically, within the literature on business models for sustainability, it is considered: the stakeholder groups that create or (co-create) the value, the value exchanged, and the stakeholders that receive the value. From this analysis, we derived and classified the stakeholders associated with a business model for sustainability. We derived and adapted a framework from the literature, that we explained below.

In the rows the internal stakeholders (i.e., entrepreneur, leader/manager, employees) and external stakeholders (i.e., customers, shareholders, government, society, other organizations/competitors, influence groups, universities/research institutes, natural environment) are reported.

In the columns the value flow of a business model for sustainability is reported, namely:

1. Value intention. As described by Barth et al. (2017), the value intention is the attitude of the owner-manager to change, innovate towards sustainability, and create sustainable value.

2. Value proposition. As value proposition is meant the sustainable value proposition as defined by Patala et al. (2016; p. 144), namely: "the promise on the economic, environmental and social benefits that a firm's offering delivers to customers and society at large, considering both short-term profits and long-term sustainability".
3. Value creation. Value creation "begins to flesh out the organisation and architecture of the firm. It also specifies and describes the firm's sources of competitive advantage, i.e., its resources and capabilities" (Richardson, 2008; p. 139).
4. Value delivery. It represents how the value is delivered to different stakeholders. It is the "logical next step and is most closely related with the customer. It is focused on customer relationships, customer segments and channels" (Bocken et al., 2018; p. 84).
5. Value capture. It includes different forms of value captured by different key stakeholders (Short et al., 2014).

The cells of the framework, which connect rows (stakeholder groups) and columns (value intention, value proposition, value creation, value delivery, and value capture) represent stakeholder influences on the value flow of the business model for sustainability. In the cell we described how stakeholders are connected with a specific step in the value flow.

To further explore these relationships, the explorative case study is used as research methodology. We chose three case studies to highlight aspects not yet investigated by literature. To guarantee that selected organizations are developing or implementing a business model for sustainability, we chose B Corps as case studies (Yin, 2013). Moreover, we considered other factors in selecting the companies, for instance dimension to guarantee cases will be comparable. The selected cases belong to different sectors: A to the logistics industry, B to the retail industry and C to the natural cosmetics industry. We conducted semi-structured interviews with three B Corps. Moreover, we collected information through secondary data, to guaranteed triangulation (Eisenhardt, 1989).

## 4 Results

In the following section the case studies are described by adopting a value flow perspective as summarised in Table 1.

#### ***4.1 Value flow perspective in Case A***

In Case A, the value intention is dictated by the entrepreneur who wants to pursue common benefit purposes, by proposing as customer value a tailor-made service through a sustainable and inclusive logistics in the territory. Therefore, the value creation is based on new technologies and advanced biofuels (e.g., LNG, bioLNG and H<sub>2</sub>) that reduce vehicle emissions. The value created by the company is then delivered to the customer through partnerships. In addition, Case A distributes value through industry-related trade shows or events related to B-corporations. The value flow proposed, generated and delivered is then captured not only by the company, but also by other stakeholders. For example, employees benefit from a higher insurance policy than the minimum threshold, an extra budget from the welfare project, sustainability-related training, and family engagement initiatives. The drivers that are considered as partners of the company, benefit from less pollution during the transport, greater involvement of their families, and greater safety during work hours, because the company is committed to enforcing work hours and road rules. The society, as a stakeholder, benefits from economic sponsorships in favour of local teams and defibrillators available at each company location. The main benefit for the natural environment derives directly from the creation of value and is the reduction in emissions due to the use of alternative fuels.

##### ***4.1.2 Role and function of stakeholders in Case A business model***

Various stakeholders are involved in the value flow of the business model of Case A. Employees, thanks to the awareness of the benefits obtained, take part in the value proposition by suggesting sustainability innovations through a portal made available by the company. The affiliated drivers, have an active role in the value delivery because they become promoters of the project by participating in various interviews and encouraging colleagues to adopt a more sustainable transport. Other partners are key stakeholders for the value creation: 1) the agro-livestock cooperative, which built a plant that recovers all CO<sub>2</sub> in production: the remaining methane is then purified, cooled, and used to fuel the truck. 2) a company which built the first service station in Lombardy designed for self-service natural gas refueling for heavy vehicles and open to cars as well. However, the government plays the role of a barrier to value proposition and value creation through regulatory changes.

Other stakeholder organizations are the members of the B-corporations network and participate in the value delivery by promoting events to spread the culture of sustainability.

Some groups of influence participate in the value creation. In particular, the Italian biogas consortium enables the value creation by allowing the annual production of 2000 tons of liquefied methane.

#### *4.2.1 Value flow perspective in Case B*

The value intention of Case B is dictated by the entrepreneur who wants to save wildlife and the natural environment by offering a quality product designed with entirely recyclable parts.

The value creation is possible thanks to the use of materials and components from qualified sources, with low environmental impact and respectful of social and ethical aspects. A key element in the value creation is the choice of suppliers, which are evaluated against social criteria, in addition to meeting economic and quality criteria. Value is delivered to customers through company-owned stores, e-commerce, retailers and pop-ups, or through participation in various events organized by the B-corporations' movement. Moreover, customers are reached through the main social networks. The value proposed, created and delivered is not only captured by the company, but also by other stakeholders. In particular, employees benefit from better corporate welfare; suppliers, located mainly in China, benefit from better working conditions imposed by the company policy. The society, especially disadvantaged communities and countries, benefit from donations made in collaboration with NGOs or other organizations, which include companies belonging to the B-corporation network. The natural environment benefits from reduced pollution and animal protection.

#### *4.2.2 Role and function of stakeholders in Case B business model*

Several stakeholders intervene in the value flow of the Case B business model. Suppliers participate in the value creation by selecting, manufacturing, and patenting materials that meet the highest quality and environmental standards. Customers influence the value delivery by asking for more in-depth product information, for instance usage, impacts of microfibers, and innovative features of collections. Further stakeholders of the company are the media. The media influence the value creation by discussing with the company both the sustainability trends of the sector and the measurement of environmental impacts

along the production process. Another stakeholder organization participates in the value delivery through communication activities and strategic brand consulting with a focus on corporate social responsibility strategies and economic, social and environmental sustainability. Other organizations as B corporations are stakeholders of Case C and participate in the value delivery by organizing and promoting events to spread the culture of sustainability.

#### *4.3.1 Value flow perspective in Case C*

In Case C the value intention is dictated by the entrepreneur who wants to enhance the value of his territory by proposing lines of personalized natural cosmetics that respect the environment. The value proposition is then created through the control of the entire supply chain and the use of organic cultivation. Part of the value created comes from the choice of suppliers. Actually, the company turns only to suppliers belonging to the B-corporations network or to companies that have in place a process of change towards sustainability. As regards the value delivery, customers are reached through industry events and demonstrations. In addition to the value captured by the company related to the commissioned product, the company's employees benefit from an extra bonus. The company captures a portion of value related to increased tourism related to the company-owned wellness centre. In addition, the society benefits from sponsorships related to youth entrepreneurship initiatives and donations destined for schools, also with the help of local associations. The natural environment benefits from reduced land use and low-impact cultivation.

#### *4.3.2 Role and function of stakeholders in Case C business model*

Several stakeholders are engaged in the value flow of Case C business model. Specifically, several stakeholders participate in or influence the value creation. For example, the suppliers or partners participate in the value creation by providing sustainable packaging and resources. Secondly, the customers influence the value creation by requesting and defining product characteristics. Finally, the university tests the product efficacy, a key process of the company's activities and the value creation. As regards the other organizations the influence the value flow, there are all companies that join the B corporations network. They participate in the value delivery by promoting events to spread the culture of sustainability. In the case of C, the natural environment does not only play a passive role by deriving

benefits but plays an active role in the value creation by offering quality raw materials.

Table 10 - Synthesis of results

		<b>Value Intention</b>	<b>Value Proposition</b>	<b>Value Creation</b>	<b>Value Delivery</b>	<b>Value Capture</b>
<b>Internal stakeholders</b>	Entrepreneur	Pursue common benefit purpose for society, environment and local territory				
	Employees		Suggest sustainability innovations			Benefit from corporate welfare, family engagement, sustainability-related training
<b>External stakeholders</b>	Suppliers/ partners			Adopt, manufacture, and patent sustainable materials and practices	Promote company sustainability projects	Benefit from family engagement, greater safety during work hours. less pollution
	Customers			Request and define product characteristics	Ask for in-depth information regarding the sustainability	
	Government		Change regulations	Change regulations		

	Society			Discuss both the sustainability trends of the sector and the measurement of environmental impacts along the production process		Benefit from generalized welfare (e.g., donations, sponsorships)
	Other organizations/competitors				Promote and communicate the culture of sustainability (e.g. B-corporations network)	
	Influencing groups			Enabling the production		
	Universities/research institutes			Test products		
	Natural environment			Offer quality raw material		Benefit from reduced pollution, animal protection, low-impact cultivation

## 5 Discussion and conclusions

This section discusses the results in light of the relationship of stakeholders and suggests future research directions in the field of business models for sustainability. Stakeholder engagement is rising attention of companies seeking to increase their competitiveness by moving towards a business models for

sustainability. This implies a rising importance of re-assessing their business models.

This paper looked into both stakeholder and business model theory in order to develop stakeholder value flow framework (Figure 1). The framework is then applied to three case studies belonging to different industries, which consider sustainability having a key role in their strategy. The adoption of the value flow as perspective in analysing the companies' business models led to the following results.

The value intention of the entrepreneur is key in the business model for sustainability; even if it is not a result that emerges explicitly from the case studies, it can be deduced that the value intention of the entrepreneur is influenced by society and the environment. Actually, the entrepreneur does business with the intention of having a positive impact on his main stakeholders which are society and the environment.

The value proposition is the direct consequence of the value intention that takes the form of a promise to offer value not only to the customer but to a wider group of stakeholders. The stakeholders that influence value proposition are the employees that could suggest innovations to make the product or service offered more sustainable. Moreover, the government could influence the value proposition by changing the regulations.

Value is created by a range of activities involving a number of stakeholders. A sustainable value creation is a multi-stakeholder issue, whose aim is to stimulate the balanced exploitation of natural resources at the local level and to limit the social and environmental impacts. The value creation is strongly influenced by suppliers and partners, that provide sustainable packaging and resources and are selected through sustainability criteria. Moreover, the universities or research centres can play a role in creating sustainable value as they test the sustainability characteristics of the product. In the case of production to order, customers can influence the creation of value through requests of sustainable product or service. A final stakeholder that impacts on the value creation are the media through the discussion with the company about the industry sustainability trends and the measurement of environmental impacts along the production process.

The value delivery mostly concerns the communication and dissemination activities of the company's sustainability initiatives. Therefore, other organizations as the members of the associations or networks to which the company belongs influence the promotional activities of the product or service that increase

consumer awareness towards the company's commitment to sustainable development. Moreover, the suppliers or partners have a role in the value delivery, because they promote the sustainability projects of the company. Finally, the customers ask for in-depth information regarding the sustainability of product and service.

The value capture involves other stakeholders, not only the company. The main stakeholders engaged in the value capture are the employees, benefitting from welfare projects, sustainability-related trainings, and family engagement initiatives. The society could capture value especially disadvantaged communities and countries, through donations. Companies are committed to having a positive impact on society and the natural environment, so that they as stakeholders could partially capture the value deriving from the business activity.

The research aims at contributing to the knowledge on business models for sustainability by looking for relationships with stakeholders that could be replied by other companies. The paper contribution is a stakeholder value flow framework of business models for sustainability that categorizes the stakeholders in the specific value flow step. The framework can facilitate a systematic and deeper analysis of stakeholder influences. Moreover, the stakeholder value flow framework can be used to map from the company point of view the most significant relationship and to help companies to inspire and facilitate the stakeholder engagement for business models for sustainability in the future.

Coherently with the objectives of the study, the identification of stakeholder relationships with the business model could support both researchers and enterprises in mapping the value flow. From the academic point of view, the research attempts to reduce the knowledge gap on business models for sustainability and stakeholder theory. From the managerial point of view, the research proposes a framework that could be adopted and implemented in real corporate environments.

As regards limitations of the study, this is mainly due to the explorative aim of the study. Thus, the limited set of cases could show industry-dependent features, which could not be generalized to an overall discussion on companies.

### Abstract

Cultural mapping aims to capture and visualize tangible and intangible cultural assets. This extended abstract proposes the consequent extension of analogue forms of cultural mapping using digital technologies, and its contribution is two-fold. First, the necessary theoretical basis is provided by a literature review of the still-young field of cultural mapping and the complementary disciplines of participatory mapping and digital story-mapping. Second, we propose a digitally enhanced Cultural Mapping 4.0 vision based on a case study from an ongoing research project in the Lake Constance region. Digital

participatory mapping approaches are applied to capture data, and to validate and disseminate the results, story-mapping – a spatial form of digital storytelling – is used.

**Keywords** – cultural mapping, GIS, digital regional planning, participatory mapping, story-mapping.

**Paper type** – Academic Research Paper (Extended Abstract)

## 1 Introduction

In recent decades, knowledge has been considered “a key driver of success” in the regional studies discourse (Lönnqvist & Laihonon, 2013). For complex systems such as regions, various stakeholders can act as knowledge carriers and contribute understanding to regional-cultural planning processes. In this respect, cultural mapping can be used as a tool for knowledge management to make different forms of (spatial) knowledge visible and actionable in regional development.

According to Duxbury, Garrett-Petts, and MacLennan (2015), cultural mapping is a method that uses different techniques to capture not only cultural resources but also local histories, memories, and rituals (among other things). It is used in the fields of urban planning, sustainable cultural development, and community development. The digitization boost sparked by the COVID-19 crisis offers new opportunities for capturing, collecting, analysing, and disseminating such data, most of which have a spatial dimension. Geoweb platforms such as Open Street Map make data freely available, and even non-specialists can easily publish local knowledge in the form of geotagged photos, texts, or audio files. Furthermore, mashups, i.e., the combination of data and functions, can be implemented relatively easily through application programming interfaces (APIs) on geoweb platforms.

The core proposal of this extended abstract is the extension of analogue forms of cultural mapping using data capture, visualization workflows, and techniques from geoinformatics, namely, geographical information systems and science (GIS and GISc). Supporting this proposal, the contribution of this extended abstract is two-fold: First, a thorough literature review of the still-young field of cultural mapping and the complementary disciplines of participatory mapping and digital story-mapping provides a theoretical basis. Second, a digitally enhanced “Cultural Mapping 4.0” vision is proposed, based on a case study from an ongoing research

project in the Lake Constance region, which spans the tri-border area of Germany, Switzerland, and Austria. Digitally-enhanced refers both to (a) the use of participatory mapping on the data capture side and (b) the use of digital storytelling and digital story-mapping for disseminating the results (Brown, Sanders, & Reed, 2018; Kerski, 2019).

## 2 Literature Review

The following section presents the results of a comprehensive literature review on digital approaches for participatory regional cultural planning. The literature research focused on the research areas of “cultural mapping”, “participatory mapping”, and “digital storytelling and story-mapping”. It includes research articles and project reports from relevant contributing application areas in cultural management, regional development, and geographic information science.

The table below gives an overview of the search terms used; for brevity, spelling alternatives and keyword combinations are not listed. Literature searches were prioritised for most recent research (from 2017), with selected exceptions referring to pivotal older references.

“Cultural Mapping”	“Participatory Mapping”	“Digital Storytelling and Story-Mapping”
<ul style="list-style-type: none"> <li>• Cultural mapping</li> <li>• Participatory mapping</li> </ul>	<ul style="list-style-type: none"> <li>• Participatory mapping</li> <li>• Participatory GIS (PGIS)</li> <li>• Public participatory GIS (PPGIS)</li> <li>• Volunteered geographic information (VGI)</li> </ul>	<ul style="list-style-type: none"> <li>• Story maps/GIS</li> <li>• Digital/spatial storytelling</li> <li>• Story maps/story-mapping</li> </ul>

### 2.1 Cultural mapping

In recent years, an interdisciplinary field of research has developed around cultural mapping that has attempted to visualize tangible and intangible cultural assets on maps in various contexts. Especially in the cultural sphere, which is relatively complex and ambiguous, mapping has been identified as a valuable tool to understand and compare cultural environments (Duxbury et al., 2015; e.g. Lee & Gilmore, 2012; Sacco, 2017). Early cultural mapping research in the 1960s sought to identify cultural differences, preserve cultural diversity, promote

intercultural dialogue, focusing mainly on indigenous communities (Crawhall, 2007; Poole, 2003). Mainly, analogue mapping processes have been applied in the indigenous context and have proven valuable in making community knowledge, relations, and communication visible through maps (Stewart & Allan, 2013).

Later on, UNESCO also used cultural mapping to visualize cultural differences and boundaries (Poole, 2003), and cultural mapping was soon recognized as a helpful tool for developing public policy measures adjusted to local contexts. As part of its application to become the 2018 European Capital of Culture, Malta's capital – Valetta – hosted a cultural mapping conference in 2015. This revealed different areas of application in research and showed that "mapping projects happen at all kinds of scales, on the initiative of an extremely varied range of actors, and are formalized and transmitted in a variety of different ways" (Sacco, 2017, p. 1). Several case studies in European cities demonstrated the versatility of cultural mapping, for example, as a platform for community engagement to improve understanding of the local culture and creative economy (Murray, 2017), to develop and negotiate a sense of place between city planners and residents (Savić, 2017), as a way for narrative-based ethnography to capture city identities (Huovinen et al., 2017), and by linking geography with art through visually mapping transformational cultural exchanges in migration between Africa and Europe (Khoury, 2017).

In cultural mapping, a distinction is generally made between the mapping of tangible and intangible cultural assets. Cultural mapping has proved successful in various studies (e.g. Lee & Gilmore, 2012) for mapping tangible assets through quantitative approaches, such as cultural organizations, heritage sites, or material resources. However, a qualitative research approach is needed for mapping intangible assets, such as identities, beliefs, or norms, although this is still in its infancy. Therefore, mapping intangibles has evolved in recent years as a critical dimension of current research within cultural mapping (Longley & Duxbury, 2016, p. 2). In recent studies, attempts have been made to solve the problem of portraying the immaterial in maps by using artistic approaches (Carter, 2018; Irwin, 2018; see Radović, 2016) or digital tools (see García-Díez et al., 2020; Martin et al., 2020). The main advantage of cultural mapping in this context is that these maps can be created from the perspectives of indigenous and local people in a participatory process and are, therefore, a powerful way of collecting, visualizing, and interpreting data in different cultural contexts. By making visible how "local cultural assets, stories, practices, relationships, memories, and rituals constitute

places as meaningful locations” (Duxbury et al., 2019, p. 3), cultural maps can – as a methodological tool – promote participation in planning processes, enabling innovative access to cultural perceptions and value attributions that would otherwise be difficult to contextualize and compare. Consequently, digitalization offers new opportunities for creating cultural maps through participatory mapping.

## **2.2 Participatory mapping**

Participatory mapping aims to engage the general public and stakeholders in decision- making for regional planning, typically using online and web-based surveys for data collection (Fagerholm et al., 2021). A wide variety of research fields have shown increasing interest in participatory mapping, typically referring to public participatory geographic information systems (PPGIS), participatory geographic information systems (PGIS), or – increasingly – to volunteered geographic information (VGI) (Brown et al., 2020; Fagerholm et al., 2021). For an in-depth academic discussion about the nuanced differences between these concepts and their theoretical underpinnings, we recommend the review articles by Brown & Kyttä (2014) and Fagerholm et al. (2021).

For a speedy approach to these concepts for applications in cultural-regional planning, each term is presented here with an illustrative example. PPGIS aims to use GIS, the web and communication technologies to enhance public involvement in planning and decision-making in regional development (Fagerholm et al., 2021; Sieber, 2006). For example, Nummi (2018) used map questionnaires for revealing locals’ personal place-based memories and experiences of intangible cultural heritage for regional development in Finland. While PPGIS are often situated in developed countries, PGIS carries a distinct empowerment notion and is usually located in developing countries, where mapping is often educational, and the resulting spatial data are secondary (Brown & Kyttä, 2014). For example, Fagerholm et al. (2019) combined semi-structured interviews with participatory mapping to study spatial patterns of cultural landscape services in rural Tanzania. Finally, in 2017, Michael Goodchild coined the term volunteered geographic information (VGI), reflecting the growing number of applications using the internet to collect and disseminate geographic information using “citizens as sensors” (Goodchild, 2007). Well-known examples of this idea include

OpenStreetMap<sup>1</sup> and FixMyStreet<sup>2</sup>, while Gonzalez-Ramiro et al. (2016) collected substantial variables for their spatial multi criteria evaluation (MCE) to assess the potential of rural tourism in Extremadura, Spain.

To conclude, participatory mapping concepts are strongly related to “sense of place” values and closely associated with the cultural ecosystem services (CES) sub-category within the ecosystem services framework (Brown et al., 2020). The data collection concepts applied in the proposed Lake Constance Cultural Mapping 4.0 framework below are based on PPGIS and VGI.

### ***2.3 Digital storytelling and story-mapping***

Story-mapping is a spatial form of digital storytelling combining textual, visual, and audible communication through interactive web maps (Molden, 2020). Digital storytelling can refer to various forms of developing narratives, ranging from short video sequences applied initially to community development (De Jager et al., 2017) for augmented reality applications in museum exhibitions (Rizvic et al., 2020). While the original notion of “story-mapping” proposed by Nitsche and Thomas (2003) referred to experiencing events within the developing world of 3-D virtual reality, the current notion of story maps refers to combining online content with 2-D web maps – similar to a slide presentation with embedded interactive maps (Walshe, 2016). Story maps have been enthusiastically adopted in classroom applications, offering smooth integration of complex geoinformatics topics in geography teaching (Cope et al., 2018; Walshe, 2016; Wu & Chen, 2020).

Given its elegant and accessible potential to connect the experiences of researchers and participants through digital narratives, story maps have been used in a wide range of contexts in the humanities disciplines (Kallaher & Gamble, 2017). These include the development of user-friendly interactive resources in archaeology (Alemly et al., 2017), setting up a historical geographic information system (Lafreniere et al., 2019), and community development (Lung-Amam & Dawkins, 2020). There are also a few story-mapping applications in the context of regional-cultural planning. While Cabana et al. (2020) presented and integrated an evaluation and communication strategy for cultural ecosystem services, Rizvic et al. (2020) discuss a form of story-mapping to present tangible and intangible cultural heritage. Story-mapping has also offered an excellent way to preserve

---

<sup>1</sup> <https://www.openstreetmap.org/>

<sup>2</sup> <https://www.fixmystreet.com/>

experiences and reflections during the COVID-19 pandemic through rich media storytelling and GIS mapping (Bacon & Xu, 2020).

Previous studies have identified limitations of story-mapping worth consideration. For example, by relying on proprietary software solutions such as the Esri Story Map interfaces, communicative interaction between researchers and participants can be restricted by the templates provided (Molden, 2020). The same source also asks for critical reflection about power relations and exclusion when applying story-mapping – another challenge shared with participatory mapping.

All the above examples demonstrate that story-mapping is not only the process of creating web-map-based plots, but it crucially also refers to the process and method of narrative-building relating “to the construction and representation of spatial knowledge between researcher and participant” (Molden, 2020, p. 133), hence underpinning its power to engage with participants. These shared goals with participatory mapping lay the groundwork for Cultural Mapping 4.0, combining the concepts of story-mapping with participatory mapping.

### **3 Study Area and Methodological Approach**

#### ***3.1 The Lake Constance case study***

As one of the oldest European cultural landscapes and located on a tri-national border in the heart of Europe, the Lake Constance region is characterized by its spatial structural diversity. It has both intensely rural areas popular with tourists as well as dynamic, urban centres that belong to the most economically competitive regions of their respective nation-states (Scherer, 2016, p. 3). In addition to their shared history and language, the countries bordering Lake Constance are united by a cultural and economic area that is becoming ever more closely intertwined due to the increasing mobility of their populations. Through this Lake Constance case study, the authors examine the interaction between regional identity, culture, and mobility from a spatial perspective. Residents, tourists, and regional businesses will be asked about their spatial perceptions of the interplay between cultural identity and mobility through participatory mappings. Our focus is on four core topics – cultural resources, civil society and integration, business and labour, and tourism and mobility.

### 3.2 Methodological proposal

In this case study, economic and social science methods are combined with new participatory data capture procedures, geoinformatics, and geo-visualization approaches. Cultural mapping is perceived and used as a method and an outcome simultaneously. Specifically, the methodological proposal presented here extends Duxbury's concept of cultural mapping (2015, 2019) with (a) participatory mapping to capture the local sense of place regarding cultural assets and (b) the use of story-mapping for the dissemination of insights and results (see Figure 1).

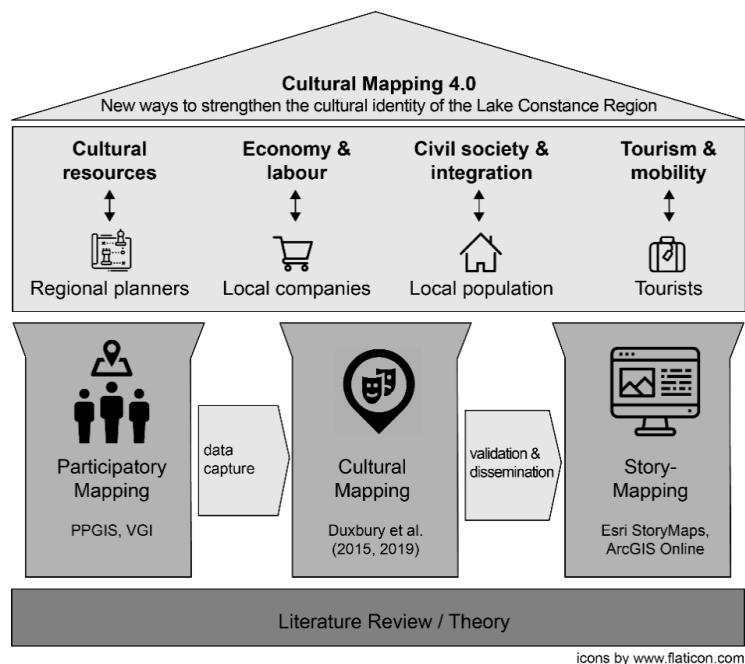

Figure 1. Cultural Mapping 4.0 for the Lake Constance Region

Following a successful pilot study in 2020, summer 2021 will see an extended semi-structured survey combined with web-mapping questionnaires targeting the stakeholder groups and related topics shown in Figure 1 above. While the local population and tourists will be targeted through on-site surveys at popular locations around Lake Constance and by a web survey related to the topics of civil society and integration, tourism and mobility, regional planners and the

commercial sector will be addressed through stakeholder workshops, combining surveys with guided mapping questionnaires. For dissemination and validation purposes, all the results will be summarized into customized story maps.

A cultural mapping study relying largely on field studies conducted by the shores of Lake Constance in the summers of 2020 and 2021 will inevitably be affected by COVID-19 restrictions such as evening curfews, closed restaurants, or travel bans. Our study has reacted to these challenges by further exploiting the potential of digital communication and offering flexible online ways to record stakeholders' cultural sense of place. Where necessary, the survey and participatory mapping questionnaires were swiftly moved from hand-held tablets to web-based questionnaires distributed through social media and targeted dissemination. On reflection, this might be viewed as an excellent example of the added flexibility arising from the digitization of conventional social-science workflows.

#### **4 Concluding Remarks**

This extended abstract focuses on a literature review and a brief overview of the methodological approach regarding participatory regional-cultural planning at the tri-border region around Lake Constance. It explains related concepts such as "cultural mapping", "participatory mapping and participatory GIS", and "digital storytelling" while drawing special attention to their value for stakeholder research. Regarding the case study in question, this stakeholder research comprises cultural resources, civil society and integration, business and labour, and tourism and mobility. The vital inclusion of different stakeholder groups helps generate a differentiated picture of the Lake Constance region depicted in the form of story maps. The data collection necessary to achieve this will be the next stage in this research project and it will deliver information on the identity and image of the Lake Constance region. Our ultimate goal is to provide a viable planning tool for decision-makers.

#### **Acknowledgements**

This extended abstract and the underlying ongoing research project "Cultural Mapping 4.0. – New ways to Strengthen the Cultural Identity of the Lake Constance Region" is supported by the International University of Lake Constance (IBH).

### **Abstract**

In recent years, the integration of sustainability principles in urban planning has become increasingly important. The growing attention to economic, social and environmental aspects is also influencing the practice and policy of urban regeneration. In particular, the search for new ways to regenerate cities in a sustainable way has led to the concept of sustainable urban regeneration. However, despite the relevance of this concept, only a few contributions have quantitatively examined the actual sustainability outcomes of different urban regeneration interventions. This study aims to fill this important gap by examining the level of sustainability of urban regeneration interventions in the Apulian context. The results of the multiple case study analysis show a high level of sustainability of the interventions in all three contexts examined. However, they show some weaknesses related mainly to the absence of strategies aimed at the inclusion of women in the labour market

and to the low efficiency in the use of energy. The results offer important implications and guidelines for municipalities implementing urban regeneration projects.

**Keywords** - Urban regeneration; Urban sustainability; Sustainable urban regeneration; Sustainability indicators; Apulia

## 1 Introduction

The dynamics of urbanisation have changed considerably over time, driven mainly by industrialisation, which has increased the concentration of socio-economic organisations in cities, thereby increasing the urban population (Korkmaz and Balaban, 2020). Today, most of the world's population lives and carries out economic activities inside cities. However, unbridled urbanisation has important consequences mainly related to economic, environmental and social aspects. According to the United Nations (2015), cities occupy only 3% of the earth's surface, but are responsible for 60-80% of energy consumption and 75% of carbon emissions. The disproportionate growth of cities could, therefore, lead to a depletion of the earth's water and food resources, the suffocation of natural ecosystems and could also have major consequences on public health, both because of the high presence of slums (with all the resulting hygiene and public order consequences) and because of the worsening climatic and atmospheric conditions (United Nations, 2015).

In view of this, cities are considered among the key players in achieving the 17 Sustainable Development Goals set out by the United Nations (2015) in the so-called 2030 Agenda. Considered as huge human collectors, economic aggregators and high-impact elements, cities will necessarily have to configure themselves as real spaces for change in economic, social and environmental terms. In this regard, among the 17 Sustainable Development Goals, Goal 11 reads 'Make cities and human settlements inclusive, safe, durable and sustainable'. Therefore, achieving this goal by 2030 should include combating inequalities, improving public transport, strengthening and implementing waste management systems. Moreover, it should include the protection of cultural and artistic heritage, the direct participation of citizens in the management of the city, the enhancement of network economies within the public space and, above all, it should prefer urban regeneration to building speculation.

In this context, the need for sustainability approaches for the definition of urban transformation practices and policies is therefore increasingly emerging (Newman and Jennings, 2008; Evans, 2012; Vojnovic, 2014; La Rosa et al., 2017). The implementation of strategies, programmes and planning strategies for sustainable cities, such as the redevelopment of degraded urban spaces or the reuse of abandoned buildings and previously disused urban land (La Rosa et al., 2017), help to increase the attractiveness of urban centres and the well-being of citizens (Couch and Dennemann, 2000; Turcu, 2012). In this regard, urban regeneration represents one of the most effective tools available to urban planners and designers to address a wide range of urban issues and to find long-term solutions to the economic, social, environmental and physical problems that plague contemporary cities (Roberts, 2000; Alpöpi and Manole, 2013). Urban regeneration represents a multidisciplinary field of research and a broad practice. It is characterised by an integrated and comprehensive vision aimed at solving urban problems and promoting the development of the urban communities concerned (Roberts, 2000; La Rosa et al., 2017). Best practice models and general principles underpinning urban regeneration are fairly well known (La Rosa et al., 2017) and emphasise that urban regeneration interventions should always be adapted to local governments' urban development models and specific geographical contexts (Kleinhans, 2012; La Rosa et al., 2017; Korkmaz and Balaban, 2020). In particular, sustainable urban regeneration interventions (Evans, 2012) should have effects not only at the neighbourhood level but at the city scale (La Rosa et al., 2017) and should address issues such as: the redevelopment of public spaces and the enhancement of public services (Privitera et al., 2013), upgrading urban infrastructure (Huston et al., 2015), improving living conditions in residential neighbourhoods (Alpöpi and Manole, 2013), increasing earthquake response and energy performance (Deakin et al., 2012; Güzey, 2016) and improving the working conditions of inhabitants (Korkmaz and Balaban, 2020).

However, despite the relevance of urban regeneration interventions in the development and design of sustainable cities and in achieving SDG 11, only a few contributions have quantitatively examined the actual sustainability outcomes of different urban regeneration interventions (Villagra et al., 2014; Zheng et al., 2014; Laprise et al., 2015; La Rosa et al., 2017; Korkmaz and Balaban, 2020). This study aims to fill this important gap by examining the level of sustainability of urban regeneration interventions in the Apulian context (an important Italian tourist

territory). In particular, therefore, this study answers the following research question:

RQ1: What is the level of sustainability of urban regeneration interventions in the Apulian context?

In order to answer these questions, this study examines the urban regeneration interventions implemented in the northern Salento area. This area was chosen mainly because of its great relevance from the point of view of tourism.

The reminder of this work is organized as follows: Section 2 introduces the background of this study; Section 3 presents the research methodology. Section 4 offers the results, while Section 5 draws conclusions.

## **2 Background**

### ***2.1 Evolution of sustainable urban regeneration***

Because urban systems are assumed to be affecting physical and social and economic transformations, they are particularly dynamic and complex. It follows that urban regeneration, as a tool used in urban policy following the eighties, cannot merely imply a city's physical development as it refers to all crucial and significant urban development's aspects.

Literature on planning has provided a host of urban regeneration's definitions. Amongst those, there is one that comprehensively explains urban regeneration as an across-cutting vision aimed at finding solutions to urban problems by delivering strategic and long lasting physical, social, environmental and economic opportunities and improvements to area subjected to change and transformations (Lichfield, 1992).

Another definition asserted by Roberts (2000) depicts urban regeneration as an emerging integrated action oriented toward the search of long-term solutions to physical, social, economic and environmental issues through the engagement of stakeholders who co-operate between them.

By the same token, there is the argument put forward by Donnison (1993) that considers regeneration as a method as well as a way that solve simultaneously the environmental, physical, social and economic problems occurring in areas subject to collapse.

It is possible to discern a common denominator to all three definitions: urban regeneration has a multi-dimensional and complex nature.

The concept, however, has evolved over time. According to Güzey (2009), from being a mere physical change it has changed into a more holistic and general approach to regenerating cities through the adoption of via place-specific strategies to solve physical, economic, environmental and social issues.

Currently, urban regeneration is acknowledged to be, as Leary and McCarthy (2003) have assumed, a multidisciplinary model which combines processes of policy-making and implementation in the field of urban development, sustainable solution, economy, urban planning, housing design, urban design, and transportation.

According to Güzey (2009), urban regeneration practices are diverse and there is no single recipe for urban regeneration that stands as a crosscutting field of urban policy.

Nevertheless, urban regeneration's common denominator is fourfold:

- a policy intervention that has an integrated and a wide-ranging nature,
- it refers to a specific area and is durable and strategic,
- as a long-term process, it involves actors across different sectors which are organised according to partnerships,
- it is oriented towards the achievement of a sustainable environment.

The latter provides a solid and inextricable bondage between urban development and environmental issues towards whom cities are deeply responsible. It is for this reason that, according to scholars, sustainability is instrumental to the planning and development of cities that it has been included into systems and processes of planning and management (Wheeler and Beatley, 2008; Evans, 2012). Even though sustainability became popular in the eighties as combined to development, it is, today, is very central to cities' development across the world. Both terms became notorious in 1987 when the World Commission on Environment and Development released the Brundtland Report on common future.

The report gave an inspirational definition of sustainable development where the latter fulfils present needs without compromising next generations' capacity to fulfil their own. In this light, it is assumed that sustainable development implies harmony on human-environment interactions so that relationships among population, resources, environment and development is balanced so establish the foundation of sustainability and health of resources and environment for future generations.

After the failure of the projects of urban regeneration conducted in the eighties, the agenda on urban regeneration has been dependent upon the discussion on sustainable development to the extent that the latter has influenced the former. From 1990s, both concepts have become inextricably connected (Balaban and Puppim de Oliveira, 2014) to the extent that the concept of sustainable urban regeneration emerged. Considered as an urban policy, Güzey (2009) has argued that projects of urban regeneration have been considered as an important instrument and a chance to attain sustainable development through a balanced combination of urban development and natural preservation.

Arguably, urban regeneration carried out through the key of sustainability does not simply emphasises on the physical and economic dimensions of regeneration processes. Above all, in any regeneration, it purposely combines the economic, environmental and social dimensions of sustainable development, at the same time. By this perspective, sustainable urban regeneration has the goal to avoid natural environment be destroyed by urbanization, hence, it prevents that urban resources decrease in the long run (Wheeler and Beatley, 2008; Evans, 2012). Therefore, it could be argued that sustainable urban regeneration represents a policy framework that, from one side, aims at protecting natural environment from eventual urban development's negative impacts, and from the other side, it represents a policy framework that improves the social and economic circumstances inside urban areas. Moreover, this concept offers a host of strategies and policies that while improving the spatial, social and economic organization of urban cities do also preserve the environment by adverse impacts.

Some scholars put forward the argument that sustainable regeneration supports the attainment of other targets such as the delivery of social care through providing social and regional balance, the prevention of local people displacement, support in building participation, engagement of stakeholders and creation of partnership between government and local actors, in other words, the improvement of the quality of urban life (Tallon, 2010; Czischke et al., 2015). Recent evidence from some countries on urban regeneration projects conducted according the perspective of sustainability includes an unequivocal dimension of climate change as they are oriented toward the building of climate-friendly and resource-efficient neighbourhoods. In these urban contexts, as Balaban and Puppim de Oliveira (2014) have demonstrated, the potential of global warming has been reduced by establishing an ecological imprinting to urban development.

## ***2.2 Sustainable urban regeneration and social innovation***

There has been a wide consensus amongst scholars that social innovation, considered as a process of territorial development that takes place within urban regeneration, is creative and contextual. Social innovation has a relationship of path dependency with urban regeneration (Moulaert et al., 2013). Urban regeneration brings to life of urban areas with the cooperative effort of municipalities, citizens and all the stakeholders involved in improving living conditions, enhancing the quality of the environment and the social fabric while strengthening the local economy. Given this backdrop, urban neighbourhoods have become a privileged unit of observation because social innovations aim to develop a specific territory in order to improve the quality of life.

Social innovation is considered as a new structural solution to a social problem and generates a social change. It is a solution because it determines either an improvement in the existing situation either an increase in the quality of life for groups of individuals, communities and the whole society. Social innovation is a solution that is disseminated and adopted whose main purpose is not the profit of a group of people.

According to Cooperrider and Pasmore (1991), the first researcher who used "social innovation" as a term was Taylor (1970). However, literature shows that, at the same time, researchers seem to have adopted a developmental or territorial approach. According to this perspective, social innovation refers to new ways of doing things for the clear purpose of addressing social needs, such as delinquency and poverty. Therefore, the emergence of social innovations is the result of the creation of multidisciplinary teams. By this light, it comes that the object of social innovation, is the solution to the problem and refers exclusively to what is being implemented.

Gabor (1970), for example, views social innovation as a tool for fighting against pollution, crime and corruption, violence, economic inequality, urbanization. Social innovation, therefore, in the development of such a "new social arrangement", stand as a positive response to the social consequences that they entail.

Eradicated within the context of neighbourhoods, social innovation is assumed to generate both spatial and social change in urban quarters by altering social connections between individuals and groups and transforming power relations throughout the process of planning. Social innovation can also promote an

innovative and learning society. In other words, it is a starting point for creating the social dynamics. In fact, given the orientation to community groups and to their surrounding environment, social innovation fits into practices of urban regeneration process ready to be implemented in a marginalized, poor and socially isolated urban area (Walters, 2001).

If at one side, heterogeneous neighbourhoods are expected to show a high degree of capacity to socially innovate, at the other side there is a debate on how social innovation practices develop in such an inclusive and cohesive manner.

Scholars and academics interested in social innovation have emphasised on the potential risk that, within the urban fabric, weak social groups' (Marconi and Ostanel, 2016), needs are marginalised despite a social innovation-based approach. In fact, it could be argued that policy interventions that do not contemplate social exclusion and fragmentation at the local community level have the risk to reproduce and deepen that social gap between the excluded groups versus the integrated ones. The social innovation's debate, more specifically, urges institutions to encourage regulation of durable and enduring practices of social innovation that unfolds within the realm of a democratic state where all citizens' rights are fully recognised.

There is a scholarly recognition on the extent of social innovation initiatives to drive change that particularly occurs in neighbourhoods whose problems are intensified by macro-economic forces. Place-based mechanisms and initiatives that increase the welfare of the individuals drive towards the development of urban regeneration's innovative multilevel governance that sustain institutional learning while solving, at the same time, that "solo" local policies are ineffective. This perspective leads to configure the social and spatial change not in moral communities but in spatialized ones since inequality is considered to be within the spatial and social distribution of disadvantage.

From these premises, it follows that social innovation is a context-specific issue which is studied inside spatial and institutional sites. Rather than being considered as a convenient "tool box" as it offers fast and easy solutions to challenging and demanding issues, social innovation can be better represented as an existing potential, hence as a local resource for change, inside any community.

By this light, this approach views urban regeneration as a process that is bottom-up and incremental to the extent that it leverages on community's cohesive organizations that overcome the top-down regeneration initiatives that, for long, have demonstrated their weaknesses. In this scenario, it is clear that

investments of revitalization as well as regeneration initiatives are supposedly originated from inside the community. This means that the latent potential is expressed and activated by the current community assets.

What is pivotal and crucial in processes of urban regeneration is the public space. The latter is, from one side, a means of empowerment, and at the other side, a host of significant secluded comfort areas that lead up to relevant forms of marginalisation and exclusion as well as enclavization. Also, public space is conceived as an asset used to mobilize a place's genius loci through facilitating social interaction. However, it is opportune to point out that, at times, public space has been used, in a strategic manner, to enhance and boost marginal community groups' exclusion during processes of gentrification (Lees, 2008). Nevertheless, it is worth depicting daily urban space as a set of mutual and dynamic relations enriched with power and symbols (Ostanel, 2014). In this scenario, heterogeneity and differences such as class, ethnicity and gender are portrayed in social constructions and representations that deliver a novel perspective through which the relationship between space and society is interpreted and analysed (Sandercock, 2000).

This study, therefore, considers urban regeneration as a practice of social innovation. However, for an urban regeneration intervention to be in line with social innovation, it must respect the parameters of sustainability.

### **3 Methodology**

This study is based on a multiple case study analysis. This methodology is particularly suitable for analysing the sustainability of urban regeneration as it is particularly effective in investigating complex phenomena that represent a relatively new line of research (Eisenhardt, 1989; Vitolla and Raimo, 2018). In particular, the use of a multiple case study makes the results more robust and favours their generalization (Yin, 1996).

#### **3.1 *Selecting case studies***

This study involves the analysis of three different cases represented by three different areas: San Vito dei Normanni, Brindisi and Mesagne.

The first case study concerns the San Vito dei Normanni area. Among the urban regeneration projects that the municipality of San Vito dei Normanni carried out in 2011, aimed at identifying tools and governance models for the available

public real estate, is a community incubator called Ex Fadda. This project was set up in 2011 thanks to the Apulia Region's 'Bollenti Spiriti' youth policy program, which included, among its measures, a massive urban regeneration action through the transformation of a series of disused, publicly-owned properties into spaces for youth activation. Among these properties was the former 'Dentice di Frasso' wine factory in San Vito dei Normanni. Ex Fadda is now a public space where people can come together, create and innovate in society. It has enabled the urban regeneration of not only the physical but also the human aspects of a community, with the aim of creating relational devices useful for activating the entire population for the revitalization of urban space through the sustainable use of disused green areas. The regeneration project for this container also envisages cultural activities as well as catering based on the principle of employing people with disabilities. An xfarm has also been set up to reuse land confiscated from crime, with the aim of involving young people in agricultural work.

The second case concerns the Brindisi area. Specifically, Punta Del Serrone area is located on the north coast of the city of Brindisi, and was inaugurated in 2014 after the restoration and reclamation of the area known as "cavallino bianco", which reaches as far as the Granchio Rosso beach area. It is a park covering 23 hectares and includes a large expanse of rocks with spontaneous vegetation with various autochthonous essences of the Mediterranean maquis, some of which are also endangered. The area is fenced off with free fronts with gates and pedestrian entrances. Inside, there are flush pedestrian paths with suspended walkways with the addition of signage and information and illustration boards. The park contains elements of naturalistic and landscape interest as well as historical interest.

The third case concerns the Mesagne area. More in detail, the regeneration of Potì Park represents a project inaugurated on 8 May 2016 thanks to funding from PO-FESER Puglia 2014-2020. The inauguration party was accompanied by the marathon of peoples and other various events aimed at sponsoring the different areas of the park. The main themes are those of urban and social regeneration in an area of about 25,000 square meters. In the 1940s and 1950s, the district where the current Potì Park is located hosted the weekly municipal market, a commercial, social and cultural meeting place for the city. Within the area there was a sports facility that was abandoned in the 1990s. The inhabitants of the neighbourhood were mainly elderly people forced to stay at home because of the lack of services and facilities. This project aimed to reverse the situation and create a large public green park in the area of the former sports ground, making

the neighbourhood a new central part of the city. Together with the large park, new services have been created and the entire mobility has been rethought, making it sustainable, slow and safe. Of the 25,000 square meters of the entire park 7590 were allocated to the green area; 13000 have been allocated to a drainage area; 4000 have been allocated to the so-called "zone 30".

### ***3.2 Identification of the framework for the assessment of sustainability***

In the framework of the academic literature related to sustainable urban regeneration, an important question is how to assess the sustainability performance of urban regeneration projects. However, the academic literature has not identified an unambiguous answer. In fact, although there are several studies and researches aimed at identifying tools and frameworks for sustainability assessment, studies assessing the performance and effectiveness of urban regeneration projects against the social, economic and environmental pillars of sustainable development are still insufficient (Zheng et al., 2014). Some of the current evaluation frameworks suggest measures to assess situations where urban regeneration strategies have been implemented and analyse the effects of policy actions (Hemphill et al., 2004). Although good practices for urban regeneration seem to have benefited from some general principles, it is widely accepted that urban regeneration projects should always take into account the circumstances of the territory and be adapted to specific local contexts (Kleinhans, 2012). This principle is also crucial for the design or selection of methods and criteria for assessing the sustainability of urban regeneration projects (Korkmaz and Balaban, 2020). There is a growing recognition that sustainability assessment methods need to be more representative of local conditions and aligned with the values of the target audience (Dahl, 2012). The local context is therefore the most important element in the evaluation of urban regeneration projects (Conte and Monno, 2012). This circumstance makes it necessary to use methods that are more flexible and adaptable to different contexts (Korkmaz and Balaban, 2020). Methods for assessing the sustainability of urban regeneration should also be dynamic in order to allow researchers to understand the long-term effects of interventions (Korkmaz and Balaban, 2020). The academic literature, among the tools for assessing the sustainability of urban regeneration projects, shows a prevalence of indicator-based frameworks (Peng et al., 2015).

However, such frameworks have some limitations. Indeed, they represent a highly technical means of measuring sustainability and, therefore, tend to reduce the idea of sustainability to a set of easily quantifiable aspects of socio-economic development (Weingaertner and Barber, 2010; Elgert, 2018). Thus, the use of indicator-based frameworks carries the risk of ignoring the qualitative outcomes of the urban regeneration project due to a virtually exclusive focus on quantitative results (Korkmaz and Balaban, 2020). This is an important limitation since sustainability cannot be expressed only in quantitative terms (McCool and Stankey, 2004). Therefore, to overcome this limitation, sustainability assessment frameworks from urban regeneration must necessarily include indicators that go beyond quantitative measures (Boyle et al., 2018; Hemphill et al., 2004). So, a third characteristic that urban regeneration evaluation frameworks should have is a proper balance between quantitative and qualitative indicators. The academic literature has identified several indicator-based frameworks for assessing the sustainability of urban regeneration projects (Balaban, 2013).

However, there is no consensus on which framework is the most suitable. The main frameworks are the one developed by Hemphill et al. (2004), Laprise et al. (2015), Larsson (2012), Couch and Dennemann (2000) and Korkmaz and Balaban (2020). In particular, this study is based on the framework used by Korkmaz and Balaban (2020) to measure the sustainability performance of urban regeneration interventions implemented in the Turkish context. This framework is based on the one developed by Couch and Dennemann (2000), but at the same time takes into account the local context. In this regard, the specificities of the Italian context are similar to those of the Turkish context. Both are characterised by the difficulty in collecting quantitative data. These circumstances make the framework developed by Korkmaz and Balaban (2020) particularly suitable for the present study. Table 1 presents in detail the framework used, highlighting the three dimensions of sustainability, the eight aspects analysed and the twenty indicators used. It also provides an overview of the data and information sources in relation to each indicator.

Table 1 - Assessment of the sustainability of urban regeneration, adapted from Korkmaz and Balaban (2020)

Dimensions	Aspects	Indicators	Data
<b>Social</b>	Participation of Stakeholders	Encourage decision-making and action-taking at the local level Community involvement in developing the project	S, I, DO S, I, DO
	Land Use and Buildings	Under-represented groups are taken into account sufficiently	S, I, DO
		Amenities/services are provided locally	DO
		Low capacitated residents are provided with improved access	S, I, DO
		Building are reused or conserved	S, I, DO
<b>Economic</b>	Economy and Jobs	Increased chances for employment Improved environmental awareness of local businesses Support local employment by creating new jobs around the project site	S, I, DO S, I, DO S, I, OD
<b>Environmental</b>	Transportation	Walking & cycling are encouraged Public transport use is encouraged Private car use and traffic is discouraged	S, I, DO S, I, DO S, I, DO
	Environmental Pollution	Reduced levels of air and water pollution	S, I, DO
	Energy Use	Maximization of efficiency in energy use Renewable energy generation and use	S, I, DO S, I, DO
	Waste Management	Reduced waste generation Encourage recycling, reuse and/or repair	S, I, DO S, I, DO
	Open Spaces and Wildlife	Increase the sum of green space per capita Supporting connection with the city's green axis created Support the use of open spaces for public interest	S, I, DO S, I, DO S, I, DO

Note: S: Survey; I: Interviews; DO: Direct observation

### **3.3 Data collection and analysis**

This study is based on primary data. In particular, it is based on data collected through surveys, interviews and direct observation.

The questionnaire consisted of 29 questions under eight titles: community participation; land use and buildings; economy and jobs; transportation; environmental pollution; energy use; waste management; and open space and wildlife. Sixty surveys were completed for each of the three contexts examined. Therefore, a total of 180 surveys were completed. In order to allow for quicker compilation, the web and social networks were used as channels for the transmission of the questionnaire.

In addition to the questionnaires, numerous interviews were conducted with main actors who took part in the conception and implementation of the urban regeneration projects examined. In particular, interviews were conducted with representatives of the municipalities and the companies that carried out the works. In a first phase, the interviews were not structured and were aimed at providing a first approach to the survey topic to the interviewees. Subsequently, in a second phase, the interviews opted for semi-structured interviews in order to enhance the phenomenon with respect to the research objectives of this work.

Finally, in addition to the questionnaires and interviews, direct observation was carried out by the researchers. In particular, the researchers visited several times the places affected by the urban regeneration interventions and the surrounding areas in order to understand and evaluate first-hand the effects of these interventions in relation to sustainability.

The data collected were aggregated and subjected to triangulation. This technique corresponds to the reliability tests of quantitative research (Creswell, 2007; Morrone et al., 2020; Ricciardelli et al., 2020; Vitolla et al. 2020; Raimo et al., 2021a, b) and ensures validity, credibility and accuracy to the results of qualitative studies (Denzin, 1984; Stake, 2000; Creswell, 2007). This study has used three types of triangulation.

Taking into account Katamba, Marvin Nkiko, and Ademson (2016), the first type is defined in terms of data triangulation implying that data, previously collected from the available diverse sources, have been subject to examination (direct observation, survey and interviews) and comparison. This triangulation of sources guarantees a more complete view of the phenomenon that has been investigated.

In addition, triangulation of sources ensures that the collected data are compared by allowing reliability of data themselves.

The second type of triangulation is the methodological one. It contemplates that there are diverse methods for data collection from different sources available. The goal of this technique is to clean data collected from eventual weakness deriving from each single method that has been used.

The theoretical triangulation is the last type of triangulation being used. In this regard, it is necessary to point out that researchers have carried out investigation and, later, implementation of data analysis by leveraging on their different personal theoretical background. To be more precise, one side of researchers has specific knowledge of organisational studies, the other side, instead, owns a background in managerial studies. By this technique it has been possible to emphasise on the common elements of all researchers by leaving aside their diverse theoretical backgrounds. It is important to stress out that all three types of triangulations have enabled not only data reliability and validity but they have, more importantly, increased awareness of the phenomenon on which this subject is based on.

The process of data analysis has unfolded in three different phases: cross-examination of raw data, derivation of descriptive statements and themes from raw data, and interpretation. In the first phase, an assessment and visualisation of the data was carried out, which led to the exclusion of data considered not in line with the objectives of this study. In the second phase, a data coding activity was carried out which involved the identification, naming, extrapolation and classification of the data collected. These activities were fundamental in order to obtain a holistic overview of the sustainability of urban regeneration. Data were classified according to the method used (survey, interview, direct observation). The third phase involved the collection of explanations that clarify themes and observations obtained by data.

## **4 Results**

In this section we examine in detail the sustainability performance of urban regeneration interventions in the Apulian context with particular reference to three different areas: social, economic and environmental.

#### **4.1 Social sustainability**

Some important characteristics of social sustainability are justice, stakeholder participation in the decision-making and implementation processes of urban regeneration interventions and land use. These are the aspects examined in order to assess the social sustainability of urban regeneration interventions in the Apulian context.

With regard to the first elements, the results show an important justice and participation of stakeholders in the decision-making and implementation processes of urban regeneration interventions. In particular, the results of the questionnaire showed particularly high results to the questions related to community participation in all three cases examined, as highlighted in Table 2. In particular, as emerged from direct observation, the three cases examined demonstrate the participation of stakeholders in the decision-making process through the creation of specific information campaigns through the use of social networks. These information campaigns were aimed at learning about stakeholders' needs, presenting projects and gathering feedback from citizens. In addition, as emerged from the interviews, numerous meetings were organised with cultural and environmental associations in order to make citizens participate in urban regeneration processes. These associations were also listened to and involved during the implementation phase of the urban regeneration interventions in order to know the citizens' opinion about the progress of the works. The most vulnerable citizens, such as the elderly and the disabled, were also listened to in order to ensure that their needs and requirements were met. They may have different interests and needs than the rest of the population. The interviews also showed that local governments have tried to involve not only active citizenship, but also those who normally do not care about urban regeneration issues in their area. This fact, according to the interviewees, represented the real challenge, since only urban regeneration projects of a certain value attract the interest of citizens who are not familiar with urban regeneration and the issues of their territory.

In addition, the results of the questionnaires showed a high level of citizen satisfaction with land use and buildings. Accessibility is an increasingly important issue in urban regeneration projects. In this regard, the project areas have easy pedestrian access for people with limited mobility, such as disabled, elderly and pregnant people. Direct observation also showed us a strong relationship

between pedestrian pathways, sociocultural and open spaces. Furthermore, an important need of citizens is connected to the possibility to access all daily services and facilities in and around the urban regeneration project area. In this regard, it is necessary to underline the presence of several essential services for citizens in the urban regeneration areas. Citizens can easily access banks, pharmacies and supermarkets. Finally, the presence of numerous socio-cultural facilities, also demonstrated by the values obtained in the survey, is also noted.

Table 2 - Results of the survey regarding social sustainability

	San Vito dei Normann i	Brindis i	Mesag ne
<b>COMMUNITY PARTECIPATION</b>			
The Municipality organized regular meetings along the planning process to inform all stakeholders and enabled them to participate	3.5	3.1	3.5
Your demands and expectations were taken into consideration and the promises granted during the planning process were sufficiently fulfilled	3.4	2.9	3.3
The promises made during the project planning process have been kept	3.8	3.5	3.8
Strong relationship between the Municipality and the stakeholders continued after the project	3.8	3.4	3.7
You can easily transfer your demands and expectations to the Municipality via nongovernmental organizations	3.8	3.3	3.8
<b>LAND USE AND BUILDINGS</b>			
The pedestrian access is easy and well designed in project area	3.7	3.6	4
You can easily meet your daily needs from project area and its nearby surroundings	4.1	3.8	4.1
There are enough socio-cultural facilities in project area and its surroundings	4.1	3.5	3.8

#### **4.2 Economic sustainability**

Economic aspects are the second pillar of sustainability. In the context of urban regeneration, projects should contribute to the growth and economic development of the project area and its surroundings. In this respect, it is to be expected that a valuable urban regeneration project will create new job

opportunities for the local inhabitants and in particular for special categories such as young people and women in the different phases of planning and implementation as well as in the post-completion phase.

The results of the survey, as shown in Table 3, demonstrated a wide satisfaction of citizens with the impact of urban regeneration projects on employment levels. Through the interviews and direct observation, the involvement of local businesses in the works related to urban regeneration emerged first. This concerned both the definition and implementation phases of the projects. The involvement of local enterprises not only increased the employment level of the municipalities surveyed but also fostered a sense of belonging among the citizens who felt directly involved in the urban regeneration projects of their territory. In addition, people living in the project areas were employed in commercial structures and in the provision of cultural and artistic services within the urban regeneration areas. The increase in employment levels mainly concerned young people. However, it must be stressed that there were no specific strategies and policies to support the participation of women in the entrepreneurial life of the project areas either in the design and implementation phases of the projects or in the post-completion phases.

Table 3 - Results of the survey regarding economic sustainability

	San Vito dei Normanni	Brindisi	Mesagne
<b>ECONOMY AND JOBS</b>			
The project provided job opportunities for you and your acquaintances during preparation and implementation processes	3.5	3	3.3
After the project was completed, new job opportunities emerged, and some of my acquaintances could find work	3.9	3.1	3.3
The project created new job opportunities for women	2.3	1.7	1.9

#### **4.3 Environmental sustainability**

Environmental sustainability is assessed mainly in terms of transport, environmental pollution, energy use, waste management, and open space and wildlife. In this perspective, sustainable urban development is based on the extensive use of efficient and well-organised transport systems, the reduction of

environmental pollution and energy consumption, the use of sustainable energy resources, extensive waste recycling, and the use of large green open spaces. In light of this, urban regeneration interventions should contribute to improving aspects related to transport, pollution, energy, waste and green open spaces. The results of the questionnaire firstly showed a high level of citizen satisfaction with transport. These results are also confirmed by interviews and direct observation. They showed that urban regeneration projects discouraged the use of cars and favoured the use of bicycles and bus-based public transport. They have also encouraged walking by citizens. These interventions have therefore reduced city traffic both in the urban regeneration area and in the surrounding areas. The questionnaires also showed high results in relation to environmental pollution. In this regard, citizens were particularly satisfied with improvements related to air and soil quality, while there was less satisfaction with water quality. This is also evident from the interviews and direct observation that the many green spaces created have significantly increased air and soil quality. In relation to energy use, the results of the questionnaire showed a low level of citizen satisfaction. Interviews and direct observation confirm the lack of use of renewable energies and a not total maximisation of the efficiency of energy use. In this respect, the absence of motion sensors does not support the achievement of full efficiency. In relation to waste management, the results of the questionnaire showed a high level of citizen satisfaction.

This satisfaction derives both from the level of information local governments provide to citizens about waste issues and from waste management. The interviews and direct observation showed that, thanks to urban regeneration interventions, levels of waste production and abandonment have been reduced. Furthermore, thanks to the urban regeneration interventions, the level of waste separation has increased and the level of waste recycling has increased. In addition, these urban regeneration interventions have also changed the culture of a part of the citizens previously not oriented towards separate waste collection. Finally, in relation to open space and wildlife, the results of the questionnaire showed a high level of citizen satisfaction. The urban regeneration interventions have in fact provided citizens with additional green spaces which, as emerged from the interviews and direct observation, are used as meeting places for young people and families. In this perspective, urban regeneration interventions further stimulated the use of open spaces by citizens who increasingly prefer to enjoy

nature instead of staying at home or going indoors. The creation of new green spaces is also an engine for tourism.

Table 4 - Results of the survey regarding environmental sustainability

	San Vito dei Normann i	Brindis i	Mesag ne
<b>TRANSPORTATION</b>			
There is easy pedestrian access to public transportation as well as between public transportation stops, facilities and residences	3.8	3.6	3.9
Pedestrian and cycling routes are well designed and integrated to each other	3.6	3.7	3.7
The frequency of public transportation is not adequate	3.5	3.5	3.8
Having a car is a need that makes life easier in project area	3.6	3.5	4
Low-capacitated residents (i.e. disabled) can reach anywhere on foot in the area	3.9	3.6	4.1
<b>ENVIRONMENTAL POLLUTION</b>			
The project has improved the quality of the air in the area	3.2	3.3	3.5
The project has improved the quality of the water in the area	2.9	3	3.2
The project has improved the quality of the soil in the area	3.2	3.2	3.5
<b>ENERGY USE</b>			
Residential units have no heating problems due to good insulation and solar orientation	2.1	1.9	1.9
Heating expenditures is quite high	1.7	1.6	1.7
<b>WASTE MANAGEMENT</b>			
Municipality collects the wastes regularly	3.9	2.8	4
Residents are informed about waste separation and importance of recycling	4	3.9	4
Recyclable wastes and vegetable oil wastes are collected separately	3.4	3.3	3
<b>OPEN SPACE AND WILDLIFE</b>			
There are enough green spaces, sports areas and playgrounds in project area	4.3	3.9	4.4
You are pleased with the use of open and green spaces around residential areas	4.2	4	4.4
You can use public spaces in the project area at any time of the day	4.2	4	4.1

There are public spaces where different income groups can come together	4.3	4.1	4.4
You prefer to meet with your acquaintances in open spaces in project area	4.4	4.1	4.3

## 5 Conclusions

This study aimed to investigate the sustainability of urban regeneration interventions in the Apulian context. The results showed a high level of sustainability of these interventions in all three contexts examined. However, there are some weaknesses related mainly to the absence of strategies aimed at the inclusion of women in the labour market and to the low efficiency in the use of energy. This study contributes to the academic literature and practice in different ways. Firstly, it contributes to knowledge about the sustainability of urban regeneration interventions. In particular, it represents one of the first attempts to measure the sustainability of urban regeneration in Italy. Secondly, this study provides an important framework for measuring the sustainability of urban regeneration. This framework will be useful for practitioners and professionals to examine this phenomenon in other contexts and for professionals interested in assessing the goodness of urban regeneration interventions implemented by municipalities.

The results of this study have important implications for municipalities implementing urban regeneration projects. In particular, it shows a number of elements that municipalities should pay attention to in order to increase citizen satisfaction and thus gain acceptance. In particular, when implementing urban regeneration projects, municipalities must pay attention to social, economic and environmental aspects. In the field of social aspects, municipalities must first of all involve stakeholders in the planning and implementation of urban regeneration projects. In particular, they must pay attention to and involve the weakest and least represented stakeholders. Furthermore, municipalities must pay attention to land use and the preservation and re-use of buildings. In the field of economic aspects, municipalities must pay attention to revitalising the local economy and increasing the level of employment. In this regard, they must also devise strategies for getting young people and women into work. Finally, in the area of social aspects, municipalities must pay attention to policies related to transport, environmental pollution, energy use, waste management and open and green spaces. With regard to transport, municipalities should discourage car use and

encourage the use of public transport and bicycles. Regarding environmental pollution, they should develop policies to reduce noise and improve air and water quality. Regarding energy, municipalities should maximise the efficiency of energy use and promote the generation and use of renewable energy. Regarding waste management, municipalities should develop policies aimed at reducing the amount of waste produced and increasing separate waste collection. Finally, with regard to open spaces, municipalities should create new green spaces that welcome young people and families.

However, this study is not without limitations. A first limitation is related to the use of only primary data and the absence of secondary data. This may limit the objectivity of the data collected. A second limitation is related to the relatively low number of answers to the questionnaires. However, these limitations do not reduce the overall quality of this work and offer important insights for future research. In relation to the first limitation, they will be able to replicate the study by extending the number of sources used and incorporating secondary data. In relation to the second limitation, they will be able to extend the number of responses to the questionnaires by identifying additional dissemination channels to facilitate circulation. Finally, future studies could examine the sustainability of urban regeneration projects in other contexts and make international comparisons.

### Abstract

This paper aims to understand factors and processes that leverage from tangible and intangible cultural heritage (i.e., local know-how, tacit and codified knowledge linked to arts masterpieces and cultural heritage assets but also to local crafts and tradition) to sustain citizens' social, cultural and economic wealth. So far not enough attention has been paid about the regeneration of smaller cities which hold major artistic heritage but do not have adequate resources to leverage on it and bring positive societal impacts. The paper adopts a qualitative approach and we followed an abductive approach oriented to the generation of new concepts and the development of new explanatory lens, rather than the confirmation of existing theories. It focuses on the case of Urbino, a UNESCO world heritage site whose population and economic status is declining because citizens and businesses are attracted by the lure of higher revenues and better quality of life of nearby cities. Findings revealed that culture and artistic knowledge and capabilities that belong to the tradition of a city rich in heritage can be the lever of innovation and boost civic wealth. Searching the past for looking to the future is, however, a difficult task and divergences in vision, resistance and even political tensions are among the factors that hinder the city regeneration.

**Keywords** – civic wealth; cultural heritage; historic city centre, social innovation; urban regeneration

**Paper type** – Academic Research Paper

## 1 Introduction

Urban regeneration is a wide research area that mainly focused on how to innovate degraded districts and abandoned modern buildings to contribute to city development. However, urban regeneration also applies to historical cities, rich in cultural heritage, that lack of social and economic opportunities for citizens and risk desertification of their historical centers (Stolarick & Florida, 2006; Cooke & Lazzeretti, 2008; Ertan & Eğercioğlu). The key challenge is to reinvent the way spaces are exploited, build on culture to breathe new life into historic centers and activate local knowledge and capabilities that generate new opportunities to achieve civic wealth creation (Lumpkin & Bacq, 2019; Rock H2020 project). Unfortunately, the mechanisms of how cities can capitalize on cultural legacy, heritage and past knowledge to activate effective and sustainable urban regeneration has not been investigated under a knowledge management perspective with a few rare exceptions (Dameri & Demartini, 2020). Therefore, this paper aims to understand factors and processes that leverage from tangible and intangible cultural heritage (i.e., local know-how, tacit and codified knowledge linked to arts masterpieces and cultural heritage assets but also to local crafts and tradition) to sustain citizens' social, cultural and economic wealth (Magistretti et al., 2020). An important source of stimulus for professionals and researchers is the UNESCO Creative Cities Network (UCCN), which functions as a laboratory of ideas and innovative experiences intended to capitalize on the full potential of culture and creativity for sustainable urban development. However, best practices and existing literature have mainly focused on the regeneration of the historic centers of large cities (Carillo, 2004; Zukin et al., 2015) or great tourist destinations (Martí-Costa & Pradel, 2011; Ginzarly & Teller, 2018), in which the availability of human and financial resources allowed the launch of important culture-driven regeneration projects. On the other hand, not enough attention has been paid about the development of smaller cities or even villages which hold major artistic heritage but do not have adequate resources. Reflecting on these shortcomings, our paper questions: *How can a local administration of a small historical city leverage a World Heritage site to foster the regeneration of the local economy and bring positive societal change?*

Our study has taken advantage of an abductive approach (Dubois & Gadde, 2002). Similar to 'grounded theory', the main concern of the abductive approach

is related to the generation of new concepts and the development of new explanatory lens, rather than the confirmation of existing theories.

The remainder of the paper is structured as follows: section two presents the different research streams we combined to build our framework of analysis; section three elucidates the abductive protocol and provides a brief description of the case study; finding and discussion follow in section 4; conclusions are presented in section 5.

## **2 Combining different streams of research to reinterpret historical cities regeneration**

In order to explore how to foster urban regeneration several interdisciplinary contributions have addressed their attention on cultural heritage (CH), regarded by scholars and policy-makers as a driver of development—especially for historic cities—and a key element of civic wealth and urban sustainability (Cervello´-Royo et al., 2012; Echter 2015; Nyseth & Sognnæs, 2013; Nocca,2017). As a contribution to prior literature on urban regeneration, we combined different streams of research focusing on:

- the context (i.e., regeneration of historic city centres);
- the purpose (i.e., creation of civic wealth);
- the process (i.e., a path for a participatory governance based on context and purpose).

### ***2.1 Regeneration of historic city centres leveraging on CH***

CH includes both tangible culture (material aspects of culture, such as buildings, monuments and objects, e.g., books, works of art and artefacts), natural heritage (e.g., landscape) and intangible culture (non-material aspects, such as folklore, traditions, language and knowledge), which are embodied in social practices and community life (Throsby 1999 and 2003; Blake, 2000).

In recent years, the role of CH role has been extensively recognized, both at the academic and institutional level (UN, 2015; ICOMOS, 2015; Camagni et al., 2020), thus marking a shift towards a holistic, interrelated perspective on CH, which is seen as socially constructed, dynamic and functional. Hence, CH it is conceived both as an element and a tool for socio-economic development (UN-Habitat, 2014; CHCfE Consortium, 2015) and an integral element of territorial capital,

capable to influence local economic dynamics since “it shapes cultural and psychological attitudes of local communities; represents an important component of local social and identitarian capital; enhances creativity of the local intellectual and artistic milieu” (Camagni et al., 2020:35). Indeed, its conservation and valorisation are at the centre of a lively debate on what – how – whom – it contributes in revitalizing cities, local areas and historical districts (UNESCO, 2008; Murzyn-Kupisz, 2012; Azmi et al., 2021).

Moreover, both the New Urban Agenda (UN, 2016; UNESCO, 2016 and 2018) and the 2030 Agenda (UN, 2015) have opened up new avenues to integrate culture into policies for social and economic inclusion and environmental sustainability, resting on the idea that CH and creativity are linked to local places and communities, thus directly and indirectly contribute to a number of targets, particularly SDG 11 (to ‘make cities and human settlements inclusive safe, resilient, and sustainable’).

In this vein, the revitalisation and the social upgrading of historical city centres has become a strong priority and an aspiration of urban policy in all parts of the European continent (Rudokas & Grazuleviciute-Vileniske, 2021).

Historic city centres and historic districts are symbols of the city’s image; above and beyond their own cultural value they fulfil an important mission in modern urban development: they create the identity and the city’s image and are key geographic factors for the local and regional economy (UNESCO, 2008: 9).

The enhancement and regeneration of the historic city centre are considered by many to be an opportunity for sustainable economic development based on the spur of culture and creative industries and sustainable tourism (Sacco, Ferilli, & Blessi, 2014; Sacco, Ghirardi, Tartari & Trimarchi, 2019; Blessi et al., 2016; Ertan & Eğercioğlu, 2016).

A further topic attracting the attention of scholars and politicians is represented by the recovery and resilience of historic small towns (Azmi et al., 2021) included among the World Heritage Sites (WHSs) where the mobilisation of cultural resources for economic revitalisation could be pivotal for the development of a “culture-based economy” (Amin & Thrift, 2007; Power & Scott, 2004; Rakic & Chambers, 2008).

However, there was no lack of criticism because there is also a risk of abusing “the role of culture and creativity in urban processes to legitimise and even encourage organised forms of appropriation of common symbolic and material resources” (Sacco et al., 2019: 200). Culture-driven gentrification is one example

of this type of appropriation (Atkinson & Bridge, 2005; Zukin, Kasinitz, & Chen, 2015).

In this vein the Historic Urban Landscape (HUL) approach proposed by UNESCO (2011 and 2016) and the UN-Habitat New Urban Agenda (2014), suggests that it is possible to integrate CH conservation and socio-economic development of cities (Grefe, 2009) if we consider the urban landscape as an "organism" made of complex characters, and multidimensional inter-relationships (Veldpaus & Pereira Roders, 2014).

## **2.2. Regeneration of historical villages and towns and creation of civic wealth**

Historical villages and towns that populate Europe have many of the attributes and qualitative elements (e.g., pedestrian zone, restaurants, retail shops) that create a dynamic social and cultural place and make the location a great place dear to the community and capable to attract talent companies. However, many of them suffer from unemployment, disengagement and economic stagnation (Thurley et al., 2015). In particular, Italian historic centres have progressively lost their social and economic attractiveness (Micelli & Pellegrini, 2018). Citizens often moved out to search for jobs and opportunities, following the same trend of companies and institutions searching for more rational and better connected locations. In other cases, citizens left historical quarters because life quality was clashing with large flows of overtourism (Jover & Díaz-Parra, 2020). Either the case, cities lose their most valuable resource: the community (Higgings, 2020).

Municipalities and local governments attempted to address these issues using heritage to regenerate towns. However, many initiatives failed because investments focused on restoration only, while social and economic benefits are achieved if wider targets than building conservation, including employment, training and business development are set. Failure of initiatives promoting a sustainable economy that safeguard the tangible and intangible heritage also occurred because they often forgot to put the community at the centre, while the engagement of the broader community is critical in achieving this vision (Feehan & Zingsheim, 2019).

A promising solution is civic wealth creation, i.e., the creation of social, economic, and communal endowments that benefit local communities and allow these communities to be self-sufficient, therefore generating positive societal

change and sustainable impact (Lumpkin & Bacq, 2019; Bacq et al., 2020). This type of wealth goes beyond material resources and physical assets of a community to include intangibles such as health, happiness, culture and social justice. It is a wealth created as outcome of local stakeholders' collaboration and takes the form of new or improved local capacity, capabilities, culture, material and immaterial resources that help to find solutions to community problems and bring about change (Alvord, Brown, & Letts, 2004; Haugh, 2005). According to this perspective communities (people who share place, identity and interests) are actors for societal change and not merely passive beneficiaries (Glynn, 2019). Therefore, communities directly contribute to create real societal impacts (Branzei et al., 2018).

According to this stream of literature, three stakeholders category shall jointly collaborate: local communities, enterprises and supporters/facilitators (i.e. providers of financial, technical, and political assistance) to create civic wealth. Collaboration is successful only when the different stakeholders intentionally pursue joint interests to achieve positive societal change. If one stakeholder category is not committed because its interests diverge from others' interests or because they are only partially involved, civic wealth is not created, although other positive impacts can still be achieved. The mechanisms or strategies to achieve fruitful collaboration that generate civic wealth are mainly three: engaged participation, collaborative innovation and resource mobilization (Lumpkin & Bacq, 2019). The key actor (or orchestrator) that may initiate the process of civic wealth creation can be any key stakeholder, who is committed to bring about positive societal change or maintain the civic vibrancy of a community. Although, in practice, this stakeholder is usually a public subject.

### *2.3 1 Participatory Governance and a shared vision for culture-led civic wealth*

According to the literature (Sacco, Ghirardi, Tartari, & Trimarchi, 2019) a participatory governance, which involves citizens and stakeholders in the culture-led processes of urban regeneration, is a condition to generate positive and lasting impacts over time.

The cultural regeneration of a territory is achieved, indeed, through a plurality of cultural participative initiatives (PCIs) that involve different stakeholders and unfold over time (Biondi et al., 2020). A single project relating to the investment of contributions for the preservation of cultural heritage will not be sufficient to trigger a virtuous spiral of cultural, social and economic growth and impact on

civic wealth. The idea behind this positive spiral is transforming people into "cultural citizen" who, in turn, would nurture culture as an endogenous growth process (Sacco & Segre, 2009).

It is therefore a virtuous growth path that must be activated and nurtured over time and that requires orchestrator (s), usually a public actor. But it can also be a grassroots initiative, in which citizens, members of an association, of a community initiate a cultural project for the regeneration of a public space, a district, an historic city center (Aureli, Del Baldo & Demartini, 2020; Demartini et al., 2020). The role of the orchestrator(s) is fundamental in shaping the vision and enabling participation of all relevant stakeholders (Biondi et al., 2020). The starting phase of a culture-led regeneration project is characterised by the orchestrator's vision, which is long-sighted and requires others to be convinced of its aims and merits. Hence, a key issue is to transform the individual visions of single actors and, specifically, their means and ends into a joint understanding. As Della Lucia & Trunfio (2018: 36) argue, "In the creation of a shared vision of urban development, the greatest challenge is to overcome the significant barriers that inevitably arise when a wide variety of stakeholders are involved, all with different backgrounds, power agendas, aims, roles and competencies."

For this reason, understanding the sharing of the broader strategic vision behind projects for the preservation and reuse of individual heritage assets is fundamental to understand whether or not there is a widespread perception of the value of cultural commons and a cultural project shared by local actors on the enhancement of cultural heritage (Del Baldo & Demartini, 2021).

These last considerations are particularly interesting because they facilitate reflecting on the theme of the renewal of an historical small town thanks to the transfer of tacit and codified knowledge over time among those who, as residents or city users, base their identity on the tangible and intangible cultural heritage left by previous generations. The latter is a phenomenon deeply investigated for business and known as "innovation through tradition strategies" (DeMassis et al., 2016; Magistretti et al., 2020) that can be translated to our context as follows. As scholars reveal that firms leverage knowledge from the past mainly to preserve firm identity, in the same way a cultural project of regeneration of an historical town should innovate while preserving their link with the past, thanks to processes of combination and reinterpretation of past knowledge.

### **3 Methodology**

#### **3.1 *The abductive approach***

The paper adopts a qualitative approach. It focuses on the case of Urbino, a UNESCO world heritage site whose population and economic status is declining because citizens and businesses are attracted by the lure of higher revenues and better quality of life of nearby cities. Maintaining the vibrancy and the well-being of the community represents a challenge for the local government, which launched a series of initiative under the umbrella project named "Urbino per Bene" (Municipality of Urbino, 2016). The paper relies on abductive approach, which is a form of logical inference that begins with an observation or a series of observations and then tries to find out explanation. The basic assumption is that theory cannot be understood without empirical observation and vice versa (Dubois & Gadde, 2002).

Based on the observation of actions and outcomes obtained through one civic initiative known as "the Relaunch of the Data space" (the ancient stables of the Duke Federico da Montefeltro), the paper reconstructs the premises that activated the community process devoted to create civic wealth putting together different visions and perspectives on urban regeneration.

Information on the case study were obtained from six semi-structured interviews with key representatives of the main institutions involved in the Data project, namely the following: the prior Councilor of the Municipality of Urbino appointed for the city planning and, currently, for Tourism; a consultant for public communication of the city Council; three local representatives of art schools (i.e., the Higher Education in graphic design and visual communication; the Academy of fine arts; the Artistic high school of Urbino); the local representative of the Trade association of crafts and small businesses

Further four unstructured interviews regarded the Rector of Urbino University and the University delegate to the third mission; an architect from the city planning office of the Municipality, responsible for urban regeneration, who also dealt with the drafting of the UNESCO site management plan; the CEO of the Incubator appointed by the Municipality to support the most promising business ideas, which take shape within the Labs organized at "the Data space". In our interviews, the Data project opened a discussion on the role of CH in the city of Urbino. Hence, the focus moved from the Data space new functions to the vision

/ strategic plan of the city of Urbino. Insightful information was also obtained from a previous survey launched by the Municipality under the broader project "Urbino per Bene", based on semi-structured questionnaires and interviews addressed to Urbino citizens, tourists and university students. Additional information was extracted from the analysis of public documents such as the municipality website, public speeches and the city strategic plan.

All the conversations were recorded, and notes taken during the meeting formed the basis to write more extensive reports at a later time. In our analysis, we found the use of excerpts highly worthwhile, as they draw attention to the interviewees' perceptions.

On a regular basis, the team members shared the outcomes of the interviews during face-to-face meetings and teleconferences to discuss questions arising from the empirical investigation and identify the main features of the observed phenomenon.

The Data project has launched a discussion on the role of CH in the city of Urbino path of development. Hence, the focus of the interviews moves from the Data project to the vision / strategic plan of the city of Urbino. Following the abductive approach, this dialectic led to a refinement of selected concepts to interpret the phenomenon.

### ***3.2 The case study in brief***

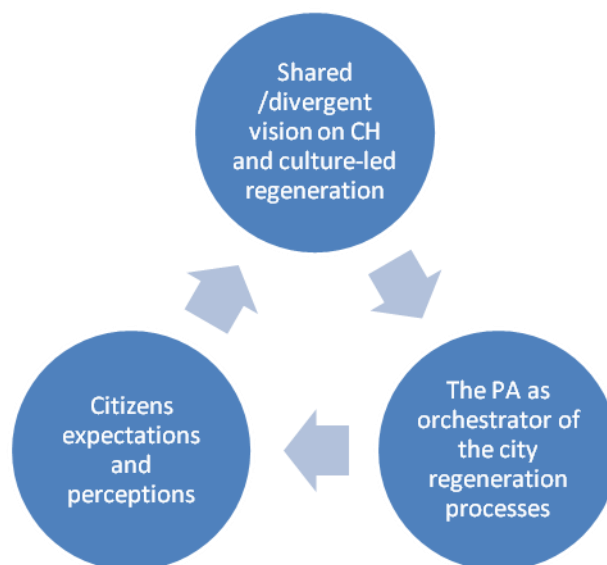

The city of Urbino, included in the UNESCO List of World heritage since 1998 for its outstanding universal value (see the site [whc.unesco.org](http://whc.unesco.org)), offers a paradigmatic case study and an interesting laboratory that allows us to scrutinize and discuss this issue both from a theoretical and practical point of view. Therefore, in selecting the specific Data project, embedded in the UNESCO site management plan, we applied a purposeful sampling technique (Etikan et al., 2016; Patton, 1990). Namely, we aimed to select a project among the different initiatives launched under the umbrella project named "Urbino per Bene", and supported by the Italian Minister for Culture, that: a) was identified as an urban regeneration project for the development of a UNESCO cultural heritage site; b) had received attention and media coverage at the regional level; c) included a considerable number of different initiatives and expected impacts; c) implied the involvement of different stakeholders. The "Data space" is located in the ancient stables of the Duke Federico da Montefeltro, built by the famous architect

Francesco Di Giorgio Martini in the fifteenth century as a part of the nascent Ducal Palace. The Data provides an example of a historical and military place converted into a cultural, social and economic engine. Thanks to the intervention of a prestigious architect Giancarlo De Carlo, it was renovated and transformed into a city observatory, with the intention of making it a multifunctional center equipped with a library, exhibition spaces and a multimedia study center.

#### 4 Findings and discussion

Findings from interviews reveal divergences of vision, resistance and even political tensions. In attempting to understand these dynamics, the interrelated aspects depicted in Figure 1 are discussed in the reminder.

*Figure 1-Refinement of selected concepts*

##### **4.1. The strategic vision on CH and culture-led regeneration projects**

Starting from the analysis of the purposes of the Data project, different visions of city regeneration emerged from the interviews. All of them leverage on the city heritage combined with form of past codified and tacit knowledge. Although

different, all of those visions can be interpreted with the above-mentioned approach "innovation by tradition".

From the point of view of the former Councilor for the city planning who acted as the orchestrator of the Data project, this latter initiative in itself represents a way to activate a catalytic process of the energies present in the territory. *"Experimenting with the Data possibilities of use - letting an old space to live and living the space to make it alive and trigger ideas, energies, relationships and contaminations among different actors: youths, schools and university students, entrepreneurs, artists, etc.- made it possible to verify the concrete feasibility of the cultural, economic, tourist revitalization project, leveraging local excellence"*. From his words, as well as from the interviews conducted with other economic actors, a predefined conception of the city's vocation does not emerge, but rather the awareness of the existence of cultural heritage and knowledge that can be recombined and revitalized through experimentation. *"The co-working activity has already generated a start-up that aims to market local traditional foods with the "Sapori del Duca-Flavours of the Duke" brand. The start-up was born and survived in the context of Data in collaboration with BP Cube which acts as an incubator"*.

On the other hand, representatives of local art schools, express a vision of regeneration of the territory more anchored to the enhancement of the exceptional nature of its cultural heritage. Although the cultural heritage of Urbino, recognized all over the world, dates back to the Renaissance period, they believe that an important example of revitalization took place in the 900s, thanks to great men of culture (including Italian writers such as Volponi, Luzi, Parronchi and even the Noble Prize Ungaretti; scholars such as Carlo Bo and internationally renowned architects such as De Carlo) who have been able to appreciate and enhance the city, seen as an example of beauty and culture. In this perspective, the words of the Director of the School of Fine Arts are exemplary: *"the historic center of Urbino must rediscover its own identity and express a new renaissance, based on the principles of Humanism"*. Consistently, the Data project should be "a space **Devoted to Ars** (Latin word that stands for talent/genius) and **Techne** (ancient Greek word for know-how)". The conception underlying the new functions to be attributed to heritage assets is, therefore, that of offering spaces to develop new technologies and skills for arts. *"A fluid space, a laboratory that recalls the humanistic conception of the knowledge of the enlightened Cortegiano, artist, scientist and scholar at the Duke's court "*. The renewal of the city must therefore focus on the enhancement of art, beauty and quality of life.

In summary, the historical legacy is an important lever for the renewal of Urbino by all our interviewees, but its enhancement is conceived differently. However, without a common and concerted vision on the overall regeneration project of the city, the risk is to remain at the level of individual initiatives that disperse potential of innovation.

#### **4.2. The stakeholders/citizens expectations and perceptions of the PA action**

Findings from the interviews revealed different visions of the city of Urbino and how the local government guides the city development. Visions are linked to the different interests and needs of each stakeholder category. For example, on one hand, entrepreneurs complain that *"the culture and practices of Urbino have remained unchanged over the years"* while there are grand societal challenges to face; *"Urbino is a place of dreams, it does not innovate, politics does not think about the future"*. On the other hand, representatives of local art schools indicate that Urbino is famous because of its artistic heritage, dating back to the Renaissance time but also to the recent artistic graphic design movement of early 900s. Therefore, Urbino's future shall be based on its physical cultural artefacts and artistic spirit: *"public investments should be devoted to the creation of libraries, museums and activities that can employ young people and artists, so that they will not leave the city after the degree.....investments should also focus on aesthetic education of small traders, entrepreneurs and inhabitants that offer or ask for services that are in sharp contrast with the artistic beauty of the city"*.

Despite such differences, common bonds, attachment to the legacy of the place, and proud of belonging to an ancient and important city of the Italian history were considered strong enough to raise active collaboration from different stakeholders around a specific goal: making a public space named Data a lively place where the regeneration of the city could start. The local municipality identified the desire for city regeneration as a shared interest capable to activate collaboration and generate change. The Data project was born *"to serve as a common place to bring the energies of the territory and convey them to sustain the economic, cultural and touristic revitalization of the city"* as reported by the Councillor for Tourism. The local municipality was actually the orchestrator that initiated the public debate and organized meetings on the usage of Data and it was the entity that allocated funds to this project. Discussions and great participation in meetings seemed promising. One year of experimentation in

using the three floors of Data to organize events, exhibitions, public meetings and open a co-working space for start-uppers, a library, a showroom of local products and a bistro also seemed successful in its attempt to attract artists, inhabitants, entrepreneurs and tourists. However, as reported by one interviewed *"the Data project is still a work in progress...After one year of experimentation the project stops and it is not clear the vision of the place"*. Most importantly, the project did not develop capabilities in the community useful to continue creating civic wealth. The civic vibrancy given by the encounter of inhabitants, artists, students and entrepreneurs in the Data space stopped very soon. One key strategy was partially missing: the engagement of all stakeholder categories. While the participation of supporters (i.e., the local municipality) was clear and demonstrated by the commitment in supplying financial and human resources and legal authority to the project, community members and enterprises moderately contributed. Limited participation of students and inhabitants did not favour community empowerment and poor involvement of businesses did not favour the development of effective and long-lasting entrepreneurial solutions that can nurture the regeneration of a city after the stop of public funding (Young, 2006).

Strong communication and public meetings with citizens promising a participatory decision-making process in designing the uses of the Data space generated an initial phase of enthusiasm and resource mobilization. Besides the restored building of the Data, volunteers, professional networks and personal relationships were devoted to the project and contributed as material and immaterial resources to civic wealth creation by building cohesiveness and strengthening mutual interactions among stakeholders. But except a few cases, the sharing of ideas, knowledge and expertise in such meetings did not fully translated into practice with concrete collaborative innovations outcomes.

#### **4.3. The PA as orchestrator of the city regeneration processes**

The strategic plan of the city (Municipality of Urbino, 2016) represented a first attempt to directly involve multiple actors and implement a HUL (UNESCO, 2011) approach to the urban regeneration project of the city centre, thus changing the top-down approach that was prevailing in the previous years when the PA acted more as a "patron of the heritage". In this vein, the project "Urbino per bene" was conceived as a tool useful to trigger and improve dialogue with citizens and city

users and collect new and fresh insights (i.e., by addressing attention to the perceptions and perspectives of youth, tourists, city users and inhabitants of the centre). Hence, the results obtained from the questionnaire administered in early 2018 to students, tourists and permanent inhabitants (Del Baldo & Demartini, 2021) allowed the municipality to understand the coexistence of different and sometime conflicting viewpoints, needs and perceptions among city users, and collect suggestions to trigger innovative ideas to make the historical centre more attracting, and to engage citizens (included youth) in the renewal and regeneration of the cultural and socio-economic fabric. (Sacco & Segre, 2009).

The local PA played a key role in initiating collaborative actions, aimed to fostering dialogue and facilitate the composition of single "voices" and views, eliciting several projects, and among them, launched the Data project.

From the municipality perspective *"the Data project represents an experimentation to learn how to better involve citizens in the protection and revitalization of the site"*. As the city planning councillor states *"Data was -born as a common place to bring the energies of the territory and represented a space for hosting and sharing, and a useful laboratory to trigger ideas, relationships and contaminations among different actors: youths, schools and university students, entrepreneurs, artists, and other city users. The experience made it possible to verify the concrete feasibility of the cultural, economic, tourist revitalization project, leveraging local excellence"*. Hence, drawing from the PA point of view, it could be considered as a first initiative of a regeneration path embedded in the strategic plan of the city and in the UNESCO management plan.

The local PA played a key role acting as a stimulator in starting collaborative actions and supporting the process of involvement and awareness of the various communities and city users and initiated a participatory governance approach (Biondi et al., 2019). Its role was similar to that of "an orchestrator" - that entails gathering together diverse actors, ranging from public to private, industrial associations, local communities, as well as citizens (Abraham & Platteau, 2004; Della Lucia & Trunfio, 2018; Farinosi et al., 2018). *"The current urban regeneration project requires a great amount of financial resources; to complete it, new funding is needed. Private actors (i.e., entrepreneurs, associations, and citizens) begin to move. All this in line with the UNESCO management plan approved in 2013 which contemplates public-private synergies"*.

However, the PA is still at an initial step, that requires to progress and we deem that the role of PA was rather that of a stimulator and a participatory governance

approach is still in its infancy stage (Abraham & Platteau, 2004; Sacco et al., 2014; Della Lucia & Trunfio, 2018; Farinosi et al., 2018). Other interviewees, point out that different visions exist about the value they attributed to CH in driving the socio-cultural and economic regeneration of the place. Such visions mirror and underpin different interests and expectations among stakeholders on the quality of life in a historic center like Urbino and the perspective of urban revitalization expressed by different communities with "different souls".

## **5 Conclusions**

The case study analyzed revealed that culture and artistic knowledge and capabilities that belong to the tradition of a city rich in heritage can be the lever of innovation and boost civic wealth. Searching the past for looking to the future is however a difficult task.

Empirical data allowed to identify the main challenges that a city manager has to face: attract talent, create jobs and trigger the spur of new ventures; establish spaces for artists and cultural activities; preserve and promote local know-how; develop a strategy to attract SMEs belonging to the cultural and creative sector. Moreover, it shows the relevance of involvement of multiple stakeholders in societal change initiatives and the importance of managing assets through public-private cooperation. However, it also identifies the missing elements that hindered the city to continue exploiting its potential related to cultural heritage (e.g., absence of a financing ecosystem available for the creative and cultural sector, scarcity of resources). Lastly, the paper highlights the power of participatory cultural initiatives (Biondi et al., 2020) be used for the preservation, restoration and revitalization of physical heritage assets (Dameri & Moggi, 2019).

The practical implications of our research are as it follows.

Preserving the city's identity while enhancing and revitalizing traditional knowledge is a challenge for policy makers, called to experience innovative, collaborative and circular systemic approach for adaptive reuse of historic city centres by implementing a repertoire of successful heritage-led regeneration initiatives. Additional issues may affect historical World Heritage sites (WHS) where local communities and local people's attitudes towards conservation of the cultural environment and a WHS status can diverge (Jimura, 2011). In such contexts administrations and inhabitants have a dual challenge: "on the one hand the urban fabric has to be preserved; on the other, support must be given to the

vitality of the city's cultural heritage" (UNESCO, 2008:10). The sole preservation of buildings and monuments cannot save historic cities and could generate a "museum" phenomenon (elitist revitalization), thus freezing any development opportunities and hindering social revitalization.

Our findings reveal that the PA is still tackling with an initial step that requires to progress the efforts in stimulating sharing and participation in the current review of the strategic plan of the city and the UNESCO management plan. Therefore, we deem that the role that the PA can play with reference to initiatives aimed to leverage cultural heritage as an engine of development of Urbino historical center should be conceived as flexible and dynamic in nature, being that the role of orchestrator should be merged (or transformed into) that of a mediator of interest.

### **Abstract**

Smart Working (SW) refers to new ways of working integrated in a way that enables spatial and temporal autonomy, favor cultural exchanges and trust, enable technological advances, and allow wider intellectual connections. SW is seen to be a way to “modernize” working practices by using ICT applications and new organizational settings, so that flexibility, creativity, engagement and, also, satisfaction of workers can be improved, for the benefit of employees, companies, and societies. However, the literature shows that SW requires the adoption of specific measures and levers, to fully exploit its potential benefits and reduce the risk of refusal by workers.

During the COVID pandemic, many companies, schools, and public organizations all around the world asked their employees to start working from home (WFH). After the pandemic, some observers think that WFH can remain a common way of working especially for knowledge workers. So, it is necessary to understand to what extent this experience can really lead to SW - in other words, to investigate if WHF can be automatically a “smart” working modality for knowledge workers.

The goal of this paper is, therefore, to explore if keeping workers at home can be a first important step towards SW, or if there can be some barriers or possible sources of inefficiency. The “forced” condition caused by the pandemic provides a unique opportunity to investigate what can happen when entire offices move to WFH. The paper reports the

results of an online survey of WFH knowledge workers conducted in Italy during the first weeks of the lockdown (April and May 2020). The research provided some descriptive statistics and classifications, especially regarding the viewpoint of employees. Their real involvement and perception of usefulness of WFH was investigated. The data made it possible to analyse the potential points of strength and weakness of WFH, how a massive introduction of WFH can be seen as a really “smart” working modality for this elective category of employees, and what lessons can be drawn for work management.

**Paper type** – Academic Research Paper

## 1 Introduction

The term Smart Working (SW) is used to refer to new ways of working opportunities integrated in a way that enables spatial and temporal autonomy of workers, favor cultural exchanges and trust, enable technological advances, and allow wider intellectual connections across social, ethical, and environmental sensitivities “all harmonized to suit the individual working style” (Blackwell, 2008). SW is seen as a way to “modernize” working practices by using not only recent ICT applications but also new organizational settings, so that flexibility, creativity, engagement and also satisfaction of workers can be improved, for the benefit of employees, companies, and societies in a sort of “win-win” strategy (Clapperton and Vanhoutte, 2014). According to the literature, to be really “smart” and produce the positive results that are expected, SW requires numerous technological and organizational solutions be planned and implemented properly (Lake, 2008; Thompson, 2008).

In the last 2 years, during the COVID-19 pandemic, these issues gained momentum. Many companies, schools, and public organizations all around the world asked their employees to start working from home (WFH) (Brynjolfsson et al., 2020; Gottlieb et al., 2020). Conversely, before COVID-19, SW, WFH and the other forms of “working at a distance” from the office were generally restricted to a limited number of employees (Messenger et al., 2017; Sostero et al., 2020). Now, it is likely that after the pandemic this will remain an important way of working especially for clerical workers. Indeed, governments see the potential advantages of reduced pollution (due to less commuting and car traffic), and companies can cut office costs and travel expenses.

The “forced” condition caused by the pandemic provides a unique opportunity to investigate what can happen when entire offices move to WFH. In particular, WFH may impact primarily on knowledge workers, i.e., employees whose task is mainly intellectual, involves complex cognitive processes, learning activities, interactions, and exchanges of knowledge with colleagues and other business partners. The main goal of this paper is to examine if WHF can be automatically a “smart” working modality for knowledge workers. In other words, its purpose is to explore if keeping workers at home can be a first important step towards SW, or if there can be some barriers or possible sources of inefficiency.

At this aim, the paper reports the results of an online survey conducted in Italy during the COVID-19 lockdown. Almost 1,000 responses of a convenience sample of employees of various companies and organizations were collected during the first weeks of the lockdown (April and May 2020), when a large part of clerical work suddenly moved to WFH. The research provided some descriptive statistics and classifications, especially regarding the viewpoint of knowledge workers, about their cognitive interpersonal interactions, their real involvement and perception of usefulness of WFH, and the use of technologies for knowledge sharing.

The data made it possible to analyse the potential points of strength and weakness of WFH from the viewpoint of knowledge workers. Also, it was possible to understand whether and how a massive introduction of WFH can be really seen as a “smart” working modality for this elective category of workers.

## **2 Comparing WFH and SW**

### ***2.1 Definition of WFH and SW***

Working from home can be defined as “a working arrangement in which a worker fulfils the essential responsibilities of his/her job while remaining at home, using information and communications technology (ICT)” (ILO, 2020; p. 5). It can be seen as a special case of “telework” which is generally described as a way to work from any other places outside their “usual” office by means of electronic connections (Malik et al., 2016).

Compared to the previous terms, in the case of “Smart working” there is an emphasis on the adjective “smart” and on the potentially radical (and positive) impacts that are expected on both companies and workers. For Kim et al. (2017),

SW is “telework that individuals perform in a smart and innovative manner”, so that they can “positively accommodate the latest information technology environment without being constrained by time and place” (Kang and Kwon, 2016), “achieve maximum value” and “be more productive” (Fragouli and Ilia, 2019). With SM, they are expected to have more “spatial and temporal flexibility” (Fogarty et al., 2011), better working conditions (Kim and Oh, 2015), improved creativity, and opportunities for change (Kang and Kwong, 2016).

In short, compared to SW, WFH is a situation where employees are asked to or are offered the opportunity to work just from home instead of their offices. In principle, like SW, WFH is still expected to provide benefits for individuals, companies, and societies (Nakrošienė et al., 2019) - e.g., reduction in costs of travel and office space, reduction in pollution and time wasted in commuting, more freedom to combine time of work with personal life, increased flexibility of time work, and more comfort of employees. However, many scholars observe that, to be considered “smart” – i.e., to get the full benefits that this transformation can really bring about – the new working modality requires special conditions of implementation, as will be examined in the next subsection.

## **2.2 SW success factors**

The factors affecting SW success (for employees and firms) have been considered in the literature. Hassan (2016) detected a number of significant factors, namely: nature of the job, clear goals and policies, fitting to immediate needs of workers, and also capability to respect the personal life of the people. Similarly, Kang and Kwon (2016) analysed the determinants of a positive adoption of SW at firm level (such as, the organizational environment - e.g., innovation climate, or style of personnel evaluation - or the characteristics of the information system adopted to support SM), and for the single individual (for example, capability of self-control). The possible differences in acceptance and perception between workers have also been widely considered.

SW efficacy can depend on the specific work organization. For instance, van der Lippe and Lippényi (2020) signal the problems for teams when there are too many members working remotely. Furthermore, job position (Park, 2018) and leadership style (Park and Kim, 2013) can play a role. Finally, SW can have an impact on socialization processes and personal work styles (Mallia and Ferris, 2000; Troup and Rose, 2012). SW may change the forms of interaction between

colleagues, which in turn can modify the processes of knowledge sharing and knowledge management. Effectiveness and quality of work - especially for knowledge workers (Bélanger and Allport, 2008) – can be affected. Dalkir (2008) used the distinction between tacit and explicit knowledge and Nonaka's (1994) model of knowledge conversions to explain that different ICT applications can be more or less effective for interpersonal knowledge sharing, in relation to their capability to transfer tacit and/or explicit contents efficaciously. From another perspective (Bratianu and Bejinaru, 2020) it may be argued that the use of SW can require that workers find a new dynamic balance between the different forms of knowledge (i.e., rational, emotional, and spiritual) which characterize actions and decisions of people.

A final mention deserves gender equality. In principle, it may be expected that women are likely to carry out more domestic responsibilities whilst working flexibly (Chung and van der Lippe, 2018). Therefore, differences may be expected regarding the perception of SW usefulness for different genders.

### ***2.3 Principles and levers of SW***

In consideration to the success factors analysed in the literature, for companies that are willing to adopt SW in their organization, it is important to understand the main points to consider for a fruitful implementation. These can be summarised in the form of 5 principles and 4 levers.

The principles of SW are the characteristics that work (and its management) tends to assume in this modality, and namely:

- Flexibility: this refers to the capability of workers to decide where, how and when to work (Hill et al., 2008). For companies to be able to exploit this flexibility, it is necessary to avoid framing SW into a rigid scheme (Flexibility, 2010).
- Trust: in an organizational context where workers can be dispersed everywhere, building a trustworthy climate facilitates knowledge exchange (Nahapiet and Ghoshal, 1998).
- Collaboration and communication: collaboration is essential in modern organizations that are used to working in teams and networks (Callahan et al., 2008). In a SW environment, collaboration requires very effective communication channels between workers, and between management and workers.

- Autonomy: workers need to become more responsible for their own tasks, and a new balance between organizational control and worker autonomy becomes important (Tafti et al., 2007).
- Empowerment and individual advancement: autonomy leads to a re-distribution of power in the workforce, and it becomes necessary to adopt new technology-based measures that facilitate the exploitation and development of personal talents (Schweyer, 2010).

The levers are organizational and technological settings that a company must adopt to support and facilitate the exploitation of SW principles, namely:

- Job management policies: companies need to adopt appropriate guidelines to facilitate SW implementation, positive perception, and appreciation by workers. This includes policies to facilitate temporal and spatial flexibility of work (Kossek and Friede, 2006). For SW, this doesn't necessarily imply moving all jobs away from the offices to workers' homes, but rather a careful selection of what working style and location can be the most fruitful for each specific job and worker, depending on their peculiar characteristics (Lake, 2016).
- Physical layout: for SW, providing the best physical conditions is the main goal. According to Myerson and Bichard (2010), this implies designing a worker's office space in a way that facilitates the "4 Cs", i.e.: collaboration, concentration, communication, and contemplation. When workers work at home, it becomes essential that the characteristics of their home-office be consistent with these goals (Lake, 2016).
- Leadership: in a new environment where workers must interact at a distance and have a high degree of autonomy, new management styles are required (Cascio, 2000) for leading companies, company departments, or even project teams.
- Digital communications: as mentioned, SW is not simply working from remote, but indeed digital communication technologies are at its core (Vescoukis et al., 2012, Jacobs, 2004). They allow workers to be dispersed but still be able to accomplish work effectively and efficiently (Fisher and Fisher, 2001) across time, geography and culture (Bailey and Kurland, 2002; Kurland and Bailey, 1999). The "new generations" of ICT applications have further raised the expectations for a "revolution in the office" (Messenger et al., 2017). Companies which are more

prepared to digitalization may find it easier to implement SW (Fletcher and Griffith, 2020), although the great variety of systems, platforms, and applications, implies appropriate selections and implementations in relation to the characteristics of each job, worker, and remote office place. In addition, remote communication can impact on the ways of interacting and “socializing” among colleagues and can also affect working performance.

#### **2.4 Perception of the users**

Recent studies show that the perception of users counts in the implementation of SW. For example, drawing inspiration from the popular Technology Acceptance Model, Ollo-Lopez et al. (2020) argue that the success of SW ultimately depends on the acceptance by users, and this, in turn, is associated to their perceptions of usefulness and ease-of-use of this working modality in their specific case.

These perceptions can depend on how the single individuals see their working experience in combination with their personal expectations and private lifestyle, and also on local conditions (including e.g., working organization, legislations, and also cultural or social features – Peters et al., 2016) that can contribute to shape these individual perspectives.

### **3 Research questions and methodology**

The main goal of our study is to address the following research question:

*RQ: to what extent is WFH closed to the “ideal” model of SW as indicated in the previous section?*

A survey was conducted to analyse the people’s experience when they were working from home during the COVID-19 outbreak. The fundamental idea is that this “forced” condition, in which workers had suddenly to change their working habits and adopt WFH with no particular organizational measures or implementation plans by employers, better allows to examine if WFH can become a SW modality “automatically”, i.e. it directly reflects the principles and implementation levers that are considered essential for a successful implementation of SW. In other words, the purpose is to assess “how smart” is WFH.

An online questionnaire was administered during the lockdown of 2020 (March-May 2020) in Italy and other countries. Here, data of Italian workers are

presented. 932 responses were collected. The questionnaire included 23 questions (mostly closed) concerning opinions about their experience of WFH, use of digital technology, modality of working, perceptions of usefulness and problems, and also some essential demographic data. Anonymity was guaranteed. Further information about the questionnaire, its aim, theoretical background, and validation of the single questions, can be found in Ipsen et al. (2020) and Bolisani et al. (2020). The largest part of the questions required a response based on a 5-point Likert scale. The survey was promoted through the personal network of the authors and by using a “snowball technique” (i.e. respondents were also asked to invite their friends to respond to the survey – Baltar and Brunet, 2012).

For this reason, this is a convenience sample with some bias. The adopted method made it possible to collect a relevant number of responses which provided an interesting picture of the investigated matter. Also, responses mainly came from knowledge workers whose job has intellectual or clerical contents, which are generally the main target of SW implementations.

## 4 Findings

### 4.1 Essential demographics

In terms of age, the sample has a balanced representation of working-age population (table 1). As for the educational background (table 2) and the kind of job (table 3), it is confirmed that the sample mainly covers knowledge workers.

Table 1: Age classes and gender of respondents

	Age classes				
Gender	21-30 years	31-40 years	41-50 years	51-60 years	> 60 years
Females	44 (4.7%)	84 (9.1%)	138 (15.0%)	96 (10.4%)	15 (1.7%)
Males	74 (8.0%)	155 (16.8%)	175 (19.0%)	106 (11.5%)	35 (3.8%)

Table 2: Sample composition by educational background

Diploma	Respondents	Percentage
Middle school	8	0.9%
High school	252	27.3%
Professional diploma	33	3.6%
Bachelor's degree	123	13.3%
Master's degree	461	49.9%
PhD	37	4.0%
Other	10	1.0%

Table 3: Sample composition by kind of job (note: more than one response was admitted)

Kind of job	Respondents	Percentage
Clerical work	208	22.3%
Research and development	65	6.9%
System planning and modelling	88	9.4%
Management	157	16.8%
Communications	20	2.1%
Teaching and training	50	5.3%
Sales	103	11.1%
System control and management	77	8.2%
Operations	131	14.1%
Creative works	3	0.3%
Other	25	2.6%

#### 4.2 Changes in work modality

The entire sample regards people that were asked to work from home: 80% of respondents declared they worked only at home during the lockdown, and the rest (20%) declared they worked at least sometimes at home. Almost 90% of the sample affirmed that they worked for home because they were simply ordered to do so or because of a quarantine condition. Table 4 shows that, for the large majority of respondents, WFH was substantially a novelty. Table 5 displays the differences between jobs, confirming that even for this sample some activities require presence in a laboratory, operations site, plant, etc. This not only includes operational activities or system control, but also highly knowledge-intensive work (e.g., R&D activities) that is, however, connected to the use of special equipment and cannot be conducted from remote. Similarly, it is notable that other

intellectual activities like management (e.g., executives, plant managers, project managers) still required some presence in the office.

Table 4: WFH before COVID

	<b>Respondents</b>	<b>Percentage</b>
Never worked at home	639	68.5%
Max 2 days per week	168	18.0%
More than 2 days per week	125	13.4%

Table 5: Intensity of WFH in connection to job

<b>Kind of job</b>	<b>Always WFH</b>	<b>Sometimes WFH</b>
Clerical work	84.6%	15.4%
Research and development	76.9%	23.1%
System planning and modelling	87.5%	12.5%
Management	73.3%	26.7%
Communications	95.0%	5.0%
Teaching and training	90.0%	10.0%
Sales	90.3%	9.7%
System control and management	77.9%	22.1%
Operations	71.7%	28.3%
Creative works	100.0%	0.0%
Other	92.0%	8.0%

The effects on working routine are summarized in table 6. Results represent the average score in a 1-5 Likert scale, where 5 indicates that respondent strongly agreed with the statement. It results that, for the majority of cases, work was considered the same demanding as before (average score 3), and with a comparable productivity, though with more working hours. No problems were signalled regarding the preparation to WFH and the lack of physical contacts with colleagues.

Table 6: Effects of WFH on working routines

	<b>Average</b>
I am working longer than usual	3.42
I am achieving less results than usual	1.98
WFH is more demanding	3.00
My past working experience/education knowledge make me feel prepared to WFH	4.10
I can still keep good relations with colleagues	3.90

As regards how demanding is WFH, there were some differences between those that had experienced WFH before COVID and those that never had, but these differences were not marked. For example, those that declared that there was no significant change in their work routine were 41.6% of those that had some previous WFH experience and 36.6% of those that had none. Actually, it seems that there is some learning effect, given that the perceived problems in working from home tended to reduce the longer the workers had used this modality during the lockdown (table 7). Table 7 is interesting because it shows that, while workers can learn how to work from home, this also implies that they tend to work more - or more intensely - once they learn how to exploit this modality.

Table 7 Effects of learning (average score)

<b>Days of WFH during the lockdown</b>	<b>WFH is more demanding</b>	<b>I fear my results will be insufficient</b>	<b>I need data that I don't have access to at my home</b>	<b>I am achieving less results than usual</b>	<b>WFH is more intense or complex</b>
1-15 days	2.70	2.57	2.86	2.07	2.28
16-30 days	2.90	2.44	2.47	2.41	3.17
31-50 days	2.92	2.04	2.11	1.96	3.00
>50 days	3.16	1.83	1.92	1.81	3.20

In any case, the condition of WFH results to be substantially neutral, given that, in a Likert scale from 1 to 5, the responses of all the various groups to the question "how demanding is WFH" tend to centre around the average value (3), with very slight differences between gender or age (table 8).

Table 8: Differences by gender (average score)

	<b>Age classes</b>			
<b>Gender</b>	<b>21-30 years</b>	<b>31-40 years</b>	<b>41-50 years</b>	<b>&gt;50 years</b>
Females	2.86	2.92	3.15	3.12
Males	2.90	3.00	2.96	3.10

#### **4.3 Technology and communications**

The sample intensely used a range of different technologies, not only simple communication systems, like e.g., email or SMS, but also more complex systems,

like social media platforms and groupware systems, in a mixed combination. Videoconferencing resulted one of the most employed communication technologies. Table 9 shows the average intensity of use by respondents measured in a 1-5 Likert scale.

Table 9: Use of communication systems

<b>System</b>	<b>Average</b>
E-mail	4.42
Shared online folders	4.00
Videoconferencing	4.00
Facebook	1.20
Other groupware systems	2.80
Phone calls	3.80
Chat apps	3.40
SMS	1.56

Table 10 shows the number of contacts that respondents were able to keep daily. Clearly, these numbers can depend on the kind of job, but on average it is likely that, probably thanks to the multiple systems adopted, WFH did not limit interactions with colleagues and other business partners, as confirmed by the fact that respondents indicated, as previously seen in table 6, that they had no particular problems in keeping good relations with colleagues.

Table 10. Number of contacts per day

<b>N° of contacts per day</b>	<b>Respondents</b>	<b>Percentage</b>
1-4	220	23.4%
5-9	319	34.0%
10-19	269	28.6%
> 19	130	8.0%

#### **4.4. Perceived benefits and drawbacks**

Table 11 shows the perceived benefits of WFH workers. It reports the average 1-5 Likert scale of respondents. The main benefits regard more personal life than working modality.

Table 11: Perceived benefits

<b>Benefit</b>	<b>Average</b>
Time saved to reach office	4.52
Preparing and eating own meals	3.92
No distractions	3.78
Staying with family and friends	3.60
Changing routines	3.56
Having a break whenever one likes	3.36
Doing work for which there is no time normally	3.32
Enjoying home atmosphere	3.14
No need for long meetings	2.92
Easier contact with others	2.60
No control	2.20

Table 12: Perceived drawbacks

<b>Drawback</b>	<b>Average</b>
Discomfort to be stuck at home	3.56
Feeling stuck to a computer	2.97
Limited interactions with colleagues	2.81
Less physical exercise	2.58
Discomfort to be without an office routine	2.47
Necessity of special equipment	2.44
Inappropriateness of home as office space	2.29
Lack of documents or data	2.15
Feeling disturbed by people at home	2.15
Less interesting work when at home	2.06
Feeling that work at home is unproductive	2.05
Feeling that some tasks can't be fruitfully performed at home	2.30
Difficult concentration when alone at home	1.67
Missing benefits of office work	1.58
Lack of directives	1.41
Financial problems	1.36

As regards the drawbacks (table 12), it is interesting to note that the average scores are lower than those of the perceived benefits, which confirms the substantial appreciation for WFH. It is worth noting that respondents affirmed that at home they were able to be really productive, especially because they were

able to stay focused without the risk to be disturbed. Is also worth underlining the fact that the lack of directives is not perceived as a problem, which seems to confirm that our sample includes individuals who are able to work autonomously, as knowledge workers are.

## **5 Discussion**

A key point is the large majority of the sample thought they were working more at home (or, at least, not less than at the office), both those who declared they considered WFH more challenging and those who did not. Apparently, for those who felt WFH less challenging, having longer working times (with no waste of time in commuting or in distractions) was an opportunity to accomplish more goals. Those who felt WFH more challenging, may have needed to work more to keep the pace with the requirements of their job. In both cases, all this may confirm that WFH tends to lead to a certain degree of self-control and exercise of autonomy, where the people feel engaged with what they are doing – which is a key principle of SW.

Another point is that the majority of respondents felt that they already had enough knowledge and competence for WFH. This may signal that, for most tasks of knowledge workers, work is already well organized in a way that is compatible with WFH. Clearly, experience and learning can help, as the data confirm.

The relationships with colleagues apparently did not suffer. This may confirm that it is still possible to work at a distance, without continuous contacts with colleagues. This may be explained by the fact that offices are not necessarily a place for personal relationships, and that the people can work together remotely once a sufficient trustworthy climate has been created – which is also in line with the principles of SW.

In any case, although the sample mostly included knowledge workers, i.e., people who have intellectual tasks, this category comprises completely different kinds of jobs. Some may still require the use of special equipment (like, e.g., highly specialized R&D activities, or the management of complex systems or plants), and working remotely may be hard. Executives and management positions may also require some work in the office, to better exercise a control over the activities for which they are responsible.

The variety of communication tools that are now available facilitates the exchange of the knowledge that is necessary for the people to work. In the case

under scrutiny, however, these technologies were more a mix of general applications, already available to people, who can choose what is best for each specific communication.

Finally, as regards work-life balance, beyond the appreciation for some small comfort, apparently WFH did not lead to radical changes. A point to note is that the adoption is neutral regarding age or gender.

## **6 Conclusion**

Coming back to our research question ("to what extent is WFH closed to the ideal model of SW?") the results provide contrasting indications. Firstly, it can be affirmed that WFH has partially some points in common with the characteristics of the SW model depicted in the literature. The principles of personal responsibility and mutual trust between colleagues are apparently the same as those that WFH requires. Similarly, the data show that WFH workers perceived similar benefits (for example, autonomy of organization and home comfort) and drawbacks (e.g., sense of isolation and fear to be stuck at home with a computer) that may be expected in the case of SW. Instead, no clear indication regards the main characteristic of SW, which is spatial and temporal flexibility. In particular, as regards spatial flexibility, WFH simply replaced office with home and no other places.

As regards SW levers, WFH workers showed a high use of communication technologies of many kinds. What is notable is that workers used a mix of generic applications rather than platforms specifically designed for SW. This may also explain why no particular adoption problem was signalled and is also an important message for companies willing to implement SW modalities. As for physical layout, as mentioned WFH just employs homes as office spaces. In SW, instead, the idea is that workers can work wherever they like, so that they can exploit their potential and talent: office space thus becomes an ingredient itself of work. Therefore, it is not a matter of moving work to personal homes: measures to make this process easy and comfortable can be necessary. In this regard, the survey shows contrasting results. On the one hand, for many workers being at home was comfortable, but no particular emphasis was generally put on this. For some, instead, being stuck at home was a problem. In conclusion, simply adopting WFH (like in the "forced" way we experienced during the lockdown)

without appropriate measures and interventions in the home space is not a guarantee of full benefits and appreciation of SW.

Finally, the data show that, contrarily to what can be expected, not all knowledge work (and/or not for every time) is suitable for WFH and SW. Therefore, companies willing to adopt this modality must be flexible, which implies that different approaches must be adopted for the different workers and no standard solution should be adopted. This can raise the prospects of success but, also, makes the management of work more complex.

As a final remark, it can be said that, on the one hand, companies willing to adopt SW cannot simply move workers to their homes. On the other hand, the pandemic has shown that many workers have easily learnt the appropriate way to manage part of their work from home, and therefore some possible barriers to SW can be more easily overcome in the future.

The study is not without limitations. The most relevant ones are that a non-probabilistic sample of respondents was used - which could limit the generalizability of results - and that answers of respondents were affected by the particular conditions due to the lockdown.

### **Abstract**

The COVID-19 pandemic forced knowledge workers to switch from company offices to working from home. This switch was abrupt and needed to be conducted without preparation making it potentially challenging particularly to those with little previous experience working from home. Against this backdrop, our study examines what kind of job crafting, i.e. proactive modification of one's work practices without formal approval, can help in dealing with enforced working from home among knowledge workers. The

results of the study illuminate different ways physical, relational, and cognitive crafting can be leveraged when adapting to such a situation. Findings also raise questions whether current rigid theoretical distinctions between job and leisure crafting are sensible in the remote work context as work-life boundaries blur both spatially and temporally.

**Keywords** – job crafting, remote work, work-life balance, COVID-19, public sector

**Paper type** – Academic Research Paper

## 1 Introduction

The COVID-19 pandemic resulted in social distancing measures that forced companies to find new ways to continue operations despite the extraordinary situation (O'Connor et al., 2021; Tuzovic & Kabadayi, 2021). This increased the prevalence of remote work at an unprecedented scale: many who previously did little remote work were suddenly working fully remotely (Eurofound, 2020; Parker et al., 2020). The transition was abrupt and undertaken with little preparation (O'Connor et al., 2021).

It is questionable whether lessons from previous research on remote work can be leveraged as guidance due to the highly distinctive features of COVID-19 induced remote work: remote work was not a voluntary choice, it touched all parts of an organization rather than a predefined group, and mobility overall was restricted (Waizenegger et al., 2020). Waizenegger et al. (2020) even suggest that one should not even talk about remote work but use a different term — enforced work from home (EWH) — to highlight the distinctiveness of the current situation.

The rapidly growing body of research on the implications of COVID-19 to organizations and knowledge workers offers insights into organizing, and especially how management and leadership behaviour needs to be adjusted (Bartsch et al., 2020; Kirchner et al., 2021). Such management-oriented focus is logical as organizing and the ways of working are often determined by those in a leadership position (Parker et al., 2017). However, following the established notions by Alvesson (2001) and Davenport (2015) regarding knowledge work, freedom to promote individual habits is central for enhanced task performance. Thus, management should focus on promoting knowledge workers' independence through nurturing their creativity, well-being and self-efficacy (Drucker, 1999) also in the context of EWH.

This independence can be exercised through employees' proactive modification and adaptation of different aspects of their work without formal approval. This is referred to as *job crafting*, that is, proactive behaviour of individuals to modify different aspects of their work for better fit with one's personal characteristics and preferences (Wrzesniewski & Dutton, 2001; Tims et al., 2013; Lazazzara et al., 2020). Autonomy and the possibility to modify one's job has been observed to support in dealing with the pandemic, but compared to the managerial perspective the phenomenon has been studied less (Kuntz, 2020). In addition, job crafting has not been studied specifically in the context of knowledge work and, more importantly, it has seldom been explored in the context of remote work. A few recent studies have, for example, explored the relationship between job crafting and stress reducing behaviour (Ingusci et al., 2021) and the relationship between job crafting and job engagement (Constantini & Rubini, 2021), but the forms of job crafting have been left outside the scope in these studies. The present study aims to contribute to this emerging research area by examining the role and practices of job crafting among public sector knowledge workers at the early stages of EWH during the COVID-19 pandemic. The specific research question of the study is: "What kind of job crafting knowledge workers suggest for dealing with enforced work from home during the COVID-19 pandemic?"

## **2 Theoretical Background**

Job crafting refers to self-initiated activity that employees engage in to modify the characteristics of their jobs to better fit their personal knowledge, skills, abilities and motivations (Wrzesniewski & Dutton, 2001). Research on job crafting has identified various positive benefits related to this activity, including work engagement (e.g., Bakker et al., 2016; Demerouti et al., 2015), organizational commitment (Ghitulescu, 2007) as well as job performance and satisfaction (Leana et al., 2009).

Job crafting can be directed towards the task (task crafting) or the relational aspects of the job (relational crafting), or it can involve changes in the cognitive orientation towards the job (cognitive crafting) (Wrzesniewski & Dutton, 2001). When engaging in task crafting, individuals make changes to the scope and nature of the tasks, for example, through taking on new responsibilities or requesting more autonomy (Tims et al., 2015). Relational crafting on the other

hand concerns the social domain of work and refers to alterations regarding with whom one interacts and the quality of interaction with others at work, for example, through avoiding contact with emotionally demanding colleagues (Wrzesniewski & Dutton, 2001) or creating new collaborative relationships (Berg et al., 2013). Cognitive crafting involves the changes in how an individual employee perceives and makes sense of his or her job (Wrzesniewski & Dutton, 2001). For example, an individual may engage in cognitive job crafting by reframing the purpose of their job to achieve meaningfulness at work (Geldenhuis et al., 2020) or cognitively emphasizing the positive aspects of their job (Vuori et al., 2012).

Job crafting approaches have been further divided into approach crafting and avoidance crafting (Brunner & Campion, 2018). Approach crafting refers to active efforts toward improvement-focused goals to enrich and expand boundaries of the job (Brunner & Campion, 2018; Zhang & Parker, 2019). Avoidance crafting, on the other hand, focuses on reducing and limiting dimensions of work that are stressful such as avoiding straining interactions or making demanding work tasks easier to perform (Bipp & Demerouti, 2015).

The concept of *leisure crafting* has been used outside the job domain to how craft their free time (Berg et al., 2010; Petrou and Bakker, 2016). Leisure crafting is defined as the proactive pursuit of leisure activities targeted at goal setting, human connection, learning, and personal development, which foster a sense of meaning (Berg et al., 2010). Demerouti et al. (2020) have further suggested *home crafting* to signify the balancing of home demands and resources with personal abilities and needs to experience meaning. In the extant literature, job crafting and leisure/home crafting have been discussed as taking place in completely different life domains, however, relations between these activities have been identified. According to earlier work, leisure crafting is, for example, used to compensate for limited crafting opportunities in the work domain (Petrou and Bakker, 2016) and that it supports the pursuit of occupational callings in the free time that are difficult or impossible to incorporate into one's job (Berg et al., 2010). A recent study by Abdel Hadi et al. (2021) demonstrates the effectiveness of leisure crafting in counteracting emotional exhaustion in remote work during the Covid-19 pandemic. Demerouti et al. (2020) found that individuals engaging in job crafting employ similar approaches in crafting the home domain.

What has so far been left outside these discussions is the blurring of the work and leisure/home domains in the context of remote work from home and the

opportunities this creates in terms of job crafting. Sturges' (2012) indeed acknowledges work-life balance as a domain of crafting. Building on the job crafting dimensions identified by Wrzesniewski and Dutton (2001), Sturges (2012) categorizes work-life balance crafting into physical crafting, cognitive crafting and relational crafting. Cognitive crafting refers in this context to the definition and framing of what work-life balance is and relational crafting to the management of social relationships in a way that enables the achievement of the desired work-home balance (Sturges, 2012). Physical crafting, on the other hand, refers to the crafting of the physical dimensions of work, including the time spent on working, the location of working, choosing the employer and time spent on traveling to work. Remote working (locational crafting) thus represents in Sturges' (2012) study a form of work-life balance crafting, not the object of crafting itself.

Against this background, utilizing the theoretical lens of job crafting our study explores what kinds of suggestions knowledge workers in the field of public administration provide for dealing with enforced work from home caused by COVID-19 pandemic. We presume that explicitly communicated advice and hints are based on personal experiences of practices and ways of working that individuals have found to well fit the new conditions—i.e., results of job crafting. We pay attention especially to how the blurring of the work and leisure/home domains is reflected in the suggestions since further research on this topic seems particularly warranted.

### **3 Research Material & Methods**

The study is based on a larger online survey that was distributed to Finnish knowledge workers from early April to late May 2020, three weeks after the Finnish government made working from home mandatory to all public administration employees whose job role afforded it. The goal of the survey was to understand the changes pandemic brought to respondents' work through nine open-ended questions that probed issues like emotional responses and organizational support.

This paper concentrates on data from responses to a single open question "What kinds of tips for remote work would you give to others in your organization?" since it specifically aimed to understand what kinds of volitional changes switch to remote work entailed. Respondents with strong former experience of remote work (used to working remotely more than one day a week

before the pandemic) were omitted from the dataset. This choice was driven by the assumption that respondents without earlier experiences did not yet have well-established remote work practices and thus were particularly likely to have engaged in crafting due to the pandemic and EWH. Further, we focused our examination on those respondents who reported to work in the field of public administration, as we were particularly interested in the knowledge worker perspective, which public administration workers represent (Fischer, 2020). Also, for public sector workers EWH was mandatory at the time, which was not the case for those working in the private sector. Because of this, they were particularly fitting group to study.

After empty and unintelligible answers were removed from the data, 389 responses remained. The analysis process as a whole followed was explorative and followed an abductive logic (Dubois and Gadde, 2002). Content analysis proceeding from open to axial coding was conducted (Bryant & Charmaz, 2019) to gain an understanding of what kind of job or leisure crafting-related suggestions respondents voiced. Early on in the coding process, it was observed that job crafting models seemed to fit the data well, especially when supplemented with the leisure crafting perspective. While some responses dealt with other issues like top-down job design (Parker et al., 2017), only 15% of the content in responses related to issues outside job or leisure crafting. This suggested that the open question succeeded well in capturing how knowledge workers could proactively modify and adapt different aspects of their work. It also suggested that job crafting was a suitable theoretical lens for analysis.

As the analysis work progressed, different crafting frameworks were explored for structuring the data including Zhang and Parker (2019), Wrzesniewski and Dutton (2002), and Sturges (2012). After an iterative process, the general categorization of Sturges (2012) which divides crafting into physical, cognitive, and relational crafting was found to be the best fit for our data. While her framework was originally developed for examining work-life balance crafting, it seemed to explain our data better than traditional job crafting categorizations, such as those proposed by Wrzesniewski and Dutton (2001) or Zhang and Parker (2001). Considering also the fact that the context of work in the present case was enforced work from home, this observation makes intuitive sense as well. Due to the breadth of our data, we decided to further divide physical crafting behaviour into three subcategories: temporal crafting, which takes inspiration again from Sturges (2012) model; task crafting, which is a part of the original job crafting

categorization of Wrzesniewski and Dutton (2002) and environmental crafting, which is a new category that emerged in our data. For the other two main crafting categories of cognitive and relational crafting sub-categorization was not perceived necessary.

## **4 Results**

The results are organized based on the crafting categorization of Sturges (2012). First, we discuss physical crafting, then proceed to cognitive crafting and finally, relational crafting.

### **4.1 Physical crafting**

In general, suggestions related to physical crafting were more prevalent and detailed in the data compared to other forms of crafting. Because of this, our examination of this crafting type is slightly richer than the other forms.

#### *4.1.1 Task crafting*

Task crafting (Wrzesniewski & Dutton, 2001) was represented in the responses particularly from the perspective of work planning and utilizing new technology. Respondents suggested paying attention to putting effort into making plans, schedules, TODOs and achievement lists rather than doing ad hoc decisions on what to work on.

*I've started making myself a list, where I mark daily all the work I've gotten done, so that the feeling of accomplishment and progress remains when I'm off work. (Informant #59)*

Many also had suggestions regarding the use of digital technologies at work. These tips tended to fall under two categories. The first was leveraging new tools in general. The focus on the suggestions was especially in video and teleconferencing solutions as well as break exercise apps. The second category of tips addressed strategies for dealing with information systems under high load. In particular, respondents suggested trying to time use of such systems during hours when the number of users would be lower, downloading files to one's computer beforehand and just to take into account the fact systems might be working slower when one needed to access the data.

*Make sure beforehand that you have access to necessary databases, documents etc. or stored to your computer / usb-stick if network connections get overloaded or disconnected. (Informant #33)*

#### 4.1.2 Environmental crafting

Physical crafting behaviour present in the data was also addressing the physical environment where one was working. Suggestions discussing this topic could be divided into two broad categories: ergonomics and physically enforcing work-life separation

In terms of ergonomics, respondents underlined the importance of paying attention to workstation ergonomics and posture while working. More concretely, suggestions included acquiring proper digital equipment like displays, noise-canceling headphones, mouse, keyboard etc., rather than simply working with one's laptop. Infrastructure like having a good internet connection was also mentioned as was making sure that one had proper office furniture, including a good table and working chair.

*It's good to have a workstation that you use. Heights (chair & table) to right levels, lightning also. I cleared the work desk I had integrated to my bookshelf so now I have a proper surface where laptop, one big screen, keyboard, mouse with mousepad, headphones and a notepad fit. My wheeled work chair is also in its proper use and not under a pile of clothes. (Informant #21)*

Many respondents also emphasized that it was critical to try to physically enforce work-life separation to prevent the boundaries of the two blurring in a problematic way. Concrete suggestions included completely closing laptops and phones when one finished the workday or even hiding them all together out-of-sight so that their presence would not remind one about work or challenges related to it.

*When work hours end, it's good to put your work equipment away and not to touch them during leisure time. It can be difficult and work things remain in your mind, when they are present in the same space during leisure time. (Informant #53, regular employee)*

Other tips were given too, including trying to dedicate certain spaces to work or leisure specifically, to create a clear divide between the two.

*You should not work in a place where you're used to doing something else (bedroom, living room, hobby room etc. (Informant #32)*

People also proposed creating rituals for starting or ending work. One could, for example, end the workday by going outside to exercise to create a strong symbol for the workday ending. For some respondents, such rituals seemed to represent the building of work-life boundaries. However, this was not always the case. Others saw rituals as positive habits that helped to start orienting to working.

*I change into "work jeans" every morning and put on a nice shirt, so that I feel like I'm going to work. (Informant #49, regular employee)*

#### 4.1.3 Temporal crafting

Suggestions related to temporal crafting were particularly strongly represented in the data. Many respondents emphasized the importance of creating a meaningful rhythm to working. For some, this meant instilling one's personal needs and desires into the work routine and taking advantage of the fact that work and leisure environments were not spatially separated as they normally were. Informants were suggesting utilizing lunch break to go exercising, spending time with family or even cooking or cleaning during meetings.

*Blend work and leisure time by having breaks, where you cook in your own kitchen or clean your terrace. Things you cannot do on office breaks. (Informant #67, supervisory position)*

Others proposed adapting oneself to external factors, by for example working outside regular hours to avoid having to access databases etc. when they were under the biggest usage load and worked slowly. There were also those who recommended keeping the same temporal routine that one had when working at the office to create continuity between the "normal" and "new normal".

*I've noticed that trying to preserve the same rhythm as at the office works for me. I start and end work around the same time as I normally would. I have coffee, lunch etc. breaks and try to remember to do some break exercising sometimes too. (Informant #94, supervisory position)*

While some recommended taking advantage of the possibilities that working from home enabled in terms of creating work-life synergies, others suggested paying particular attention to enforcing temporal work-life separation. EWH was seen as a situation, where the job easily took over and work-life boundaries become hazy. To combat this, one should set time limits to working and avoid working overtime.

*Having a schedule is important both for work and for breaks. You gotta make sure that work and leisure time don't get mixed (Informant #207, regular employee)*

*Hold on to working hours always when possible. And when you stop [working], close skype and email. Otherwise work just goes on and on... (Informant #153, supervisory position)*

#### **4.2 Cognitive crafting**

Suggestions for cognitive crafting were present in the data both from avoidance and approach crafting perspectives (Brunning & Campion, 2018). Many respondents argued that the pandemic situation was by nature such that it created problems and challenges that one couldn't influence, and thus it made sense to simply avoid stressing. Suggestions included being merciful to oneself, accepting slower performance from oneself and others. Some also underlined that work is not the most important thing in the world, especially in the present situation.

*There's never such a hurry with a task that it should be prioritized over own health and well-being. While remote working one is allowed to and should work slowed if technical problems or bad ergonomics require more time / breaks (Informant #27, regular employee)*

Trying to relax mentally and not worrying about things out of one's control were also considered important by the informants. Some also specifically underlined how it is important to make a distinction between issues that are one's own task to solve and those that are the responsibility of the organization.

*Enjoy long mornings without commutes and have breaks. Things you cannot influence you shouldn't worry about. If for example network connections don't work, it's employer's problem, not yours (Informant #117, supervisory position).*

As exemplified in the previous quote, some informants also emphasized how important it is to try to look at the situation positively. It was mentioned that one should appreciate the fact that the requirement to work remotely meant increased freedom and autonomy.

*Now you can also enjoy your own ways of working, for example play music in the background, have breaks based on your own rhythm or even eat garlic without bothering anyone. While working remotely, we all have individual*

*surroundings to work and now it is possible to enjoy those positives.  
(Informant #42, regular employee)*

Further, some mentioned that in EWH, the normal distractions that are present at the office are not necessarily present at home, meaning an increased possibility to do concentrated work. It also provided opportunities for learning that would be difficult to seize under normal conditions.

*Look for information and training related to work that you would not have time to search and learn amidst normal routines! (Informant #210, supervisory position)*

### **4.3 Relational crafting**

Informants' recommendations related to relational crafting were particularly addressing social needs that one might have through leveraging and fostering work relationships. People were suggested to take time for having informal discussions and share things that went outside one's work.

*Give your colleagues more about yourself than just the "work you" and share to your whatsapp group pictures of the house plants you talked about during winter, tell about good recipes that you've tried and share or ask tips about good books. Your workmates are at the moment the only people you can connect with almost daily so respect and acknowledge them. (Informant #12, regular employee)*

In terms of concrete practices, organizing or attending virtual coffee breaks and reaching out to colleagues even without reason was particularly prevalent in the data. This seemed to be tied with looking after one's colleagues and maintaining a sense of togetherness both personally and within the organization in general.

*You should from time to time just contact your colleagues just to contact them, this way you preserve a feeling of belonging to some community.  
(Informant #23, regular employee)*

Further, there were also those who emphasized the importance of leveraging out-of-work relationships and putting particular effort into interacting with one's close ones.

## 5 Discussion

### 5.1. Theoretical implications

The present study does several contributions to the discussion on job crafting and knowledge workers' coping methods to enforced working from home (Lazazzara et al., 2020). Coping refers to resilience and adaptivity as an individual attribute, but it builds organizational capability too (Okkonen 2021). In general, the study contributes to the discussion on knowledge worker performance and how it is constituted by individual freedom to define the framework for working, i.e. environment, conditions, temporality, and approaches. The autonomy in knowledge work is also about how job and leisure are designed and connected, and the autonomous management of this interface is a dimension of knowledge work this study has also explored.

More specifically, the present study contributes to the discussion on job crafting (Lazazzara et al., 2020) by questioning the traditional defining characteristics of job crafting that modification efforts focus on the job especially (Zhang & Parker, 2019). Crafting behaviour outside work has been analytically separated into its own construct, leisure crafting (Petrou and Bakker, 2016), work-home balance crafting (Sturges, 2012) or home crafting (Demerouti et al., 2020). However, the results of the present study illuminate how knowledge workers recommend creating synergies between work and leisure time as a way to make EWH more sensible. Is using break time to clean one's terrace job or leisure crafting or something else? Technically, one could argue that it is not job crafting, because the act does not directly modify the characteristics of one's job, particularly its task-related or relational boundaries, which is the basis of the definition of job crafting by Wrzesniewski and Dutton (2001). On the other hand, such behaviour does modify the temporal experience of one's working day to better-fit one's preferences, making the interpretation that the act is indeed job crafting sensible. These kinds of overlaps and "grey areas" between work raise questions about whether a rigid analytical distinction between leisure and job crafting is advisable, at least in the EWH context. While earlier research has explored the relationship between job crafting and leisure/home crafting and found that individuals engage in similar crafting approaches in the work and home contexts (Demerouti et al, 2020), blurring of the crafting practices within these different domains has not been previously addressed.

The findings of the present study also lend support to recognizing environmental crafting as a category of crafting. In previous literature, modifying one's work environment has not been widely accepted as a form of job crafting, since it too fails to fulfill the traditional definitions of job crafting (see Wrzesniewski & Dutton, 2001). However, some scholars have suggested that such limited perceptions are not necessarily warranted and suggested that time and spatial dimensions of work should be incorporated into the concept of job crafting particularly in the context of knowledge work where flexibility in terms of when and where to work is prevalent (Wessels et al, 2019). In these studies, spatial crafting typically refers to the choosing of the location of work (Sturges, 2012; Wessels et al, 2019). The results of the present study point in the same direction, but deepen the concept of spatial crafting with the concept of environmental crafting, which refers to more micro-level modifications to the work setting. In our data, environmental crafting emerged as a significant type of crafting, suggesting its importance especially when crafting is used to cope with transitioning to enforced working from home. It could be expected that environmental crafting is particularly relevant when working from home, as in such a situation, employees have greater power to influence their surroundings compared to the regular office context. Further, they also have less automatic support from the organization as workstations, tables and chairs are seldom automatically provided and maintained.

Finally, the findings of the present study contributes to previous literature by providing further information on what kind of crafting behavior is used to foster work-life balance. Previous literature on the topic noted how employees preserve work-life balance by selecting a suitable employer, job or project, customize their definition of work-life balance to fit their situation and manage work relationships to preserve good work-life balance or perception of it (Sturges, 2012). The present study extends this discussion by illuminating previously unrecognized ways to enforce work-life separation and synergies. In terms of temporal crafting, respondents created separation by setting time limits to work as well as avoiding working overtime and generated synergies by fostering a fitting rhythm between work and break time, by doing chores, spending time with family or other leisure activities, etc. In terms of physical crafting, respondents were creating rituals to start/end the workday and closing and hiding their work equipment to help ensure one didn't think about work outside working hours. These results provide more depth to our current understanding of the practical ways employees

engage in fostering work-life balance, thus answering calls in previous research (Sturges, 2012).

## **5.2. Limitations and future research directions**

The present study includes certain key limitations, which are critical to recognize. The first one relates to our somewhat unorthodox method of studying job crafting. Traditionally the topic is examined with cross-sectional quantitative surveys (Zhang and Parker, 2019) or in-depth qualitative studies based on interviews, ethnographies or similar (Lazazzara et al., 2020). In our study, neither of these traditions were closely followed, as our dataset consisted of qualitative answers to an open question in a longer survey, analysed with an abductive process (Dubois and Gadde, 2002). Due to this choice, our approach did not enable us to clearly measure the effects of crafting behaviour on well-being or performance, nor gain a deep understanding of the intricacies related to specific crafting approaches and particularly the motives behind them. However, this choice enabled us to collect and use a much broader dataset in terms of informants and organizations compared to traditional qualitative research approaches, while still preserving the ability to get a more detailed understanding of the phenomenon in focus in practice, compared to traditional quantitative approaches. However, with this in mind, it would be interesting from future studies' perspective to try to measure quantitatively how the different job crafting suggestions relate to performance or well-being. Further, it would also be interesting to explore more deeply with qualitative research methods how the observed job crafting suggestions are enacted in practice. Examination of environmental crafting would be especially interesting since this area is currently particularly understudied.

The second key limitation of the study relates to the generalizability of the findings. In the present case, the informant sample consisted of knowledge workers working in the area of public administration. From this perspective, it could be argued that the results are not necessarily directly transferrable to other contexts, such as private companies. Thus, further studies in other contexts are warranted.

More studies of job crafting in the remote work context, in general, are needed too. So far research in this area has been sparse as remote work has merely been seen as one specific job crafting outcome. However, the results of the present

study suggest that in remote context job crafting, leisure crafting, and work-life balance crafting might be intertwined to the extent that separating them can be challenging. Future work is needed to theorize these interrelations further. It would also be interesting to examine what kind of job crafting approaches could be particularly beneficial in dealing with challenges of remote working, both from the perspective of performance and employee well-being.

### **5.3. Practical implications**

Our results lend support to two practical implications. First, it is notable how many suggestions provided by informants were contradictory: For example, some outlined EWH as an opportunity to experiment with new routines allowed by working from home. Others recommended transporting the established routines to home context to the point of dressing up as one would do for the office. This suggests that remote work-related job crafting might result in the proliferation of work practices. Management needs to be attentive to this process to ensure that heterogeneity in ways of working does not lead to unclarity in company values or issues in key work processes.

The second implication relates to the need for knowledge workers to engage in environmental crafting when working from home. When working in the regular office, companies tend to provide employees with workstations that are well-thought-out in terms of ergonomics, which helps to foster the physical well-being of organizational members. If remote working remains popular after the pandemic – as expected – it raises questions whether it might be smart for companies to transfer similar support to home context and go beyond just providing digital equipment like displays etc. Proper desks, chairs, access to ergonomics experts who can help fine-tune home workstations so physical strain from working is minimized might be a good idea particularly in the long run to ensure that the company workforce remains healthy and happy.

### Abstract

Although different studies investigated the SW phenomenon during last years and its evolution during the pandemic, reporting several benefits and advantages, there seems to be a lack of studies investigating whether and to what extent the SW can really impact on company's performance. It is not clear to what extent smart working, especially in the emergence phase, has impacted the organizations, at macrostructure level and at the micro structure level, and whether the SW may be considered as a leverage to achieve new, incremental productivity, both at "people" and "process" level. This paper develops a conceptual framework, built on a series of testable propositions about the impact of SW on the organizations and the characteristics of SW as leverage to improve productivity. Then, a questionnaire to empirically test our theoretical framework is presented. Each construct of the model corresponds a set of questions.

**Keywords** – smart working, remote working, survey, pandemic era.

**Paper type** – Academic Research Paper

## 1 Introduction

The development and diffusion of digital technologies (especially those supporting communication, collaboration and social networking), along with the pervasive dissemination of powerful and easy-to-use mobile devices, can support organisations in developing a Smart Working (SW) system (Ahuja et al., 2007). The organizational literature proposes different definitions of SW, each focusing on different key aspects related to this new working culture. According to the definition provided in 2008 by the Chartered Institute of Personnel and Development (CIPD) *"Smart Working is an approach to organizing work that aims to drive greater efficiency and effectiveness in achieving job outcomes through a combination of flexibility, autonomy and collaboration, in parallel with optimizing tools and working environments for employees"*. This definition reveals both the objectives of SW and the ways of organizing work in order to achieve them. Referring to the definition of the CIPD, McEwan (2013) proposes, years later, the following: *"Smart Working practices are agile, dynamic and emergent. They are the outcomes of designing organizational systems that facilitate customer-focused, value-creating relationships that are good for business and good for people"*. Finally, a sufficiently complete definition of SW is provided by the Smart Working Observatory of the Politecnico of Milan (2018): *"Smart Working means thinking about work from a different, clever angle. It questions the traditional links with working times and locations and gives people a greater say in defining their working conditions, while at the same time making them more responsible for the outcome. Autonomy and flexibility and giving people responsibility and trust are the bywords for this new approach to work"*.

This definition describes SW as a flexible approach in managing workplace, timetable, and technological tools, allowing employees to reach both greater professional efficiency and better work-life balance, through the increase of trust and autonomy, from the company towards the employees, in return for a greater responsibility and accountability on results.

Although the different contributions on the theme of SW present in the organizational literature have focused on specific key aspects characterizing SW, it is possible to identify three essential levers for the implementation of a complete and effective SW model (Birkinshaw et al., 2008; Elsbach and Pratt, 2007; Mann, 2012; Reyt and Wiesenfeld, 2015): organizational culture and managerial practices; ICT-based solutions; workplace.

A growing body of research that recently points to what post-pandemic working patterns may look like reported SM as a common practice due to the Covid-19 emergency. A recent article from Economist reported that "Before the pandemic Americans spent 5% of their working time at home. By spring 2020 the figure was 60%." (The Economist, 2021). In one paper José Maria Barrero, Nick Bloom and Steven Davis, three economists, survey thousands of Americans and conclude that, after the pandemic, the average employee would like to work from home nearly half the time (Barrero et al., 2021).

In Italy, before the crisis SW was adopted in formal and informal ways and involved 58% of large-sized enterprises, 12% of small and medium-sized enterprises, and 16% of the public administration (PA) sector, for a total of 570.000 workers (Smartworking Observatory, 2019). The situation has radically changed since March 2020 when, following the Covid-19 emergency and the need to implement social distancing rules, the Government issued the decree of March 1, 2020, de facto establishing, then extended with subsequent decrees, the possibility to apply SW to any subordinate employment relationship, even in the absence of individual agreements, until the end of July 2020.

In April 2020, according to the Ministry of Labour's data, a total of 1.827.792 workers resulted in SW mode, 1.606.617 of which were started following the epidemiological emergency (Ministry of Labour and Social Policies, 2020). For some companies it was an implementation on a larger scale of a working model already tested and used, for others it was a first experiment.

Although different studies investigated the SW phenomenon during last years and its evolution during the pandemic, reporting several benefits and advantages, there seems to be a lack of studies investigating whether and to what extent the SW can really impact on company's performance.

It is not clear to what extent smart working, especially in the emergence phase, has impacted the organizations, at macrostructure level and at the micro structure level, and whether the SW may be considered as a leverage to achieve new, incremental productivity, both at "people" and "process" level.

This understanding is important because SW requires investments by the companies, in technologies, workspaces, HR management systems, training etc. (Antogiovanni, 2020), that needs to be offset with appropriate benefits.

In light of this main objective, we develop a conceptual framework, built on a series of testable propositions, about the characteristics of SW as leverage to achieve new, incremental productivity, both at "people" and "process" level.

Then, we develop a questionnaire to empirically test our theoretical framework. Each construct of the model corresponds a set of questions. Gathering the answers to each question it will be possible to test the constructs of the model.

This paper presents first findings of this research study, namely the research framework and the validation of the questionnaire developed to empirically test out the theoretical framework.

## **2 The impact of smart working on performance: A theoretical framework**

With the concepts that the organizational studies offer us, we develop a theoretical framework, built on a series of testable propositions, about the characteristics of SW as leverage to achieve new, incremental productivity, both at "people" and "process" level. The overall theoretical model depicted in Figure 1.

Conceptualizing on the effect of SW on the organization, at the level of macro structure and micro structure, the framework hypothesizes whether SW affects the productivity, both at "people" and "process" level, and therefore if SW may improve the organizational performance.

As for the impact of the SW on some structural dimensions of the organization, the adoption of SW brings about changes in processes, knowledge flows, and activity sequencing to the point of radically transforming the coordination mechanisms. In particular, giving greater autonomy to employees reduces the need to adopt coordination mechanism based on direct supervision as well as mutual adjustment mechanisms based on face to face interactions are replaced with virtual interaction, via "broad band" communication technologies (Arnaud and Schminke, 2007; Barney and Hansen, 1994; Serrien, 2008).

Based on this, we formulate the following assumption of the model:

*H1: SW puts in place alternative coordination mechanisms, which are equally effective and far less costly, thus positively affecting the performance.*

As for the impact of the SW on some job characteristics, the micro organizational structure, it is widely accepted that the adoption of SW requires a profound change in the organizational culture and behaviour and the adoption of new managerial practices and leadership styles. In the new SW result-based culture, where the goals are defined collectively, and the individual is accountable for the results he accomplishes, employees have a greater level of autonomy and responsibility for taking decisions about how to schedule their work and how to

do it. The job autonomy is closely linked to the concept of empowerment of employees. Empowerment is the freedom of employees to make decisions on how to schedule the job and on how to reach the goals (Hackman, 1980). According to Blanchard et al. (2007), empowerment can raise their level of involvement and can result in improvements in performances and in the level of efficiency, quality, and profitability.

Based on this, we formulate the second assumption of the model:

*H2: SW enlarges job autonomy and empowerment.*

A further key feature of Smart Working is that it reduces or even completely eliminates the time and space constraints. Through appropriate ICT tools, SW allows employees to define where and when to carry out their work and, consequently, to be efficient wherever they are. Flexibility therefore refers to both dimensions, time and spatial flexibility. In the academic literature, there is clear evidence that flexibility in choosing both when and where to work is generating a positive influence on work-life balance (Byron, 2005; Mesmer-Magnus and Viswesvaran, 2006; Shockley and Allen, 2007).

*H3: SW increases time and spatial flexibility, by positively affecting work-life balance.*

Academic literature provides many examples of how higher levels autonomy on the job, a trustworthy environment, in which employees are given the possibility to acquire higher responsibility, and a higher work-life balance increase job satisfaction, and in some cases, motivation to perform the job (Boxall and Macky, 2014; Ezra and Deckman, 1996; Staines and O'Connor, 1980).

*H4: A higher work-life balance and greater autonomy/empowerment increases job satisfaction and motivation.*

No one questions the central role motivation plays in shaping behavior and, specifically, in influencing work performance in organizations (Ambrose and Kulek, 1999). Nonetheless, as important as motivation is, it is not the only factor that determines performance. A variety of other variables thought to play an important role in performance have been suggested. These include ability, instinct and aspiration level as well as personal factors. Blumberg and Pringle (1982) classify these variables in three categories and relate job performance to the capacity to perform, which is related to the degree to which an individual possess task-relevant skills, abilities, knowledge, and experiences; the opportunity to perform, and the willingness to perform or motivation. The presence of motivation per se, coupled with a capacity to perform, does not ensure high

performance, it is important to create an opportunity to perform, which depends on the availability of equipment, technologies, and organizational and managerial best-practices.

Based on this we formulate the following hypothesis:

*H5: The higher is the opportunity to perform, namely the adoption of targeted interventions to raise awareness and knowledge on the subject, the implementation of SW programs and the provision of correct ICT tools to support SW, the higher will be the job performance.*

SW does not involve simply staggering start times or rethinking support technologies for working from home, or stepping up training throughout the organization on basic digital competencies that serve to effectively use the collaborative platforms that so many have had to grapple with. SW adoption radically transforms work methods and tools. It involves a profound change at each level of the organization and in each of its components.

Change is what presses out of the comfort zone and for most of the people it is uncomfortable to change from one state to the other. Workers in organization may not welcome change with result in a worsened of their work performance.

In a change management process, choices and decisions that managers make are fundamental to mitigate the risk of failure of the organizational change program and avoid a drop performance. Managers as leaders play a crucial role in helping workers let go of past behaviour and move forward to new and different ways of working, increasing workers' propensity and motivation to change, building employee commitment, so increasing employees to perform in a changing organizational environment.

Based on this we formulate the following hypothesis:

*H6: SW may have a negative impact on job performance. The higher is the opportunity to perform, the lower is such a negative effect.*

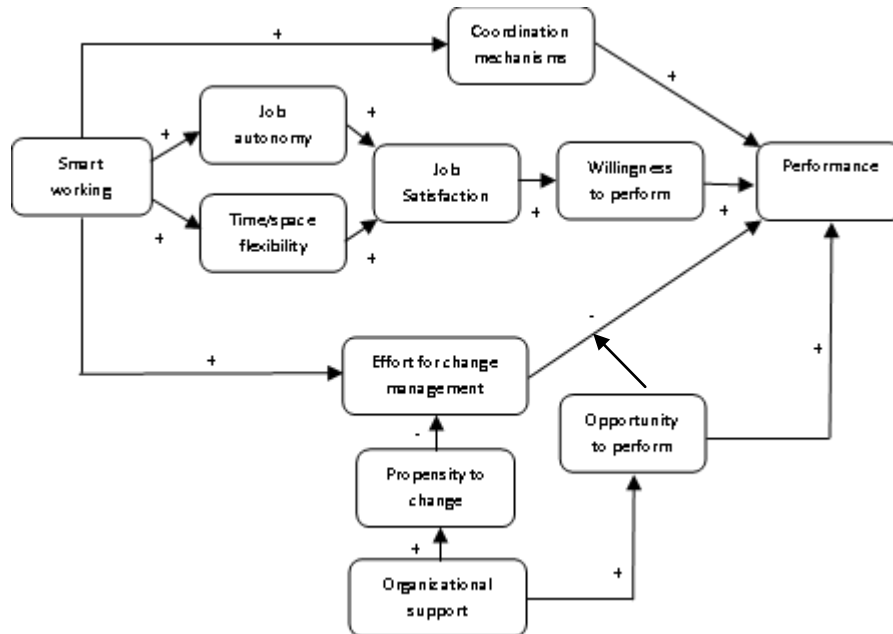

Figure 1. The model.

### 3 The empirical research design

Once having defined the model to be tested, the following step was that of designing the empirical research.

Firstly, we have built a questionnaire, the next step consisted of test the quality and robustness of the questionnaire, finally the data analysis and the test of the model.

#### 3.1 The questionnaire

The questionnaire is composed of 28 questions. The first 8 questions aims at collecting the socio-demographic information of the respondents; the rest of the questions (20) gather information about the workers' perceptions regarding the application of smart working in their own company and are useful to assess the constructs of the theoretical model.

In particular, the sections of the questionnaire are:

1. General data: the focus of this first set of questions is on demographic variables as well as generalities of the respondents (gender, age, type of role they

cover, etc.). This area has also helped to disclose the presence of some control variables to take in consideration. This section consists of 8 of the 28 questions.

2. Impact of SW on the organization: the second section investigates the impact of SW on the coordination mechanisms. It also aims at gathering information on each respondent's perceptions on the degree of time flexibility and spatial flexibility, on his job satisfaction and empowerment, as well as on how much the working practices have changed due to smart working. This section presents 12 of the 28 questions.

3. Organizational support: the third section investigates the working environment of the company in which each respondent, namely the adoption of targeted interventions to raise awareness and knowledge on the subject, the implementation of SW programs and the provision of correct ICT tools to support SW, with the aim of assessing the opportunity to perform. This section presents 4 of the 28 questions.

4. Impact of SW on the performance: the last section aims at gathering information on the performance. This section counts the last 4 questions.

The questions within the first macro area are either multiple choices or blank spaces that the respondent had to fill in. Instead, the other sections are in the form of statements, to which the respondent has to indicate to what extent he/she agrees on a qualitative five-point scale.

### ***3.2 Distribution of the questionnaire***

The questionnaire was administrated in Italian language from June 2020 up to October 2020, was fielded online, respondents were reached both via social media networks and through mailing lists. Data was anonymously collected through Google and Office365 platforms and analysed in aggregate form.

## **4 Results**

In the present study a descriptive analysis of the examined sample and an internal consistency analysis was performed, after coding the variables. In particular, we transform the qualitative variables into quantitative ones, by using a scale ranging from 1 to 5. Then we convert the 5-point scale into 3-point scale: where 1= disagree, 2 = neutral, and 3 = agree.

#### 4.1 The sample

This section provides a complete overview of the respondents' characteristics. The questionnaire reached 1.804 responses, of which 1.648 were fully completed and reported in the database.

Table 1. Characteristics of the respondents

Variable	N (%)
Gender	
Females	890 (54%)
Males	758 (46%)
Age groups	
< 30 years	297 (18%)
30-50 years	824(50%)
> 50 years	527 (32%)
Level of education	
High school licensed	280 (17%)
Post-Secondary Education	890 (54%)
Post-graduate degree	478 (29%)
Responsibilities of respondents	
Children at home	445 (27%)
Elderly people	198 (12%)
Caregiver for disabled	66 (4%)
No responsibilities	939 (57%)
Type of company	
Public Administration	643 (39%)
Small and medium-sized private company	461(28%)
Large private company	544 (33%)
Type of role	
Executive	66 (4%)
Manager	264 (16%)
Office workers	808 (49%)
Schoolteacher	247 (15%)
Academic	82 (5%)
Professionals	132 (8%)
Others	49 (3%)
Distance between home and work	
0-5 km	1.034 (38%)
6-30 km	1.170 (43%)
> 30 km	517 (19%)
Previous experience in SW	
Yes	610 (37%)
No	1.038 (63%)
<b>Total</b>	<b>1.648 (100%)</b>

The characteristics of the respondents are shown in Table 1. The majority of the respondents were women (54%). Three age classes were identified, with 50% of the personnel aged between 30 and 50 years, 18% younger than 30, and 32% older than 50. The level of education is quite high, 54% of respondents declared to be graduated, 29% have a post-university degree and only 17% a high school degree.

Regarding the professional classification, 6 out of 10 work in private companies (61%) and the remaining 39% in the Public Administration. As for the former, 28% works in small and medium-sized companies, and 33% work in large companies.

The workers doing Smart Working that answered the survey have different roles: Almost half of the respondents (49%) is an office workers, 16% works as manager, 4% as executive, 15% are schoolteachers.

Most of the respondents (81%) live and work in the same city or at least in a 30-kilometer range, while the other 19% lived more than 30 kilometers away from the workplace, they have children at home in the 27% of cases, are responsible for elderly people in the 12% of cases, and have no responsibilities in the 57%.

Only 37% of respondents have experienced smart working before the Covid-19 crisis, for 6 out of 10 workers, smart work is a completely new experience.

#### **4.2 Reliability analysis**

Before using the results of the survey to test our theoretical framework, we test the quality and robustness of the questionnaire by performing an internal consistency analysis. Cronbach's alpha was selected to measure the internal consistency of the questionnaire (Cronbach, 1951). This statistical indicator measures reproducibility over time and the homogeneity among the questions. Cronbach's alpha refers to the degree of correlation between the analyzed variables. It is computed among the items of the questionnaire and provides information about the correlation level. The closer to 1 the value of Cronbach's Alpha, the higher the level of correlation among items, thus each item provides a valuable contribution. Conversely, when the Cronbach's Alpha is close to 0, the level of correlation among the items is low, hence some of them are not appropriate. In this case, it is needed to eliminate the items that reduce the value of Cronbach's Alpha (Cho and Kim, 2015).

Cronbach's alpha value should be more than 0.70 in order to give good support for internal consistency reliability (Morgan et al., 2007). Hence, we consider as acceptance threshold of this parameter 0,7.

We perform the analysis of internal consistency of the 20 questions regarding the impact of SW on the organization (second section of the questionnaire), the organizational support (third section) and the impact of SW on the performance (last section).

The analysis showed an overall standardized Cronbach's Alpha of 0,8, corresponding to a very good reliability.

In the analysis by item the value of the alpha decreased to a minimum of 0,77 when the items 19 and 20, related to the impact of SW on the performance, were deleted, while the deletion of items 2, 6, 9, and 11, related to the impact of SW on the organization, led to an increase in the value of alpha. A maximum of 0,86 is reached with the deletion of item 2. The analysis is reported in Table 2.

Table 2. Analysis of internal consistency of the questionnaire

<b>Sections</b>	<b>Items</b>	<b><i>Cronbach's Alpha when the item was deleted</i></b>
Section 2 Impact of SW on the organization	Item1_coord1	0,80
	Item2_coord2	0,86
	Item3_coord3	0,78
	Item4_coord4	0,82
	Item5_coord5	0,82
	Item6_flex1	0,84
	Item7_flex2	0,81
	Item8_emp1	0,83
	Item9_emp1	0,84
	Item10_motiv1	0,82
	Item11_change1	0,85
	Item12_change2	0,83
Section 3 Organizational support	Item13_support1	0,81
	Item14_support2	0,82
	Item15_support3	0,83
	Item16_support4	0,83
Section 4 Impact of SW on performance	Item17_perfm1	0,83
	Item18_perfm2	0,78
	Item19_perfm3	0,77
	Item20_perfm4	0,77

## 5 Conclusion

Recently there has been a proliferation of studies reporting SW as a common practice due to the Covid-19 emergency. Looking at the post-pandemic world, several studies are questioning about the future of SW and whether it will be adopted by companies as an established successful practice. Actually, providing an answer to this issue requires the investigation on whether and to what extent the SW can really impact on company's performance.

Pursued by this objective, this research study aims at investigating to what extent SW may contribute to improve company's performance and, in this vein, it can be considered a successful practice to be adopted in the post pandemic scenario.

This paper presents first findings of this research study, namely a conceptual framework, built on a series of testable propositions, about the characteristics of SW as leverage to achieve new, incremental productivity, both at "people" and "process" level and the validation of the questionnaire developed to empirically test out the theoretical framework.

As a next step of this research study, we will use the results of the survey to test our theoretical framework. This will enhance understating about effect of SW on the organization, at the level of macro structure and micro structure, thus providing an answer on whether the characteristics of SW enable the achievement of new, incremental productivity and therefore if SW may improve the organizational performance.

This understanding is important because it will support companies in investment decisions about technologies, workspaces, HR management systems, training etc., to be adopted in order to make SW an established practice also in the post-pandemic scenario.

### **Abstract**

In the last year, due to the COVID-19 pandemic outbreak research in resilience has flourished. During the first pandemic wave, health systems had to cope with a high number of severely ill patients and a high degree of unpreparedness at the organizational level. In that period, having a clear understanding of the pandemic situation within the organizations and the systems was essential. Resilient healthcare organizations need to develop information systems concerning positive patients. In light of this evidence, the purpose of this study is to investigate how the use of information systems influence resilience in healthcare organisations during the COVID-19 pandemic.

According to the aim, this research adopts a qualitative approach based on multiple case study to strengthen the findings by triangulation of evidence. Empirical data were gathered from multiple sources, i.e. observations, reports and interviews adopting a multiple case study methodology. In the healthcare organisations involved, the interviews were carried out to the head of the COVID units and the medical directions.

Moving from the literature on resilience and knowledge management and information systems, firstly, the research identifies the elements required for building resilience. Secondly, the knowledge management processes fostered by the use of data. Then, using multiple case studies, it provides a number of propositions concerning the relationships between knowledge management activities, based on the use of information systems, the selected organisations developed and the resilience-building elements they nurtured.

The study shows the importance of integrated COVID-related information systems between healthcare organisations to effectively face the crisis. By the analysis, the development and use of information systems boost resilience elements such as collaboration, flexibility, visibility, etc.

The paper highlights the importance of data integration during the COVID-19 first wave and how the development and use of information systems can enhance resilience

elements. Moreover, it contributes to shedding light on the relationship between the use of knowledge and resilience in healthcare organisations during pandemic events.

## 1 Introduction

Over the last year, the COVID-19 pandemic has put pressure on health systems as never before (Auener et al., 2020; The Lancet Infectious Disease, 2020). Policy-makers and healthcare scholars are putting all their efforts into finding strategies and sharing the best ways to face the current pandemic (European Group on Ethics in Science and New Technologies, 2020; EXPH, 2020; HSRM, 2020).

Framed in this pandemic context, research in resilience has flourished. Related to healthcare, resilience is defined as the ability and capacity of the healthcare systems to absorb, effectively respond and adapt to shocks and structural changes while sustaining day-to-day operations (EXPH, 2020). Even it is not a new concept, it is increasingly crucial today because of the widespread unpreparedness of health systems for a pandemic of this magnitude.

During the COVID-19 first wave, Italian hospitals and local health authorities had to manage huge flows of patients affected by COVID-19. To handle these flows of patients, healthcare organisations needed to have a clear and complete understanding of the patient flows concerning the number of COVID and non-COVID inpatients, the bed occupancy rate, etc. Information systems are already widely adopted to gather data through electronic health record (EHC), to support clinical decision making through clinical decision systems (CDS), to collect information about bed management, etc. During pandemics, they became even more important (Devadoss et al., 2005). They were tasked with collecting epidemiological information and tracking people affected by COVID-19, and they would provide information about bed occupancy rates, bed turnover, etc. to draw up plans for reorganising activities. Whereas a huge literature investigates the relationship between information systems and knowledge management (KM) processes (Alavi and Leidner, 2001; Devadoss *et al.*, 2005), blossoming studies start to investigate KM as a resilience element referred to a specific field of resilience, i.e. supply chain resilience (Ponis and Koronis, 2012; Ponomarov and

Holcomb, 2009; Scholten et al., 2014; Umar et al., 2020). In their recent work, Umar *et al.* (2020) investigated the effects of KM on supply chain resilience (SCRES) and they conclude by highlighting SCRES is enhanced by KM processes through a robust KM infrastructure, among which information systems and technology. However, differently from Umar et al. (2020), we aim at deepening only how the KM activities developed by the use of COVID-related information systems influence resilience in healthcare organisations.

To provide a deep comprehension concerning how KM activities, performed thanks to the development and use of information systems, support patient flow management in order to enhance resilience, we studied the supply chain perspective of resilience. Indeed supply chains in healthcare concern not only material flows but also patient flows (de Vries and Huijsman, 2011) and service provision (Meijboom et al., 2011).

Based on these premises, the purpose of this study is to investigate how the use of information systems favour resilience in healthcare organisations during the COVID-19 pandemic. To gain the purpose of our research, we adopt an inductive based case study research built on multiple case studies in order to strengthen the validity of the study.

The paper is structured as follows. Firstly, we deepen the theoretical background in Section 2. Secondly, Section 3 describes the methodology that we adopted. Section 4 highlight the main findings and discuss them. And finally, Section 5 emphasizes the conclusions and the future research.

## **2 Theoretical background**

Resilience has become a growing concern over the past years. One of the most studied literature reviews carried out by Bhamra et al. (2011) identified five perspectives of resilience: ecological, individual, community, organisational and supply chain.

Supply chain resilience received a blossoming interest starting from 2001 (Bhamra et al., 2011), and after few years Sheffi and Rice (2005, p. 41) emphasized resilience as the ability of a company to recover from a disruption developed by creating flexibility and redundancy into its supply chain. They gave attention both to the development of resilience by improving the supply chain and to the elements that characterized the supply chain. Resilience elements secure supply chain resilience before, during and, after a disruptive event (Jüttner and Maklan,

2011). Just because of their role, in the past years, interest in resilience elements raised among researchers (Christopher and Peck, 2004; Hohenstein et al., 2015; Ponomarov and Holcomb, 2009; Sheffi and Rice, 2005).

Collaboration, flexibility, redundancy, agility and visibility are the most studied resilience elements in the literature. Whereas collaboration enables the human resources to work effectively together at intra- or inter-organisational level (Ali et al., 2017; Christopher and Peck, 2004; Hohenstein et al., 2015; Jüttner and Maklan, 2011; Kamalahmadi and Parast, 2016; Lima et al., 2018; Pettit et al., 2010, 2013; Ponomarov and Holcomb, 2009; Scholten et al., 2014; Scholten and Schilder, 2015), flexibility enables the organization to adjust and change processes and structures according to the contingent situation (Blackhurst et al., 2011; Christopher and Peck, 2004; Hohenstein et al., 2015; Jüttner and Maklan, 2011; Kamalahmadi and Parast, 2016; Pettit et al., 2010, 2013; Ponomarov and Holcomb, 2009). Unlike flexibility, redundancy has been identified as the process of creating a surplus of capacity and/or resources needed during a disturbance (Christopher and Peck, 2004; Dolgui et al., 2018; Hearnshaw and Wilson, 2013; Hohenstein et al., 2015; Ivanov et al., 2019; Kamalahmadi and Parast, 2016; Pettit et al., 2010, 2013; Ponis and Koronis, 2012).

Finally, agility that represents the ability to respond rapidly to changes (Ali et al., 2017; Christopher and Peck, 2004; Ponis and Koronis, 2012; Ponomarov and Holcomb, 2009; Wieland and Wallenburg, 2013), is constituted by flexibility (Jüttner and Maklan, 2011), velocity and visibility (Christopher and Peck, 2004). Visibility is the ability to see throughout the supply chain (Ali et al., 2017; Blackhurst et al., 2011; Brandon-Jones et al., 2014; Jüttner and Maklan, 2011; Pettit et al., 2010; Ponomarov and Holcomb, 2009; Scholten and Schilder, 2015). Its notion is strictly related to communication, information sharing and knowledge (Barratt and Oke, 2007; Brandon-Jones et al., 2014; Jain et al., 2017).

Knowledge is seen as part of visibility for some authors (Barratt and Oke, 2007; Brandon-Jones et al., 2014; Jain et al., 2017), and properly as a resilience element for others (Ponis and Koronis, 2012; Ponomarov and Holcomb, 2009; Scholten et al., 2014; Umar et al., 2020). Knowledge and more rightly knowledge management has been studied as the element that enables companies to share information across the supply chain (Ali et al., 2017) or as the element that favours the learning capability of the organization (Ponomarov and Holcomb, 2009). Umar et al. (2020) identify more widely knowledge management as a driver of resilience through the development of knowledge generation, sharing and utilization.

Knowledge management has been defined as a set of activities to manage knowledge within the organisations, whereas KM referred to information systems perspectives has been described as an effective tool to enable KM processes (Dorasamy et al., 2013). KM processes facilitate the acquisition, sharing and utilisation of knowledge (Alavi and Leidner, 2001). However, even if some authors emphasized the importance of a cultural change to be combined with the development of technology to enable KM processes (Davenport and Prusak, 1998; Nonaka and Takeuchi, 1995), during emergency context knowledge management tools favour the development of KM processes (Dorasamy et al., 2013). In their review, Dorasamy et al. (2013) listed 17 tools as enablers of KM processes among which there are the data and information systems, emails, intranet, videoconferencing, etc. As also Ammirato et al. (2020) analyzed in their recent work on pandemics, knowledge management is one of the topics related to managing pandemics and integrated information systems bring benefit to emergency management.

The empirical evidence shows that information systems facilitate KM processes (Ammirato et al., 2020; Dorasamy et al., 2013; Umar et al., 2020) which include knowledge acquisition, sharing and use. These are the most common categories of KM processes (Nonaka and Takeuchi, 2008). Knowledge acquisition refers to acquiring new knowledge inside or outside the organization (Magnier-Watanabe and Senoo, 2008). Knowledge acquisition is a social process between individuals (Nonaka and Takeuchi, 1995). Knowledge sharing is the process of mutually exchange knowledge, experiences and skills among individuals (Rusly et al., 2014) and it involves social interaction (Cockrell and Stone, 2010; Nonaka and Takeuchi, 1995). This interaction to share knowledge can be facilitated through formal training or informal interaction (Umar et al., 2020).

Knowledge use is the way by which knowledge is used by organisations. This third KM process is the one the supply chain scholars referred to (Ponomarov and Holcomb, 2009; Scholten et al., 2014).

### **3 Methodology**

To provide a useful insight into the contemporary events in the healthcare sector during COVID-19, an inductive case study research was carried out (Benbasat et al., 1987; Meredith, 1998).

Moving from the literature on supply chain resilience and KM, firstly, we identified the most studied elements of resilience and, secondly, the KM processes fostered by the use of information systems. Then, using multiple case studies, we empirically investigated the relationships between KM activities, based on the use of information systems, the selected organisations adopted and the resilience-building elements they nurtured.

Through case study research, we were able to collect data using several methods and tools, such as direct observations, interviews, documents and reports in the setting under investigation (Yin, 2018). Moreover, for increasing the understanding of such a new and rapidly evolving phenomenon and strengthening the grounding of theory (Eisenhardt, 1989), this research investigates three public healthcare organisations. The study of multiple case studies follows three stages, i.e. the research design, the data collection and analysis. Semi-structured interviews involved members of the strategic unit and its support staff unit from each organisation to investigate the use of the data systems at the strategic level.

### **3.1 Research design**

This research focuses on the hospitalized COVID patient flows. In order to deepen how the hospital directors and the clinicians carried out KM activities to build resilience, we involved the medical directions and the units that deliver care to COVID patients (e.g., Intensive Care Unit, Pneumology, Infectious Disease, etc.).

The research protocol was designed to answer the following research question (Yin, 2018):

*How the knowledge management processes enabled by the use of information systems favour resilience in healthcare organisations during the COVID-19 pandemic?*

To investigate the relationship between the KM activities supported by the use of information systems and supply chain resilience, we selected multiple cases considering the following criteria:

1. Continuity of care criterium: the emergency room has to be always kept open during COVID-19 first wave;
2. Geographical criterium: healthcare organisations placed in the most COVID-19-affected Italian regions;
3. Service typology criterium: only public organisations;

4. Quality of care criterium: at least acceptable levels of care (i.e. score  $\geq 160$ ) defined by the Health Italian Ministry (Griglia LEA 2018, "Ministero della Salute").

The selected public healthcare organizations could be defined resilient as they kept emergency services open at all times, although heavily affected by the pandemic. They indeed belong to two Italian regions severely impacted by COVID-19, i.e. Emilia Romagna and Veneto. The spread of COVID-19 began on the 21<sup>st</sup> February 2020 in Lombardy. After few days also Veneto and Emilia Romagna reached consistent percentages of confirmed cases ("COVID-19 ITALIA", 2020).

Finally, concerning the quality of delivered care criterium, Veneto obtained the highest score for delivered levels of care in 2018 (222) and Emilia Romagna reached the second (221) highest value ("Ministero della Salute", 2021).

In order to gather useful information about the use of information systems at the strategic and unit level, we involved one or more members of the strategic unit and the support units (e.g. medical direction unit, health profession unit, etc.) and the directors of the units involved with the COVID-19 inpatient pathway. Table 1 synthesizes the profile of the healthcare organisations involved.

Table 11. The profile of the selected organisations.

	<b>Case A</b>	<b>Case B</b>	<b>Case C</b>
Region	Emilia Romagna	Emilia Romagna	Veneto
Typology	University hospital	Local Health Authority	Local Health Authority
No. of hospitals	1	6	6
Beginning of the crisis	01/03/2020	27/02/2020	24/02/2020

### **3.2 Data collection**

Once identified the cases, we designed the interview protocol to drive the semi-structured interviews, observations and document analysis (Eisenhardt, 1989; Yin, 2018). As Table 2 shows, the interviews involved mainly the medical directions in order to collect data about how they use information systems at the strategic level and to the head of the COVID unit in order to deepen how they manage information across the units.

Whereas the investigated period is from the beginning of the COVID-19 outbreak in Italy, i.e., the 21<sup>st</sup> February 2020, to September 2020, the data has been collected mainly during summer 2020.

The duration of the interviews was about 45 minutes and they were audio-recorded and transcribed ad verbatim.

Table 12. Summary of data collection.

		Case A	Case B	Case C
Investigated units	Health Director	✓	✓	✓
	Infectious Disease	✓	✓	✓
	Emergency Unit	✓	✓	✓
	Internal Medicine			✓
	Pneumology		✓	✓
	Intensive Care	✓	✓	✓

	Medical Direction	✓		
	Health Profession Unit			✓
	SUEM 118			
	Microbiology	✓		✓
	Maternal and Child Health Area	✓		
	Surgery	✓		
No. of interviews		10	6	11
Duration of each interview		45 minutes	45 minutes	45 minutes
Data collection period		08-09 2020	08-09 2020	07-08 2020

### 3.3 Data analysis

To strengthen the data analysis, we adopted RQDA, an open-source Computer-Assisted Qualitative Data Analysis (CAQDAS). "A CAQDAS increases the transparency, validity, rigour and trustworthiness of qualitative research", as Chandra and Shang highlighted (Chandra and Shang, 2017) (p. 95). A research group coded separately the transcription of the recorded data to enhance the

validity and reliability of analysis (Voss et al., 2002; Yin, 2018). Then, meetings were held to discuss the coding. In cases of disagreement, the decision on codes was discussed and mutually agreed upon, following an iterative approach to coding and analysis (Miles and Huberman, 1994).

The coding process permits the identification of the activities related to the KM acquisition, sharing and use developed by means of information systems (first-order coding). Then, the second-order coding enables us to link these activities to the resilience elements identified in the literature review (i.e. collaboration, flexibility, agility, redundancy, visibility). Finally, in order to increase consistency, the interview data were integrated with the internal documents, the websites of the organisations (Voss et al., 2002; Yin, 2018). Thanks to data triangulation, we were able to verify the reliability of the multiple sources gathered and to increase the understanding of the collected data (Yin, 2018).

Section 4 highlights the empirical evidence derived from the analysis in order to answer the research question.

#### **4 Findings and discussion**

During the COVID-19 first wave, the selected cases experienced the development of information systems at a different level.

Case A created a COVID patient information system integrated with the local health authority of the city to which they both belong and with the private healthcare organisations close to the city. Similarly, case B developed a COVID patient information system integrated with all the hospitals of the local health authority and the private healthcare structures belonging to the province of case B.

The creation of such integrated systems generated a clear understanding of the pressure on hospitals. They enable indeed both the public and private healthcare organisations to coordinate and manage the patient flows by continuing to deliver care.

*"A success element was the dashboard that enables the organization to have a clear understanding about bed occupancy rate, [...] in all the hospitals of the city. This was essential to manage patient flows across the units. [...] Several services could access on the dashboard because there was no confidential data, this was a strength." (Health Director, Case A)*

Besides its ordinary information systems, case C had the access to the regional platform created ad hoc for the COVID pandemic crisis. The organization nurtured the platform with COVID patient information and then it can access and use the system to gather the data to manage the patient flows.

*"At the beginning, we were not aware of COVID epidemiological trend. Then, the Region created and made a platform available to provide a clear reference framework of the hospital pressure, [...] several services have the access to the platform (hospital top management, public hygiene service)."*  
(Health Director, Case C)

In addition to patient information systems, the cases were provided by regional intensive care information systems to manage the available intensive care beds, personal protective equipment (PPE) monitoring systems, emergency unit dashboard (only for case A).

The high degree of autonomy of these cases in creating and managing information systems was a strength of these organisations as they create ad hoc systems based on their needs.

On the contrary, case C used the regional platform as the organization have considered it a helpful tool. The ways by which the information systems have been created have been always seen as a strength. The emphasis indeed has been put on the information gathered. However, top management of case A and B showed greater ease in reaching and providing data from the COVID platform.

Moving from the information systems developed to how they have been used, we listed in Table 3 the activities related to KM acquisition, sharing and utilisation.

Table 13. Activities classified by KM processes developed by the selected cases.

	Activities	Peculiarities of the cases
Knowledge acquisition	Gaining information by:	– Case C gained information by a regional platform
	– COVID patient information system	– Case A and B developed a platform integrated with the hospitals placed in the city/province
	– Regional intensive care information system	– Case A developed a dashboard for the emergency unit
	– Emergency unit dashboard	– The PPE monitoring system is regional for case C.
	– PPE monitoring system	

<b>Knowledge sharing</b>	<ul style="list-style-type: none"> <li>- Access to information systems depending on the interest area</li> <li>- Regional meeting to share information between the top management of the organisations</li> <li>- Crisis unit meeting to share information concerning COVID flows</li> <li>- Cascading communication between the organizational levels by email, intranet and shift change meetings, chat</li> <li>- PPE use training activities</li> </ul>	<ul style="list-style-type: none"> <li>- Top management of case C received a daily report via WhatsApp</li> <li>- Case A shared information about PPE procurement activities</li> </ul>
	<ul style="list-style-type: none"> <li>- Service integration to admit patients from other regional hospitals</li> <li>- Integration and coordination of services with the other healthcare organisation of the city</li> <li>- Integration between the emergency services of the region to manage intensive care beds</li> <li>- Creation of separated paths for COVID and non-COVID patients</li> <li>- Care delivering to urgent activities</li> <li>- Outsourcing of the surgery</li> </ul>	<ul style="list-style-type: none"> <li>- Case B developed service integration also for the coordination with the primary care</li> <li>- Case A coordinated the outsourcing of surgery services with the other hospitals of the city thanks to the information about bed occupancy rate</li> </ul>

The activities divided by KM processes are almost the same even if the information systems are managed in different ways. Thus, even if the selected healthcare organisations acquire knowledge in different ways, they share and use the information to develop similar activities.

Moving from first-order to second-order coding, activities were categorized by elements of resilience they are building.

Firstly, knowledge acquisition activities are related to the activities of gathering information from the information systems. Whatever the information system adopted, the collection is carried out in the same manner if the required information is available in the system. This activity increases the visibility inside and outside the organisations involved in the integrated data management of the information systems. As previously described, visibility represents the element that enables an organisation to see throughout the supply chain (Jüttner and Maklan, 2011; Pettit et al., 2010; Ponomarov and Holcomb, 2009; Scholten and Schilder, 2015). Integrated information systems allow the organisations to see

through all the healthcare organizations involved by showing all the data related to COVID patient flows.

*P1. Knowledge acquisition from data gathered by real-time integrated information systems enhances the visibility of the healthcare organisations involved.*

Secondly, knowledge sharing activities refer to the activities of sharing information from the individual level to the organizational level (Rusly et al., 2014). The healthcare organisations firstly facilitate the sharing of acquired knowledge by using different communication strategies: they provide the access to information systems to the top management and the COVID unit directors, they scheduled daily meeting among crisis unit members to share information gathered at different levels (regional level for the regional information systems and in-house level for enterprise information systems), and they train the workers on PPE use for not wasting them. These differentiated activities to share information promote the development of redundant ways to share information at the organizational level. Redundancy defined as the process of creating a surplus of capacity and/or resources needed during a disturbance (Christopher and Peck, 2004; Dolgui et al., 2018; Hearnshaw and Wilson, 2013; Hohenstein et al., 2015; Ivanov et al., 2019; Kamalahmadi and Parast, 2016; Pettit et al., 2010, 2013; Ponis and Koronis, 2012), is here favoured by creating a surplus of an intangible resource, the differentiated communication strategies, to secure that the information reaches all organizational levels.

*P2a. Knowledge sharing through differentiated communication strategies enhances redundancy within healthcare organisations.*

Knowledge sharing concerns also the vertical integration between the different levels inside and outside the organisations. The cascading communication from the Region and/or the crisis unit at the strategic level to the clinicians and nurses in the units was required. The members of the crisis units communicated news in the units mainly through email, chat and change shift meetings. Securing an effective cascading communication to share knowledge, required working effectively together at intra- or inter-organisational level, i.e. collaboration (Ali et al., 2017; Christopher and Peck, 2004; Hohenstein et al., 2015; Jüttner and Maklan, 2011; Kamalahmadi and Parast, 2016; Lima et al., 2018; Pettit et al., 2010, 2013; Ponomarov and Holcomb, 2009; Scholten et al., 2014; Scholten and Schilder, 2015). In that period, informal communication was the fastest and the most effective way to share knowledge. This new need increased the collaboration

between workers at different levels, as each level was responsible for communicating the new insights to its colleagues to ensure effective cascading communication.

*P2b. Knowledge sharing from the top management to the units enhances collaboration between the healthcare workers.*

As previously described, visibility is the ability to see throughout the supply chain. Concerning knowledge acquisition, visibility has been enhanced because information systems enable few individuals of the organizations involved to “see” the patient flow data. Whereas, concerning knowledge sharing visibility is enhanced by the share of useful information, filtered by the role and task, among all the workers. This enables the workers to have a clear understanding of what is happening inside and outside the organizations.

*P2c. Knowledge sharing to all organizational levels enhances visibility throughout all healthcare organizations.*

Knowledge utilisation is the way by which knowledge has been used. Firstly, thanks to the gathered information, the crisis unit was able to forecast the availability of beds depending on the emergency access, the bed turnover rate, etc., to manage the patient flows inside the organisations, between the units, and outside the organisation, thanks to the integration with the other hospitals. The real-time available information improves agile decision-making processes. The agility element, defined as agility the ability to respond rapidly to changes (Ali et al., 2017; Christopher and Peck, 2004; Ponis and Koronis, 2012; Ponomarov and Holcomb, 2009; Wieland and Wallenburg, 2013), in KM perspective is enhanced by an updated and available information flow.

*P3a. Knowledge utilisation provided by real-time information systems enhances the agility of decision-making processes.*

Knowledge use concerns also the activities of creating new pathways inside and outside the organisations to manage COVID patient flows. The selected cases developed two different pathways inside the organisation to divide the COVID and non-COVID areas. Then, thanks to the integration of the systems with the other hospitals, they can manage the patient flows efficiently. The regional intensive care information systems, for example, manage the patient transfers towards the hospitals with more available beds. Flexibility, thus, as the adjustment and changing processes and structures according to the contingent situation, has been improved.

*P3b. The knowledge used for integrating care services inside and outside the hospitals enhances the flexibility of patient pathways.*

As previously described redundancy is the process of creating a surplus of capacity and/or resources needed during a disturbance (Christopher and Peck, 2004; Dolgui et al., 2018; Hearnshaw and Wilson, 2013; Hohenstein et al., 2015; Ivanov et al., 2019; Kamalahmadi and Parast, 2016; Pettit et al., 2010, 2013; Ponis and Koronis, 2012). By the use of knowledge, the organizations created not only flexible pathways but also redundant services, diagnostic rooms, etc. Due to the differentiation of paths indeed organisations needed to organize multiple diagnostic rooms, elevators, etc. to ensure the safety of patients and workers. Moreover, thanks to the information gathered from the PPE monitoring systems, the hospitals estimated the need for PPEs and developed procurement activities to ensure a surplus of PPE capacity needed during the crisis.

*P3c. The use of the knowledge provided by the monitoring systems enhances redundancy either in the creation of COVID pathways and in ensuring PPE procurement.*

Figure 1 shows the analysed relationships between resilience elements and KM processes making explicit by the previously described propositions.

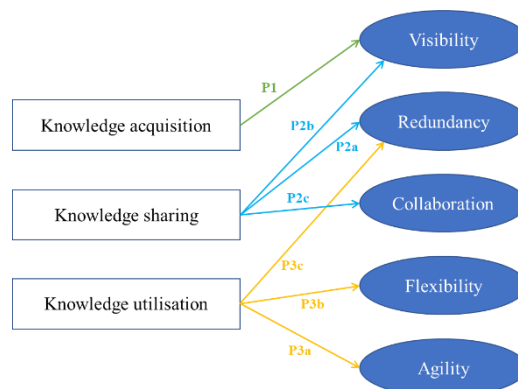

Figure 10. The research findings.

The analysis of the findings sheds light on how the knowledge derived by information systems is acquired, share and use to enhance the most studied resilience elements. In line with Dorasamy et al. (2013), information systems during pandemic events enable healthcare organisations to develop KM processes effectively. However, differently from Ammirato et al. (2020)'s review, KM processes are the drivers for the development of the elements of resilience.

The research highlights the role of KM in developing resilience. Even if some authors (Ponis and Koronis, 2012; Ponomarov and Holcomb, 2009; Scholten et al., 2014; Umar et al., 2020) consider knowledge management as one of the resilience elements, this research shows that it is an antecedent needed for the development of resilience elements.

The next section shows the contributions and the main limitations of this research.

## 5 Conclusions

This study contributes to making clear the relationships between KM and resilience elements. We explicated the KM processes developed by the COVID related information systems that favour the building of resilience elements. However, only the main resilient elements have been analysed. Future research could investigate if there are additional resilience elements enhanced by KM processes.

Moreover, the study provides empirical evidence for healthcare practitioners. Thanks to the first order coding the main activities concerning KM processes, has been identified. The resilient healthcare organisations provided by COVID information systems carried out specific KM activities that enhance resilience throughout the entire regional system.

However, the research focuses only on COVID first waves. It could be interesting to investigate how the same healthcare organisations modify their actions thanks to the new knowledge acquired, during the other two waves of the COVID-19 pandemic.

Finally, future research could investigate the benefit of enhancing resilience through KM processes also in ordinary time to achieve greater public value.

### Abstract

The Triage process is a crucial process of Emergency Departments, and scholars have proposed several solutions to streamline the processing of patients and reduce the waiting time of more urgent ones. However, a not thoroughly investigated issue concerns the factors influencing the decision-making performed by the nurses in the assignment of Triage's priority code. The Triage decision-making is a dynamic and complex process: the decision emerges after an interpretation process of patient clinical conditions influenced by the interaction of organizational rules and environment conditions with nurse's experience and beliefs. We investigate the Triage process through the fuzzy Qualitative Comparative Analysis (QCA). QCA is a method used to test theory-based conditions considering multiple interrelated variables that lead to the same outcome. More specifically, we show how the QCA allows researchers to figure out how the interaction between individual, organizational, environmental factors affect the Triage decision-making. This analysis will enable us to suggest some possible interventions to improve the Triage process. This research has been performed through direct observation of the Triage carried out in an Emergency Department of a Hospital located in the South of Italy.

**Keywords** – Triage Accuracy, Qualitative comparative analysis, Individual and organizational factors, decision-making

## 1 Introduction

Even before Covid-19, scholars have given great attention to make Triage more efficient to streamline the processing of patients and reduce the waiting time of more urgent ones. Triage is the front-office process of Emergency Departments. It aims to prioritize access to health treatment, "determining who will not be disadvantaged by longer waiting times and who requires immediate attention to achieve optimal outcomes" (Fitzgerald et al., 2010, p. 86). Nurses perform the Triage process, and a potential incorrect decision increases the waiting time of patients with life-threatening conditions (Considine et al., 2007; Fernandes et al., 2005; Fitzgerald et al., 2010; Traub et al., 2015; Wuerz et al., 1998). Nurses can over-assess the priority code and, consequently, more urgent patients could wait longer than necessary. On the contrary, nurses can under-assess the priority code of a patient extending his waiting time.

Scholars have proposed several solutions to improve Triage, but they focused on new organizational pathways for mitigating the patient's flow as well as more accurate algorithms for helping nurses in the assignment. For example, some scholars focused on the layout, such as standardized pathways for managing patients with specific disease conditions (Terris et al., 2004) or fast track areas for low-acute patients (Rodi et al., 2006). Other scholars designed more accurate algorithms for prioritizing patients (Ashour and Okudan Kremer, 2016; Elalouf and Wachtel, 2015).

Few studies investigate nurses' decision-making quality. Moon et al. (2019) evaluated the accuracy of nurses' in Triage assessment with the help of an expert to determine the causes of mistakes. Tam et al. (2018) analyzed the accuracy of Triage, and they prompted emergency department managers to activate training actions. These two works assess the accuracy by analyzing some cases retrospectively. Instead,

Göransson et al. (2006) assessed the accuracy and the concordance among nurses in codifying the patient's urgency using patient scenarios. Instead, a key challenge of Triage is to understand on which information nurses make the decision prioritizing non-urgent patients (Göransson et al., 2005).

How nurses make decisions is an issue not fully investigated, although understanding what factors influence decisions is a relevant aspect to improve Triage effectiveness (Wouters et al., 2020).

Nurse's decision-making is based on cognitive heuristics (Noon, 2014) as he/she attributes patient's priority level based on few cues and small laps of time through an interpretation process of patient's clinical conditions affected by his/her experience and the uncertain conditions of his/her everyday work (Benner and Tanner, 1987; Carnevali et al., 1985). Cognitive heuristics are shortcut strategies used by individuals to make decisions when the information, time, and processing capacity are limited (Simon and Newell, 1971). Ambiguous information, turbulent environments, and time pressure prompt a decision-maker to leverage on few cues to decide a short amount of time (Drechsler et al., 2014; Martignon and Hoffrage, 2002). The decision-making based on cognitive heuristic is a dynamic and complex process: the social-organizational context interacts with an individual's experience and beliefs, guiding the individual in selecting the subset of the available information against which the decision is made (Hogarth, 1981). The inability to distinguish relevant information can lead the decision-maker to misinterpret the subset of the available information, making a wrong decision (Pleggenkuhle-Miles et al., 2013). Individuals can choose the information recalling similar situations from memory (Bazerman, 2003) or through simple organizational rules easy to remember (Eisenhardt and Sull, 2001). From an organizational and management perspective, cognitive heuristics can be applied to coordinate nurses and doctors in treating patients (Rico et al., 2008). The social-organizational context, formed by formal and informal rules, support systems, institutional commitments, becomes a means of providing directions for the decision even if the individual can leverage on his/her discretionary judgment in the final decision to be made (Vuori and Vuori, 2014). In the Triage process, the interplay between social-organizational context and individual discretionary affects the complex interaction between nurses and patients within a turbulent environment (Andersson et al., 2006), causing the variation of nurses' decision-making in assessing the urgency of any individual patient (Andersson et al., 2006; Cone and Murray, 2002; Göransson et al., 2008). This complex interaction nurse-patient concern the interpretation of verbal information (the patient's history), visual cues (non-verbal communication), and possibly vital signs to determine the outcome of the decision-making process.

The Triage decision-making process is a phenomenon for which it is not the single factor but the relationships between them that determine a result: "factors interact and co-evolve, determining specific answers to specific situations, these latter being filtered and interpreted in the light of the constraints and resources of the context in which the decision is made. It is therefore necessary to not isolate individual factors from each other and from the organizational and contextual ones in the analysis" (Ponsiglione et al., 2018, p. 2166).

Against this backdrop, this work aims to understand how individual, organizational and environmental factors or their combinations affect Triage's accuracy in the priority level assigned to patients. Unlike other works, the study collects data for the analysis directly through observing the Triage process while the nurse welcomes the patient and then assigns the priority code. Moreover, we embrace causal complexity (Misangyi et al., 2017) rather than net-effects approaches to theory (Delbridge and Fiss, 2013). Hence, our study aims to investigate asymmetrical relationships and alternative causal paths (equifinality) of combinations of factors (conjunction) that can produce the investigated outcome (Ragin, 2008).

Finally, this study can also offer interesting insights on how to identify possible interventions to improve the accuracy of the Triage in a specific context.

The paper is structured as follows. In section 2, we report the literature on factors affecting nurses' decision-making. Section 3 introduces the Qualitative Comparative Analysis (QCA) methodology to understand the complexity of a phenomenon, focusing on a set of theory-based conditions rather than considering separately the effects of individual factors. In section 4, we present the application of QCA to the Emergency Department of a hospital located in the South of Italy. Discussion, practical implications, and conclusion close the paper.

## **2 Factors influencing the Triage decision-making**

Triage decision-making is a complex decisional process (Arbon et al., 2008) in which the nurse making Triage assessment interacts with the patient and other nurses or physicians. Different factors are outlined in the literature as affecting this process (Ponsiglione et al., 2018). Furthermore, multiple information is in place when the nurse takes the decision, such as visual cues, verbal reports, the clinical history of the patient, and vital signs. Each kind of information could contribute to an effective Triage, with each of them playing a role changing

according to the specific case (Cooper et al., 2002). Additionally, the outcomes of the Triage process are several and are related to effectiveness and efficiency measures. For example, a decision that underestimates the level of severity and urgency of a patient can prevent critical intervention at the right time, while prolonged Triage processes can contribute negatively to safety (Cioffi, 1998; Gerdtz and Bucknall, 2001; Travers, 1999). The accuracy and the duration of the Triage process are the most common aspects used to measure Triage's performances.

A study conducted in an Emergency Department (ED) in Sweden (Andersson et al., 2006) has outlined two categories of factors affecting the decisional process of Triage's nurses: internal factors and external ones. Internal factors include individual knowledge, competencies, and expertise of nurses and their personality traits, such as the individual approach to uncertainty, the risk aversion, and the capacity to support the patient. External factors refer to those elements concerning the organization of work and the environmental aspects in which the Triage assessment occurs. According to the literature (Ponsiglione et al., 2018; Wolf, 2013), this last category could be articulated into two groups: one referring to organizational aspects (i.e., the specific protocols adopted by the organization, the typology of Triage, the organization of work-shifts, the rules of interaction between colleagues) and the other referring to the work environment (i.e., interruptions by colleagues or other patients, the overcrowding of the ED, the layout of the work environment with the position of the Triage desk). Despite this articulation, some factors could be referred to one of the two groups considering the specific analyzed case.

Personal traits, knowledge and competencies, and previous experience are individual factors mainly analyzed in the literature on Triage decision-making (Chung, 2005; Cone and Murray, 2002). According to Handysides (1996), a practical Triage nurse must have three basic skills: the ability to estimate conditions based on the patient's reported clinical history, clinical measurements, and physical examination; comprehensive knowledge of severe injuries as well as extensive knowledge of pathologies; intuition developed through long-standing experience, which helps to decide the patient's condition.

The acquisition of skills or knowledge and the exposure to events are criteria to measure experience jointly to the time spent in a situation or a job position (Watson, 1991). Indeed, some believe that there is a relationship between knowledge, skills, and experience (defined by how nurses transform or change).

Others, instead, think that the exposure to events that define the value of familiarity is the critical factor in making critical decisions (Considine et al., 2007).

The experience is intended both as a time of exposure to the same or similar clinical situations and valuable skills expected to be used in the assessment (Cioffi, 1998). The time spent in an activity or a job position is commonly used to define the nursing experience, where years of experience are used to classify nurses. Experience is also related to the number of years spent in emergency departments (Andersson et al., 2006).

Another relevant internal factor that is analyzed as affecting the decisional process and the outcome of the assessment in Triage is the use of vital signs by nurses to define the Triage priority code. Detection of vital signs is usually considered an internal factor because it depends on a specific choice of individual nurses and is often related to their level of experience. Some studies have investigated the interaction between the nurses' years of experience and the use of vital parameters. In particular, more experienced nurses tend to under-use objective parameters, while for the novice nurse, they represent a handy tool to assess the patient's symptoms (Chung, 2005). Other research evaluated the impact of vital signs' use both in terms of the accuracy of triage decisions and in terms of the duration of the triage-patient interaction (Chung, 2005; Cooper et al., 2002; Gerdts and Bucknall, 2001; Ponsiglione et al., 2018), in order to identify whether an objective reference guarantees a more accurate and timely choice. Gerdts and Bucknall (2001) have established that experienced nurses are more prone to neglect the measurement of vital signs; furthermore, the measurement of vital parameters, as expected, impacts negatively on the time needed to assess the priority of cases. Finally, in the same study, it was verified that a greater recourse to vital signs is needed when the severity and the urgency of the case are higher.

Cooper et al. (2002) researched to understand if and to what extent the use of vital signs can change the judgment of nurses by asking them to formulate the priority code before and after detecting the vital parameters. The study involved 625 nurses who collected data on more than 14,000 patients. Knowledge of vital signs led to an 8% revision of Triage decisions based only on clinical history, visual signs, and limited physical examination. In particular, for the entire sample, 5.5% of the changes concerned an increase in urgency, while 2.4% a reduction in severity.

Contextual factors also affect triage performance (Andersson et al., 2006; Göransson et al., 2005) due to the strict relationship in the context in which this occurs (Smith et al., 2008). These factors include organizational factors and environmental ones. Organizational factors concern staff availability, workload, and work-shifts organization, the type of Triage adopted (Soremekun et al., 2011), the protocols/guidelines used (Cone and Murray, 2002). Therefore, these factors are related to the managerial decisions that determine the organization of the triage process and the objectives and rules shared in a given context, which, internalized through experience in the specific work environment, can influence the perceptions and motivations of nurses. Environmental factors capture the dynamic nature of the EDs, where the unexpected is always a possibility, makes Triage's decisions highly contextual and influenced by several environmental factors such as the occurrence of continuous interruptions during the patient interview, time constraints, and overcrowding (Andersson et al., 2006; Chung, 2005; van der Linden et al., 2016). A potential barrier to providing high-quality patient care could be the occurrence of disruptions intrinsic to the emergency room environment. An interruption can be defined as any activity that requires the nurse to switch his attention away from the patient or any activity that causes the nurse to leave the Triage zone (Johnson et al., 2014). The interruptions cause errors and delays in the treatment of patients and represent a real threat in the Triage decision-making process. The categories of interruptions identified include the provision of services to visitors, interruptions related to colleagues, interruptions related to patient care, localization of family members in ED, and requests from other patients or the arrival of new patients (Johnson et al., 2014). When the Triage process is interrupted, there is a significant increase in the duration of the nurse-patient interaction (Gerdtz and Bucknall, 2001; Johnson et al., 2018), delay in patient treatment and an increase in errors in nursing assessment (Johnson et al., 2018). The occurrence of frequent interruptions and the different sources of these interruptions seem to refer both to specific organizational arrangements (i.e., the number of nurses in each work-shift or the protocols and guidelines established by the health structure) and to environmental aspects (i.e., socio-cultural characteristics of the served population, the level of overcrowding).

Only the actual situation can capture these factors. Gerdtz and Bucknall (1999) state that a limitation of the studies carried out on the decisions of Triage's nurses relies on simulated scenarios that do not adequately replicate situational

elements of the environment in which such decisions are made. Furthermore, literature does not deeply investigate these relationships formally; most real case analyses are conducted on simulated scenarios (Gerdtz and Bucknall, 1999; Ponsiglione et al., 2018), and surveys are, for their nature, retrospective collections of data. This implies the difficulty in identifying the interrelations of individual and contextual factors in determining a decision as well as the lack of data on specific organizational or environmental aspects (for example, the number of interruptions). Additionally, from a methodological perspective, the models applied to analyze collected data on factors and their influence are pure descriptive models or traditional regression analyses that assume an additive linear perspective.

Starting from the premise above and the recognition of the complex nature of the Triage decision-making process, we aim at answering the following research question: How individual, organizational, and environmental factors influence, through their combination, the effectiveness of the Triage decision-making? In particular, we aim at identifying the combination of factors of different categories (individual and organizational/environmental) affecting the accuracy of the Triage process, adopting a configurational methodology such as *fuzzy set Qualitative Comparative Analysis*.

### **3 Qualitative Comparative Analysis (QCA) model**

Qualitative comparative analysis (QCA) aims to understand the complexity of a phenomenon, focusing on a set of theory-based conditions rather than considering separately the effects of individual variables. The conditions are the variables that can affect the outcome. QCA is used in different research fields, and also business and management scholars are showing an increasing interest in this method. Kraus et al. (2018) offer an overview of the existing research on QCA in different management research areas, highlighting its relevance for a deeper understanding of a complex phenomenon. More in-depth, QCA is a comparative case-oriented technique that allows performing an analysis on a small or intermediate number of empirical cases to identify the configurations of causally relevant conditions linked to the outcome under investigation (Marx et al., 2013). This method analyzes the relationships between the conditions and identifies the configurations of conditions that can produce a given outcome. It is an inductive research method inspired by complexity theory based on the principles of

conjunction, equifinality, and causal asymmetry (Misangyi et al., 2017). Conjunction concerns the evidence that we can obtain an outcome with different configurations of conditions. Equifinality means that we can find more effective configurations related to a given outcome. Causal asymmetry implies that some conditions can be absent in a configuration or inversely related and present in another one. This situation is since "the directionality between X and Y depends on what additional simple conditions occur in given contexts" (Woodside et al., 2018), where X is the condition, and Y is the outcome.

QCA conceptualizes the conditions as sets with a different membership degree according to the considered real case: if the condition is not present, the case has a membership degree equal to 0 for such condition; otherwise, the membership is equal to 1 if the condition is fully present. We apply the fuzzy sets (fsQCA and therefore, the membership is a value between 0 and 1, as the condition can be present but not fully present. Finally, QCA assesses the necessity and the sufficiency of the relationships between conditions and the outcome. We have a relationship of necessity if the condition has to be present for the outcome to occur. While, for the sufficiency, the condition can produce the outcome and is a subset of the outcome itself.

QCA methodology is proposed to be the answer for understanding phenomena for which it is not the single variable but the relationships between them that determine a result. This feature of QCA is also well suited in the field of decision-making based on cognitive heuristics such as the Triage process.

In this paper, we adopt a fsQCA approach to analyze row data obtained from the analyzed and observed real cases, according to the following steps:

#### *1) Data Calibration*

The cases are represented as configurations of causal conditions through a matrix whose rows are cases and whose columns are the conditions and the outcome. The cases are the patients arriving at the Emergency Department, whereas the conditions emerge from the literature influencing the decision-making. The calibration process concerns setting membership scores to cases using theoretical and empirical evidence (Wagemann and Schneider, 2010). While the csQCA considers set memberships restricted to binary values of 0 (full non-membership) and 1 (full membership); the fuzzy version that we used allows us to calibrate partial memberships in sets using values in the interval between 0 and 1, without abandoning core set-theoretical principles and operations. In particular, fuzzy membership of the variables derived by the theoretical guidance and the

essential experience on the empirical cases developed by researchers. The calibration was made through the use of the fsQCA R package.

### *2) Truth table Construction*

Unlike the necessity analysis, which derives its Boolean solution directly from the calibrated data, the sufficiency analysis proceeds by first converting the calibrated data into a truth table and then reducing that into a set of Boolean expressions. Thus, constructing the truth table is the second step in fsQCA. Assumed that a calibrated data set represents a multidimensional vector space with one dimension per causal condition, the Truth tables summarize the distribution of observations across the vector space emerged by the calibration. Therefore, it shows as many rows as there are combinations of causal conditions, obtaining a matrix of  $2^k$  rows, where  $k$  is the number of causal conditions.

Then, the FsQCA consists of applying Boolean algorithms using counterfactual analysis (Wagemann and Schneider, 2010) that simplify the configurations in the truth table into three solutions evaluated by two metrics called consistency and coverage. Consistency refers to the degree to which a condition or combination of conditions relates to an outcome within the data (similar to significance for statistical model). Coverage, instead, provides a measure of relevance (similar to  $R^2$  in regression models).

### *3) Necessity and Sufficient Analyses*

The goal of FSQCA is to identify causal condition or groups of them ('configurations') which are either necessary or sufficient for the outcome to occur. A necessary condition is one where the outcome cannot be achieved without it, yet its presence is not enough to produce the outcome. A sufficient condition is one where the outcome always occurs if it is present, but other conditions may also produce the same outcome. As Legewie (2013) notes, a few cases will deviate from the general necessity or sufficiency relations in real data. Thus, the two fit measures described above are used to assess the degree to which groups of causal conditions are associated with the outcome variable. For this step, we adopted the software fsQCA 3.0.

## **4 The application of fsQCA to the Triage process**

Field research has been conducted in the Emergency Department of a private-public Hospital in Naples, South of Italy. The Emergency Department serves the population which does not require specialistic care. Firstly, the research team

shared with the Hospital's management the research plan, obtaining the ethical consensus to perform the analysis. Secondly, the research team observed and mapped the Emergency Department processes with particular attention to Triage and the waiting room, which regulates access to care treatments. Finally, in April–June 2019, before the Covid-19 pandemic, the research team collected data on Triage, observing directly the Triage assignment decision-making made by different nurses, in different daily hours and on different days of the week. Researchers collected priority codes assigned to 100 patients. The 100 patients represent our real cases in the application of fsQCA.

In order to apply the fsQCA, we have, first of all, identified the conditions that are the factors affecting the Triage process.

According to the analysis of literature and after an observation of the Triage, we selected the following factors:

- vital signs (the measurement of vital signs made by nurses to take a decision);
- nurse experience measured as working years;
- number of nurses in each work shift;
- number of interruptions during the Triage process by colleagues;
- the arrival of patients with an ambulance;
- the number of interruptions during the Triage process by patients.

These variables are related to individual, organizational, and environmental factors modeled as causal conditions of the fsQCA model.

The subsequent step concerned the definition of the outcome of the model. The outcome is related to the accuracy of the Triage process, affecting ED's quality. An under or over the assessment of patients can increase the waiting time of urgent patients (Considine et al., 2007; Fernandes et al., 2005; Fitzgerald et al., 2010; Traub et al., 2015; Wuerz et al., 1998). Over-assessment triage occurs if the patient receives a higher priority level than expected, and this could affect the waiting time of more urgent patients. Under-assessment Triage implies that the patient has to wait more time to access care than required. As an outcome, we considered the under Triage as it impacts directly on the waiting time of a specific patient while over Triage can indirectly impact patients.

After defining conditions and the outcome, and after collecting data, researchers performed the calibration phase using both fuzzy variables and crisp ones (Table 1). For crisp variables, we have just the value "yes" or "not". Instead

for fuzzy variables we have a membership function built on the characteristics of the Triage.

Table 1: The variables used in QCA model

Variable	Acronym	Typology	Measurement	QCA Variable
Vital Signs	PV	Individual	Yes (1): if the decision is made measuring the vital signs No (0): otherwise	Crisp
Nurse' Experience	AE	Individual	Number of working years (Exp) in the health sector	Fuzzy
Number of nurses in each work shift	NT	Organizational	Yes: if three nurses are present in the work shift No: otherwise	Crisp
Number of interruptions during the Triage process by colleagues	NI	Organizational	Number of interruptions detected	Fuzzy
Arrival with ambulance	AM	Environmental	Yes: the patient arrives with an ambulance No: otherwise	Crisp
Number of interruptions during the Triage process by patients	NP	Environmental	Number of interruptions detected	Fuzzy
Accuracy	OUTCOME		Difference between priority code assigned by the nurse and priority code reported on the patient's medical record (assigned by the physician after a deep assessment of the patient)	Fuzzy

The calibration phase returns the following table of relationships between cases and conditions (table 2).

Empirical Cases (EC)	Conditions						OUTCOME		Empirical Cases (EC)	Conditions						OUTCOME

Table 2: Calibration data and membership of conditions

Based on the calibrated data, we proceed with constructing the "truth table", which proposes a list of all possible theoretical combinations of the causal conditions, the relative outcome, and the cases conforming to each combination (Ragin, 2000). The truth table treats each case as a combination of characteristics or 'configuration' in fsQCA terminology.

Then, the truth table is compared with the raw data table. The substantial difference between the two tables is the following: the first represents all possible configurations; the second, instead, report only the configurations emerged by empirical cases. In this way, we selected all the configurations of the truth table that we found in empirical cases. Furthermore, we simplified the truth table by applying a specific algorithm of fQCA that minimizes the number of rows, eliminating those not relevant to explain the outcome. The minimization process returns the minimum number of configurations that explain the outcome (Figure 1).

Figure 1: Overview of the solution

In Figure 1, the columns are the configurations of conditions that emerged after reducing the truth table. The analysis aims at finding a logical relationship between the lack of under assessment (that is assumed as a proxy for the accuracy of Triage) (~ Outcome1) and the six conditions considered in the model (PV, NI, NP, AM, AE, NT). The configuration of conditions related to each path represents a sufficient but not necessary condition for obtaining the result.

Six configurations were extracted, and for each configuration, we can identify if a condition is present or not in the specific term of the solution. The presence of a condition in a path is represented by the black circle, while its negation is a crossed circle.

For the overall solution (made by six terms) and for each term, we have the relative value of coverage and consistency in order to facilitate comparison. For the coverage, Ragin (2009) does not propose any threshold value as it is linked to empirical relevance of the combination (how much of the outcome the combination can explain), whereas for the consistency, the value must be around 0.8, certainly not lower than 0.75. The results show that the combinations and the solution far exceed the value of the consistency threshold. In particular, the solution has an overall consistency value equal to 0,94. Therefore, the model has a strong explanatory power of the outcome.

## 5 Discussion and practical implications

The results of the study show that the configuration presenting the highest coverage value (0.248679) and a good level of consistency (0.934) is the

configuration (AE \* ~ NP \* ~ AM \* ~ NI \* NT). This configuration considers a triage process carried out by an expert nurse (AE), with the presence of all expected nurses in the Emergency Department area in the work shift analyzed (NT), in conditions of absence of interruptions by colleagues (~ NI) and by patients (~ NP), and patients not arrived by ambulance transportation (~ AM).

We can assume that the presence of all nurses and the absence of a crowd allow nurses to focus on specific patients, avoiding interruptions. Furthermore, an expert nurse can assign the correct priority code for patients not arriving with ambulance and without a pre-evaluation made by the ambulance's crew. In fact, all cases related to this configuration are registered by the same nurse, with 26 years of experience, and always in the morning, when the maximum number of nurses assigned to Triage is in the emergency room.

The configuration with the highest consistency level (0.996) is (PV \* AE \* ~ NP \* ~ NI \* NT), but it has a lower level of coverage than the previous combination (0.103). This configuration presents the measurement of vital signs (PV) by an expert nurse (AE), the absence of interruptions by patients (~ NP) and colleagues (~ NI), and the maximum number of nurses per shift (NT). This partially confirms the result described by the previous combination. In fact, this configuration also has the presence of the measurement of vital parameters. Although many studies state that more experienced nurses tend to do not measure vital signs (Chung, 2005; Gerdtz and Bucknall, 2001), in both cases related to this configuration, the detection of vital signs (PV) has been made. We can justify this choice by analyzing specific cases. In one case, the patient had abdominal pain, a symptom that requires the measurement of vital signs. In the other one, the arrival of the patient took place in an ambulance, so the vital signs had already been detected in the ambulance, but the long waiting time in the patient queue (12'30") to access the Triage prompts the nurse to detect the vital signs again to grasp an evolution or changes in symptoms exhibited.

The other combinations confirm the presence of all nurses scheduled for the shift and the absence of interruptions by colleagues and patients. In a quiet environment, the nurse can detect the vital signs for the patients who arrived by ambulance to confirm the priority code assigned by the ambulance's crew or to capture any change in symptoms. In a quiet environment, also less expert nurses assign the correct priority code to the patient.

According to these 4 out of 6 configurations, we can infer that the Triage should be performed in a dedicated room avoiding interruptions and that the

measurement of vital signs could be a valuable support for the accuracy even for expert nurses that usually make decisions based primarily on their intuition.

The other two configurations with a lower value of coverage and consistency confirm that the presence of three nurses in the Emergency Department is an ever-present condition; unlike the other four configurations, these last two presents the lack of experience (~ AE), the scarce use of vital parameters (~ PV), and the evaluation of patients who arrived at the ED independently (~ AM). Such configurations suggest that, despite the lack of experience, the nurse relies mainly on their "intuition" rather than on vital parameters in evaluating patients arriving independently. Additionally, it seems that the presence of all scheduled nurses in a work shift can instill a greater sense of security in less expert nurses who can always rely on more experienced colleagues. However, less experienced nurses take more time to assess the patients. In fact, a more profound analysis of the cases relative to these two configurations showed a high number of questions for the attribution of the code, confirming what emerged by the literature: less experienced nurses collect more information from the patient to formulate the Triage decision (Cioffi, 1998).

These results suggest some managerial interventions on the Triage process. Firstly, the accuracy of Triage can be improved if almost an experienced nurse is devoted exclusively to the Triage. In this way, he/she can concentrate fully on the Triage process without external pressure. Furthermore, the great experience allows the nurse to make an accurate decision even for walking patients, which are not pre-assessed for their clinical conditions. This suggests a redesign of the layout of the analyzed Hospital, with a room dedicated exclusively to Triage with an expert nurse in crowded situations or less expert nurses in quiet situations since they take longer to assign the priority code. Concerning the organizations of the work shifts, our results show that the number of Triage nurses simultaneously present in the Emergency Department has to be the maximum number available and that disparities among the work shifts have to be removed.

Another interesting result concerns the vital signs that are not the main information used by nurses. These findings could encourage the Emergency Department to adopt tele-Triage or pre-Triage to better address the patient towards Emergency Departments or other structures to face the social distancing due to COVID-19.

## 6 Conclusion

The Triage process prioritizes access to health treatment in an Emergency Department. Although many scholars gave strong attention to this process to streamline the processing of patients and reduce the waiting time of more urgent ones, we propose an under-investigated perspective to analyze this process: understanding the factors that can affect the Triage accuracy. This paper presents the application of fuzzy Qualitative Comparative Analysis to the dynamic decision-making in Triage assessment. Unlike other works, this research is carried out through direct observation of the Triage process in its empirical reality; this allowed to consider also environmental factors in the study.

Findings suggest that the accuracy of the Triage process requires that an experienced nurse carries out the assignment process in a situation in which all scheduled nurses are present in the work shift with the absence of interruptions by colleagues and by patients. All configurations confirm as relevant the presence of all nurses in the work shifts, whereas the measurement of vital signs can be helpful support for the accuracy even if the nurses rely primarily on their intuition.

Following a methodological perspective, this application shows that fsQCA is an effective method for understanding the cognitive heuristic decision-making process, highlighting how individual, organizational and environmental factors interact for producing an effective Triage.

From a practical perspective, these findings can give helpful insights to managers of a hospital or an Emergency Department to improve the follow of patients starting from Triage.

The study has already been used to organize a training session for the hospital nurses involved in the research. Unfortunately, the advent of the outbreak has not allowed completing the training process and the discussion with managers of the Emergency Department to design organizational interventions on Triage. This aspect will be the object of future developments of this work.

### **Abstract**

Integrated Care Pathways (ICPs) are multidisciplinary approaches designed and adopted by hospitals for achieving more efficiency and effectiveness in the care processes. Despite these advantages, it is still needed to demonstrate their economical and organizational positive effect, by taking into account specific contextual variables such as the existing resources and technologies of the hospitals (van Hove et al., 2020).

In addition, since the complexity of the care processes is high, the development of an integrated dashboard of monitoring indicators of ICPs is a critical issue in the referred literature. In particular, the framework should be holistic and designed for a large spectrum use of actors; the indicators should be easily measurable and computable.

For this reason, we design a framework of indicators measuring the effect of ICPs on multiple dimensions including quality of care, cost and productivity, and research and development. The framework was validated by a group of experts belonging to different

functional areas. Afterward, we investigate the feasibility of the proposed set of indicators to the performance of the lung and the breast cancer care pathways in a specific hospital, i.e., the Cancer Institute "IRCCS Giovanni Paolo II" (Italy).

The healthcare organization can use this tool to 1) monitor whether the pathways meet the requirements of continuity, responsiveness, and appropriateness of health services; and 2) optimize the allocation of resources.

## 1 Introduction

Integrated Care Pathways (ICPs) are multidisciplinary care plans that explain the significant steps in the care process for patients with specific health conditions (Richter et al., 2017). The ICPs help translate clinical guidelines into local protocols and clinical practice (Campbell et al., 1998) as a tool for quality improvement. They are designed and adopted by hospitals, for achieving the following main objectives: increase of care standardization (Ishiguro et al., 2008), improvement of care quality (Allen et al., 2009; Kobayashi et al., 2019), optimization of resource usage (Kobayashi et al., 2019), and cost efficiency (Everink et al., 2018). ICPs are effective for improving communication and coordination among multiple stakeholders (Allen et al., 2009).

Despite this, it is still needed to demonstrate the positive effect of the adoption of ICPs from multiple reasons. First, literature has mainly focus the attention of the effect on the quality of care (Altini et al., 2019; van Hoeve et al., 2020), while other dimensions, such as the economic one, have been less investigated. Furthermore, mixed results have been also obtained (Rotter et al., 2010). One reason for this is that the ICP protocols are designed without a specific consideration of existing capacity and resources of the hospital, are calibrated on an "ideal patient" in an "ideal health system" (van Hoeve et al., 2020). Even though the ICP protocols are designed by the healthcare professionals who know the context, they often are not be aware of management and digital tools that should be needed for the effective implementation (Berler et al., 2005; Coltart et al., 2012), so that the expected results are put in question. Most ICPs are still paper-based and not fully integrated with Health Information Systems (Alahmar et al., 2020). This is also aggravated by the complexity of the care processes involving a

large number of activities, carried out by several actors in different departments and, in some cases, organizations.

Therefore, the development of an integrated dashboard of monitoring indicators of ICPs is still a critical issue in the referred literature. This is even more true for oncological diseases which are one of the most expensive cares.

The objective of this paper is twofold. From one hand, we design a framework of indicators measuring the effect of ICPs on multiple dimensions including quality of care, cost and productivity, and research and development. From the other hand, we investigate the feasibility of the proposed set of indicators to the performance of the lung and the breast cancer care pathways in a specific hospital, i.e., the "IRCCS Istituto Tumori Giovanni Paolo II" (Italy).

The framework was designed on the basis of the literature and then validated by a group of experts belonging to different functional areas. The indicators are grouped according to three broad classes: "quality of care and health services", "use of resources", "research, development and innovations". The framework proposed is designed to be used in an interoperable manner by a large spectrum of actors (administrative staff, clinicians, clinical governance). The indicators are easily measurable and do not contain ones referenced to specialist medical concepts. In particular, they can be measured using administrative databases or hospital discharge card.

The paper is so organized. First, we discuss the classes of indicators, with some examples of KPIs' set developed in literature; then, we explain our theoretical framework. Finally, we discuss the application in a specific case and conclude introducing the next steps of the research.

## **2 Indicators to assess Integrated Care Pathways**

Indicators are measurement tools used as guides to monitor, evaluate and improve the quality of patient care, clinical support services, and organizational function that affect outcomes (Mainz, 2003). In general, the measured data is of interest to patients, payers for care, and providers who receive data for quality improvement purposes.

A care service is evaluated using both qualitative and quantitative indicators. Qualitative ones are not objectively measurable and include the results of professional practice, such as staff satisfaction, documentation quality, or patient satisfaction results. Quantitative ones include specific outcomes, such as the

length of stay, the number and types of services provided, the hospital costs and patient outcomes, such as hospital mortality, longer follow-up mortality, hospital readmissions, hospital complications and hospitalizations in intensive care (Mainz, 2003; Rotter et al., 2010; van Hoeve et al., 2020).

The ICP's KPIs can be generic or they can measure particular aspects of the care related to specific diseases. Both generic and disease-specific KPIs can focus on structure, process, or outcomes. Structural indicators concern the type and number of resources used by the healthcare system to provide programs and services and refer to the presence or number of staff, customers, money, beds, supplies and buildings (Mainz, 2003). Process indicators measure activities and tasks in patient care episodes (Mainz, 2003). Outcomes concern the health states or events following care and may be affected by healthcare (Mainz, 2003).

On the base of the type of care, indicators are classified in preventive, acute or chronic ones (Schuster et al., 1997). According the function of care, they may involve screening, diagnosis, treatment and follow-up (Schuster et al., 1997). Finally, depending by the way in which assistance can be provided, the KPIs refer to the physical examination of the patient, the laboratory or radiological study or the prescription of drugs (Schuster et al., 1997).

Recently, Altini et al., (2019) identify seven KPIs for the ICP of breast cancer. The indicators are designed to improve efficiency in resource use by monitoring the inadequacy of diagnostic tests, by measuring the inadequacy of possible interventions, and by evaluating the inadequacy of time of administration from the indication of surgery. However, the framework adopts a medical approach, takes into consideration the entire CP of breast cancer. The paper by Cafagna et al., (2018) shows the application of different indicators to the clinical pathway of heart failure (HF). The aim is to examine the potential impact of improving equity in the quality of care on financial sustainability.

### **3 The framework**

In this Section, we develop a framework of indicators to assess the ICPs based on the literature. We reviewed papers published on scientific journals but also, we included grey literature, considering some protocols written by organizations that have formally implemented the ICPs. The list of KPIs were reorganized according to common themes and then they were discussed and prioritized through interviews with experts involved in the development and delivery of the ICPs. The

prioritization criteria were "ease of interpretation", "ease of calculation", "importance to decision makers" and "innovation". This phase led to a final list of indicators covering different areas.

The proposed framework (Figure 1) is structured on three areas: 1) "Quality of Care", 2) "Use of resources" and 3) "Research, development and innovation". For each area we identify three specific dimensions, which are then translated into 31 indicators.

The "Quality of care" area includes the following dimensions (indicators) "Communication with staff" (4 KPIs), "Hospitalization" (3 KPIs) and "Service" (10 KPIs). The dimensions "Cost" (2 KPIs), "Resource Productivity" (4 KPIs) and "Wastes" (2 KPIs) refer to the "Use of Resource" area. The "Research, development and innovation" area includes the "Clinical Trials" (2 KPIs), "Continuing medical education (CME)" (2 KPIs) and "Scientific publications" (2 KPIs).

Table 1 reports all KPIs developed.

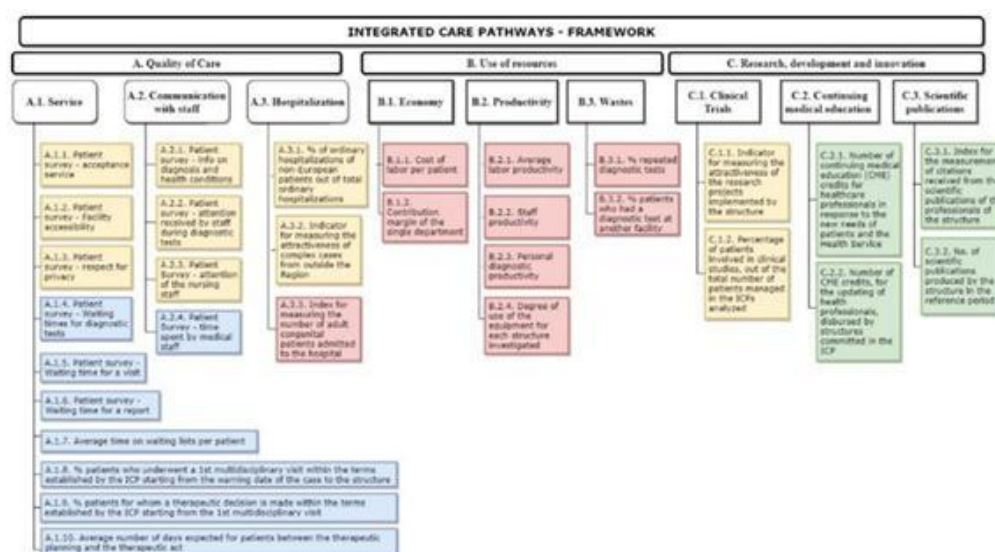

Figure 11 It is depicted the framework representing the areas of interests and related dimensions.

Table 14: Key Performance Indicators (KPIs) grouped by dimensions and area of interest.

KPI	Formula	Type	Ref.
<b>A. Quality of care – A.1. Service</b>			
A.1.1. Patient survey - acceptance service	(Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.1.2. Patient survey - Facility accessibility	(Likert 1-5)	Outcome Survey –	Adapted by A.R. (Veltri & Adamo, 2010)
A.1.3. Patient survey - respect for privacy	(Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.1.4. Patient survey - Waiting times for diagnostic tests	(Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.1.5. Patient survey - Waiting time for a visit	(Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.1.6. Patient survey - Waiting time for the report	(Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.1.7. Average time on waiting lists per patient	Total N° of waiting days / Tot patients	Process	(Berler et al., 2005)
A.1.8. % Patients who underwent a 1st multidisciplinary visit within the terms established by the ICP starting from the warning date of the case to the structure	(Patients in regular terms) / (Total Patients) x 100	Process	personal elaboration
A.1.9. % Patients for whom a therapeutic decision is made within the terms established by the ICP starting from the 1st multidisciplinary visit	(Patients in regular terms) / (Total Patients) x 100	Process	personal elaboration
A.1.10 Average number of days expected for patients between the 1st multidisciplinary visit(that corresponds to the moment of the therapeutic planning)and the therapeutic act	Tot. Waiting days / Tot. Patients	Outcome – HIS	personal elaboration
<b>A. Quality of care – A.2. Communication with the staff</b>			
A.2.1. Patient survey - info on diagnosis and health conditions	Patient evaluation (Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.2.2. Patient survey - attention received by staff during diagnostic tests	Patient evaluation (Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)
A.2.3. Patient survey - attention of the nursing staff	Patient evaluation (Likert 1-5)	Outcome Survey –	Adapted by (Veltri & Adamo, 2010)

KPI	Formula	Type	Ref.
A.2.4. Patient survey - time spent by medical staff	Patient evaluation (Likert 1-5)	Outcome – Survey	Adapted by (Veltri & Adamo, 2010)
<b>A. Quality of care – A.3. Hospitalization</b>			
A.3.1. % of ordinary hospitalizations of non-European patients out of total ordinary hospitalizations	$(\text{Extra-European ordinary hospitalizations}) / (\text{Total ordinary hospitalizations}) \times 100$	Process	(Pediatrico Bambino Gesù Ospedale, 2016)
A.3.2. Indicator for measuring the attractiveness of complex cases from outside the Region	$(\text{Extra-regional ordinary hospitalizations with weight} > 1.9) / (\text{Extra-regional ordinary total hospitalizations}) \times 100$	Process	(Pediatrico Bambino Gesù Ospedale, 2016)
A.3.3 Index for measuring the number of adult congenital patients admitted to the hospital	$(\text{Patients aged} > 18) / (\text{Total Patients}) \times 100$	Process	(Pediatrico Bambino Gesù Ospedale, 2016)
<b>B. Use of resources – B.1. Economy</b>			
B.1.1. Cost of labor per patient	$(\text{Hours worked} / \text{quantity produced}) \times \text{hourly wages}$	Outcome	(Sanna, 2012)
B.1.2. Contribution margin of the single department	$(\text{Single department revenue} - \text{Single department costs}) / \text{Total revenue}$	Outcome	(Zanella, 2011)
<b>B. Use of resources – B.2. Productivity</b>			
B.2.1. Average labour productivity per employee	$\text{Real value of production} / \text{number of workers}$	Outcome	Adapted by (M. Calderini, P. Neirotti, E. Paolucci, P. Ravazzi, 2007)
B.2.2. Staff productivity in the therapeutic phase	$\text{No. of SDOs} / \text{hours worked in the health facility}$	Outcome	personal elaboration
B.2.3. Personnel diagnostic productivity	$\text{No. of diagnostic tests} / \text{hours worked}$	Outcome	Adapted by (Zanella, 2011)
B.2.4. Use of the equipment in the reference period, in order to evaluate its efficiency	$\text{No. of examinations performed in the time interval (per device)} \times 100 / (\text{max daily examinations} \times \text{No. of days in the Timeframe})$	Outcome	Adapted by (Neri, 2009)
<b>B. Use of resources – B.3. Wastes</b>			
B.3.1. Percentage of diagnostic tests for which a retest was required	$\text{No. repeated exams} \times 100 / \text{total exams}$	Process	personal elaboration

KPI	Formula	Type	Ref.
B.3.2. Patients with diagnostic tests in another facility after being taken in charge by the facility under study	No. of patients * 100 / tot treated patients	Process	personal elaboration
C.Research, development and innovation – C.1. <i>Clinical Trials</i>			
C.1.1. Indicator for measuring the attractiveness of the research projects implemented by the structure	Funding received from external bodies for scientific research / Total funding for scientific research	Outcome	(Pediaterico Bambino Gesù Ospedale, 2016)
C.1.2. Percentage of patients involved in clinical studies, out of the total number of patients managed in the ICPs analyzed	N. Patients involved in trials / N. Total patients in the analyzed ICPs	Process	personal elaboration
C. Research, development and innovation – C.2. <i>Continuing medical education (CME)</i>			
C.2.1. Number of continuing medical education (CME) credits for healthcare professionals in response to the new needs of patients and the Health Service	Sum of CME credits gained by actors committed in the ICP	Outcome Agenas database	- personal elaboration
C.2.2. Number of CME credits, for the updating of health professionals, disbursed by structures committed in the ICP	Sum of CMEs credits disbursed	Outcome Agenas database	- personal elaboration
C.Research, development and innovation – C.3. <i>Scientific publications</i>			
C.3.1. Index for the measurement of citations received from the scientific publications of the professionals of the structure	Average impact factor per researcher	Outcome Scopus Database	- personal elaboration
C.3.2. No. of scientific publications produced by the structure in the reference period	N ° scientific publications (six-monthly data)	Outcome Scopus Database	- personal elaboration

## 4 Application

### 4.1 The Giovanni Paolo II" Cancer Institute

The "Giovanni Paolo II" Cancer Institute in Bari (Italy) is an IRCCS, i.e. "Hospitalization and Care Institute with Scientific Character". It belongs to a national network of 51 IRCCS and to a European network of Organization European Cancer Institute (OEI). It has excellent clinical and research performance; it also performs several ICPs, as many as the oncological diseases it treats.

The Table 2 reports a characterization of contextual and structural dimensions. The information is gathered by some Institution's documents.

Table 15: Features of healthcare organization

<b>Contextual dimensions</b>	
<b>Strategy</b>	<p><i>Vision:</i> The Institute is a candidate to become the Regional Reference Center for oncological pathologies, pursuing the quality of care and the rapid transfer into care practice of the tools that research makes available to clinicians to fight cancer more effectively.</p> <p><i>Mission:</i> Any waste is avoided. For this reason, the appropriateness and efficiency of care choices are constantly pursued through continuous monitoring of production, costs and results. Any potential conflicts of interest are fought. With regard to research, efficiency is also pursued in the choice of areas of medicine to be tested.</p>
<b>Context</b>	<p>It is financed on the basis of national and regional financing, in order to obtain integration between healthcare and research policies. The Institute also accepts liberal donations. On the national territory, there are 51 IRCCS, of which 21 public and 30 privates, which refer to different areas of expertise, including oncology.</p> <p>The Institute is recognized to be among the European Certified centres – OECL.</p>
<b>Geographic location</b>	The registered office of the Institute is in Viale Orazio Flacco 65 - 70124 BARI, where its administrative, assistance and research structures are located.
<b>Culture</b>	Absolute respect for the ethics and for the patient's dignity. The personalized medicine and to the individuality of the patient are very important.
<b>Dimension</b>	166 care beds
<b>Logo and motto</b>	The Institute logo is represented by the image of a tumor cell "attacked by therapy"; the logo is intended to graphically express the company mission.
<b>Technology</b>	High level of technology of machinery for clinical and research activities. Low level of interoperability of hospital information systems among the different units.
<b>Structural dimensions</b>	
<b>Hierarchy</b>	<p>The organizational structure is hierarchical.</p> <p>The Institute is divided into the following types of Organizational Structures: Departments, Complex Structures, Simple structures with departmental value, Simple Structures (S.S.) and Research Areas.</p> <p>It should be noted that the generic term Operating Unit includes both complex and simple structures.</p> <p>The Departments are aggregations of homogeneous Operating Units, similar or complementary to each other. These have common purposes and are strongly integrated with each other, while maintaining their autonomy and organizational, managerial and professional responsibility. The Director of the</p>

	Department is appointed by the Director General; he must necessarily be Director of a complex structure. He is hierarchically superordinate to the Structure Directors. The Complex Structures (CS) are internal divisions of the department with a specific specialized and organizational reference of a complex nature. The Simple Departmental Structures (S.D.S.) are structures that in a perspective of transversal support to the production process are placed hierarchically under the Department Director and not a complex structure. Simple Structures (SS) are articulations of the complex structures of which they are part. The SS is awarded a defined amount of resources by the Director of the relevant SC and specific objectives are assigned within the operational budget (objectives and resources) of the SC to which it belongs. Research Areas are areas of activity usually entrusted to professionals with professional coordination assignments whose technical-professional autonomy is exercised in compliance with operational protocols.
<b>Staff indicators</b>	Research staff is evaluated based on research outputs, but there are not other productivity indicators, except the Absence rates. Total Staff expenditure (2018): € 36.640.040. Medical Executives: € 15.770.000 Nurses / Auxiliary Health Assistant: € 12.296.040 Other personnel € 8.574.000

#### *4.2.1 Breast and Lung Cancer Integrated Pathways*

We referred our analysis to two ICPs concerning the breast and lung cancers. The related protocols have been approved and made public in 2016 (IRCCS di Bari, 2016b, 2016a). They have a similar structure consisting of epidemiological premise, purpose, core team or multidisciplinary group, description of the ICP at each stage (diagnosis, staging, treatment, intervention, follow-up), bibliography and guidelines, and accompanying documentation.

We characterize the two ICPs according to different variables (Table 3), concerning the health professionals involved in the process, the monitoring frequency and references to the indicators already considered in the protocol. Actually, the ICPs performance are not currently monitored by the clinical governance of the organization, but those sent and analyzed by the Regional Health Authority.

Table 16. Characterizations of the Breast and Lung ICPs of the Healthcare Organization.

ICP	Breast Cancer	Lung Cancer
<b>Multidisciplinary Team</b>	Radiologist, Breast Surgeon, Plastic Surgeon, Pathologist, Oncologist, Radiotherapist, Nuclear Doctor, Case Manager and, depending on the need, other specialized professionals (psycho-oncologist, onco-geneticist, gynecologist, pain therapist, Doctor of Physical and rehabilitative medicine and the physiotherapist). General practitioners, patient and volunteer associations can also be involved.	Medical Oncologist, Thoracic Surgeon, Radiologist, Interventional Radiologist, Pathologist, Molecular Biologist, Radiotherapist, Case Manager Nurse. The Anesthetist for pain therapy and palliative care, the General Practitioner, the voluntary associations collaborate with the Team.
<b>Process Monitoring</b>	The Team carries out a review of the process once a year and meetings for case discussion at least twice a month.	The Team reviews the process once a semester, with case discussion meetings at least twice a month.
<b>ProtocolKPIs</b>	The breast cancer protocol includes specific disease indicators both of process (10 KPIs) and of diagnosis and outcome (2 KPIs). Structure indicators are absent.	For the lung ICP protocol, there are annexes: on process indicators (4 KPIs) and on Pathological Anatomy procedures (with indications on the average reporting and response times to examinations). Structure indicators are absent.
<b>Formalization</b>	The grade of formalization is medium. Actors communicate orally, but the emails are predominant.	The grade of formalization is medium. Actors communicate orally or through calls and sometimes through emails, for example to organize meetings.
<b>Digitalization of ICPs</b>	The Breast ICP is included in a project that involves others Breast Hub in Italy. For this reason, the procedure of collecting data is more formalized. These clinical data are updated and saved on a software dedicated. However, this software does not communicate with other databases of the organization, such as PACS system and administrative database. Some persons (are usually the case managers) are dedicated to activities of data-entry.	This dimension is scarcely considered. Actors used to trace data on files saved on local memory until the role of case manager was present. Now, they are collecting all documents (pdf files) for each patient in folders saved on the pc.
<b>Cross-hospital collaboration</b>	There are more specialized exams executed in other facilities, such as the Lymphoscintigraphy is an exam to be carried out in another hospital.	There are more specialized exams executed in other facilities: the Positron Emission Tomography (PET) exam in a

ICP	Breast Cancer	Lung Cancer
		Teaching Hospital of Bari and the ROSE guided navigation system used in another hospital of Bari.
Seniority	We do not consider all units committed in these ICPs, but those that are particularly important.	
	<i>General surgery hospitalization for breast cancer.</i> It includes 32 healthcare professions. 6 medical managers, 20 professional healthcare collaborators (1 physiotherapist, 18 nurses, 1 expert nurse), 2 specialized auxiliaries, 3 socio-health operators. Average career time in the Institute is 18 years.	<i>Thoracic surgery hospitalization.</i> It includes 28 healthcare professions. 8 medical managers, 17 professional healthcare collaborators - nurses, 3 social health workers. Average career time in the Institute is approximately 7 years.
Cases a year	502 surgeries in the 2020	356 surgeries in the 2020

#### 4.2.2 Process explanation

The process is initiated by the first symptom in the patient, who books a first specialist visit privately or by request of the General Practitioner (GP). At the same time, he/she carries out a first level diagnostic examination (e.g., an X-ray). During the first visit, the medical oncologist assesses the patient's performance status and can request further diagnostic tests by evaluating hospitalization (ordinary or day hospital) or orsend it back to the GP successfully.

The first event starts the diagnosis-staging phase, in which the goal is to assess the type and extent of the tumor. At this stage, the medical oncologist decides whether to present the case to the multidisciplinary team or not. This choice causes the effect known in the literature as "exclusion" for patients not referred to the integrated pathway. This condition could lead to longer waiting times, violating the fundamental principle of providing good health care on equal terms for the entire population(Smeds & Poksinska, 2019).

When the patient is taken care of by the team, the various medical specializations meet to discuss the specific case and evaluate the subsequent steps, namely the indication of intervention and the type of treatment. At the end of the therapeutic phase, the patient is discharged, and the follow-up phase begins. If necessary, the case is referred to the multidisciplinary team for discussion. Throughout the process, the patient is managed by the case manager,

who coordinates and follows all the activities planned across the various departments.

## 4.2 Discussion

This paragraph evaluates whether the proposed framework of indicators is suitable for the IRCCS of Bari. It is checked whether the indicators are measurable and what data sources (professional roles and information systems) they need.

We noticed that currently it is possible to compute 19 KPIs in both the ICPs considered. Respectively for the Breast and Lung cancer, others 6 KPIs and 1 KPI are computable with a proxy, while 6 and 11 KPIs are not measurable. The information about which KPIs are measurable or not, grouped by dimensions (see Paragraph 3 "The Framework"), are reported in the Table 4. The Table 5,6 and 7 evaluate each KPI application.

Table 17: Results of the KPIs applicability

<b>Breast Cancer ICP</b>	<b>A.1</b>	<b>A.2</b>	<b>A.3</b>	<b>B.1</b>	<b>B.2</b>	<b>B.3</b>	<b>C.1</b>	<b>C.2</b>	<b>C.3</b>	
N° Measurable KPIs	4	0	3	2	3	1	2	2	2	19
N° Not Measurable KPIs	4	1	0	0	1	0	0	0	0	6
N° KPIs Measurable with a proxy	2	3	0	0	0	1	0	0	0	6
<b>Lung Cancer ICPs</b>	<b>A.1</b>	<b>A.2</b>	<b>A.3</b>	<b>B.1</b>	<b>B.2</b>	<b>B.3</b>	<b>C.1</b>	<b>C.2</b>	<b>C.3</b>	
N° Measurable KPIs	4	0	3	2	3	1	2	2	2	19
N° Not Measurable KPIs	6	4	0	0	1	0	0	0	0	11
N° KPIs Measurable with a proxy	0	0	0	0	0	1	0	0	0	1
N° KPIs for dimension	10	8	6	4	8	4	4	4	4	

Table 18. It reports the analysis of KPIs applicability belonging to the class "Quality of care".

A. Quality of care –A.1. Service					
KPI	Formula	Type	Ref.	Usable?	Notes
A.1.1. Patient survey - acceptance service	(Likert 1-5)	Outcome – Survey	Adapted by (Veltri & Adamo, 2010)	Breast ICP: The KPI isn't measurable with Likert scale. Lung ICP: Data absent	Breast ICP: The information can be collected from a questionnaire of evaluation of quality perceived by patients. Example of a proxy: "In general, how do you evaluate this treatment path, from a clinical, welfare and rehabilitation point of view? (Choose a score ranging from 0 to 10 where 0 = very bad and 10 = very good)"

A.1.2. Patient survey - Facility accessibility	(Likert 1-5)	Outcome – Survey	Adapted by A.R. (Veltri & Adamo, 2010)	Breast ICP: The KPI isn't measurable with Likert scale. Lung ICP: Data absent	Breast ICP: The information can be collected from a questionnaire of evaluation of quality perceived by patients. Example of a proxy: <i>"Where did the treatments after surgery? (More than one choice can be made)". "Where did you check after the treatments: surgical, chemotherapy, radiotherapy? (It is possible to make more than one choice)".</i>
A.1.7 Average number of waiting days per patient, starting from entering the facility up to therapeutic planning.	Total N° of waiting days / Tot patients	Process	(Berler et al., 2005)	Breast/Lung ICP: The KPI is measurable through an integration of clinical data and administrative databases. Data of the 1st visit, and data of the 1st multidisciplinary meeting are needed.	The doctors collect data on clinical outcomes and on patient's health history. They report the results of the multidisciplinary meetings in files saved on local memory in the case of the Lung cancer, or on a dedicated software for the Breast cancer. All services (in-patient or out-patient) provided to the patients are registered only in the administrative database and they are coded according to the ICD-19-CM. The information, on 1 <sup>st</sup> multidisciplinary meeting, can be deduced by the multidisciplinary reports reported in files saved on local memory in the case of the Lung cancer, or on a dedicated software for the Breast cancer. The information, on cases entering the facility, can be obtained from the administrative database.
A.1.8. % Patients who underwent a 1st multidisciplinary visit within the terms established by the ICP starting from entering the facility	(Patients in regular terms) / (Total Patients) x 100	Process	personal elaboration	Breast/Lung ICP: The KPI is measurable through an integration of clinical data and administrative databases. The information on numbers of patients underwent a 1st multidisciplinary visit within the terms isn't automatically computable.	The information, on 1 <sup>st</sup> multidisciplinary meeting, can be deduced by the multidisciplinary reports reported in files saved on local memory in the case of the Lung cancer, or on a dedicated software for the Breast cancer. The information, on cases entering the facility, can be obtained from the administrative database because it corresponds to the first performance executed for the patient by the organization.
A.1.9. % Patients for whom a therapeutic act is made within the terms established by the ICP starting from the 1st multidisciplinary visit	(Patients in regular terms) / (Total Patients) x 100	Process	personal elaboration	Breast ICP: The KPIs can be supported by the Breast Unit software Lung ICP: The KPIs can be measured manually	The moment, in which the therapeutic act is undertaken, corresponds to the first day of the therapy. It can be obtained from the administrative database.

A.1.10 Average number of days expected for patients between the 1 <sup>st</sup> multidisciplinary visit, that corresponds to the moment of the therapeutic planning, and the therapeutic act	Tot. Waiting days / Tot. Patients	Outcome - HIS	personal elaboration	Breast ICP: The KPIs can be supported by the Breast Unit software Lung ICP: The KPIs can be measured manually	The moment, in which the therapeutic decision is undertaken, corresponds to the starting of the therapy.
A. Quality of care – A.2. Communication with the staff					
Subdimension	KPI	Type	Ref.	Usable?	Notes
A.2.1. Patient survey - info on diagnosis and health conditions	Patient evaluation (Likert 1-5)	Outcome - Survey	Adapted by (Veltri & Adamo, 2010)	Breast ICP: The KPI is not measurable with Likert scale. Lung ICP: Data absent	Breast ICP: The information can be collected from a questionnaire of evaluation of quality perceived by patients. Example of a proxy: <i>"Did they explain what symptoms to keep under control?"</i> . <i>"After the follow-up exams, did you receive clear explanations of the results?"</i>
A.2.2. Patient survey - attention received by staff during diagnostic tests	Patient evaluation (Likert 1-5)	Outcome - Survey	Adapted by (Veltri & Adamo, 2010)	Breast ICP: The KPI is not measurable with Likert scale. Lung ICP: Data absent	Breast ICP: The information can be collected from a questionnaire of evaluation of quality perceived by patients. Example of a proxy: <i>"Did the health personnel book appointments for visits, exams and therapies directly? (Before / After surgery)"</i>
A.2.3. Patient survey - attention of the nursing staff	Patient evaluation (Likert 1-5)	Outcome - Survey	Adapted by (Veltri & Adamo, 2010)	Breast ICP: The KPI is not measurable with Likert scale. Lung ICP: Data absent	Breast ICP: The information can be collected from a questionnaire of evaluation of quality perceived by patients. Example of a proxy: <i>"Did the health personnel who treated and assisted you give you a sense of reliability and trust?"</i>
A. Quality of care – A.3. Hospitalization					
Subdimension	KPI	Type	Ref.	Usable?	Notes
A.3.1. % of ordinary hospitalizations of non-European patients out of total ordinary hospitalizations	(Extra-European ordinary hospitalizations) / (Total ordinary hospitalizations) x 100	Process	(Pediaterico Bambino Gesù Ospedale, 2016)	Breast/Lung ICP: It can be measured.	The nationality of patients can be obtained from administrative databases (hospital discharge form)
A.3.2. Indicator for measuring the attractiveness of complex cases from outside the Region	(Extra-regional ordinary hospitalizations with weight > 1.9) / (Extra-regional ordinary total hospitalizations) x 100	Process	(Pediaterico Bambino Gesù Ospedale, 2016)	Breast/Lung ICP: It can be measured.	The nationality of patients can be obtained from administrative databases.

A.3.3 Index for measuring the number of adult congenital patients admitted to the hospital	(Patients aged > 18) / (Total Patients) x 100	Process	(Pediaterico Bambino Gesù Ospedale, 2016)	Breast/Lung ICP: Yes, it is measurable. It is not useful because for these ICPs it corresponds to the 100%	
<b>A. Quality of care – A.1. Service - Not measurable</b>

Table 19. It reports the analysis of KPIs applicability belonging to the class “Use of resources”

<b>B. Use of resources – B.1. Economy</b>					
Subdimension	KPI	Type	Ref.	Usable?	Notes
B.1.1. Cost of labour per patient	(Hours worked / quantity produced) X hourly wages	Outcome	(Sanna, 2012)	Breast/Lung ICP: It can be measured.	This information is retrievable from administrative and human resources databases
B.1.2. Contribution margin of the single department	(Single department revenue - Single department costs) / Total revenue	Outcome	(Zanella, 2011)	Breast/Lung ICP: It can be measured.	This information is retrievable from administrative database

<b>B. Use of resources – B.2. Productivity</b>					
Subdimension	KPI	Type	Ref.	Usable?	Notes
B.2.1. Average labour productivity per employee	Real value of production / number of workers	Outcome	Adapted by (M. Calderini, P. Neirotti, E. Paolucci, P. Ravazzi, 2007)	Breast/Lung ICP: No, it cannot be measured directly. Actually, this kind of evaluation is absent.	Other productivity assessments should be done first.
B.2.2. Staff productivity in the therapeutic phase	No. of hospital discharge forms / hours worked in the health facility	Outcome	personal elaboration	Breast/Lung ICP: It can be measured.	This information is retrievable from administrative and human resources databases

B. Use of resources – B.2. <i>Productivity</i>					
B.2.3. Personnel diagnostic productivity	No. of diagnostic tests / hours worked	Outcome	Adapted by (Zanella, 2011)	Breast/Lung ICP: It can be measured.	This information is retrievable from administrative, PACS systems and human resources databases
B.2.4. Use of the equipment in the reference period, in order to evaluate its efficiency	No. of examinations performed in the time interval (per device) * 100 / (max daily examinations * No. of days in the Timeframe)	Outcome	Adapted by (Neri, 2009)	Breast/Lung ICP: It can be measured.	This information is retrievable from the PACS systems
B. Use of resources – B.3. <i>Wastes</i>					
Subdimension	KPI	Type	Ref.	Usable?	Notes
B.3.1. Percentage of diagnostic tests for which a retest was required	No. repeated exams * 100 / total exams	Process	personal elaboration	Breast/Lung ICP: It can be measured.	The number of repeated tests can be obtained from administrative databases per patient.
B.3.2. Patients with diagnostic tests in another facility after being taken in charge by the facility under study	No. of patients * 100 / total treated patients	Process	personal elaboration	Breast/Lung ICP: No, the number of patients with diagnostic tests in another facility cannot be measured.	A qualitative information can be obtained from the questionnaire of evaluation of quality perceived by patients (Breast Unit). Example of a proxy: "Where did you carry out the checks following the treatments: surgical, chemotherapy, radiotherapy? Where did the treatments after the surgery performed? (More than one choice can be made)".

Table 7. It reports the analysis of KPIs applicability belonging to the class "Research, development and innovation"

C. Research, development and innovation – C.1. <i>Clinical Trials</i>					
Subdimension	KPI	Type	Ref.	Usable?	Notes
C.1.1. Indicator for measuring the attractiveness of the research projects implemented by the structure	Funding received from external bodies for scientific research / Total funding for scientific research	Outcome	(Pediatrico Bambino Gesù Ospedale, 2016)	Breast/Lung ICP: It can be measured manually.	
C.1.2. Percentage of patients involved in clinical studies, out of the total number of patients managed in the ICPs analyzed	N. Patients involved in trials / N. Total patients in the analyzed ICPs	Process	personal elaboration	Breast/Lung ICP: It can be measured manually.	The number of patients involved in clinical trials can be obtained by each Principal Investigators.

C. Research, development and innovation – C.2. <i>Continuing medical education (CME)</i>				
Subdimension	KPI	Type	Ref.	Usable? - Notes
C.2.1. Number of continuing medical education (CME) credits for healthcare professionals in response to the new needs of patients and the Health Service	Sum of CME credits gained by actors committed in the ICP	Outcome	personal elaboration	Breast/Lung ICP: It can be measured manually.Agenas database
C.2.2. Number of CME credits, for the updating of health professionals, disbursed by structures committed in the ICP	Sum of CMEs credits disbursed	Outcome	personal elaboration	Breast/Lung ICP: It can be measured manually.Agenas database
C. Research, development, and innovation – C.3. <i>Scientific publications</i>				
Subdimension	KPI	Type	Ref.	Usable? - Notes
C.3.1. Index for the measurement of citations received from the scientific publications of the professionals of the structure	Average impact factor per researcher	Outcome	personal elaboration	Breast/Lung ICP: It can be measured.Scopus Database
C.3.2. No. of scientific publications produced by the structure in the reference period	N ° scientific publications (six-monthly data)	Outcome	personal elaboration	Breast/Lung ICP: It can be measured.Scopus Database

## 5 Conclusions

This paper develops a theoretical framework of monitoring indicators for integrated care pathway. It can be useful for the healthcare organizations, willing to monitor the care pathways and improving its performance on multiple dimensions. The framework consists of 31 KPIs grouped in three broad areas and includes organizational aspects of the management of a care pathway – patients' perspectives, staff productivity, cost of labour per patient, staff education and research transferability in care practice. Furthermore, it introduces the attention towards indicators monitoring Research and Development, an important dimension for an IRCCS given its mission.

The framework has been then validated by a group of experts and an analysis of its applicability is done on two ICPs – lung and breast cancer-, of the Institute "Giovanni Paolo II" of Bari (Italy). For both the ICPs considered, it was possible to compute only 19 KPIs. Some can be computed only manually, by comparing information among different source of data. Others 6 KPIs and 1 KPI, respectively for the Breast and Lung cancer, are computable with a proxy; the remanent indicators are not measurable. According to the dimensions, greater than the half of the KPIs related to the "Service" and "Communication with staff" dimensions cannot to be measured currently. The impossibility to compute the indicators are mainly due to the lack of integration among the hospital databases -

administrative and clinical ones. The next steps of research will regard the measurement of the KPIs.

### **Abstract**

In response to the Covid 19 pandemic emergency, universities found themselves to rethink the way of doing university. They have veered towards new circular economy models capable of actively involving users by strengthening the right of access to information and services through sustainable digitization. production systems with greater involvement of the territories. Our work uses multi-criteria methods to analyze the actions of universities to face the Covid 19 pandemic emergency. In particular, the study analyzes the choices on the reorganization of the main services offered to students with a particular focus on teaching. The actions considered from a digital sustainability point of view for teaching aim at the use of technologies not only to remotize the lessons but with a view that technology can be of support in the redesign of the didactic paths in their complexity.

**Keywords** – Multi-criteria methods; Circular Economy; Knowledge, Decision Analysis

**Paper Type** - Academic Research Paper

## 1 Introduction

The paper, with the use of decision support tools as in multi-criteria decision methods (MCDM), analyzes the choices made by the Public Administration, with particular focus on Italian universities, in response to the Covid 19 pandemic emergency. The pandemic due to Covid 19 has highlighted the poor capacity to contain and adapt to the systemic risks associated with a pandemic in a highly interconnected world based on rapid and borderless global flows for people, goods and information. More importantly, the pandemic has highlighted the limitations of our economic system based on the linear model linked to the inappropriate use of resources until they are exhausted (Ghorui et al., 2021). Italian universities have found themselves having to rethink the way of doing university. In this sense, universities have veered towards new models of circular economy capable of actively involving the users of the services, therefore the students, strengthening the right of access to information and services also through digitization. The goal was to define a real sharing of knowledge between the university world and students. The strategy towards a circular economy (Zhao et al., 2017) aims to pursue the following objectives: achieving economic and social benefits; increased competitiveness; introduction of a more effective technology that can achieve net cost savings, through various modalities including better use of resources, greater process efficiency, improvement of quality, logistics and so on. MCDM (Greco et al., 2016) concerns generally to models based on the explicit consideration of multiple criteria in choice problems. MCDM are oriented to describe different situations due to the structure of the problem, the nature of the knowledge and information available, the elements of uncertainty that characterize the decision-making context (Cavallo et al., 2014). Multicriteria analysis (Ishizaka & Nemery, 2013) is a tool for complex situations in which, providing the decision maker with a tool to support the identification of a solution (Roy, 1993) that represents a good compromise with respect to the different aspects of the problem. Instead of the optimal solution we refer to a set of efficient solutions, able to offer a good compromise between the different

needs posed by the problem. The multi-criteria decision support models allow improving the quality and the speed of decision-making processes by accessing the knowledge of the organization when needed. When decisions have to be made, the decision support systems facilitate access to the opinions and experiences of different people, which can contribute to the choices to be made. MCDM in particular expect that decision makers actively participate in the construction of the decision-making model; this generates greater awareness in decision-makers (D'Apuzzo et al., 2009). In this way, a knowledge management system is created that allows organizations to accelerate their learning capacity, but also their efficiency and innovation (Esposito et al., 2013). In this sense, the use of MCDA makes it possible to trigger organizational control improvement mechanisms that push to change within organizations (Lerro et al., 2014). The methodology used in this paper is PROMETHEE I-II belonging to the outranking methods. This methodology, in particular, allows the decision maker to express his preference by means of a degree of preference and to identify the indifference threshold and the preference threshold to simplify the choice process.

## **2 Literature review**

The generic MCDA problem can be defined as a particular decisional problem in which we highlight: the need to operate by choosing, ranking, sorting or describing a finite number or infinity of potential or alternative actions; the existence of at least two decision criteria; the presence of at least one decision maker (Ouerdane et al., 2010). The problems of MCDA, in relation to the objective of the decision-making process, without claiming to exhaustiveness, can be classified into the following four categories: Choosing problems; Sorting problems; Ranking problems; Description problems (Roy, 2013). In the real world, the most common problems faced with multicriteria techniques are ranking and sorting problems. Based on how the problem is characterized and how the DM wants to approach it, different methodologies can be used. Among the most used are two families of methods: Outranking Methods (Roy, 1990; Vincke, 1999) and Hierarchical methods (Saaty, 1990). The Outranking Methods are based on binary relations of preference (called outranking), do not present axiomatic bases and are computationally onerous as the number of alternatives increases. Among them the most used are the ELECTRE and PROMETHEE I-II methods. Hierarchical methods, defined as the main objective of the decision problem, allow the

ordered classification of potential alternatives with respect to a multitude of criteria. Among the most used methods are Macbeth (Costa et al., 1999) and the Analytic Hierarchy Process (AHP) method (Saaty, 1990). The use of multi criteria decision making techniques in the public sector is not new. Massam, already in the second half of the 1980s, identified a first set of multi-criteria applications aimed at strategic planning in the PA (Massam, 1988). The first applications of MCDMs in the PA are mainly oriented to the strategic evaluation of service location options and not to the decisions of merit characterizing their management. Several authors have used multicriteria methodologies in PA, in particular the most commonly used method is AHP. Takamura and Tone (2003), make a proposal for a consensus-making method for the reallocation of government agencies outside the city of Tokyo; based on a combination of the analytic hierarchy process (AHP) and the Assurance Region model of data envelopment analysis (DEA). The study of Jackson and Keys (1984) is concerned with problem-solving methodologies, and the criteria for classifying problem contexts must therefore identify relevant similarities an contexts which are important with respect to problem-solving methodologies. Specifically the authors have as their main objective the choice of the best marine environment development plan given 3 alternatives and 5 evaluation criteria, using the PATTERN as a multi-criteria technique. In Rivett (1977), the author aim to select the "best" policies given different alternatives in which each policy is evaluated in terms of the degree of achievement of a series of objectives. The proposed method is based on multidimensional scaling techniques further developed by Kendall to draw maps based on fragmentary information. Brans et al (1986) present the PROMETHEE methods, which is a new class of outranking methods in multicriteria analysis. Two treatment modalities are proposed: PROMETHEE I to obtain a partial pre-order and PROMETHEE II for the final classification, both on a finite set of feasible actions. This technique is then compared with the ELECTRE III method. The final objective is the choice of the best allocation for a hydroelectric plant given 6 alternatives and 6 evaluation criteria. The stability of the results provided by the two methods is then analyzed. According to (Brans et al., 1986), in the paper we use the PROMETHEE I-II methods described in the methodology section. These methodologies allow, like hierarchical methods, a good interaction with decision makers and are reliable in the results thanks to the scenario analysis for the verification of the method.

### 3 Methodology

The PROMETHEE method (Ishizaka & Nemery, 2011) belongs to the family of outclassing multicriteria (Vincke, 1992). For each criterion  $g_i$ , and for each pair of ordered alternatives, the decision maker expresses his preference by a degree of preference. The degree of preference  $P_i(a, b)$  indicates whether or not an action  $a$  is preferred over  $b$  on the criteria  $g_i$  based on the difference between their evaluation  $d_i(a, b)$ . This degree of preference is achieved by using the preference function which may require various parameters such as the indifference threshold  $q_i$  and the preference threshold  $p_i$ . If the difference  $d_i(a, b)$  between the score of action  $a$  and  $b$  on criterion  $g_i$  is greater than  $p_i$ , action  $a$  is preferred over  $b$ . If  $d_i(a, b) < q_i$ , then action  $a$  and  $b$  are indifferent. Formally, we will have:

$$\begin{aligned} P_i(a, b) &= 0 && \text{if } d_i(a, b) < q_i && \text{(Action } a \text{ is indifferent to } b) \\ P_i(a, b) &= 1 && \text{if } d_i(a, b) > p_i && \text{(Action } a \text{ is preferred to } b) \end{aligned}$$

Several typical forms are proposed (Brans & Mareschal, 1995) for the preference functions as linear step or Gaussian preference function (see Fig. 3 for the linear function).

Fig. 3

Source: Ishizaka, A., & Nemery, P. (2011).

To evaluate to what extent action  $a$  is preferred over  $b$  on all criteria, the preference index  $\pi(a, b)$  calculated as the weighted sum of the degrees of preference  $P_i(a, b)$  is constructed. The weights  $w_i$  represent the importance of each criterion in the decision:

$$\pi(a, b) = \sum_{i=1}^n P_i(a, b)w_i \quad (9)$$

where:

$P_i(a, b)$  is the degree of preference on criterion  $i$ .

$w_i$  is the weight of each criterion  $i$ .

$n$  is the number of criteria

If  $\pi(a, b) = 0$  implies a weak preference or global indifference of  $a$  over  $b$

If  $\pi(a, b) = 1$  implies a strong global preference of  $a$  over  $b$ .

Since each action is compared to  $m-1$  other actions, two flows can be constructed, the positive flow (10) representing the overall preference of the action over all other actions (this score must be maximized) and the negative flow (11) which represents the overall weakness of  $a$  with respect to all other actions (this score must be minimized):

$$\phi^+(a, b) = \frac{1}{m-1} \sum_{x \in A} \pi(a, x) \quad (10)$$

$$\phi^-(a, b) = \frac{1}{m-1} \sum_{x \in A} \pi(x, a) \quad (11)$$

where:

$m$ : number of actions

$A$ : the set of the actions  $m$ .

Based on the positive and negative flows, the partial classification according to PROMETHEE I is defined as follows:

$a$  is preferred to  $b$  if  $\phi^+(a) \geq \phi^+(b)$  e  $\phi^-(a) < \phi^-(b)$   
or  $\phi^+(a) > \phi^+(b)$  e  $\phi^-(a) \leq \phi^-(b)$

$a$  is indifferent to  $b$  if  $\phi^+(a) = \phi^+(b)$  e  $\phi^-(a) = \phi^-(b)$

$a$  is incomparable to  $b$  in the other cases

However, these two flows are generally combined to obtain the net flows (12) defined as follows:

$$\phi(a) = \phi^+(a) - \phi^-(a) \quad (12)$$

This leads to the complete ranking using PROMETHEE II. The higher the flow, the better the degree of an action. A deeper discussion of net flow scores can be found in (Brans & Mareschal, 1995) and (Mareschal et al., 2008).

#### **4 Case study**

The paper aims to analyze the choices of the Public Administration, with particular attention to Italian universities, in response to the Covid 19 pandemic emergency. In particular, the research question that guided the work was to understand whether the actions taken by public administration in the management of university activities for the provision of teaching and management of student services could be framed in a circular economy perspective.

In particular, among the different multicriteria methods we have chosen to use the PROMETHEE I-II methods (Brans & Vincke, 1985) that is a well-established decision support system that deals with the evaluation and selection of a set of options based on different criteria, with the aim to identify the pros and cons of the alternatives and to obtain a ranking among them. In evaluating the decision alternatives, the key question is whether there is sufficient information to assert that one alternative is comparable to another in terms of the quality of the information. Based on the so-called outranking relationships, which are constructed in a first phase, it is possible to draw up a ranking of alternatives (Ishizaka & Nemery, 2011).

MCDM takes on particular relevance the ways in which, for the purpose of the evaluation, the performance of all potential actions or alternatives and contributions of all criteria; two potential actions or alternatives can in fact present conflicting performances with reference to one or more of the criteria rating. The great value of MCDM techniques in general, but even more so in the public sector, is the constructive approach of these techniques in which the definition of criteria and the identification of alternatives allows the different actors of the decision-making process to confront each other by fielding the different one's objectives and different needs (Norese, 2017). For the analysis of the main actions undertaken by universities to deal with the covid-19 epidemic, 4 criteria are taken into consideration:

- Suitability: applicability in the public administration;

- Economic: describes the extent to which time, effort or cost is well used for the intended task or purpose;
- Usability: ease to use and learnability of tools;
- Utility: utility of tools.

The actions considered in the case study mainly concern the analysis and understanding of how universities have had to rethink and reorganize teaching using a series of new tools. The provision of teaching is one of the most important issues that universities have had to face in the pandemic situation as the impacts of the solutions identified have a systemic dimension, affecting the daily life of millions of families, mobility in cities, and the dynamics of diffusion of the contagion. Addressing the problem from the point of view of a circular economy and from a sustainable point of view means looking at the phenomenon in its direct and indirect impacts, considering the role of the actors involved. The decision support tools, such as PROMETHEE, can concretely support the DMs by analyzing the pros and cons of choices. These choices can only be taken in the awareness that each of them will impact on numerous other areas. In this sense, the actions considered from a digital sustainability point of view for teaching aim at the use of technologies not only the lessons remotely but with a view that technology can be a support in the redesign of the didactic paths in their complexity. Among the actions considered there are:

- a) Provision of remote lessons. In this action the best tools are also evaluated to meet the need such as the choice of the best platform to support teaching and so on.
- b) Provision of teaching with dynamic balancing in presence and remotely. In this sense, all the strategic actions aimed at ensuring the safety of the structures and access to them are considered. In this sense, we consider the redefinition of adequate didactic models to best deliver lessons while maintaining the quality of teaching.
- c) Provision of teaching with new training models such as the use of webinars.

The use of the PROMETHEE I-II method makes it possible to express a degree of preference and indifference for each action considered and for each sub-action, with the possibility of identifying thresholds that allow the decision-maker to attribute his preference with more awareness. The application of this methodology in the Public Administration, with a view to identifying the best solutions from the perspective of a circular economy aiming at digital

sustainability, is particularly adequate because it allows for scenario analyzes. These analyzes allow us to understand what happens when the variables considered or the degrees of preference considered vary.

## 5 Conclusions

Rethinking the university from a circular economy perspective and therefore considering teaching in the perspective of digital sustainability does not only mean looking at the need to ensure quality education, but also taking into account that education must be fair and inclusive. In a pandemic scenario, universities have found themselves having to reorganize their activities by rethinking digital teaching also on the basis of accessibility criteria that allow everyone to benefit from teaching activities. In this work, we propose the use of a multi-criteria methodology that can allow the DM to take into consideration more criteria and more alternatives in such a delicate process of choice. The use of the PROMETHEE I-II method concentrates in particular to express degrees of preference on the alternatives, which will then be classified from most to least preferred. The strength of this methodology is to allow you to carry out scenario analyzes that in this sense can allow the DM to reconsider their decisions in relation to their needs or circumstances.

### **Abstract**

The issues of food losses and food waste have reached such proportions that global economies are looking for solutions to limit their impacts. In this work, we describe an innovative e-marketplace for the agri-food supply chain (ASC), designed in the context of a R&D project (MEC) aimed at supporting the operators in reducing waste products and finding new sales channels. The MEC project involves the development of new knowledge

management methods and technologies aimed at the design, modelling and experimentation of a new logistics network. Within the MEC project our purpose is to create a virtual commercial and logistics network, also functional to open the market to small businesses; to reduce the food products losses and waste; to extend the value to the uneaten food, waste and otherwise lost products; to strengthen the market of agricultural and agri-food specialties with a strong local/regional connotation through product management and control systems that allow for an improvement in the chemical, physical, organoleptic and nutritional qualities of the products at the time of consumption; to create a technological platforms for the integrated management of logistics for various commercial channels and the use of models for decisions based on the integration of "field" information with those acquired directly from the customer/final consumer, in the order and purchase and after-sales assistance. The system will be implemented as a web-based platform aimed to offer users: a decision support systems to aid sales services, also through demand forecasting algorithms that will allow optimization of the processes for locating goods with consequent maximization of consumption and reduction of waste; a route optimization systems, to strengthen distribution logistics services that will allow the selection of the best itineraries, also from the point of view of environmental sustainability; a systems for the valorisation of scraps, lost and wasted products through the definition of models of optimal use for energy production purposes of products no longer destined for food consumption; an ecosystem and social services related to the reduction of waste, production of energy from renewable sources, reduction of greenhouse gases linked to the optimization of the distribution phase, support to the third sector for the procurement of food for people in need. The expected results is the improvement in the competitiveness and sustainability of national agri-food supply chain linked to a reduction in the amount of product lost and/or wasted and pursued through a coherent set of innovative measures.

**Keywords** – Food losses, Food wastes, Sustainability, Decision Support System, Sustainable marketplace

**Paper type** – Practical Paper

## 1 Introduction

The agri-food sector plays a crucial role for society, as the production sector is dedicated to the production of food. The continuous economic growth has also marked the development policies of the primary sector and the industry linked to it, prompting producers to raise the quality standards of food also in terms of purely hedonistic as well as organoleptic and health characteristics. This has had an impact on the growth of food waste still suitable for human consumption or, in any case, that can be used in other areas. According to FAO estimates, 1.3 billion food waste, of which about 80% is still edible, is sent for disposal. Food waste therefore represents one of the most important issues related to the concept of

sustainability. In economic terms, food waste on the planet costs 1,000 billion dollars every year, a figure that rises to 2,600 billion if we consider the "hidden" costs related to water and environmental impact. The European Union alone throws away 90 million tons of food, just as domestic waste is worth a total of 8.4 billion euros per year in Italy (Waste Watcher Report 2015). The phenomenon of food waste and food loss has now acquired global significance and there are various initiatives to tackle the problem.

In Europe, there are over one hundred initiatives aiming at reducing the accumulation of food waste. The strategies include raising awareness through campaigns, information, education, waste measurement and logistics improvement. For example, in some Belgian municipalities regulations have been enacted requiring supermarkets to donate unsold products that are still good to voluntary associations that redistribute them to poor people. Same approach used in Portugal, where a network of volunteers collects food from restaurants and grocery stores and then redistributes it (Refood Project).

An expanded food-sharing system is implemented by CropMobster™, a tool that allows San Francisco Bay Area farmers, merchants, restaurateurs to post notices offering surplus food for sale, donation, or trade. Messages are immediately sent to various social media, including Facebook and Twitter. Since its launch in March 2013, CropMobster has put £ 500,000 worth of food back into circulation, around one million servings for people, food banks, schools and other groups in need. In Italy, the first and most important experiment is Last Minute Market, a virtuous network of operators in the agri-food sector for the redistribution of products that are still edible but discarded from large supermarkets chains.

All the initiatives mentioned have in common a "restorative" type approach, that is, they aim to solve the problem once this has happened. In some European countries that have adopted intervention measures, the reduction of waste is already visible: for example in Great Britain from 2007 to 2012 a 21% decrease in waste was highlighted, and in Denmark 19% of respondents report wasting much less food than before the corrective intervention. In Italy, a Law of 2016 "Provisions concerning the donation and distribution of food and pharmaceutical products for social solidarity purposes and for the limitation of waste" provides for interventions to reduce waste in the stages of production, transformation, distribution and administration of food products.

It is also important to outline that the agri-food sector has undergone profound structural transformations over the years to meet the changes in demand due to new consumption needs. At first, the development of globalization generated a process of "de-territorialization" for which consumers have lost interest in the origin of the products consumed (Rossi et al., 2008). In addition, due to the expansion of distribution chains, there has been an extension of the agri-food supply chains (Corrado et al., 2018). All this has led to the homologation process of productive crops and to the deterioration of biological and cultural diversity. The subsequent evolution in the needs and preferences of consumers, increasingly attentive to their well-being and the environment, has led to interest in new and alternative business models. Thus, new alternative networks of a collaborative nature to support the agri-food sector, the Alternative Agrifood Networks (AAFNs) (Goodman, 2003; Watts et al., 2005), are arising as a response to the growing demand for safer and quality food.

The AAFNs are born as a solution opposed to the conventional system, characterized by a deep industrialization of agriculture and the expansion of large-scale distribution, held responsible for a multiplicity of negative socio-economic effects and environmental issues including social inequity, environmental non-sustainability as well as the possible negative consequences that agro-industrial products can have on the health of individuals (Dansero and Puttilli, 2013).

The AAFNs have been widely analysed by North American and European literature. The first pays particular attention to the social, ethical, environmental, safety and social equity values connected with these particular forms of collaborative networks (Harris, 2009). On the other hand, European scholars focus mainly on the production of quality products, on the processes of re-localization of food webs and on attempts to incorporate a sense of place or geographical origin in food products through short supply chains. These latter characteristics are perceived as an economic added value (Holloway et al., 2006).

According to different relationships that can be established between producers and consumers, four different forms of AAFNs are proposed (Venn et al., 2006):

- Producers as consumers, that is food is grown by the same subjects who will then consume it;
- Producer–consumer partnerships, a relation between farmers and consumers, where the risks and benefits are shared between the two

parties, on the basis of different types of agreement, such as subscription to a service, joint investments, etc;

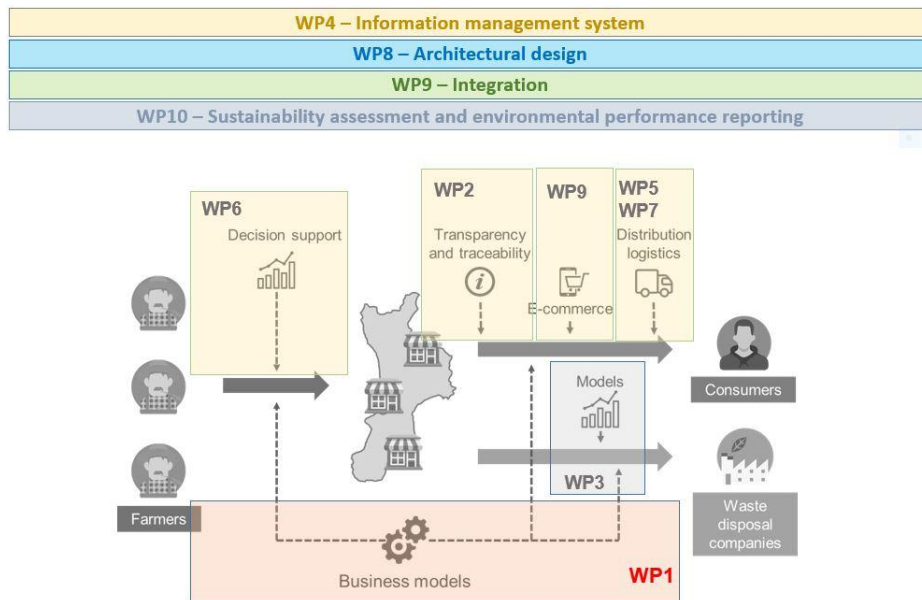

- Direct sell initiatives, where farmers or producers "cut" the intermediary and sell directly to consumers;
- Specialist retailers, producers can sell to consumers through specialized markets aimed at selling quality products, typical and local specialties.

In recent years, with the spread of new digital technologies, decision support systems have been introduced to provide effective services to operators at different levels of the supply chain. Particular attention is paid to the emerging sector of platforms that promote sustainable local development actions in the agri-food context, with positive environmental, economic and social effects. Several e-commerce giants have expanded their business by entering this sector, such as Amazon Fresh, which is Amazon's service dedicated to online grocery shopping.

In this work, we describe an innovative e-marketplace for the agri-food supply chain (ASC), designed in the context of a R&D project (MEC) aimed at supporting the operators in reducing waste products and finding new sales channels. The MEC project involves the development of new knowledge management methods and technologies aimed at the design, modelling and experimentation of a new logistics network. The main aim is the design and development of a wide and integrated action in all phases of the supply chain in order to act on the various problems that generate the phenomenon of food waste. The rest of the paper introduces the main building blocks, both from a functional and technical point of view, and the main results of the project.

## **2 Materials and methods**

The MEC project is organized in 10 work packages (WP), independent but strictly correlated, in order to ensure integrated action to obtain the results envisaged by the project (Fig. 1).

*Fig. 1 – Work Breakdown Structure of MEC project*

A first WP will aim to propose organizational models and cooperation mechanisms that can promote the creation of a "long-term" collaborative network within the Calabrian agri-food chain. On the one hand, this network will include agricultural producers (eg direct farmers) and processing companies, and consumers of agricultural products on the other. The latter, depending on the type of product to be purchased, may be:

- Individual consumers and purchasing groups, interested in purchasing local agricultural products directly from the producer without the intermediation of retail markets;
- Third sector operators, interested in food near to expiry, for distribution to disadvantaged social groups;
- Companies that deal with the recovery of food waste for energy production.

The components of the resulting collaborative network will be characterized by a common business culture, a shared sense of community and a common adherence to eco-sustainability issues. The characteristics of the most suitable organizational model for the case study will then be defined and the methods for managing the network creation process in the Calabrian area will be studied. For

the network partners, roles and relationships will also be defined within the new collaborative system to which it is intended. Therefore, the analysis of the processes and information flows that will be supported by the platform will be carried out. For this purpose, an intermediation model will be introduced and the role of a third party (intermediary subject) in support of the network partners acting as Trusted Service Manager (TSM): the Trusted 3rd Party (TTP), whose main function will be the generation of value through the management of the collaborative network.

Once the business model has been defined, it will be necessary to act at a technological level on the products in order to prevent the phenomenon of food loss and waste. Due to their perishable characteristics, food products have to be managed respecting their shelf life. The latter, defined as the period of time within which the food retains an appreciable level of quality, has a duration that depends on the kinetics with which the degradation phenomena run. In the case of fresh products, the evolution of degradation phenomena is strongly influenced by the development of phytopathogenic microorganisms capable of infecting and colonizing plant tissues. These microorganisms can be bacteria and especially phytopathogenic fungi. In order to manage the warehouse, with the aim of minimizing food waste, the consumption of the food must take place before its expiration date or its minimum conservation term. Knowledge of these time intervals depends on:

- a) intrinsic characteristics of the food;
- b) conservation methods;
- c) initial level of the quality marker;
- d) kinetics of degradation of the phenomenon;
- e) development of phytopathogenic microorganisms.

The use of intelligent packaging systems is one of the main aims of the project and plans to include devices in the package that allow to identify the approach of reaching the end of the shelf-life. For this reason, the following actions will be carried on:

- Development a monitoring system that allows the identification of the shelf-life term both as an expiration date and a minimum storage term, in order to optimize warehouse management;
- Reduction of food waste following the notice of approaching the end of shelf life and the possibility of using batches with the characteristics still suitable for their consumption.

However, the adoption of such devices will not be enough to face the phenomenon of food loss and waste. In this context, the enhancement of food products no longer suitable for consumption and their conversion into clean energy will represent strategies for maintaining the value chain and reducing the phenomenon of waste generation.

At this aim, the third WP deals with the definition of strategies for the enhancement of non-edible products, with the main objective of biogas production. In particular, the attention will focus on:

- The assessment of the biogas production capacity from a series of food products no longer fit for consumption;
- The identification of the ideal composition of the mixture for a higher biogas yield through the optimization of the parameters of the fermentation process (operating temperature, hydraulic retention time, organic load reduction rate and biogas yield, etc.).

The methodology is based on the BMP (Biochemical Methane Potential) biomethanation test in laboratory or batch scale, for the different matrices, both in mesophilic and thermophilic conditions.

On the basis of the above mentioned research activities and of an analysis of the detailed requirements, which will be carried out within the preliminary phases of the project, the data structures and the main management procedures will be created in order to prototype the system storage. Since the data archives will be subject to incremental updates, efficient mechanisms must be designed for the insertion of new data as well as for the correlation of these with the reference source. Finally, a database population activity will be carried out through the insertion of data necessary for the testing and production start-up phases of the resulting platform.

The last part of the chain, from the producer to the consumer, will be carried out through the definition and modeling of processes for distribution logistics, suitable for the new commercial channels of the short circuit. In particular, new optimization models and methods aimed at optimizing the short-range transport process will be defined, starting Capacitated Vehicle Routing and Capacitated Vehicle Routing with Time Windows algorithms. Through the subsequent implementation of the models, the platform will be able to offer optimized delivery plans to any actors who provide the delivery service. The goal of the optimization will be to maximize the quantity of goods delivered, while reducing

the number of vehicles used and the distances traveled, with significant benefits from the point of view of environmental impact.

As regards the disposal phases, it will be possible to calculate performance indicators, such as the correct balancing of the goods that are no longer consumable, in order to support the interested parties in the related process. Furthermore, the platform will be able to calculate, on the basis of historical data and information related to the goods sold and their shelf-life, estimates on the quantity of goods that must be disposed of. These indicators will offer valid decision support to implement actions within the business model aimed at mitigating waste and maximizing both consumption and the value obtained by producers.

As regards the knowledge representation, an ad hoc software model will be created. In particular, the domain model should not only faithfully represent the results of the analysis of the literature, but also effectively support subsequent processing. The opportunity to create self-contained modules independent of pre-existing frameworks will be evaluated based on the assessments that will be carried out during the analysis of the proposed algorithms. An architecture oriented to the management of data, processes that the system must be able to manage will be evaluated, and the most critical application components will be designed, in the prototype phase, in order to be able to perform benchmarks. The design of the architecture, as well as the implementation, may include refactoring phases since it is intended to conduct the development phases with agile methodologies and an incremental approach (SCRUM).

Finally, the impact in terms of sustainability of the new logistic model with respect to conventional ones will be evaluated by means of Life Cycle Management methodologies. In particular, some specific analysis of the processes that make up the individual links of the supply chain (eg production, storage, distribution, marketing, home purchase and storage, disposal, management of by-products) will be carried out and the results, expressed according to different units of measurement functional to the process studied, will be implemented in the platform. These will be used as inputs in the optimization models, evaluating in real time the impacts generated by the innovative business models (eg variation of CO<sub>2</sub> emissions due to the improvement of distribution paths). All the optimization processes will therefore be implemented according to an eco-design logic that will also take into account the benefit. Just to name a few, the reduction of waste and, therefore, all those processes necessary for their management

(reduction of waste treatment) as well as the effects positive due to the production of renewable energies such as the reduction of consumption of fossil fuels.

### **3 Expected results**

The research activities that will be carried out within MEC project aim at achieving an overall innovation of the production-consumption system that involves both the product and the process in a coherent and synergistic way. Specifically, the research and the new technologies that derive from it are aimed at:

- The creation of a virtual commercial and logistics network, also functional to open the market to small businesses, located in marginal areas and with a strong territorial connotation, favoring the marketing of agricultural products at "km 0" through a direct interface between producers and consumer;
- The reduction of product losses and food waste;
- The valorisation both for food consumption and for energy purposes of the remaining waste and otherwise lost products;
- The commercial enhancement of agricultural and agri-food products with a strong local/regional connotation through product management and control systems that allow for an improvement in the chemical, physical, organoleptic and nutritional qualities of the products at the time of consumption;
- The creation of technological platforms for the integrated management of logistics for various commercial channels and the use of models for decisions based on the integration of "field" information with those acquired directly from the customer / final consumer, in the order and purchase and after-sales assistance.

The platform that will be implemented will offer services to various actors of the supply chain:

- Producers, who will have a new, more transparent and interactive short-range sales channel at their disposal. It is planned, in fact, to offer manufacturers a software platform for monitoring the sales process and select the best store for each type of product, on the basis of analytical data that support the user's decision. The producer, in fact,

will be assisted in order to maximize sales and therefore reduce waste. Among the users of this segment, the following are preliminarily recognized:

- Direct farmers,
  - Food processing operators.
- Consumers, who will have the opportunity to purchase local products directly from points of sale or from the internet. The goal of the platform, in addition to provide a sales channel, will be to provide traceability and quality level of the goods through the data collected from the models and technologies used. Among the users of this segment, the following are preliminarily recognized:
  - Private consumers;
  - Purchasing groups;
  - Entities operating in the third sector in favor of weaker social groups.

The new paradigm, together with the functionalities offered by the platform, will affect the following processes:

- Sale and purchase of goods, including online transactions;
- Delivery of the goods, through a sales network which will be supported by optimization models and algorithms;
- Disposal of products no longer intended for consumption, with the support of scientific models aimed at maximizing the energy enhancement of the process.

At this aim, several ad hoc effective services will be provided, in particular:

- A decision support systems aimed at supporting sales services, also through demand forecasting algorithms that will allow optimization of the processes for locating goods with consequent maximization of consumption and reduction of waste;
- A route optimization systems, aimed at strengthening distribution logistics services. In this way, the distribution of goods can take place based on the outputs of optimization algorithms that will allow the selection of the best itineraries, also from the point of view of environmental sustainability;
- Systems for the valorisation of scraps, lost and wasted products through the establishment of a short-range logistics network and the

definition of models of optimal use for energy purposes of products no longer destined for food consumption;

- Eco-systemic and social services related to the reduction of waste produced, production of energy from renewable sources, reduction of climate-altering gases related to the optimization of the distribution phase, support to the third sector for finding food for vulnerable groups.

The final goal of the project is the creation of a new logistics network aimed at reducing food waste, through the construction of an economic / organizational model coordinated with a platform of decision support services and the integrated management of "short" production chains. The expected results for the MEC project are consistent with National strategies, borrowing their priority objectives and addressing their achievement through innovative and effective models that can be easily implemented in a real-life context

#### **4 Conclusions**

The innovations proposed in the project deal with the problem of reducing waste and lost food products with a multi-level approach, aimed at first to prevent the problem of waste from occurring. A new product/service will be generated, a software ecosystem, which will allow the improvement of both food products and production and distribution processes, in order to avoid that the food goods are exposed to the risk of deterioration and can therefore be discarded or lost. At present, no virtual environment has been identified created with the aim of reducing food waste, which acts at all stages of the supply chain and which aims to improve production, logistics and commercial processes, increasing the level of economic, environmental and social sustainability. MEC therefore stands as a completely innovative solution that implements a bottom-up approach aimed at reducing the phenomenon of food waste even before this has been achieved. The new business model will also integrate the possibility of redistributing products that will in any case be subject to deterioration, while enhancing what already exists thanks to the shortening of the steps to which food is subject, directly networking producers, distributors and traders with associations operating in the third sector. In addition, products that are no longer suitable for food consumption will also be managed in a completely innovative

way, favoring their use for energy production purposes, with a view to sustainable development and circular economy.

## Abstract

Organizations today live in a complex business landscape that requires them to be increasingly resilient, resourceful, intuitive, and flexible. Organizations must confront increasing complexity, turbulence, unpredictability, and the speed of change in the competitive environment. Many different forces and trends are shaping the new business landscape, and rapidly evolving digital technologies are forcing breakthrough and disruptive innovations. For companies to survive and thrive, they must transform their business and behaviours to respond to the evolving business landscape and turn challenges into opportunities for development and growth. Unlike change management, transformation aims to reinvent the organization and encourage the adoption of new approaches and discover new or revised business models that shape the perceived vision of the future. In particular, it is a digital transformation: the current business landscape is characterized by a continuous and inevitable digital evolution, so any type of organization should adopt the transformation considering digital factors.

In this perspective, companies need to generate, manage and leverage tacit, explicit and practical knowledge to drive transformation and remain competitive. Creating a transformation culture is not easy and many factors contribute to this outcome. Leadership represents one of the critical catalysts of a transformation-focused organizational culture. Transformative leaders today are responsible for fostering an organizational cultural mindset that aims to support and encourage transformation. For this reason, it is important to attempt to identify and measure the critical competences that drive and facilitate the generation, management, and use of knowledge for continuous innovation.

The study is at a preliminary stage and focuses on the following imperative research question, "How are the competences assessed that lead a Transformative Leader managing an organization to continuously innovate and drive transformation considering the digital age?". Proposed is the Transformative Leadership Assessment Framework, a first draft of a competency model to assess the characteristics of leaders who drive organizational transformation in today's complex business landscape. It lays the foundation for defining the specific skills, knowledge, and behavioural requirements that enable a leader to be transformative and lead an organization toward continuous innovation.

Competences provide individuals with exemplary performance that has an appropriate impact on business outcomes. This analysis helps specify a set of useful behaviours of transformative leaders, provides a tool that individuals can use for self-development, and outlines a leadership framework that can be used by to select, develop, and understand the effectiveness of transformative leaders in transformative organizations. To develop the Transformative Leadership Assessment Framework, the principles of grounded theory were adopted and, using secondary data such as recorded interviews, the authors examined the profiles of some of the most influential and inspirational modern tech leaders.

**Keywords** – transformative organizations, leadership competences, transformative leadership, assessment framework, digital transformation (max 5 words)

**Paper Type** - Academic Research Paper

## 1 Introduction

Technology innovation is increasingly influencing organizations evolution in today's competitive scenario: today's businesses have to respond to evolving trends. A global change towards a fully networked society is in progress all over the world: technology is omnipresent, and in particular the access to digital services is playing an increasing role in everything that is done (Bauer, W., Hämmerle, M., Schlund, S., & Vocke, C., 2015). One of the most impactful **transformation** that characterizes organization is **digital**: the impact of emergent technologies such as AI, machine learning, chatbots, big data and the Internet of Things are disrupting all aspects of operations and disrupting all established business practices. All types of organizations are influenced by digital transformation. Microsoft CEO Satya Nadella, says that by now every company is a software company, that has to start thinking and operating like a digital company (Microsoft Asia Digital Transformation Study, 2018). Thinking to the concept of Digital Darwinism, organizations incapable of embracing digital transformation to implement new business solution are destined to fail (Goodwin, 2018; Vollmer, 2019). It is important to point out that digital transformation is not only about technology innovation: is an accelerator for new business models (Castorena et al., 2014), products, services and experiences, so it is more about the creation of renewed knowledge and cultural viewpoints (Tabrizi et al., 2019). Digital transformation is about technology and people (Frankiewicz and Chamorro-Premuzic, 2020), so it is possible to talk about a really cultural transformation, affecting the majority of the people working. In order to deal with a complexity context and to stimulate or create a digital transformation culture, organizations are challenged to be more and more flexible, resilient and creative (Schiuma et al., 2012, Santarsiero et al., 2019; 2020) but flexibility is not enough (Bauer W., et al., 2015).

Flexibility, in the sense of capacity flexibility, as utilizing available existing elements of a system to satisfy short terms needs, is no longer adequate. The concept of **transformability**, that steams from discussions on flexibility (Bauer W., et al., 2015), refers to structural changes to any system and it seems to be more appropriate to talk about current transformation organizations are living. Indeed, transformability refers to the capacity to make rapid and lasting changes to an existing system. Considering organizations as systems, people have a key

role in this act: they are the essential link in organizational initiatives and provide transformable responses in rapid process changes (Hirsch-Kreinsen, H., 2016).

Following these reflections, absolutely **transformative organizations**, which we understand as organizations applying transformability, needs leaders able to explore the behavioural shifts that are needed to bring about lasting change: **leadership** represents one of the critical catalysers of an organization-culture oriented to transformation, particularly in the digital era (Li et al., 2016).

Considering the transformability factor, this paper considers **transformative leaders** as the key figures able to embrace digital transformation and it aims to understand how assess the vital competences to lead an organization towards a disruptive innovation.

The paper is structured as follows: the second section briefly illustrates the competences of the Transformative Leadership Compass (Schiuma G. et al., 2021), the reference model used to generate the Transformative Leadership Assessment Framework. The third section describes how are applied the principles of Grounded Theory, the methodology used to start defining the Transformative Leadership Assessment Framework, and presents a first draft of the Framework, localizing some key items for each sub-competence identified. Finally, research limitations and future development are discussed.

## 2 The Transformative Leadership Compass: an overview

This research considers a descriptive model identifying the essential competences distinguish a Digital Transformative Leader, called The **Transformative Leadership Compass** (Schiuma G. et al., 2021*b*). The Digital Transformative Leader is considered as a leader capable of shaping a sustainable value-oriented organization focusing on digital knowledge generation, acquisition and application.

The model has been developed from the authors by drawing from the literature on leadership and Digital Transformation. It originates from the combination of theoretical insights on three leadership's strands considered for this study: wise, transformative and leadership views.

**Wise leadership**, linked to Nonaka and Takeuchi's study (2011, 2019), proposes a practical wisdom called "phronesis" in addition to explicit and tacit knowledge to drive organizational transformation and value creation (Schiuma G. et al., 2021*a*).

**Transformative leadership** has been addressed by several scholars in different contexts with different interpretations (Bass 1985; Montuori A., Donnelly G., 2017; Shields, 2017), many of which have been reconsidered by Caldwell's studies (Caldwell et al., 2010, 2012). Generalizing, transformative leadership can be said to be ethical leadership that combines creativity, accountability and a willingness to change, drawing largely on the idea of transformational leadership (Bass and Riggio, 2006; Burns, 2004).

**Digital leadership** is a newer strand that requires further investigation (Imran et al., 2020). According to El Sawy et al. (2016), it is about the ability to do the right things for organizations in the context of digital transformation.

Considering the theoretical background of these three leadership types and transformative leadership as the primary reference strand, the Transformative Leadership Compass was developed, characterized by six critical competences that characterize the practice of a transformative leader (see below, figure 1).

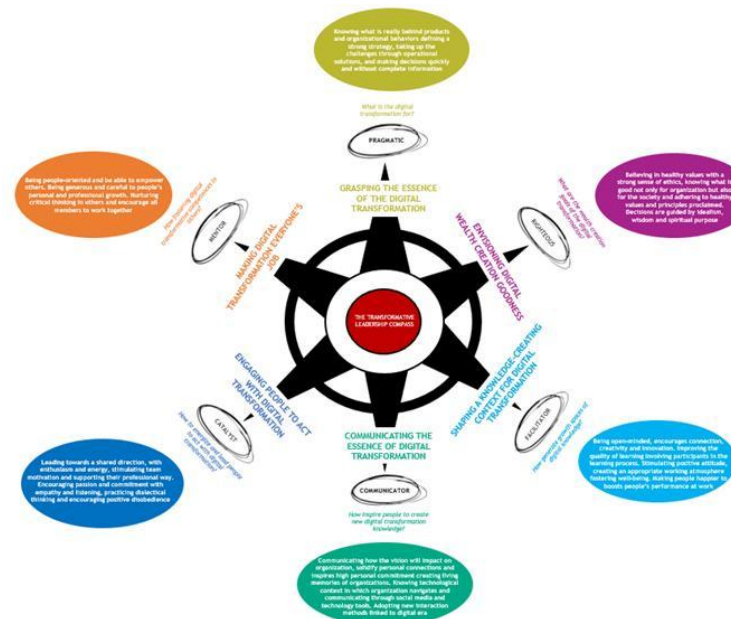

Figure 1 - The Transformative Leadership Compass

The first competence is **"Grasping the essence of the digital transformation"**, and is the capacity of connecting digital knowledge with business challenges to resolve problems, aligning dilemmas and solutions

knowing what the digital transformation is for and the knowledge foundations at the basis of the technology. The critical question characterising this competence is: *what is the digital transformation for?* This competence is linked to a leader considered *Pragmatic*, oriented to achieve the target objectives and take decision to solve problems. Different abilities and behaviours can characterize a leader with this competence: knowing what is really behind products and organizational behaviours (Nonaka and Takeuchi, 2011; 2019), defining a strong strategy, (Larjovuori et al., 2018), taking up the challenges through operational solutions, and make decisions quickly and without complete information (Lynn Pulley, M. and Sessa, V.I., 2001; Horner-Long, P. and Schoenberg, R. (2002).

**The second competence is “*Envisioning digital wealth creation goodness*”**, namely the capacity of taking decisions based on the goodness that the digital transformation will entail, considering the positive impact of goals and processes on organisation and society, to support sustainable growth. The question linked to this competence is: *what are the wealth creation goals of the digital transformation?* A leader able to answer this question with concrete actions is a *Righteous* leader. He is guided by healthy values and a strong sense of ethics, knowing what is good not only for organization but also for the society (Nonaka and Takeuchi, 2011; 2019) and adhering to healthy values and principles proclaimed (Ladkin D., 2008). Additionally, his decisions are guided by idealism, wisdom and spiritual purpose (Fry, 2003).

**The third competence is “*Shaping a knowledge-creating context for digital transformation*”**, namely the organisational capacity of creating a prolific context to nurture digital knowledge generating virtual and real growth spaces of digital and knowledge exchange. The critical question characterising this competence is: *How generate growth spaces of digital knowledge?* A leader acquiring this competence is a *Facilitator*, able to create or nurture cultural context and growth spaces, in which is possible stimulate comparisons and learn in innovative ways.

A leader with this ability is open-minded, encourages connection, creativity and innovation. He helps to improve the quality of learning involving participants in the learning process (Sousa et al., 2019). He is committed to stimulate positive attitude, to create an appropriate working atmosphere fostering well-being. Moreover, he contributes to make people happier to boosts people's performance at work (Salas-Vallina et al., 2018).

**The fourth competence is “Communicating the essence of digital transformation”** and relates the capacity to share the organisation’s purpose through a universal language, inspiring people towards storytelling tool using metaphors, stories and rhetoric. The question guide for this competence is: *how inspire people to create new digital transformation knowledge?*

A leader who implements this ability is a *Communicator*, able to create a leader-follower relationship through a strong personal bond. He communicates how the vision will impact on organization (Ismail et al., 2017), solidifies personal connections and inspires high personal commitment creating living memories of organizations. Moreover, he knows technological context in which organization navigates and is able to communicate through social media and technology tools. Finally, he adopts new interaction methods linked to digital era, and choose the right approach and tools based on his target and different situations (Cortellazzo et al., 2019).

**The fifth competence is “Engaging people to act with digital transformation”**, the capacity to engage people and overcome the barriers, inspiring and holding together—given a common purpose—people from different generations, cultures, roles and primarily digital backgrounds. The critical question characterising this competence is: *how to energise and lead people to act with digital transformation?* A leader who leads a group towards a shared direction, with enthusiasm and energy, stimulating team motivation and supporting their professional way. He is a charismatic guide who encourages passion and commitment (Senge, 2006), developed empathy and listening, practicing dialectical thinking and encouraging positive disobedience.

**The sixth competence is “Making digital transformation everyone’s job”**: the capacity to spread digital transformation, supporting people to enhance their leadership skills and digital knowledge competences. The critical question characterising this competence is: *how fostering digital transformative competences in others?* A leader who implements this ability is a *Mentor*, people-oriented and able to empower others (Rappaport J., 1981) generous and careful to people’s personal and professional growth. He nurtures critical thinking in others and encourage all members to work together (Blanchard, 2010).

This paper explores the Transformative Leadership Compass illustrated by considering the leadership profiles of some of the most influential and inspirational modern tech leaders as case studies, using an analytical approach linked to the general principles of grounded theory (Glaser and Strauss, 1967) to

outline the basic guidelines for the development of the Transformative Leadership Assessment Framework. This is a first draft of a competency model for assessing the characteristics of leaders who drive organizational change in today's complex business landscape.

### **3 Research to define the guidelines of the Transformative Leadership Assessment Framework**

#### **3.1 Methodology**

In terms of methodology applied, reference was made to the principles of Grounded Theory (Glaser and Strauss, 1967; Strauss & Corbin, 1990; Turner, 1981), considering that it is also applied in organisational research (Lansisalmi et al., 2000; Lowe, 1995; Gersick, 1998), producing a description of organisational reality. Grounded Theory refers to a style of conducting qualitative data analysis and assumes revealing elements that are analysed in a contextual way without a predetermined theoretical or conceptual framework.

Between the two main approaches to the application of Grounded Theory in organizational research (Cassel C. and Symon G., 2004), this study aims to stimulate comparison and generate new hypotheses around a specific topic area (Lansisami et al., 2000). The use of the Grounded Theory methodology is justified because the perspectives considered often do not result in large amounts of structured data that occur in rather atypical and unpredictable formats (Martin & Turner, 1986; Turner, 1981).

This research started from the following research question: *"How are the competences assessed that lead a Transformative Leader managing an organization to continuously innovate and drive transformation considering the digital age?"*.

The main research phases implemented are discussed below.

#### **3.2 Case studies and data collection**

Grounded Theory approach often combines different types of data collected through interviews, participant observation, and document analysis. To explore how the competences of a Transformative Leader company operating in the digital age are assessed, the first starting point was to analyse the competences

of Transformative Leadership Compass considering YouTube interviews of some of the most influential and inspirational modern tech leaders as case studies. The starting point was to look at the most influential tech leaders of our time according to Industry Expert, based on research conducted by Forbes Technology Council (Forbes Technology Council, 2020).

Data are collected through theoretical sampling: sample selection is guided by concept development. At this early stage, the most prominent of the 16 tech leaders considered by the members of Forbes Technology Council were selected as the initial sample: Elon Musk, Jeff Bezos, Jack Ma and Steve Jobs, with the aim of expanding the sample to other leaders in the next research step.

For data collection, YouTube interviews of the cited leaders were considered, taking into account speeches from international forums, companies, experts or television channels related to leadership. Other researchers have used YouTube as a qualitative data analysis tool to understand phenomena or analyse reference samples (e.g.; Duncum, 2014; Strangelove, 2010, Gao X. et al., 2013). In this research, the collected data is used as secondary data by using information collected from other researchers or sources for other purposes (Hox, J. J., & Boeije, H. R., 2005).

To obtain relevant information, YouTube is searched using keywords such as "leadership", "leadership style", "employee leadership", "interview", "leadership principles". Detailed testimonials and reports on YouTube are useful sources of data to study leadership behaviour and style as they provide additional information (Gao, X et al., 2013). Some new or relatively neglected topics may emerge, deepening our understanding of how Transformative Leader competences are examined by presenting to the Transformative Leadership Compass.

### **3.3 Analysis**

An inductive analysis of the data was conducted following the basic principles of the Grounded Theory (Glaser & Strauss, 1967; Strauss & Corbin, 1990; Turner, 1981), so themes emerged from the data. The applied procedure for the data collection is "open coding" (Strauss and Corbin, 1990). An extrapolation of the data process is shown in figure 2, reporting a part of the analysis carried out as understanding example, for reasons of limited space.

Leader	a) Quote	b) Code in open coding (Keywords selected)	c) Concepts (Sub-Competences)	d) Dimensions of the Transformative Leadership Compass (Competences)
Jeff Bezos	"...the cultural thread that runs thorough all this things is the same: we only have a few principles of the Amazon kind of core values that we go back to over and over again...so the first one and by far the most important on is customer obsession...."	Customer obsession	Client oriented	1.PRAGMATIC LEADER PROFILE <i>who grasps the essence of the digital transformation</i>
Elon Musk	"...if you are joining a company, the most important think is to make sure to attract great people so either view would join a group that is amazing that you really respect...and I mean all the company is a group of people that have gathered togehter to create a product or service...adn so depending upon how talented and hardworking back group is and the greeter wich they are focused cohesively in a good direction that will determine the success of the company ..."	Working hard together, attract great people	Engagement	5. CATALYST LEADER PROFILE who engages people to act with digital transformation
Jack Ma	" I told the investors: we have been believing customer at number one...because I believe if the customer is happy, enployee are happy, and the shareholders are happy..."	Customer at number one	Client oriented	1.PRAGMATIC LEADER PROFILE <i>who grasps the essence of the digital transformation</i>

Steve Jobs	"There's a temptation in our network age to think that ideas can be developed by email and iChat. That's crazy, creativity comes from spontaneous meetings, from random discussions, you run into someone you ask what they're doing you say 'wow' and soon you're cooking up all sorts of ideas"	Creativity comes from spontaneous meeting and random discussion	innovation and creativity	3. FACILITATOR LEADER PROFILE <i>who shapes a knowledge-creating context for digital transformation</i>
------------	---	---	---------------------------	--

Figure 2- Extrapolation of the data process

The interviews were analysed by extrapolating keywords associated with the behaviours or leadership style of the sample under consideration. The data were first read and transcribed into quotes (a), then categorised into codes (b), which were suggested by the data and not imposed from outside. All codes were then clustered into categories representing leaders' sub-competences (c). Identification of sub-competences often required multiple rounds of analysis by a panel of three engineering experts. Each expert individually identified some keywords, and after a group discussion, the final keywords were selected by all experts. Then, considering the most frequently listed sub-competences, a final list of 5 sub-competences associated with each profile dimension (d) of the Transformative Leadership Compass was defined, according to the characteristics of each dimension previously presented in section two.

### 3.4 Results

The following is a list of the 30 sub-competences that emerged after an inductive procedure and the analysis process outlined above. The partial competences are categorised according to the dimensions Transformative Leadership Compass':

- Dimension 1 – *Pragmatic Leader profile who grasps the essence of the digital transformation*: problem solving, solution oriented, client oriented, excellence oriented, decision making;

- Dimension 2 – *Righteous Leader profile who envisions digital wealth creation goodness*: responsibility, healthy values/ethics orientation, practical-wise oriented, sustainability oriented, well-being oriented;
- Dimension 3 – *Facilitator Leader profile who shapes a knowledge-creating context for digital transformation*: happiness orientation, innovation and creativity, growth spaces creation, teamworking, networking;
- Dimension 4 – *Communicator Leader profile who communicate the essence of digital transformation*: cultural awareness, effective communication, storytelling, social media savvy, digital awareness;
- Dimension 5 – *Catalyst Leader Profile who engages people to act with digital transformation*: listening, positive influence, empathy, engagement, coherence;
- Dimension 6 – *Mentor Leader Profile who makes digital transformation everyone's job*: mentorship, empowerment, critical thinking, transparency, team leadership.

As also illustrated in figure 3, in this early-research stage every 5 sub-competences group is linked to the six competences of the Transformative Leadership Compass, through an inductive process.

These sub-competences help to define *The Transformative Leadership Assessment Framework*, a first draft of a competency model to assess the characteristics of leaders who drive organizational transformation in today's complex business landscape.

To build the first draft of the framework, the sub-competencies has been expressed through some statements (items) largely guided by an induction analysis, to allow for a future step research the construction of questionnaire, based on Likert Scale model (Arcuri, L., & d'Arcais, G. B. F., 1974), or other psychometric techniques.

Indeed, in a subsequent research phase, a questionnaire assigning a score to each item can be created, and all the scores of the questionnaire will be combined (sum) to generate a composite score, which logically in totality measures an uni-dimensional trait (Johns, R., 2010). Therefore, the items created could be related to a scale of evaluation point for create a questionnaire assigning a score to each element. This tool will allow to understand about the behaviours of the participants related with 'latent' or "clear" variable expressed by

several 'manifested' items, for example in a Scale Likert questionnaire (Marradi A. et al., 2002; Joshi A. et al., 2015).

The Framework obtained thus allows to understand how asset the critical competence of a Transformative Leader in a digital era, considered as any actor (manager, leader, entrepreneur, etc.) possessing the capabilities to lead organization towards transformation and sustainability, thinking digital context.

	SUB COMPETENCES	ITEMS
<b>1.PRAGMATIC LEADER PROFILE who grasps the essence of the digital transformation</b>	problem solving	1. I analyse the problem and break it down into sub-problems in order to find targeted innovative solutions
	solution oriented	2. I take action to promote initiatives to identify innovative solutions to future problems
	client oriented	3. I carry out concrete actions aimed at meeting or anticipating the needs of the customer
	excellence oriented	4. I take action to make the company achieve high standards of excellence and quality in innovation
	decision making	5. I make decisions immediately and consciously in an innovative context where complexity is part of the decision
<b>2. RIGHTEOUS LEADER PROFILE who envisions digital wealth creation goodness</b>	responsibility	1. I take responsibility for the objectives set, assuming full responsibility for the positive or negative consequences on the organisational result
	healthy values e ethics orientation	2. I implement decisions based on strong professional ethics and healthy organisational values
	practical wise oriented	3. I make wise decisions, which can have a long-term positive impact on the organisation
	sustainability oriented	4. I make wise decisions, which can have a long-term positive impact on society
	well-being oriented	5. I put in place transparent and authentic actions that stimulate optimism and well-being in the organisation
<b>3. FACILITATOR LEADER PROFILE</b>	happiness orientation	1. I actively contribute to create spaces for discussion and sharing where people can work happily

<b>who shapes a knowledge-creating context for digital transformation</b>	innovation e creativity	2. I put in place actions that encourage creativity and continuous innovation
	growth spaces creation	3. I actively contribute to the creation of learning and growth spaces for the exchange of knowledge and new ideas
	team working	4. I encourage teamwork and collaboration to achieve a common result
	networking	5. I promote interactions between people by adopting an openness and sharing approach
<b>4. COMMUNICATOR LEADER PROFILE who communicate the essence of digital transformation</b>	cultural awareness	1. I share clearly mission, vision and organisational values
	effective communication	2. I employ an universal language through metaphors, examples or analogies to facilitate understanding
	storytelling	3. I employ the tool of storytelling and imagination to share the organisational culture
	social media savvy	4. I communicate through social media and technological tools
	digital awareness	5. I choose the most appropriate technological tools according to my target audience
<b>5. CATALYST LEADER PROFILE who engages people to act with digital transformation</b>	listening	1. I listen carefully to the people who work with me and talk with them politely
	positive influence	2. I instill passion and energy even in the most difficult moments
	empathy	3. I often put myself in the other person's shoes, even if I disagree with him/her
	engagement	4. I promote concrete actions to attract top talent into the company
	coherence	5. I lead the organization through adversity with resilience and tenacity
<b>6. MENTOR LEADER PROFILE who makes digital transformation</b>	mentorship	1. I support people's growth through training and coaching
	empowerment	2. I encourage delegation and empowerment of people

<b>everyone's job</b>	critical thinking	3. I encourage comparison and dialogue, even if someone has a different idea from mine
	trasparency	4. I share with trasparency objectives achieved or organisational results
	team leadership	5. I involve people who work with me, respecting differences, especially in the most critical moments

*Figure 3 - The Transformative Leadership Assessment Framework*

#### 4 Conclusions

This is a preliminary research that proposes a draft model, the Transformative Assessment Framework, as a tool of 30 sub-competences assessing behaviours of a Transformative Leader able to navigate innovation and digital transformation.

The Framework is based on an analysis of the six competences of the Transformative Leadership Compass, re-exploring them considering the case studies of some of the most influence leaders that had created the most successful enterprises in the world: Jeff Bezos, Jack Ma, Elon Musk and Steve Jobs. The principles of the grounded-theory and secondary data collected have been adopted, to formulate the hypothesis of how assess competences and strengthen the Compass model.

The paper addresses the emergent need of enterprises to have figures with a mindset prone to navigate transformation in the digital era and apply transformability, to develop organizational behaviours oriented to innovation and evolution. It is relevant understanding how are the critical competences these figures should nurture and how assess them.

The Framework proposed offers important managerial implications. It can be considered a practical guide to build a questionnaire or a self-assessment tool to measure the fundamental abilities to nurture transformative leadership in digital context. In an environment changing rapidly, the fast development of new capacities linked to innovation is critical to surviving. HR Departments or Business Consulting company could use the Framework to understand how measure specific behaviours that a leader should catalyses within organizations navigating transformation and digital evolution. A helpful model for scholars and practitioners it is also proposed, to deepen studies on leadership practices, suggesting the key items questions to explore the required capabilities.

However, the Framework presents some limitations. In developing future research, it can be considered other cases studies linked to new tech success leaders, and a series of semi-structured interviews to leaders engaged in transformation journeys in digital contexts will be gathered. A more in-depth qualitative analysis and rigorous grounded-theory application will provide further information to test and refine the framework.

Finally, defining how to measure items can be built a questionnaire or a survey to collect data valuable to also design a training growth course to prepare Transformative Leaders in organizations aim to innovate.

### Abstract

Intended study aims to identify the challenges and opportunities mature and emergent entrepreneurs faced for adoption of digital entrepreneurship in face of COVID-19 in research industry of Lahore, Pakistan in view of the Technology Affordances and Constraints Theory. A descriptive research design was executed whereby, sample was chosen using purposive sampling technique and data were collected from start-up owners and their managerial teams using a Likert scale questionnaire. A total of 253 valid responses were recovered. The study results revealed that entrepreneurial teams were engrained in the fierce challenges for adoption of the digital entrepreneurship due to the absence of an approximate framework and support infrastructure. Based on the analysis' results, a framework for digital ecosystem integration considering the life cycle of the business has been proposed along with robust digital entrepreneurship framework for the retail industry.

**Keywords** – Digital entrepreneurship, covid-19 pandemic, retail sector, business transformation, business continuity

**Paper Type** – Academic Research Paper

## 1 Introduction

The recent outbreak of COVID-19 pandemic globally has taught us a big lesson that uncertain crises and uncertainties are inevitable and as many occurred in the past, catastrophes will likely keep on occurring in future. These perilous disasters like COVID-19 although cannot be prohibited yet economies need to be proactively prepared to diminish their all-encompassing consequences on the socio-economic stability of a country. We have witnessed the unavoidable and austere economic and financial penalties of this viral outbreak at global level, keeping none of the countries unmoved. Dramatic transformation are set to occur in how retail businesses such as entrepreneurial startups will act in wake of this external environmental disturbance particularly with respect to South Asian content, more specifically Pakistan. The lockdown imposed by the Government of Pakistan amid the pandemic forced several retail businesses to shut for a longer time period. This resulted in unprecedented interruption of selling and buying pattern in the retail sector. Retail entrepreneurs faced a lot of challenges reaching their customer and consumer. It has been moreover, seen that short-term navigations of the posed challenges and problems will not actually guarantee a hopeful future. Life and ways of doing the businesses after outbreak have taken a radical shift and are different today compared to what they used to be before. Lack of financial and policy infrastructure support from the Government left the entrepreneurs with suspension of their business services. Many of them due to absence of any disaster preparedness response plan could not create any alternative market offering, resultantly many businesses remained unadjusted with the changing environment's pace.

An increased economic turbulence in wake this black swan (pandemic outbreak) forced numerous local entrepreneurial ventures to take a move toward strategic rethink. Leaders of modern tech-enabled firms are transforming their teams to proactively prepare for bouncing forward any substantial prospective disturbance. Entrepreneurs are now planning to take step toward digital shift by bootstrapping and sustaining their existing resource base for their endured survival. Unfortunately, entrepreneurial startups with a nominal investment and humble infrastructure went under pressures of downsizing, trimming their expenditures, optimizing their cost structures, deferring their business activities and processes, and also imposing an infinite suspension on new hiring. Nevertheless, it was also seen that online business processes came into play in

order to sustain the continuity of organizations. In the near future of transformed business era, we would witness an unprecedented evolution of most of retail startups switching from brick & mortar to online merchandizing systems. Lockdown resulted closure of economic and social activities and consequently, entrepreneurs and customers increased their reliance on the digital communication platforms.

Seeing the other side of the coin, this outbreak crisis also served an apex for catalysing the tech supported entrepreneurial processes in the mainstream thereby, creating multiple opportunities for them to sustain the continuity of the ventures. During this period, internet usage surged to manifolds with greater reliance on digital media, online communication & payment platforms and mobile applications' consumption. Entrepreneurs can gain opportunity with heavy reliance on internet connectivity due increase in desire for being contactless yet approachable. There is therefore, a greater need for Pakistani startups to go digital for their future growth and long term survival. A prior emergent and already existing trend has now got swiftly accelerated for digital entrepreneurial activities. New digital ventures can be an important contribution for bringing a steady stability to the shaken socio-economic balance of the country with an eminent focus on innovative tech-enabled venturing called the Digital Entrepreneurship. Uplift of the existing business landscape of emerging startups of Pakistan calls for revamping and transforming their entrepreneurial processes, agency and outcomes through digitization.

I am keenly interested in exploring how to inculcate post-pandemic Digital Entrepreneurship in Pakistan especially in Punjab region through development and implementation of suitable plan of action and policy infrastructure. Adapting to and proactively implementing digitization in commerce and trade of entrepreneurial firms' processes will likely help them sustain their financial growth. Digital transformation mechanism of entrepreneurial startups will help businessmen endure long term business continuity in face of future vulnerabilities and unprecedented crisis occurrences. Intended research study would identify the current challenges faced by entrepreneurs during and after pandemic, and plan an effective action plan for assessing the vulnerabilities associated with introducing digital entrepreneurship in the region under prevailing circumstances. The study will also provide a guideline and framework on how to address the challenges of digital transformation of entrepreneurial ventures and consider

these ventures for investment decisions that can result in sustainable system for digital entrepreneurship in Pakistan.

### ***1.1 Scope of the Research Study***

The study will comprehensively review and assess the consequences and impacts of COVID-19 pandemic on existing emerging entrepreneurial ventures. The challenges to adaptation of these startups to environmental business pressures and adoption of new digital technological platforms in the business processes and systems through probing driving and restraining forces will be explored systematically in detail. A cross-country comparative analysis will be conducted against a set of these external forces and avenues for adoption of digitization by startups. In addition to the challenges posed as a result of adopting digitization, this study will explore and plan a most appropriate decision and investment plan that can be considered for digital entrepreneurship execution and sustenance. Resultantly, intended study aims to explore following research questions:

1. What are the challenges and issues inherent to the existing entrepreneurial ventures amidst COVID-19 pandemic in Punjab?
2. What are the impacts of COVID-19 pandemic on entrepreneurial ventures (businesses)?
3. What is the most suitable plan for the adoption and implementation of digital entrepreneurship in Punjab region?

Nevertheless, considering the study and resource limitations, my research study is particularly focused on digital entrepreneurship of retail sector in Lahore district of Punjab region, whereas, a universal digitization framework for retail startups can be suggested in future.

### ***1.2 Objectives of Research Study***

The research objectives of my study involve:

1. To diagnose the challenges and issues inherent to the existing entrepreneurial ventures amidst COVID-19 pandemic in Punjab
2. To analyze the impacts of COVID-19 pandemic on entrepreneurial ventures (businesses) in retail sector

3. Develop a most suitable and optimized plan for the adoption and implementation of digital entrepreneurship in the retail sector in Punjab region

### ***1.3 Significance and Novelty of the Research Study***

The novelty and significance contributed by the intended research include:

1. Formulate and provide a comprehensive optimization agenda to the emerging entrepreneurs and organizational leaders in adopting digital entrepreneurship during turbulent business circumstances.
2. Incorporate a resilient digital entrepreneurship model through which business continuity can be navigated through identification of most suitable decision option for executing digital entrepreneurship within the content of South Asian retail sector.

This research will help retail sector to capitalize upon digital entrepreneurship framework and contribute to economic growth of the region in the country through increased job creation and assistance to new online business startups. It will also help to make further development in connotation of digital entrepreneurship with respect to retail sector of services industry. In this way sufficient and useful investment choices can be proposed to Ministry of Information Technology of Pakistan to influence the emerging trend of digitization in development and optimization of traditional small businesses for increasing business resilience. The proposed model of digital entrepreneurship can be incorporated in the policy framework of well established companies, governmental policy reform system, accelerator, incubation centers, and investors. The new proposed framework will recommend an agile and proactive action plan embedded in the risk & crisis management, resilience and business continuity management infrastructure and can also serve as resilience preparedness and adaptive response capacity development tool to help digitally enabled start-up originators navigate their businesses through any unprecedented crisis occurring in the global business environment. The new proposed framework on digital entrepreneurship and its investment decision will be a guided model for future entrepreneurs to adopt it in effectual and successful way using low cost and limited resources. This study will be used in assisting the entrepreneurs sustain their long-term business journey by incorporating digital ecosystem in their

venturing, employment, trade and contracting in order to bounce back any uncertainty such as pandemic or other crises.

Moreover, established organizations and companies, investors, government, accelerators, merchants and service providers can take insights from this research and use innovative framework of digital entrepreneurship for providing individualized solutions and services to end users. Digital Entrepreneurship is an emerging concept in Pakistan and this study can provide excellent lead to the stakeholders of our emerging market so as to close the gap of digital entrepreneurship. COVID-19 has changed the global business landscape and future of our Country's socio-economic integration and balance lies in augmenting the dependency of entrepreneurs on digital platforms. These initiatives could eventually add to digitization of economy and contribute to the GDP of Pakistan. Surging penetration of internet usage with rising 4G & incoming 5G technologies on smartphones in Pakistan evidently justifies the need for an implementation framework on digital entrepreneurship and thus upgrade the value chain of digital economy of our retail sector ventures.

Entrepreneurs of Pakistan need veracious support from investors and Government, in order to establish vigorous digital clusters in their business ecosystem. This study will be effectual in assisting entrepreneurs scale up their businesses in face of any adversary and remove any hindrances that stand in their way to reach and serve their end users. This study provides an impetus to the local small and medium sized entrepreneurs in embracing digital technology in order to create a new vibrant and dynamic market alongside enhancing the economic productivity of Pakistan. This research study will be helpful in providing a roadmap for adopting digital entrepreneurship in retail sector of industry, which would eventually lead to enhanced exports, creation of jobs to millions of graduates and strengthened economy. A sustainable digital entrepreneurial ecosystem will support a cost efficient and outsourcing of talented IT expertise. Through this, the digital service market would become more integrated and mature not only limited to ecommerce but spreading in all diverse marketplaces. Figures annexed in the appendix provide a concise yet comprehensive view of the opportunities and avenues for advancement of digital entrepreneurship ecosystem in Pakistan business climate.

## 2 Literature Review

COVID-19 pandemic was an unparalleled pandemic spread at global level, and recently it impacted millions of lives all over the world. We could see countries limiting the flux of their citizens by sealing their national borders for an infinite time period. People were quarantined to their homes due state enforced curfew and lockdown extended up to several months. Together with being vulnerable to life threats, people were also found terrified due to high job insecurity, thus this viral outbreak adversely affected our society through multiple angles leaving even the developed countries in state of chaos and socioeconomic disorderliness (Blackhurst, Dunn, & Craighead, 2011; Papadopoulos et al., 2017; Papadopoulos, Baltas & Balta, 2020). Various industrial sectors and businesses were disrupted due to immobility occurred in the economic activity, resulting in flooded unemployment. Most of the businesses based on brick and mortar model were ceased with their almost dependency on physical presence and interaction with the customers such as physical retail outlets, tourism, entertainment, hospitality, household and food etc. In face of this large scale turbulence, governments of all especially the developing countries tried hard to fuel their economic systems within constrained resources and limited infrastructure. Loss of business and jobs was another major challenge faced by states in addition to dealing with life security amid pandemic eruption (Aly, 2020).

Considering the other side of the coin, there was certain opportunism consequential to the lockdown situation i.e. an exciting escalation in internet usage, social media in particular. Due to minimal socialization of people and being confined to homes for an infinite time period, there was observed a huge inclination towards usage of social media over physical one-to-one interactions (Nowland, Necka, & Cacioppo, 2018). In essence, internet was the only source to avail essential facilities through online product and service delivery modes such as online education, online health care consultancy from doctors, online financial business transactions any so on so forth. Likewise it has been found that, developed economies such as USA, Europe and China etc. navigated their businesses from brick-and-mortar to click-and-mortar and finally to online stores under high uncertainty and complex circumstances so as to sustain their competitive position in the market (Rapoza, 2020).

Conventional, reactive, vulnerable and rigid businesses were left struggling, while agile, adaptable and resilient businesses were found thriving i.e. all those

internet enabled and supported businesses survived the setbacks triggered by the pandemic outburst. These businesses involved but were not limited to online teaching in academic sector, ecommerce reliant selling and buying of goods, work from home business models, entertainment, healthcare, banking, food and other grocery items' delivery and IT services and solutions (Senyo, Liu, & Effah, 2019; Hughes et al., 2019). Businesses took advantage of high internet and smartphone usage of customers and transformed their purchase, consumption, demand and reordering patterns. Resultantly COVID-19 plague created an exclusive opportunity to differentiate reactive and proactive businesses in regard of their continuity, it could be witnessed that dynamic businesses sustained their competitiveness and thrived in the market; contrarily, static businesses could not adjust their sails with the changing tides in the competitive and difficult waters (Jaworski, Kohli, & Sahay, 2000). Abandonment of one business was replaced with a new value creating solution/business in the market. Dynamic businesses transformed with a rapid pace in accord with the changing demands and perceptions of market stakeholders. Hence, pandemic outspread brought into play the idea of value creating 'dynamic ecosystem' (Vargo & Lusch, 2011).

Based on the recently endured COVID-19 pandemic, securing the continuity of small and medium firms has been considered to be the most critical concern chiefly for the less developed economies. Fortunately, use of digital technology can help secure business endurance and continuity of the small entrepreneurial firms, hence mitigates the risks by proactive risk identification and recovery of the business services and processes (Gibb & Buchanan, 2006). Regardless of the implications of applying digital technologies in securing the continuity of firms under circumstances of thrilling disruptions such as COVID-19, still there is dearth of the framework or an appropriate framework or a roadmap for emergent startups, small entrepreneurial ventures and IT experts and information system teams for such crisis preparedness. Earlier research studies emphasized safeguarding information security, technology strategy and tech-enabled functions of the organizations (Niemimaa, 2015). Recent incidence raised another major concern over how can small entrepreneurial firms shape and optimize their work and operations around integration of digital technological platforms as an adaptive response to uncertain and intense catastrophic event? Organizing digital technology in the strategic intent of small ventures in order to tackle the complications caused as a result of COVID-19 establishes a demand for a new research avenues (Giones et al., 2020).

"Digital entrepreneurship is a subcategory of entrepreneurship in which some or all of what would be physical in a traditional organization has been digitized" (Hull et al., 2007). Le Din et al. (2018) defined digital entrepreneurship as "the reconciliation of traditional entrepreneurship with the new way of creating and doing business in the digital era."

Considering 'Digital Entrepreneurship' as an organization's capability to respond to the external environmental adversaries (Teece, Peteraf & Leih, 2016) such as in case of COVID-19 outbreak can in order to gain long term competitiveness and sustenance can be related in the light of 'Dynamic Capability View' (Teece, 2018). Thus, for an organization to safeguard its permanence in wake of high velocity turbulence in the external environment of the business (Coronavirus pandemic), it must take into account the 'sensing', 'seizing' and 'reconfiguring' of its capabilities and resources (Teece, 2018). Another theory that links the organization's capability to foresee and predict uncertainties and complexities that can threaten its survival (exploration) and accordingly, use its resource capabilities to proactively respond to them (exploitation) is the idea of "Organizational Ambidexterity" (Gulati & Puranam, 2009; Cao et al., 2009; O'Reilly & Tushman, 2013). According to Papadopoulos et al. (2020), ambidextrous organizations possess dynamic capabilities to exploit 'sensing, seizing and transforming' actions for tactfully dealing with challenges posed by COVID-19 pandemic inherent to the continuity of the business (Papadopoulos, Baltasb & Baltac, 2020). There is therefore, now an important need for studying research on new entrepreneurial actions and practices under ambiguous and uncertain business circumstances (Bylund & McCaffrey, 2017).

Additionally, the Technology Affordances and Constraints Theory (Gibson, 1979) is critical to understand how fueling of digital ecosystems into the entrepreneurial ventures can impact and shape the processes and actions of the actors i.e. entrepreneurs. (Majchrzak & Markus, 2014; Nambisan, 2017). This offers a favoring and auspicious opportunity lens to investigate this. For sustaining their survival, organizations irrespective of any turmoil or crisis driven instability, undertake either productive or fruitless entrepreneurial actions for exploring and exploiting resources and developing a rational adaptive response (Kuckertz et al., 2020). In regard of this, an unanswered question arises, how entrepreneurial ventures can adapt their businesses to the continuing crisis of COVID-19 outbreak.

Deployment of digitization into entrepreneurial business practices is now considered critical to innovation and commercialization of the business processes. These platforms are denoted as 'digital space' and provide prospects for the businesses to interact and connect with their customers and end users of their products and services (Hsieh & Wu, 2018; Kraus et al., 2018). These digital spaces i.e. technology assisted contents to reach customers comprise of three forms that encompass 'innovation platforms' for designing corresponding services and products by the business using advanced technologies, 'transaction platforms' that entail online retailing and services to be delivered to the customers on their demands, and lastly, 'integration platforms' that are a hybrid model of the first 2, i.e. integrated business model of innovating and developing new products and services and delivering them to the customers as and when they demand (Hsieh & Wu, 2018). Therefore, digital entrepreneurship requires firms to use unique and differentiated strategies for placing their products and providing their services to a wide range of customers through online interconnected network involving multiple vendors and businesses (Srinivasan & Venkatraman, 2018). Such scheming and application platform integration strategy helps support digital ecosystem of the entrepreneurial ventures and accelerates the growth of the businesses (Sahut, landoli & Teulon, 2019). Likewise, rapid advancement in technology business ecosystem also tends to pose serious threats and risks in the form of increased competitive rivalry or breach of information security leading to the devastation of the entire business model (Giones & Brem, 2017). Entrepreneurs, therefore can pursue distinctive innovations in their ventures by capitalizing on the opportunities offered by digital system that outline and guide their decisions, transform the capabilities of their businesses and improve their performance given any disaster or crisis occurs (Nambisan, 2017; Ghezzi & Cavallo, 2018; Kraus et al., 2018; Senyo, Liu & Effah, 2019).

It is inevitable to recognise potentially appropriate digital entrepreneurship framework based on an ecosystem characterized by a multifaceted sociotechnical architectural system that embraces extended and secure participation of heterogeneous stakeholders in the digital ecosystems so as to efficaciously commence digital entrepreneurship based projects. Beginning from an abstract and broader digitization to digitalization and then incorporating digital architectures within the digital corporate business models. This shall eventually indorse optimization of sustainable business models functional on digital ecosystems, thereby, developing the grounds for digital environment and

platforms to be developed. Such innovations and transformations through digitalization in business processes is a profound prerequisite for development of sustainable model of breakthrough businesses. This is how digital entrepreneurs can broadly enjoy the freedom of interaction in new entrepreneurial undercurrents and uncertain business environment.

### **3 Research Design**

Besides using the traditional and conventional approaches of researching the intuitionism and its impact, this study will adopt a positive approach to propose the Digital Entrepreneurship Framework by applying Dynamic Capability View in the retail sector medium sized entrepreneurial firms. The reason behind this is that organization's dynamic capabilities play instrumental role for innovation and continuity of businesses in face of any adverse crisis occurrence. A quantitative approach has been used to test the opportunities and challenges for digital entrepreneurship in the retail sector. An adaptive questionnaire based on Likert Scale (1 – Strongly Disagree and 5 – Strongly Agree) was sent to the middle level management, including entrepreneurs, IT specialists, knowledge workers, software engineers etc. to get the purposeful data. A descriptive procedure was conducted to find the nature and extent of avenues of digital entrepreneurship (Zikmund & Babin, 2012). For quantitative analysis questionnaires were distributed to gather data on Likert scale. Purposive sampling technique was used in the intended study for individuals for the special purpose of getting information required in the questions. The selection of the sample was entirely judgmental as the study required (Patton, 2002; Lawrence & Tar, 2013). The key identifiers were selected after seeing their position at the company, their prior qualification and experience in digital ecosystem in start-up venturing and innovation oriented processes in the retail businesses dealing in Lahore, Pakistan.

### **4 Results**

#### **4.1 Demographics**

A total of 253 valid responses were gathered upon data collection and data were analysed. The demographic section of the data collected showed that 17% of the participants were females, whereas, 83% males were entrepreneurs

involved in digital business ecosystem. According to the age group segregation, the highest 46% respondents belonged to the age bracket of 33 to 42 years, followed by 38% for participants falling in 23 to 32 years of age stream, 11% of them accounted to having ages between 43 to 53 years and only 5% of the participants were of the age bracket of 53 to 62 years. The results declared that majority of the managers were 16 years Bachelor's (Hons) qualified, followed by Masters/MSc with 33% presence, the post graduate diploma holders accounted for 22% of the sample, while only 8% of them had completed MS/MPhil education. Likewise, mainstream entrepreneurs and managers working in the start-ups held degree related to IT/SE/CS fields i.e. 57%, whereas 47% respondents accounted for other qualification backgrounds. Based on working experience in start-up entrepreneurial firms, the highest proportion accounted for 42% having experience of 5 to 9 years. 23% of the study participants has working tenure of 10 to 14 years, 20% of them accounted for working experience of 15 to 19 years, 11% were having an initial starting working experience of maximum 4 years. Whereas, only 4% of the sample respondents had vast working experience of 20 years or more in their belt. With regard to the industrial segregation, it was found that majority of start-ups belonged to food industry with 18% representation in the sample selection, 16% for fashion and apparel accessories, 15% for IT and consumer goods, 13% for professional services, 11% for banking and financial institutions 8% in real estate industry, 7% for consultancy firms, and 2% each for transportation and healthcare. The results can be seen below in Table 1

Table-1. Demographics showing percentages and frequencies of participants from various industry start-ups

Sr. #	Demographic Items		
		Frequency	Percentage
1	Gender		
		Female	43
		Male	210
2	Age Group (yrs)		
		23 to 32	96
		33 to 42	116
		43 to 52	28
		53 to 62	13
		63 and above	0
3	Qualification		

	Bachelor's (Hons)	94	37%
	Master/MSc (Hons)	83	33%
	MS/MPhil	20	8%
	PhD	0	0%
	PGD	56	22%
<b>4</b>	<b>Having IT/CS/SE Degree</b>		
	Yes	144	57%
	No	109	43%
<b>5</b>	<b>Experience (yrs)</b>		
	0-4	28	11%
	5-9	106	42%
	10-14	58	23%
	15-19	51	20%
	20 and above	10	4%
<b>6</b>	<b>Industry</b>		
	Healthcare	5	2%
	Information & Technology	38	15%
	Banking and Finance	28	11%
	Transportation	5	2%
	Real Estate	20	8%
	Consumer / Grocery	38	15%
	Food	46	18%
	Fashion and Accessories	40	16%
	Professional Services	33	13%
<b>7</b>	<b>Best growth strategy over next 5 years of the business</b>		
	To sustain my business in its existing size for making income out of it	36	14%
	To grow my business at stable pace for offering growing opportunities for my employees and new job creation	58	23%
	To grow my business as a large business organization and trade shares in market	119	47%
	To organise for sell or closing my business	10	4%
	To apply succession while passing my business and ownership of my business to my children	30	12%
	Total (N)	253	100%

## 4.2 Descriptive Analysis

Based on the descriptive nature of the study, it aims to elaborate the characteristics of the sample population in order to explain the extent of the opportunities and challenges faced by the start-up managers. The study has utilized descriptive statistical analysis verifying the mean and the standard deviation (SD) values of each indicator as exhibited in Table 2 given below.

Table-2. Mean and Standard Deviation of the Evaluation of the Digital Entrepreneurship Opportunities and Impediments

#	Item Indicator	Mean	SD
<b>Problems/Impediments Confronted in Start-up Business Initiation in Face of COVID-19</b>			
1	Huge and fierce competition	3.765	0.642
2	Lack of Technical and Analytical Skills	4.531	0.819
3	Lack of Experience	3.912	0.741
4	Stringent Regulations	3.887	0.530
5	Lack of Opportunities	4.215	0.676
6	Lack of Resources	4.578	0.790
7	Time Constraints	3.769	0.401
<b>Technological Opportunities that Facilitated Start-up Initiation in Face of COVID-19</b>			
8	Robust competitor analysis	2.560	0.328
9	Facilitation in filling skills gap	1.367	0.132
10	Enhanced communication	2.873	0.365
11	Experiential learning	3.564	0.462
12	Online data access	2.790	0.348
13	Better know-how of Govt. regulations	3.084	0.500
14	Building of competitive team with required expertise	2.169	0.298
15	Adaptability of the consumers towards technological platforms	3.793	0.529
<b>Problem/Impediments Confronted Against Human Resource Practices in Face of COVID-19</b>			
16	Difficulty in hiring qualified and expert team	4.534	0.875
17	Absence of suitable and safe working conditions for workforce	3.590	0.651
18	Absence of team work and cohesiveness	4.179	0.739
19	Absence of team leadership and accountability	4.865	0.842
20	Difficulty in ensuring employee participation and work engagement	4.610	0.763
21	Absence of capacity to ensure smooth business transformation	4.489	0.528
22	Absence of competitive pay plan i.e. upgrading salaries and incentives	4.357	0.737
<b>Technological Opportunities in Managing Human Resource</b>			

<b>Practices in Face of COVID-19</b>			
<b>23</b>	ease in search of required talent	0.219	0.329
<b>24</b>	ease for employees working in online mode	0.288	0.287
<b>25</b>	availability of online attendance systems	0.379	0.436
<b>26</b>	Availability of security surveillance system for continuous mentoring of business operations	0.345	0.281
<b>27</b>	Availability of sophisticated ERP systems	0.225	0.193
<b>28</b>	Easy and fast communication within teams using online platforms	0.156	0.184
<b>29</b>	Continuous monitoring of teams' performance using online platforms	0.339	0.273
<b>Problems/Challenges Confronted Against Easy Access Financial Resources in Face of COVID-19</b>			
<b>30</b>	Difficulty in securing internal financial resource fund	4.583	0.860
<b>31</b>	Difficulty in borrowing external fund as loan	4.990	0.913
<b>32</b>	Difficulty in gaining monetary support from family and close acquaintances	3.879	0.784
<b>33</b>	Absence of financial and fund management skills	4.872	0.837
<b>34</b>	Inability to remain updated with ongoing market dynamics and economic cycles	4.369	0.691

It can be inferred that the start-up stream in retail industry of Pakistan is entrenched under huge burden of existing challenges due to the absence of a solid framework of digital framework in face of pandemic crises. The challenges and opportunities have been analysed different dimensions such as new business initiation, managing HR practices, ability to raise financial resources, knowledge and skill based development, managing business operations, managing business at its maturity stage. The result show that there are lesser opportunities for capitalizing on the avenues of digital ecosystem to be incorporated in entrepreneurial ventures. Table 2 shows that the indicators of challenges on digital entrepreneurship faced by start-ups having mean values above ranging from 3 to 5 are adversaries for the survival and endurance of these businesses to severe lack of a secure and systematic framework of digital entrepreneurship. Contrarily, the indicators evaluating the opportunity landscape of digital entrepreneurship in start-up businesses in face of COVID-19, showed mean values ranging from 1 to 3 reflecting a stark lack of a robust digital ecosystem and technological infrastructure for automating and transforming the retail start-ups.

## 5 Conclusion & Discussion and Digital Entrepreneurship Framework

The findings of the study reach to the conclusion that there exists a threatening and fierce competition in industry; start-ups are facing dearth of technical and analytical skill availability and well experienced team of professionals; the regulations imposed by state are stringent enough to provide a breathing room for navigating digitized business strategies, hence lesser opportunities. The respondents advocated the fact that their business strategy was short of the view to incorporate technology supportive opportunities in order to bounce forward violent competitors' moves, replenishing the existing skill gaps, enhancing communication; promoting experiential learning, gaining better know-how of Govt. regulations, building of competitive team with required expertise, and converging existing and new customers towards adopting new technological platforms.

The study also highlights the impediments witnessed by the start-up firm with respect to their HR Practices. Since, the merciless incidence of COVID-19 resulted in difficulty in hiring qualified and expert teams. There was absence of a suitable and safe working conditions for workforce. There lacked team work and cohesiveness due to absence of team leadership and accountability. The start-up owners fought with the difficulty in ensuring employee participation and work engagement due to incapacity to ensure smooth business transformation and absence of competitive pay plan i.e. upgrading salaries and incentives. Likewise, due to absence of a sound digital entrepreneurship platform, HR management practices were ill-conceived to make entrepreneurs confront never-ending problems such as difficulty in search of required talent, no appropriate planning for employees working on online mode and security surveillance system for continuous mentoring of business operations, ineffective team communication using online platforms and lack of continuous monitoring of teams' performance using online platforms.

Financial resource funding also acted as a huge impediment owing to the inaccessibility and deployment of the digital ecosystem as a proactive crisis response. The problem included difficulty in securing internal as well as external financial funding, absence of financial and fund management skills, inability to remain updated with ongoing market dynamics and economic cycles, incurring high cost in guaranteeing continuous improvement in work processes and products and services as demanded by customers. Likewise, the nonappearance of the technological systems to facilitate financial fund sourcing was quite evident such that it was determined from the results that there persisted an unavailability of digital tools to conduct financial analysis, challenging obstacles in finding and winning investors, no facilitation or support from the state regarding applying for the financial loan borrowing using online platforms or optimizing crowdfunding strategy.

Scarcity of knowledge base and up-to-date skills and abilities also came to be one of the antagonists faced by the start-ups during COVID-19 incidence in view of the non-existence digital entrepreneurship framework being exercised. The problems highlighted were unavailability of coaching and training resource facilities for skill and knowledge enhancement, absence of a clear vision and roadmap to achieve company's strategic goals, inability to identify gaps in skills and knowledge by conducting comprehensive need analysis, absence of motivation to promote learning and growth. The avenues were least explored in

terms of inculcating creative culture by supporting innovation and application of new techniques, continuous improvement and development of innovative processes, services and products, supporting new knowledge creation, developing teams' core skills and competencies, periodic training for continuous team development

The operational efficiency and conformance of retail start-ups as also highly conceded due to massive difficulty in reaching customers, delivering services and products to the final customers and reaching suppliers due to an availability of logistics. Immense inconvenience was consequential in ensuring regularity in process of payments. There was an insignificant possibility with technological support for managing start-ups' operations during COVID19 where the businesses lacked harshly in ease of communicating and maintaining customers via official websites, social media platforms and emails and using modern technology in designing products & services. Start-ups deficient in sophisticated tech-enabled platforms found it hard to manage raw material supplies and distribution logistics using online platforms, and ensure smooth and secured e-payment systems.

Lastly, those entrepreneurial firms reaching the maturity stage of their business life cycle were at total risk of having no planning to transform their business processes incorporating digital entrepreneurial passion and essence of the tech-ecosystem development. The obstacles identified included high level troubles in keeping pace with sales' consistency, smoothly performing with efficiency and effectiveness and ensuring continuous improvement. It was revealed that emergent planning and revamping of strategic goals and strategies for continuous business growth were not proactively devised, hence these businesses were unable to uphold the superior quality of the products & services and sustain competitive position in industry due to increased customer complaints and dissatisfaction, consequently failure to retain stability in profits and sustain performance of business. It was established that most of the entrepreneurs having their businesses troubled against not being able to capitalize on digital entrepreneurship in pandemic crisis are positive for technology adoption for higher innovation to seek another business opportunity.

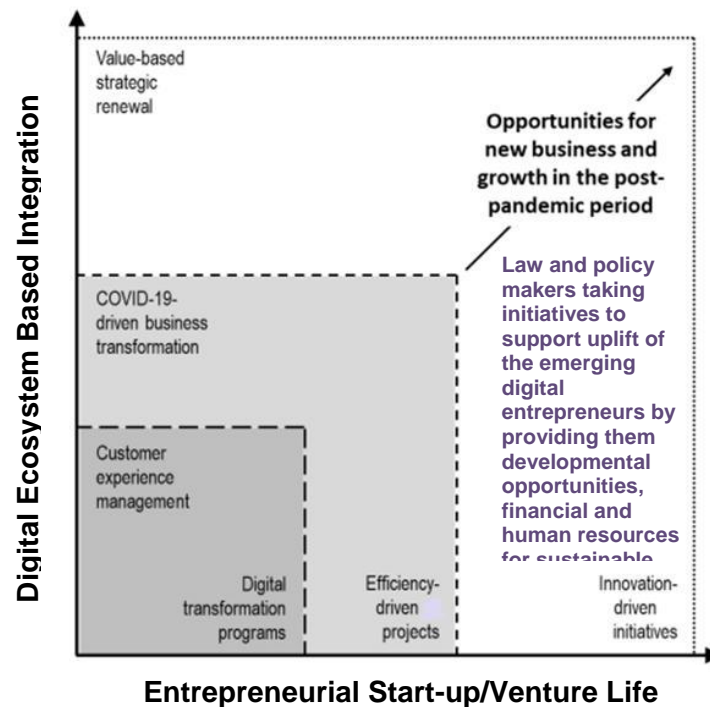

Figure 1: Framework for digital system integration in start-up business model

This backs the idea that for digital entrepreneurs to shape their enterprise around a technological platform it is essential to align their businesses' models rightly with the technological standing of the digital ecosystem. High-tech advancement of their business platforms will require a rapid improvement in business technology. Moreover, it is also an important lesson for the digital entrepreneurs to innovate and distinguish on continual basis among their competitors by seeking forthcoming technological prospects presented by the digital entrepreneurship framework (Srinivasan & Venkatraman, 2018).

These research findings also lead to a significant danger digital entrepreneurs could face i.e. progressively difficult for them to keep pace with rapid technological advancement, not only within platforms (Srinivasan and Venkatraman, 2018). To be and young digital entrepreneurs need to establish and deploy secured technological platforms for inculcating trust and confidence among the market players. As well as customers by taking continuous feedback (Hair et al., 2012).

Another critical underpinning to be taken into consideration is the decisions regarding the architectural configuration of the placement and positioning of the digital ecosystem and adoption of the tech-platform in order to reap the profitable yield of the start-up. Moreover, it also emphasizes the need for conscientiousness of the digital entrepreneurs to foresee ever-changing preferences of the customers, emerging competition and forthcoming market dynamics such as technological advancement, varying regulations imposed by the government on legal and tax related matters. This highlights the essentiality of the adaptive response & flexibility, motivation, commitment and depth as well as breadth of the current knowledge entrepreneurs need to build and maintain for ensuring team devotion and participation, eventually innovation in the business.

Finally, environmental uncertainties such as unprecedented crunch should be grasped through a positive angle where retail start-ups can actually yield substantial profits upon discovering and developing on novel opportunities systematically (Paunov 2012; Evan & Rivera 2020). This leads my research to propose a framework for digital entrepreneurship to support exploring positive and developmental avenues and endure business growth and sustenance beyond the management of crises. It may be enlighten the canvas of the entrepreneurs to search for and effortlessly exercise unceasing optimization of their businesses and safeguard their continuity under the repercussion of COVID-19 pandemic crisis.

### **Abstract**

Creative neighbourhoods are the subject of increased discussions and concerns, both in the academic and the professional communities, having various cultural, social, economic, and policy implications. Nevertheless, the theorising in the field is at the beginning. Various interdisciplinary approaches highlight especially social, economic, and urban implications. The study aims to investigate the dynamic of creative neighbourhoods in Romania to understand which are the factors leading to success stories both for the creative communities and for urban development. The dynamics associated with the local administrations in two main Romanian cities are explored: Bucharest and Cluj. The findings are shading lights on the inner dynamics of creative communities in creative neighbourhoods in relationship with public administration for better cooperation.

**Keywords** – creative neighbourhood, creative community, cultural entrepreneurship, local administration and culture

**Paper type** – Academic Research Paper

## 1 Introduction

The way culture and creative industries could contribute to sustainable local development has generated extensive discussions (Duxbury, Cullen and Pascual, 2012; Sacco, Blessi and Nuccio, 2009; Van der Borg, Russo, Lavanga and Mingardo, 2005). A main aspect to consider is the impact of culture on urban regeneration (Della Spina, Giorno and Casmiro, 2019; Gaetan and Zheer, 2017; Russo and Van der Borg, 2010; Paddison and Miles, 2020; Sasaki, 2010), as well as on community wellbeing (Stern and Seifert, 2017). Some very visible and much-acclaimed success stories as Guggenheim Bilbao are always mentioned in such contexts (Gazura, 2018; Lange-Valdés, 2018). Nevertheless, not all support of cultural and creative industries leads to local economic development and social development (Jarvis, Lambie and Berkeley, 2009). Therefore, public bodies should wisely integrate culture and creative industry as part of their development strategy.

A possible approach would be to create and/or sponsor creative communities and quarters. Designing /supporting creative neighbourhoods is a topic of interest both for local public administration which targets sustainable development, as well as for the creative communities themselves which count on a multiplying and networking effect. Although such initiatives are always praised, limitations and challenges should also be considered (Jakob, 2010). Several dimensions are to be kept in mind in the context of creative neighbourhoods: the specific cultural setting, the local cultural organisms, the cultural infrastructure, and the cultural and creative tourism in the area. The digital age added some additional factors to consider, opening these communities to the outside world (Evans, 2009).

Considering this framework, the present study aims to investigate the dynamic of creative neighbourhoods to understand which are the factors leading to success stories both for the creative communities and for urban development. To achieve this goal, a narrative literature review focused on conceptual understanding is considered, followed by a qualitative investigation. The qualitative investigation comprises two parts aiming to uncover explore the role

of public administrations in the development of creative neighbourhoods in Bucharest in Cluj, the largest and most dynamic cultural Romanian cities. Firstly, to gain a broader understanding of how local authorities are positioning their interventions as strategic planners as well as main regulatory bodies, we conducted a content analysis comprising a series of documents elaborated by local authorities Bucharest and Cluj (see Table 3). Secondly, a thematic analysis was conducted on a corpus comprising a series of written that describe four different initiatives involved in the construction and active communication about various concepts of creative quarters in Romania: Cartierul Creativ (2021), Centrul Cultural Clujean (2019).

While creative quarters might be a common encounter in many developed countries, in Romania they are a reality in the making. Therefore, understanding the associated evolution might help to find and implement effective development strategies. We have chosen two main cities in Romania, particularly relevant for our research. The findings are relevant through shading lights on the inner dynamics of creative communities grouped in creative neighbourhoods. It maps the specific networks and reveals the role that public administration might play in supporting creative neighbourhoods.

## 2 Creative neighbourhoods – mapping the concept

The term creative quarter/neighbourhood/district is increasingly more present in discussions related to urban development and community wellbeing. It seems that several concepts are used interchangeably, with the largest popularity registered by the creative district as presented in Table 1.

Table 1. The concept popularity (no. of entries)

Concept	Google	Google Scholar	WoS
Creative neighbourhood	30.600	170	1
Creative neighbourhood	131.000	267	2
Creative quarter	201.000	778	10
Creative district	262.000	810	14

Another term extensively used is a creative cluster, but this has a wider significance, not necessarily referring to specific spatial surroundings. A recent review (Chapain and Sagot-Duvaurox, 2020) shows each academic discipline investigating the concept presents its own perspective and stresses some specific

cultural, economic, social aspects. At the same time, studies seem to limit some case studies and tend to contribute to transferring approaches from Western countries to the rest of the world. Nevertheless, most of the research comes from Europe (62%), followed by the US (14%) (Chapain and Sagot-Duvaouroux, 2020). Especially in the past 10 years, the concepts of creative/cultural districts/quarters/neighbourhoods are overlapping in academic research. It seems to be a certain geographic preference for these concepts – for instance, “cultural district” seems to be preferred in the US and Italy, or “cultural quarter” in the UK and Ireland (Chapain, and Sagot-Duvaouroux, 2020).

This literature review also documents a lack of theorization of the concept, which might be related both to the complexity of phenomena associated and diversity of perspectives that could be considered (geographic, cultural, economic, urban planning, etc.). One of the definitions, of Walter Santagata, developed in 2002 for cultural district, is considered as the most influential: “Cultural districts are defined by the production of idiosyncratic goods based on creativity and intellectual property. The movie industry, the audio-visual sector, the extensive domain of industrial design and the production of arts and crafts, museum services and the ethno-gastronomic complex all draw their inspiration from some cultural link with their original community” (Chapain and Sagot-Duvaouroux, 2020). At the same time, the cultural quarter seems to be more tightly associated with a specific location, a section of a city.

The present paper takes into account a synonymy of the concepts creative district, creative quarter, and creative neighbourhood. It defines the concept as a network of places and happenings within the territory of a town/city which is developing as an urban collaborative space and encompasses a creative community and the associated means of producing cultural and creative goods and services, with place-bound characteristics and value-chains, offered to a wider public either by creatives themselves or mediated by organizations specialized in a creative and cultural offer (theatres, museums, etc.) or which integrate into their business models features defined as innovative / creative / cultural (restaurants, shops, etc.).

This is a working definition, which for sure can be improved considering the complexity of the phenomenon. We also stress that we prefer the term creative neighbourhood due to its human dimension, stressing the capital relevance of the people involved – either creatives or the beneficiaries of their work. It also seems to encompass the importance of communities, both considering the relationships

between creatives and the wider communities for which they are relevant. In such spaces, creatives are mixed with residents and visitors, all contributing to developing a creative milieu supporting different lifestyles, innovative architecture and urban planning, the development of cultural organizations, and various types of businesses.

Cultural organizations and creatives could be connected in three types of creative spaces: scenes, quarters, and clusters (Wen, 2012). The first term refers to the cultural content and human bonding. The second one includes an urban connection. The third one refers to the industry, putting the focus on organizations. We will concentrate on the second type, trying to better understand the diversity of approaches.

The typology of creative neighbourhoods seems to be wide, related mainly to the inner structure and the cooperation networks developed inside the district, portfolio, and organizational framework (Moomaas, 2004; Redaelli, 2019). Considering the sponsor of a creative quarter, we identify two main approaches: the bottom-up and the top-down strategies. The first one is developed by artists and local organizations informally, while the second is planned formally by public administration (Chapple, Jackson and Martin, 2010). Nevertheless, cooperation among all stakeholders and active creative communities are key for the success of such initiatives (Romanelli and Zbucheá, 2020).

Another typology stresses the characteristics of the offer. Three types have been identified (Lavanga, 2020). Some are more production-oriented, encompassing businesses creating cultural and creative products and services, while others are oriented towards consumption such as museum districts. The third type is a mixture of the two.

Based on the relationship between property development and cluster formation, there are four types of cultural quarters: scene-consolidating quarter, scene-displacing development, scene-spatializing quarter, and scene-imitating development (Sonn and Liu, 2014). The scene refers to "a collection of activities related to the production and consumption of cultural products". In the case of scene-consolidating neighbourhoods, the scene's spatial core existed before cultural cluster development. In the case of the scene-displacing development, one can observe a potentiality for cultural neighbourhood development in the context of the spatial existence of a cultural scene. In the case of the scene-specialising cluster, there is no spatial cultural scene before the development of the cultural cluster. In the case of scene-imitating development, there is a sponsor

of a cultural cluster who simulates the existence of a scene, hoping for cultural consumption to occur.

A typology of creative cities considering the three main reasons of intervention (social inclusion, urban planning, and economic development) identified the “natural born” approach, the culture-led social inclusion approach, the business approach, the bulldozer-business approach, the European Capital of Culture approach, the enhancing approach and the phoenix approach (Rato, Roldão and Mühlhan, 2009). This could be transferred to creative neighbourhoods.

Table 2 synthesizes types of creative neighbourhoods, discussed by various researchers (Chapple, Jackson and Martin, 2010; Cinti, 2008; Lavanga, 2020; Moomaas, 2004; Rato, Roldão and Mühlhan, 2009; Redaelli, 2019; Santagata, 2002; Wen, 2012).

Table 2. Taxonomy of creative neighbourhoods

Criteria	Typology
Developmental path	bottom-up top-down
Development strategy	formal approach informal approach
Cohesion	aggregations of organizations and individuals well-planned strategy
Main actors and scale	industrial cultural district institutional cultural district museum cultural district metropolitan cultural district
Reasons of intervention	“natural born” culture-led social inclusion business-oriented bulldozer-business-oriented European Capital of Culture enhancing approach phoenix approach
Relationship between property development and cluster formation	scene-consolidating neighbourhood scene-displacing development scene-spatialising neighbourhood scene-imitating development
Horizontal portfolio	production-centred production-consumption mixed consumption-centred
Vertical portfolio	one dominating industry multiple industries contributing

Focus	art-oriented entertainment-oriented
Financial support	public sector financed business-oriented mixed public and private support
Location	city centres marginal location
Level of openness	exclusive membership completely open to members

Independent of the evolution and type of cultural neighbourhoods, there are some joint components they display (Santagata, 2011, p.148): *"a) a local community, which is cohesive in its cultural traditions and in the accumulation of technical knowledge and social capital (trust and cooperation); b) a significant development of increasing returns to scale and increasing returns to scope; c) accumulation of savings; strongly entrepreneurial cooperative local banking; d) a bent towards open international markets; e) public financial support along the entire chain of the creation of value; f) a high rate of birth of new firms, often of household size, as a result of social capability and interactive learning; the ability to be district minded, to become a system, and to produce positive externalities."* At the same time, three distinct conditions are defining a creative quarter: specific activities, personalized built form, and cultural meaning (Montgomery apud Wen, 2012, p. 29).

The combination of these aspects contributes to the level of development of such districts as well as to the degree of creativity and innovation they display. The developed and functional creative districts could have a significant impact on urban regeneration, leading also to innovative cities and culture-led development (Pourzakarya and Bahramjerdi, 2019). Nevertheless, culture-led development has also been criticized due to some inequalities it might generate (Pourzakarya and Bahramjerdi, 2019). All these aspects stress the special attention that public administration should place on cultural districts and offer significant points of reference to cautious and strategic planning.

### **3 Public administration and governance for creative neighbourhoods**

Supporting creative neighbourhoods as public and urban innovation develops in a *plural and pluralist state* where multiple inter-dependent actors and

processes contribute to the effectiveness of public services and inform the policy-making system (Osborne, 2006). Within a networked governance, multilevel institutions are involved within civil society (Bevir, 2006), policy-makers are leaders and interpreters, and public managers act as *explorers* in interacting with people as co-producers in the pathway leading to urban value creation and innovation (Hartley, 2005).

Following a 'state-centric' view, neighbourhood governance relies on governments re-connecting with citizens and stakeholders for better decision-making and services delivery, while a 'bottom-up' view is opening to new governance spaces that enable citizens to decide how to contribute to governing according to a community-based decision-making process in a multi-actor and multi-level governance (Lowndes and Sullivan, 2008). Urban spaces enable collaborative and multi-actor involvement as governance innovation, whereas private and public organisations co-initiate the collaboration process and develop collaborative and public innovation (Sørensen and Törfing, 2018; Hartley, Sørensen and Törfing, 2013). Supporting creative neighbourhoods requires to develop urban governance which concerns the cooperation among public and private actors, and civil society (Swyngendouw, 2005), by strengthening collaboration and partnership between public and private actors as drivers of effective managerial capacity (Kort and Klijn, 2011), that contribute to value co-creation at neighbourhood level, promoting collaborative arenas within a community (Törfing, Kristjansen and Sørensen, 2021).

Governments promote long-term collaboration, voluntary participation and active public-private partnerships, strengthening the central role of stakeholders and community-led organizations (Jung, Lee, Yap and Ineson, 2015). Public authorities play a key role in giving creative entrepreneurs a chance to experiment and engage the community in reinventing a future-oriented and sustainable urban future (Della Lucia and Trunfio, 2018), promoting a vision of the neighbourhood as a driver of urban renewal and social change within communities, and identifying new ways of participation to redefine the urban culture-led and renewal processes, enabling public and private actors to shape the neighbourhood as a creative space that supports urban development and fosters a multi-cultural perspective, by involving the local community (Pradel-Miquel, 2017).

Collective actors transform urban spaces as creative places by supporting public debate and strengthening the partnership between public administration

and civil society organizations to reinforce urban and cultural renewal, social cohesion, and community life (García, Eizaguirre, and Pradel, 2015). Public administration can drive 'bottom-linked' social innovation and creative strategy for renewal of neighbourhoods promoting multi-level governance, connecting government and civil society (Pradel-Miquel, García and Eizaguirre, 2013). Culture-driven urban regeneration processes develop through collaborative spaces that foster multi-actor stakeholder collaboration and enhance the quality of life within urban communities (Sørensen and Törfing, 2011), and driving social innovation and governance through collaborative practices between civil society organizations and public actors that develop solutions meeting social needs (Galego, Moulaert, Brans and Santihna, 2021). Urban innovation by collaboration implies that public leaders and managers act as *mediators* who facilitate collaboration between stakeholders. Public sector leaders have to set the agenda, defining policies, and supporting dialogue with a plurality of actors. Public managers act as meta-governors managing collaborative arenas (Hartley, Sørensen, and Törfing, 2013).

## 4 Developing creative neighbourhoods in dynamic cities. Bucharest and Cluj

### 4.1 Methodology

The local authorities' perspective on their involvement with creative districts is investigated through content analysis, of a corpus of official policy documents elaborated by or commissioned by the public administrations in the two cities. Table 3 presents all the documents we identified as such. When this research was conducted, not all of them were publicly available (online) and, therefore, we could not include them all in the analysis.

Table 3. The body of documents regulating city-policies in the sample

Document	Date, info
Strategia de dezvoltare urbană integrată a Municipiului București și a teritoriului său de susținere și influență - Concept strategic București 2035/ Strategy for integrated urban development of the	2012 The document was commissioned by the Municipality of Bucharest and elaborated by a research center within the National University of Architecture (in Bucharest) as the main contributor and two other business partners,

Municipality of Bucharest and its hinterland – Strategic Concept Bucharest 2035	consultancies operating under an LLC regime.
Strategie Integrată de Dezvoltare Urbană (SIDU) 2021-2030 / Integrated strategy of urban development 2021-2030	Currently, the document is in public consultation (throughout 2021). The PR campaign accompanying the project describes it as a project that “takes into consideration citizen needs, to guide the urban development inclusively, strategical, sustainable and on the long term”. No draft versions of the document are available to the public on official sites or Facebook. The project is developed by the Municipality of Bucharest and the World Bank.
Bucharest Cultural Strategy 2016-2026	2016 Commissioned by ARCUB (the Center for Cultural Projects of Bucharest) – a structure within the Municipality of Bucharest; The document is the result of previous analysis implemented by a network of NGOs, as well as consultation with an impressive number of stakeholders. It was coordinated by ARCUB together with an independent team.
Strategia de dezvoltare a Municipiului Cluj-Napoca 2014-2020/ The development strategy of the Cluj-Napoca Municipality 2014-2020	2015 Developed by a larger group comprised of working groups coagulated, in their turn, around a series of problems concerning the community. The working groups were constituted chiefly by university staff, other local experts and ordinary citizens. The resulting document, adopted by the municipality is presented, in a bid to foster unity as a strategy of the entire community, not only as a strategy of the mayor’s office.

#### **4.2 Findings: local authorities on creative industries and creativity**

The Development Strategy for Bucharest 2035 (UAUIM/PMB, 2012), and awarded strategy, visions the city as “an influential and integrated European metropolis through sustainability and character, reinvented intelligently and sensitively, an open and evolved community, a dynamic and creative capital.” Nevertheless, the cultural and creative dimension is considered only through the city’s built heritage. The strategy proposes interventions considering the living conditions, the green areas, and transport. Several poles are proposed, considering competitiveness development, transport, research, and leisure. The

strategy proposed both large-scale and focused urban interventions. Culture and creativity are mentioned together in this strategy, without actually being defined; creative management of cultural landscape and creative management of the built heritage is proposed, but a definition for a “cultural landscape” is not provided, nor it is very clear what exactly “creative management” implies.

The Cultural strategy of Bucharest (2016) proposes five major development axes. In this framework, the city’s neighbourhoods are strategic centres for activating “proximity” culture and increased cohesion. The strategy registers the weak cultural infrastructure in various neighbourhoods and its continuous degradation in the past decades. At the same time, it also registered increased interest in cultural activation and raising the identity profile of various neighbourhoods, as a joint result of public cultural organizations as well as NGOs, either cultural or social. The strategy also registers small “creative quarters” – limited areas where some specialized cultural shops and initiatives tend to gather (ARCUB, 2016, p.21). Overall, the strategy proposes to support the development of local neighbourhood identities, citizen initiatives, and local cultural events, rather than more formalized “creative neighbourhoods”. The strategy pinpoints that “by raising the quality of life, the vision aims for Bucharest to become a city in which I love to live, structured on neighbourhoods of a specific nature, full of vitality and dynamism, which will ensure the inhabitants’ urban comfort, a diversified offer of places to work, public spaces for entertainment and culture” (ARCUB, 2016, p.47). Even if creative quarters are not excluded, they are suggested to be cultural hubs developed organically within larger historical neighbourhoods. Nevertheless, the public administration should provide a balanced distribution of public equipment, infrastructure, and transportation, to ensure the development of neighbourhood centers, aimed to facilitate and stimulate sustainable development (ARCUB, 2016, p.48). It would be cooperation between the central-local administration and district administrations (for details on “Culture in proximity” see ARCUB, 2016, pp.54-56). In parallel, it proposes the development of specialized cultural quarters by public investment, such as Cultural City, City of Music, Radio House, meant to be “strategic development areas” (ARCUB, 2016, p.65). The first one would have a wide area covering the city center, while the other two seem to be small areas developed around major cultural venues (ARCUB, 2016, p.48).

The development strategy of Cluj-Napoca municipality is presented as the result of a “permanent partnership between local government and the

community" and it was documented on a public online platform. Several working groups, which comprised many representatives of the prestigious university in the city, as well as representatives of the non-profit sector, were active in the process of planning of the strategy, some of them being directly connected to cultural and creative fields: People and community; Innovative, creative, competitive city; Culture and local identity (PMCN, 2015). The vision reserves to culture the following status: "Cluj will be a European landmark through its dynamic, vibrant cultural life, which supports experimentation and initiative. Culture will be a cross-cutting factor community organisation, becoming the engine of social transformation and urban regeneration" (PMCN, 2015, p. vi). Stimulating the creative industries is considered a factor of economic development, as well as communities' wellbeing (PMCN, 2015, p. x). Creativity, in general, is a keyword in the strategy, being used more than 300 times. "Creative quarters" appears seven times, being considered as facilitators of the implementation of the development strategy. Creativity is also tightly related to the idea of innovation and competition. The creative industries are part of the intelligent specialization strategy (PMCN, 2015, p. 64).

The strategy defines as an aim "stimulating entrepreneurship in creative industries by creating incubators/clusters/accelerators and by supporting the development and establishment of firms in the field of cultural and creative" (PMCN, 2015, p.71). Considering the overall strategy, which does not specifically elaborate on the development of creative neighbourhoods, the creative clusters proposed in the strategy refer to sectorial and organizational clusters, rather than geographic creative areas. The strategies of the development of creative industries are based on relationship extension and connection (PMCN, 2015, p.275). Cultural megaprojects are also proposed, such as Transylvania Cultural Center, Center for Cultural Industries, etc. These are probably in connection with the identification of the "lack of cultural/community/creative spaces in different areas of the city" (PMCN, 2015, p.552). In spatial terms, the strategy proposed the development and design of various creative spaces (PMCN, 2015, pp.552-553), but no specific area is identified by the strategy. The development of creative neighbourhoods is open, specifying a "Program for activating peripheral spaces for cultural and community activities" (PMCN, 2015, p.557). The settlement of at least one creative quartier was projected for 2020, in the context of preparing the application process of Cluj for 2021 European Cultural Capital. Although the competition was won by Timisoara, all the effort poured into preparing the

documentation was coagulated around Centrul Cultural Clujean (Cluj Culture Center), an NGO for culture and sustainable development, comprising a network of 112 members, cultural organizations and institutions, universities, associations of the business sector and the civil society, and the local and regional administration. Further steps into developing an infrastructure specific to creative districts (co-working spaces, studios, micro-production workshops, etc.) were taken during the competition for the title of the European Capital of Innovation when the city of Cluj made some strategic choices (e.g. Cluj Innovation City).

#### **4.3. Findings: creatives about public institutions and local authorities**

Using thematic analysis to inquire on how creative industries' promoters are seeing the impact of their activities on the city's cultural vitality (mainly in terms of developing creativity and innovation) as well as how they understand their relationship with public institutions and local authorities - has revealed a series of insights related to the ongoing process of constructing cooperation and cohabitation within one given space (e.g. the creative district).

*Building cohesion* and *fostering local creativity* are the most frequent themes developed throughout all the analysed corpus. They are declined either in terms of network, platform, instruments, and community and accompanied by verbs such as: to coagulate, to build, to developing (in Bucharest) or they are constructed around the divide between the individual and the collective (in Cluj).

However, when the relationship with the city itself is implied, a variety of themes emerge as secondary themes. Amongst them: *urban regeneration, empowerment, diversity, quality of life, and sustainability*.

The creative quartier in Bucharest consider its role within the broader life of the city as an opportunity to change the narrative about Bucharest (without mentioning what this narrative is supposed to be), an alternative to the city's "old town" as well as an opportunity to construct a creative city branding. The orientation to Bucharest inner "problems" seem to dominate the creative quartier projections, meanwhile at Cluj culture seems to act like an instrument enabling the city to reach out to its ambitions as local/regional pole of influence, "a leading European city in arts and culture" (CCC, 2020). Surprisingly, *diversity* - is only briefly and marginally considered by the creative quartier in Bucharest (in relation to diverse cultural experiences and to build heritage) and not at all in Cluj - a city that is almost a cliché for diversity in Romanian collective representations. Also,

*the quality of life* is only mentioned in texts related to Bucharest creative quartier, meanwhile in Cluj, although never mentioned as such is declined in terms of "collective well-being, sustainable society, common good".

All in all, the main difference between the promoters of cultural and creative industries as they are discussed by leading initiatives belonging to both cities resides in the way they position themselves in relation to other actors within the same field of interest. The creative quartier in Bucharest gravitates towards being a part of a creative ecosystem, together with other cultural organisations and (public) institutions, meanwhile in Cluj, the main perspective is emphasizing culture as a driving force for innovation and creativity / creative industry amongst others.

## **5 Conclusions**

Several concepts are referring to the area structured within a city that is credited with thriving creative communities and cultural organizations: creative neighbourhoods, creative quarters, creative districts, or even creative clusters. Preferences for various terms are related either with some geographic context or with the desire to stress a specific aspect of that area. Previous studies have highlighted especially aspects related to their social, economic, and urban implications. Inner dynamics, in relation to local administration, are main factors which influence the success of creative neighbourhoods, therefore, they require more focused attention.

The creative neighbourhood is a topic of increased concern in academia, especially due to its continued practical relevance. It is credited with contributing to the sustainable development of cities, even if some studies also pinpoint some debatable aspects. Nevertheless, there are many different stakeholders interested in this space, therefore, one registered a multitude of situations, approaches, and implications.

The rise of creative neighbourhoods as urban and culture-led spaces relies on public administration that supports creative-led and bottom-up citizens' and civil society associations' initiatives, promoting networked public governance through collaborative spaces that involve public and private actors to share ideas and information, to build decision-making processes that make urban governance as a socially innovative space engaging the whole local community.

Considering the city of Bucharest, some creative neighbourhoods have been organically developed, with no public involvement or actual support. The public strategy acknowledges some of these efforts and considers their support, including through cooperation and investments, but no specific actions have been undertaken. The city cultural strategy seems to be independent of the sustainable development strategy of Bucharest, although the one does not necessarily exclude the other. Nevertheless, up to date, there are no clear signs of implementing the strategy related to the cultural development of neighbourhoods. In the case of Cluj, considered by some the "cultural capital" of Romania, the public administration includes in its strategic development plans the concept and creative neighbourhoods and their support. Nevertheless, it seems to be no actual strategic approach in this sense. Cultural and creative initiatives might be supported by the municipality along with other social projects, within larger financing schemes.

On their part, the creative organizations and communities which support the cultural and creative development of the cities, including shaping creative neighbourhoods and clusters do not expect too much support from the part of public administration. They do not include public-private cooperation as a main pillar of their development. Nevertheless, they rely on networking and cooperation with all stakeholders which prove to be open and dynamic. The approach in both investigated cases is bottom-up (even if in Cluj de strategic documents could suggest also some interest in top-down approaches), informal, organically aggregating organizations and individuals, being a combination between "natural born" and enhancement. The public administrations in both cases seem to be optional, a desired stakeholder, but, at least in the present moment, their status floats as discretionary stakeholders.

### Abstract

Information technology is driving public organisations as smart and sustainable working organisations that facilitate processes of public value creation. Technology is opening to public collaborative innovation. As organisations seeking sustainability as a vision for strategy and action, public organisations evolve by developing strategic, managerial and technological sources to enable public value creation within society. Smart working is emerging as a new way to shape the work relationship as both collaborative space and innovation. Public organisations achieve sustainability adopting a service logic view as strategic orientation by developing the potential of information technology in order to drive innovation by building digital, smart, lean and open platforms for value creation, innovation and networking. Smart and sustainable working public organisations contribute to value creation processes and promoting collaborative innovation as a key source of public innovation. They support innovation as enabled by digital platforms, and adopt the smart working as a way to enhance collaborative innovation, enhancing the role of public managers, and strengthening the social and human factor in smart work relationships by developing the potential offered by information technology.

**Keywords** – public organisations, information technology, sustainability, smart working, collaborative innovation.

**Paper type** – Academic Research Paper

## 1 Introduction

Today, the advent of emerging information and communication technology is driving modernisation and innovation in public administration, leading to digital, smart, agile and sustainable government. Following both a service logic view to public value creation (Osborne, 2018) and a public value management view (Stoker, 2006), public organisations are rethinking how to develop a smart view in order to achieve sustainability as a vision for change, driving public decision-making, management and governance (Goodsell, 2006; Fiorino, 2010), promoting cooperation and social exchange with civil society and governance networks within social ecosystems (Dumay, Guthrie and Farneti, 2010), driving innovative collaboration as a key source of public innovation (Törfing, 2019; Törfing, 2016).

Smart and sustainable organisations perform better (Matheson and Matheson, 2001), placing the development of human capital at the heart of their strategic approach (Pfeffer, 1996; Pfeffer, 2010), promoting collaborative relationships and innovation within work environments (Aggerholm, Esmann, Andersen and Thomsen, 2011). Sustainable competitive advantage relies on promoting the role of people within the organisation, working with people, empowering them and enhancing their participation at work (Pfeffer, 1995). Sustainable companies empower the employees and enable the managers to promote collaborative and cooperative spaces within the organisation (Leon, 2013). Sustainable future refers to long term strategic and organisational orientation and requires that «managers need to embrace a process that identifies, prioritizes and processes sustainability issues» (Perrott, 2015, p. 50). Embedding sustainability in the organisation implies to support the continuous learning and organisational capacity in order to develop the orientation to change and the commitment to improvement and innovation (Haugh and Talwar, 2010).

Smartness has become a desirable outcome and key source for sustainability. Innovation is rising at the top of public agenda reform, offering a satisfying solution to emerging problems. Information and communication technology (ICT) is opening up the way to public organisations which are becoming smarter in order to drive sustainable growth and development (Gil-Garcia, Zhang and Puron-Cid, 2016). Public organisations serve the public interest as the result of dialogue with citizens (Denhardt and Denhardt, 2000), promoting public innovation through collaborative processes that involve private and public organisations in order to support value creation (Ansell and Törfing, 2014). The

advent of ICT supports open and public innovation within a networked governance (Hartley, 2005; Mergel, 2018), and helps public organisations to communicate with citizens and enable them as active co-producers of social, democratic and public value (Moore, 1995).

Smart government helps to drive successful modernisation in the public sector, rethinking the way by which government works by digitalising processes (Schendler, Guenduez and Frischknecht, 2019). Technology is opening up to digital and smart public organisations as enablers of social and public value creation. It is time to rethink the role of public organisations as smart and sustainable organisations which contribute to developing continuous innovation, facilitating the processes of public value creation, promoting multilateral and collaborative relationships between public and private actors within society, and driving smart working as a collaborative innovation and space that benefits both wealth and performance of employees within work environments. Advanced smart technology and digitalisation in government is leading public organisations to becoming smart organisations which support innovation as a key dimension that enables smartness in government as a way to continuously work by efficiency and effectiveness, and deliver services and operations (Gil-Garcia, Zhang and Puron-Cid, 2016). Public managers as agents of change should exercise leadership in interacting within organisations and with external stakeholders, acting to realize rights and responsibilities, meeting citizen preferences and interacting with community (Stoker, 2006; O'Flynn, 2007; Moore, 1995).

The advent of pandemic Covid-19, originated by the rise of a new *coronavirus* (Sars-Cov2) as a virus of the species severe acute respiratory syndrome-related coronavirus (SARSr-CoV) which is able to infect also the humans, causing, in particular, many cases of pneumonia, has led to a worldwide health crisis which impacted on the life of people and organisations, leading companies to redesigning the organisational arrangements, accelerating digitalisation, and enabling information technology as a key source for driving and managing changes, a means for driving innovation. The use of information technology at work opens to a space of collaboration by revisiting the work organisation and leading to an increase of remote working, teleworking and online working, supporting smart working practices. During the most acute phase of the emergence from Covid-19, for example, smart working involved the 97% of large companies, the 94% of Italian public administrations and the 58% of Small and Medium Enterprises (SMEs), for a total of 6.58 million agile workers, about one

third of Italian employees, more than ten times more than the 570 thousand surveyed in 2019 (Politecnico di Milano, 2021).

Employees in private, small, medium and large companies and public employees have therefore experienced a different way of working as enabled by ICT in transition from telework and remote working to smart working coherently with an organisational view to rethinking both work organisation and the role of organisation becoming smart developing the potential of ICT (Viceconte, 2020). During pandemic Covid-19 health crisis, the information technology has increasingly impacted on life of people and organisations leading to considering the smart working as an emerging and innovative phenomenon and work design experiment, becoming part of a process of profound cultural and organisational changes (Torre and Sarti, 2018), empowering managers and followers in improving the ICT-enabled work relationships (Harris, 2003). While teleworking refers to a work organisation that involves working at a distance from the company's main office and the use of information technology (Dambrin, 2004) in response to energy crisis in the early '70s (Munir *et al.*, 2018), in virtue of the acceleration provided by pandemic crisis, the developments of technology and digitalisation are leading to promoting smartness at work and within organisations are opening to smart working and driving a new way for work organisation, leading to innovation in work processes, environments and behaviours of people at work that concern and involve the relationships between employees and managers. Smart working requires that managers have to assume new behaviours in order to make more collaborative and productive the work relationships, improving cooperation with employees. While managers utilise and control human resources, leaders should motivate people, inspire, develop and innovate (Bennis, 1989). Public managers play a key role in driving the organisation to achieve the desired objectives (Van Wart, 2013), promoting collaborative practices, behaviours and management styles across governmental boundaries (McGuire, 2006), supporting public service motivation of employees to public service value, enhancing the commitments to public mission, fostering job satisfaction, work performance and quality (Van der Voet, 2014; Moynihan, Pandey and Wright, 2009; Park and Rainey, 2008).

The aim of this study is to elucidate how public organisations are becoming smart and sustainable working organisations, strengthening managerial and technological capabilities. As sustainability-oriented and value-oriented organisations, public organisations adopt a service logic view enabling the service

users to actively contribute to value creation (Osborne, 2018), driving the service co-production within communities as a means to support innovation (Osborne, 2010, Hartley, 2005; Granier and Kudo, 2016). Technology helps public organisations to develop open innovation that enables better processes and performance. ICT helps public organisations to work through networks that involve private and public actors, developing knowledge and capabilities in the pursuit of public goals (Janowski, Pardo and Davies, 2012), strengthening collaboration for service innovation (Lips, 2012). ICT is driving public organisations to become digital and smart institutions that support public value creation processes within communities and open ecosystems (Larrson and Grönlund, 2014). Public managers should construct community shared values, interacting with citizens, enhancing effectiveness and accountability within society (Bryson, Crosby and Bloomberg, 2014).

The paper is structured in sixth sections. Following the introduction and methodological section, in the third paragraph, the debate on public innovation is conducted through the lens of collaborative innovation as theoretical background. In the fourth paragraph, the role of information technology leading to smart and sustainable public organisations is elucidated. In the fifth paragraph, the smart working is conceived as collaborative innovation enabling collaborative spaces and enhancing the employee-manager relationships, following a social, interactive and relational dimension. Finally, discussion and conclusions are outlined.

## **2 Methodological section**

The study is theoretical and relies on a literature review and analysis relating to public organisations that aim to drive innovation by embracing information technology in order to develop smartness and sustainability, by opening to smart working as collaborative innovation and strengthening digital and smart platforms to contribute to value creation for public wealth. The selected contributions are drawn by literature related to smart and sustainable public organisations in relationship with the use of ICT that enables both smart working practices as innovative and collaborative approach to work organisation and digital and smart platforms as evolution of advanced information technology in government. The selected contributions are interpreted in a narrative synthesis in order to elucidate new perspectives and advance theoretical frameworks on

emerging issues (Denyer and Tranfield, 2006; Dixon-Woods, Agarwall, Young, Jones and Sutton, 2004).

### **3 Driving public and collaborative innovation**

Innovation refers to the introduction of new elements into a public service to be considered as discontinuity with the past (Osborne and Brown 2005). Public innovation is viewed as a continuous improvement. Innovation refers to development and implementation of new ideas that disrupt the common wisdom (Osborne and Brown, 2011). Innovation refers to a new practice to ensure continuous improvement of existing practice (Hartley, 2005) but also «involves a step change that problematizes and transforms the way that things are usually imagined and done» (Törting, 2019, p. 1). It is about «embracing new ways of thinking about problems and solutions and doing new thing in new ways» (Crosby, t Hart and Törting, 2017, pp. 656-657). Innovation refers to an «intentional and proactive process that involves the generation and practical adoption and spread of new and creative ideas, which aim to produce a qualitative change in a specific context» (Sørensen and Törting, 2011, p. 849). In public sector innovation develops through collaborative processes that involve public and private organisations, and facilitate value co-creation processes (Ansell and Törting, 2014), coherently with a service logic view (Osborne, 2018). Collaborative interaction becomes a source of public innovation (Törting, 2016) and value creation (Osborne, 210). Collaborative innovation helps to transform government in a significant way (Nambisan, 2008) and to bring together two opposite concepts: collaboration implies a similarity of education and values among the actors; instead, innovation relies on diversity of views and ideas as necessary sources to stimulate creative problem solving (Törting, 2019). Ensuring trust and legitimacy of government is an important driver for public sector innovation (De Vries, Bekkers and Tummers, 2016). Collaborative innovation implies that the innovation process is opened up to actors from within the organisation, other organisations, the private and third sector and citizens that are integrated in the innovation cycle (Bommert, 2010).

Collaborative innovation is enabled by the «willingness and capacity of a diverse group of actors to engage in a trust-based dialogue through which they can construct a common ground for exploiting their differences in order to produce innovative solutions» (Törting, 2019, p. 5). Multi-actor collaboration is a

key driver of public innovation and helps to develop and implement innovative solutions (Törfig, 2019). Innovation is a not linear and iterative process. The role of public managers is to enable open and flexible spaces for collaborative interaction with relevant actors. Collaborative innovation for public value creation requires that «managers should develop a pragmatic understanding of when and how different government and nongovernment actors should be a part of the collaborative endeavour» (Crosby, t Hart and Törfig, 2017, p. 663). In particular, the leadership role enables innovation and value creation. «People in leadership roles have a special responsibility and opportunity to frame and reframe public problems in ways that foster innovation and create public value» (Crosby, t Hart and Törfig, 2017, p. 663).

Public sector innovation relates to collaborative interaction among public and private actors such as politicians, civil servants, private firms and community-based association (Sørensen and Törfig, 2011). Digital public service innovation as a collaborative process helps to drive co-creation and support the development of public-private partnerships (Bertot, Estevez and Janowski, 2018). The advent of digital and interactive information technology helps to strengthen collaborative public co-production and co-creation, leading to open public innovation (Criado *et al.*, 2021).

As Scupola and Zanferi (2016) have stated, the potential offered by information technology is opening to unexpected and favourable organisational and behavioural issues. Digital government systems are driving collaborative processes (Dawes and Pardo, ). Digital public innovation and digitalisation processes develop in a collaborative way, and enable more actors who are proactively involved in collaboration, and rely on employees as explorers of new innovation opportunities, meeting the users able to play an active role in the innovation process. Technology helps public organisations to develop open innovation by including external knowledge in decision-making processes (Mergel, 2018). Digital public service innovation helps the development of public-private partnerships by engaging the citizens and the community (Bertot, Estevez and Janowski, 2018).

#### **4 Information technology is driving sustainable and smart public organisations**

Public organisations achieve sustainability as a source for strategy, action and change, as a new way to improve the internal functioning and workings, as a vision for interpreting public values and managing *res publica*, using the potential of information technology within communities and facilitating the value creation within social and economic ecosystems (Fiorino, 2010; Goodsell, 2006; Larsson and Grönlund, 2014; Larsson and Grönlund, 2016; Dumay, Guthrie and Farneti, 2010). Sustainable public organisations use digital technology in order to transform the relationship with public service users, enhancing the co-production within the service delivery system as a relational process (Osborne, Radnor, Vidal and Kinder, 2014).

Digitalisation is leading to building smart organisations able to manage complexity by using simplicity, intelligence and collaboration (Viceconte, 2020). Public organisations are using the potential of information technology to drive public organisations as digital and smart platforms and collaborative spaces in order to enable value creation processes within social ecosystems (Osborne, 2018; Bryson, Crosby and Bloomberg, 2014; Harrison, Pardo and Cook, 2012). Digital transformation in public sector organisations implies to use technology for driving change and innovation in organisational design, work processes, cultural orientation to results and customer satisfaction, relying on skills and competences of employees and managers (Buonocore, 2020). Technology helps public organisations to become more agile, flexible and adaptive organisations (Mergel, Gong and Bertot, 2018). The advent of digitalisation processes in government helps to strengthen cooperation, engagement and participation in policy-making and services design (OECD, 2014). Technology helps to drive a community/citizen centred approach to public services design (Dunleavy, Margetts, Bastow and Tinkler, 2005), empowering the citizen as a responsible partner in co-production of public services (Linders, 2012), developing digital platforms and spaces, and virtual communities that contribute to networked co-production and value co-creation (Fishenden and Thompson, 2013).

As using information technology, public organisations are becoming smart and innovative in creating new services to their citizens in order to improve their quality of life, interacting with citizens and engaging them to participate (Mellouli, Luna-Reyes and Zhang, 2014). Smart government means rethinking the way

governments works by digitalising processes through the use of emerging technology and relying also on perceptions and expectation of public managers for success or failure. Smart government initiatives require both innovativeness and collaboration (Schendler, Guenduez and Frischknecht, 2019). Information technology catalyses innovations in government, leading to public administration as a smart organisation able to achieve agile and resilient government and governance infrastructure (Gil Garcia, Helbig and Ojo, 2014). «Smart is not an end state, but can be an enabling condition that may or may not lead to other desirable outcomes» (Gil-Garcia, Helbig and Ojo, 2014, p. 12). Sustainability is a key dimension characterizing smartness in government (Gil-Garcia, Zhang and Puron-Cid, 2016). «Innovation is a key dimension characterizing smartness in government. Innovation enables a government to become smarter by continuously incorporating new and improved ways to deliver services and conduct government operations» (Gil-Garcia, Zhang and Puron-Cid, 2016, p. 526). As key components of government administrative reform, information technologies are leading to a smart State, by strengthening inter-organisational collaboration, information sharing and integration (Gil-Garcia, 2012). The advent of information, interactive and digital technology helps public organisations to become sustainable organisations which are encouraging private-public collaborations and partnerships, strengthening a community/citizen and smart approach, by involving citizens in policy-making for sustaining public values, equity and development (Larsson and Grönlund, 2014; Dunleavy, Margetts, Bastow and Tinkler, 2005).

The use of information technology in government is leading to sustainable, digital and smart public organisations (Larsson and Grönlund, 2014; Granier and Kudo, 2016; Janowski, 2015). Public organisations support public value creation, promoting driven e-governance platforms, multiple relationships with interdependent actors and co-construction and co-innovation where the locus of co-production is the service system (Osborne, 2006; Osborne, Radnor and Strokosch, 2016). Digital technology is driving the transformation of the relationships between sustainability-oriented public organisations and public services users (Osborne, Radnor and Strokosch, 2016).

Technology opens up to digital and smart public organisations as enablers of social and public value creation by involving civil society, following a service logic and public value view, promoting interaction and citizen-centred services effectiveness (Osborne, 2018; Dumay, Guthrie and Farneti, 2010; Stoker, 2006;

O'Flynn, 2007; Moore, 1995). ICT helps public organisations to drive networks that involve private and public actors, developing knowledge and capabilities in the pursuit of public goals (Janowski, Pardo and Davies, 2012). Smart government initiatives involve government and non-government actors to improve quality of life for people and communities (Gil-Garcia, Zhang, Puron-Cid, 2016).

## **5 Smart working as form of collaborative innovation between employees and managers**

Today, working by developing the potential offered by information technology refers to smart working or agile working. The work as enabled by technology should be always smart. Smart working is emerging as an innovative approach to work organisation and human resource management (Decastri, Galiarducci, Previtali and Scarozza, 2020). Public organisations are experimenting the widespread usage of technological advancements in order to offer their employees new ways of working, overcoming physical and time barriers, designing work organisation modes based on telework, home-based telework, mobile work (Reina and Scarozza, 2020), and embracing a smart working approach in redefining the work organisation in order to ensure efficiency, effectiveness, and to enhance flexibility and autonomy, promoting collaboration (Ravarini, Cuel and Varriale, 2020). Public organisations are driving smart working practices, by embracing the potential of information technology, giving value to the relationship between the administration and the employees (Reina and Scarozza, 2020; Ravarini, Cuel and Varriale, 2020). Driving smart working helps to promote a results-driven and collaboration-oriented organisation, strengthening the role of managers in empowering the employees at work and sharing with them the organisational goals by following a collaborative approach (Politecnico di Milano, 2018).

As Harris has stated (2003) «taking work into home environment challenges and changes the responsibilities of employers accustomed to a traditional employment relationship» (p. 435). Butera (2020) has defined the smart and agile work or *ubiquitous working* as a way that enables a new view to work organisation which may benefit both the employee, ensuring a smart work-life balance, and the organisation, improving costs reduction and driving productivity improvement. Smart work is results-oriented, social and collaborative, and refers to a networked way of operating. Smart working refers to an organisational

model that shapes the relationship between the individual and the organisation, which proposes autonomy in working methods in exchange for the achievement of results. It relies on an intelligent rethinking of the way by which work activities are carried out, even within company spaces, removing constraints and inadequate models linked to the concepts of fixed workstations, open spaces and single offices that are ill-suited to the principles of personalisation, flexibility and virtuality (Gastaldi, Corso, Raguseo, Neirotti, Paolucci and Martini, 2014).

Digitalisation is leading to enhancing collaborative spaces at work, promoting blended forms of work between physical, digital and relational side (Montanari, 2020). Smart working helps to support cultural change and requires organisational innovation for which a detailed roadmap must be provided (Torre and Sarti, 2018). Smart working is defined as a new management philosophy based on providing employees with freedom and flexibility in choosing the place, time and tools used in their work, in conditions of greater responsibility and accountability for results. Smart working requires social collaboration and managers who are able to promote sense of community, empowerment, flexibility and virtuality. Organisational policies, technology, physical layout and leadership behaviour and styles exert influence on the success of smart working practices and approaches (Crespi, 2016). Adopting smart working practices helps to support larger autonomy and foster confidence and propensity towards innovation (Langé and Gastaldi, 2020). Smart working practices are agile, dynamic and emergent, as the outcomes of designed organisational systems that facilitate customer-focused, value creating relationships that benefit the organisation and people (McEwan, 2016).

The rise and widespread diffusion of smart working-oriented practices opens up to a new smart workplace as a collaborative space which is driving employees to look at technology as a mean for strengthening interaction and collaboration, reinforcing shared norms, goals and identification. Smart working helps to foster an openness-driven and knowledge-exchange-oriented smart organisational culture in work environment. Promoting smart working practices helps to rethink a new workplace which is deliberately designed to produce changing attitudes and behaviours of both employees and their managers, by overcoming obstacles that refer to employees' social isolation and managers' resistance toward remote working (Errichiello and Pianese, 2019). Smart working is emerging as a collaborative space for flexible work: «the adoption of smart working implies that employees can choose when and where to work and select among various

workspaces both outside (e.g. home and coffee shop) and inside (e.g. open spaces and concentration areas) the organizations» (Errichiello and Pianese, 2019, p. 299). Smart working helps to drive organisational innovation as a means to support cultural change (Torre and Sarti, 2018). As a new way of interpreting the work, the smart working allows a better balance between quality of life and individual productivity and focuses on integration and collaboration between people, in particular, and between organisations, in general. It is an intrinsically multidisciplinary revolution, which requires integrated governance among the players involved (Hur, Cho, Lee, and Bickerton, 2019).

The role of management is central to driving high performance and satisfaction of employees working, dealing with technology between home and office. In particular, managers have a delicate task in recalibrating perceptions of the boundaries between home and work to develop positive employee relationships (Harris, 2003). Working by technology enhances the role of middle managers: «telework contributes to develop the manager's coaching role and leads to shift middle managers' role towards more monitoring and less close supervision» (Dambrin, 2004, p. 364). Telework helps to foster autonomy, leading to self-management of employees and driving managers to redefine their role in terms of coaching than control. Promoting leadership for smart working helps to ensure flexibility, coherence and integration (Iannotta and Meret, 2020).

## **6 Discussion and conclusions**

Technological advancements and developments are driving innovation in public organisations and changing the way employees and organisations relate to workplace management. Digital transformation in public sector implies to drive processes that concern work organisation and the relationship between employees and managers as enabled by the potential of technology that fosters collaboration, smartness and empowerment at work. As sustainability-oriented and smart-driven organisations, public organisations develop and integrate strategic, managerial and technological capabilities in order to gain the benefits of technological innovation as a source that enable organisations and employees to contribute to value creation processes.

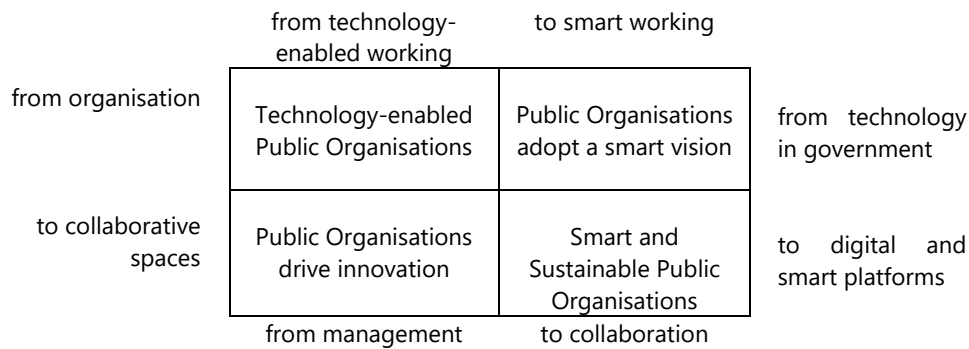

Public organisations should strengthen the potential of digital and smart government and platforms in order to involve civil society within networked governance where public managers attend to value community, interacting with

citizens to build shared partnerships. Innovation always concern the life and development of sustainability-oriented public organisations. The advent of information and digital technology offers public organisations the chance to embrace smartness as a way to redesign work organisation and develop the human capital and resources as drivers for sustainability. Public organisations consider the sustainability as a source that helps value creation processes and enables the wealth of people and business by ensuring social, financial, economic and democratic performances.

Smart and sustainable public organisations to contribute to value creation processes developing both the potential of information technology and empowering people, by managing human resources and rediscovering the leadership role of public managers in managing the relationship with employees. Smart working is becoming a new collaborative arena and space that enable innovation in work processes, behaviours and attitudes of employees, managers, citizens and other stakeholders involved in the collaborative processes.

Public organisations evolve as smart and sustainable organisation investing in human, behavioural and technological sources in order to develop capabilities for promoting healthy and wealthy work environments and relationships which involve, in particular, the cooperation among employees and managers. The pathway leading to smart and sustainable organisation requires to use information technology as a key source that drives smart working, collaboration and digital platforms. Smart and sustainable working public organisations support innovation and drive digital platforms, adopt the smart working as a way to enhance collaborative innovation and processes, and enable public managers as leaders who strengthen the potential of the social and human relationship as sustained by the potential offered by information technology.

As shown in Figure 1, the main contribution of this study is to identify some pathways that enable public organisations to use the potential of information technology in order to become a smart and sustainable organisation which is able to contribute to public value creation and support the development of communities in long-term horizon, promoting the transition from technology-enabled working to smart working, implementing the digitalisation processes, and identifying an innovation orientation to processes and services in order to promote a sustainable organisational and cultural change in long-terms.

*Figure 1 – Towards smart and sustainable public organisations*

Public organisations have to rethink a smart and sustainable vision to work processes and services delivery and production, following a service logic view to public services delivery and design within communities, strengthening the role of public managers as effective and ethical leaders able to promote collaborative processes within and between organisation and society, by developing smart and lean platforms and communities within ecosystems. Technology helps to drive collaborative innovation, enhancing organisational and human factor, enabling managers and employees to develop collaboration, knowledge sharing and empowerment. Thereby, public managers play a key role in driving cultural change in supporting behaviours and driving innovation process in order to feel themselves more identified within organisational goals, being motivated to lead employees in their work and commitment.

In this study, there are some limitations. This study identifies only a theoretical framework of analysis in order to identify the pathway leading to smart and sustainable public organisations promoting innovation by using the potential of information technology in order to both strengthen digital platform that enhance and support cooperative and collaborative processes and promote public-private partnerships, and drive smart working as a change vision to work processes and work innovation that enhances collaborative aspects of the employee-managers relationships. Thereby, any empirical research and case studies are provided in the analysis because public organisations are still in infancy in rethinking and reshaping a smart mind set and planning about how to dealing with smartness and sustainability as key drivers and sources for organisational and work change

and innovation. Further research perspectives and investigations will consider how the hypothesized propositions can be applied within local autonomies and be translated in managerial and leadership training programs, human resources policies and practices, technological advancements and digital platforms that contribute to enhancing the community and collaborative spaces development within public organisations which more and more interact with civil society in order to develop knowledge sources, organisational frameworks, strategies, value-oriented processes, and shared culture within social and economic ecosystems.

### **Abstract**

Times of emergency and confusion may pose a need to introduce and implement information systems in organizations, or to greatly hasten an ongoing implementation project. The purpose of this article is to recommend effective methods and practices that will improve implementation in times of emergency. In this article, we will discuss how organizations can deal with the challenges of implementing technological solutions for knowledge management and collaboration during crises, addressing issues such as technology selection, user capacity building, organizational trends that encourage or hinder technology adoption and organizational policies that can facilitate these solutions. The article discusses a case study of a national defence organization introducing the 'Microsoft 365' cloud-based suite, and particularly the 'Teams' service, to improve work performance during the Covid-19 crisis, while adhering to social distancing guidelines. This article will discuss the need that was generated, and the approach chosen, as well as the theoretical foundation for assimilation, focusing on motivational problems, change agents, and assimilation models. The method of gathering information and analyzing the data is then explained in depth, including surveys, participant evaluation in work teams, and data on system use. Finally, after reviewing the data and drawing various direct conclusions from it, ensuring that the final criteria ('bottom lines') are met in response to the need for functional consistency, commander preferences, and user satisfaction. In the discussion section we build on the observations made in the above case and examine the implications and perspectives of assimilation in a crisis and uncertain situation. A successful implementation of an information system can be boosted by

following three main components, particularly in times of crisis: 1. Characteristics of the technology: effective, integrated, user-friendly, scalable, and generalizable. 2. The technical efficacy of users and management 3. Using a methodical framework for implementation as a flexible contingency plan.

**Keywords** – Knowledge management, Collaboration workspace, Technology adoption, Technology implementation, MIDI model

**Paper type** – Academic Research Paper

## 1 Introduction

### ***1.1 The situation and character of the case - The COVID-19 period and the need for continuity of the military organization***

Adapting to the Corona pandemic (Covid-19) and the social confinements devised to prevent its spread has forced organizations and armies to find new ways to operate and achieve their missions. Social distancing, required to deal with the Corona pandemic, made it difficult to maintain organizational routines. It was therefore imperative to develop an effective solution to overcome these limitations.

During the Corona period (in this article, it is the first two outbreaks of widespread transmission and illness in Israel, from March 2020 to August 2020), it was necessary to allow operational continuity, but maintain an accessible environment wherever people could work from. The goal was to reduce physical presence and interaction between people in office workplaces while still allowing people in mandatory preventative isolation to continue working without risking themselves or others.

Worldwide, various organizations have focused on how to bridge the gaps that have resulted. Different technologies have been found to allow for organizational collaboration and functional continuity while maintaining social distancing (Gardner & Matviak, 2020; Shen, 2020). The sudden appearance of the pandemic, along with its specific need for social distance as well as the patterns of action that emerged from it, forced humanity to change and adapt rapidly, which is a great case study for investigating how an organization can adapt to new realities? How can we accelerate this process of adaptation? Learning from this unique

situation, however, comes with limitations that we will address at the end of this article.

## **1.2 Organizational characteristics**

Military and security organizations have unique characteristics. The IDF is the largest organization in Israel, consisting more than 100,000 personnel (formal numbers are classified). It is unlike other armies and other organizations in Israel and around the world, due to the following differences: The volume and types of combat activities; its workforce (most of them in mandatory service); as the largest employer in the Israeli economy and the related effect on the labor market (Ben Ari, 2018).

The Israeli Air Force (IAF) operates as the aerial warfare branch of the Israel Defense Forces, and its members are almost a third of the entire IDF corps.

Information security is a major and still growing concern for many organizations. There are significant limitations to the IAF's information security capabilities, since their operating characteristics demand strict conduct while separating networks and types of information passing through them. However, a technology is likely to be developed that will meet some of these requirements in the long run, as others have done. When embarking on a Microsoft Teams Web Implementation Project, an organizational policy regarding information security needed to be formalized.

IDF maintains a dialogue with various technologies and is at the forefront of some of them, while others are probably lagging behind the civilian world. It uses collaborative technologies, but sometimes adopts them in a way that does not allow them to realize the inherent potential in them.

Almost ten years prior to creating the Teams environment, there was an earlier digital work environment, accessed via a "civilian" internet network called "People Portal". The People Portal was used to store files and inform members in various groups about previous and forthcoming organizational activities. At the end of its life, the People Portal system became obsolete - it was unsuitable for browsing on mobile devices and limited end users to only textual correspondence. As far as connectivity and knowledge management is concerned, it has become a barrier to the flow of information.

In addition, IDF's motives for adopting technology differ from those of other organizations. A study by Gartner that assessed the motives for implementing MS

Teams on organizations uncovered that the five most common reasons are: 1. Innovative methods of accomplishing tasks; 2. Moving workloads to the cloud from internal networks; 3. Reducing Microsoft licensing costs; 4. Connect to the Microsoft Roadmap; 5. A better customer experience with Microsoft (Cannell, 2019). With regard to the factors we outlined above, except for factor # 1 - new ways of working - the other motives are not related to the IDF, which develops the service in parallel with its existing networks.

The IDF chose to use cloud-based technologies to maintain continuity of operations under the guidelines of social distancing, but those still were not particularly developed or took into account the demands of the Corona period, for example, widespread use of "Zoom" in favor of fast and reliable video conferencing.

### ***1.3 Teams as a collaborative working environment***

Different technological solutions are not simply different formats through which remote discussions and work are conducted, but a broader environment (ecosystem) of different services and work environments that enable new work processes and make knowledge workers more productive. In these work environments, there are many more options to improve the discussion culture and bridge the time/space divide in online work: discussion forums, discussion groups, whiteboards, recording discussions for those who cannot participate, assigning tasks to perform and managing them, and more (Cannell, 2019). Another recent Gartner study found that most organizations implement Office 365 (Microsoft has rebranded Office365 for Microsoft365) environments because of the collaborative capabilities they enable and the integration capabilities (a.k.a "integration"). Office 365's collaborative workspace lets users connect multiple applications through a dedicated multi-modal interface. The use of this interface can allow access to a very wide range of services and there are even some who claim it is the key to success (Tarzey, 2017). The degree of integration is determined by the licensing model (number of applications included) and the organization's policy for enabling connectivity to third-party applications.

#### **1.4 Theoretical lenses**

The ability of organizations to select, develop, and adopt new technologies in a way that substantially impacts the organization is limited. The reasons are numerous, chiefly a gap in organizational attention and management's commitment to incorporating technology and leading the change process. Afterwards, there is a gap in employees' ability to handle new technologies and other reasons that we will discuss later in this article (Roupas, 2008). Based on these gaps, only 16% of organizations report successful adoption of technology (e Hortense de la Boutetière et al. 2018). As a result of the significant organizational effort and large resources invested in technology, many studies have been conducted to identify the key factors that influence the successful absorption of technology, allowing an organization to become more effective and efficient at completing its various tasks. In these studies, a number of influential factors are identified, including attitudes and characteristics of managers in the organization (Pabst von Ohain, 2019); leadership and ability to lead change (Bughin et al., 2019); Sociocultural factors (Rogers, 1983); structural-environmental relationships (Christensen & Overdorf, 2000). We have selected just a few of these factors as they will provide us with a better illustration of our findings.

##### *1.4.1 Motivation to adopt technology*

In the field of technology adoption, motivation plays a significant role (Hortense de la Boutetière et al., 2018; Roberts & Flin, 2020; D. L. Rogers, 2016; Roupas, 2008; Stahlbrost & Kareborn, 2011). The IAF prides itself on being a task-oriented organization, one that sanctifies the execution of the task using the available tools. To meet the guidelines of social distancing, it was essential to find new ways to accomplish existing tasks during the Corona period, which was a key reason for change.

##### *1.4.2 The role of change leaders*

It has been well documented in literature and professional articles how technology leaders in the organization ('product champions'), contribute to change by fostering a positive environment and contributing social norms that shift the workforce to adopt new technology. Technological leaders are characterized by high technological proficiency, entrepreneurial awareness, a desire to learn from different experiences, and the desire to share their findings

with their organizations (Rogers, 1983). The presence of these leaders does not eliminate the need for an orderly organizational response but represents a temporary local response until the organization's policy is determined and implemented. Furthermore, their presence makes it possible to use the organizational response more effectively when it is implemented in the field and to promote it more rapidly. Despite familiarity with the literature in the field, it is surprising to see how the presence of personally driven leaders contributes to the degree of development and technological progress of the units.

### ***1.5 The MIDI (Model for Implementing Digital Information Systems)***

The IAF's Digital System Adoption Model, 'MIDI', aims to help implementers efficiently and effectively manage the implementation process. The framework includes a highly organized management job aid, that details roles and tasks required during the implementation process, along with a supplementary methodological document that elaborates on the given roles and helps the implementer decide the manner and importance of their execution. The framework allows the implementation leader to analyze the tasks he has to perform in accordance with the project timeline, such as: writing usage theory and instructions, user training, organizational change management, and support (Spiegler & Vardi, 2019).

While the military develops and purchases dozens of applications, software and information systems a year and puts them to use, sometimes the act of connecting users to technology comes too late ("the system is here already. We need an implementation plan") or without the necessary resources ("A few PowerPoint presentations for the users is enough, it's an intuitive system). The Framework was developed to assist implementation leaders, many of whom held middle-level operational and professional positions but did not have previous experience implementing information systems. Role holders who understand the system, usually professionally, should bridge the gap between the technological factors (the developer or implementer) and the users, as part of a standard project for a domain and data resource schedule. During the Corona period, the model completed its "baptism by fire" when used semi-structured because of an accelerated integration during a crisis. At the same time, along with adhering to the principles of the model, it was an opportunity to examine its components and see which part contributed to the adaption process.

## 2 Methodology

The **usage data** was collected using the built-in admin panel within the Teams environment, over two dates. During the first, in August 2020, a review of the system implementation was undertaken. The second was held in November 2020 in order to determine trends in usage, following the "second wave" of the Corona in Israel, as part of evaluations for further assimilation of the environment. Based on the usage data, we were able to determine whether or not the implementation and adoption of the product was successful.

The IDF Survey Center at the Applied Research Institute for Behavioral Sciences in the IDF conducted regular online surveys during the Corona period. Surveys were conducted to explore various aspects of how the IDF was addressing the corona epidemic. Among these were remote work, digital needs of servants, ways of communicating and learning, and more. In total, there were 14 surveys with over 15,000 respondents (Bar-Gil, 2020; Nadam & Hamenachem, 2020).

A major source of information used to prepare this article is the collaboration among the authors of the article in working groups relevant to the topic: discussion summaries, meetings, and personal records were used. These summaries will not be explicitly cited as is customary in organizational research through participatory observation (Clegg, 2010).

By analyzing these surveys and our participatory observations, we were able to identify places and uses where the work environment was successful and beneficial for users. And identify the factors that contributed to the good or bad performance of the implementation

## 3 The key findings

### 3.1 *the bottom line*

During the Corona period, the use of the Teams collaborative workspace enabled and streamlined work, and employees expressed great hope that their use would increase, and their long-term benefits would be realized. The surveys conducted in the Corona era stated: "I wish we understood that fewer people are needed in meetings and time management will be as efficient as it is now, and the crisis will bring less bureaucracy" (Tiargan-Orr et al. 2020). This statement

implies that the technology itself is already here and enables the change and that the servicemen expect the organization to make progress in that direction.

There has been a dramatic increase in the number of unique users accessing the Teams work environment services during the first wave of the Corona: from 4,000 users to almost 17,000 users. However, it is important to qualify and note that the experience of many unique users, was superficial and consisted only of initial identification and receiving a single verification email from the system. The use of the various accompanying applications was extremely low, especially for the flagship service, "Channels", which saw only 3,400 users. Using usage data, it can be seen that after a short period of enthusiasm, the trend soon waned and returned to the level of activity that existed prior to the first wave. According to the second wave of activity, the usage threshold for continued activity is very low.

Analyzing this data, it is concluded that the Teams environment was adopted, but not assimilated into the use routines and work processes. Despite the formal availability of the system, most users do not use it frequently as a primary means of performing tasks.

### **3.2 Users satisfaction**

As measured by adoption rate and penetration, there is considerable growth, but in terms of user satisfaction, the results are mixed. On the one hand, the abandonment of the system upon returning to non-Corona work schedules and practices, proves that assimilation was not rooted in routine and did not alter the working habits of the majority of the Corona period "adapters". Even at the height of the increase in the Teams use, only a few "formal" requests for support were made (less than 100 requests). Additionally, the support teams reported that help requests in so-called informal channels were of negligible volume, so it is reasonable to conclude that user satisfaction wasn't a major problem. Issues that were nonetheless opened reveal that users enjoyed the system's accessibility to new and unfamiliar digital spaces, but encountered difficulty editing files, especially in Hebrew, by combining separate sources, and failed to see Teams as a practical alternative to Learning Management System (LMS). Further, advanced services, premium applications, and their work environment integrations, such as PowerBI, were not widely used. The conclusion can be reached that despite scarcely major issues raised to support staff and despite seemingly appearing to

be satisfactory, the way the technology was used did not meet the needs and expectations of users.

### ***3.3 Resolving the needs of IAF operational continuity***

The expectations for functional continuity, by using the new platform were met. A senior General proclaimed the product adoption as a success, identifying great potential within a short period of time. Another significant response was the move of training processes online, allowing for a continuity of work process in this sector as well, in a very significant way.

### ***3.4 Where did there seem to be greater success?***

Following other researchers, we believe that implementing a system, especially a collaborative work environment, does not amount to a binary assessment - successful or unsuccessful (Levy, 2013). The purpose of this study was to examine the differences between the places where we identified success in implementing the system, by examining system use data and examining user satisfaction.

Some of the more frequent uses of places are to provide training and to support users. There is a common denominator in our view with processes that are highly standardized and repetitive, or that are characterized by Self Service / Self Assist on the part of users. Military trainers took advantage of the collaborative training environment in an innovative way. In addition to providing comprehensive training, the IAFs' computing unit offered a number of courses. Another interesting use was in an operational Group, where professional development and personal growth courses were delivered to dozens of permanent personnel.

The implementation of the environment allowed for the creation of an internal support application using **Flow** and **PowerAutomate** features. It took two days to set up a beta version and a week later, it was already available as a full version. When a user requested support, they entered their data in a form that provided information to the app and from there a process of support began with continuous control via a dashboard. Standard methods of knowledge gathering, and accessibility have also been implemented, especially in sites that have evolved into collaborative work, and the process has been found to be effective and efficient for responding to users.

### ***3.5 What can we learn from successful places?***

Upon examining the places where higher success can be seen in the assimilation of the environment, the main variable we identify is the effect of use on the effectiveness of the task, or in other words - how significant the "need" and organizational motivation for the unit was. Inability to execute military missions in a traditional manner, which relies on physical convergence in a military unit, has led commanders and users to try the new environment without giving up. We believe that the best implementation plan, even if it comes with other powerful parameters (shown below), will not succeed without significant value to users and the organization as a whole.

The second significant variable is technological capability. efficacy is the collection of skills that must be specified and their application, just as technological self-generating reflects the users' belief in their competence with the technology that they are provided (Pan, 2020). Capability and efficacy are separate because in most cases, the environment does not need high-level programming or operation. For some, it is a new system with unfamiliar nuances - so it presents a barrier. There were leaders in units where the technology was widely used, and they presented an expectation of success and a sense that 'it is not a problem to use the system', and even provided important support to colleagues if needed - thus strengthening both the efficacy and technological capabilities.

We can sum up both of these variables in a simple way: "whoever wants and can succeeds". Nevertheless, we find the "want and can" test in the context of a military organization, which does not necessarily hire its people according to their technological capability - to be interesting and important, so we will continue the discussion in the discussion section.

The following are other factors we identified that may impact implementation:

1. **Support from management** is important for two reasons. The first is formal resource allocation and paying attention to those users who have taken the lead. The second reason is the opening of bureaucratic bottlenecks, for example, information security, which poses a practical but also perceptual (and might as well be imaginary) barrier to the IDF's use of information systems.
2. In units with a good first connection between knowledge management department it's agents in the field, implementation has been successful. Through this connection, communication channels have opened up for personal consultations. This

communication enjoys a high level of trust from both parties: the unit representative has a safe place to ask questions and receive information that he can relay to the unit and be recognized as an "expert", while the matter of knowledge management is resolved or escalated to the senior or professional.

A topic that we were surprised about and did not expect in the field was the importance of personal example as an assimilation factor. In an organization, managing change processes involving technology and digitization is a specific case of leading change processes. Changing attitudes, culture, processes, and organizational practices can be some of these processes, as with the above example of changing the culture of discussion and sharing information or incorporating technological tools and integrating units. Numerous studies have supported these findings, with study data showing that the leadership abilities required to lead organizational transformation are similar to those required to lead broad organizational changes. At the center is the ability to build an effective team and provide leadership by example (Pring et al., 2020; Walsh). The issue surprised us mainly due to the importance that the IDF places on the issue of personal example among commanders and the extent to which this expectation is ingrained in the organizational command chain.

### ***3.6 From units that seldom use technology, what can be learned?***

The well-known military adage states that "what doesn't work routinely won't work in a crisis.". Our view is that the same applies to knowledge management and technological implementation, and we have identified a clear connection between willingness and ability to engage in knowledge management and improving the use of digital media routinely and success in implementation during an emergency. Basically, this involves the organizational maturity of the organizational bodies for absorbing and assimilating technology that develops mainly through routine. In organizations with no organizational infrastructure to rely on, it is difficult to realise the various technological options in times of crisis. While it's possible in some cases to make a step forward that will improve the process **and** incorporate technology, this more complex move has few chances of succeeding.

Let's look at an example from a department where there is a lot of emphasis on knowledge management. Implementation followed a clear pattern, which was also repeated elsewhere: 1. Ignoring or not responding to organizational

communication. 2. Under the pressure of senior executives, deciding to explore the environment. 3. Assigning a task to a medium-level leader with a general interest in information systems. 4. Obtaining information about capabilities from the leader. 5. A very high entry threshold was set by the manager - a very well-designed site was a prerequisite, excessive concern was expressed about information security, and the request was made to develop "applications." In general, the end of the pattern was marked by a waning enthusiasm for the project, a return to routine, and a lack of managerial support.

Units that routinely carry out processes of technology development and implementation will have an in-depth dialogue about the various needs and means, recognizing limitations in existing solutions, and the like, reducing such occurrences. As an example, during the first wave of deployment, the service had the ability to view up to four users simultaneously, i.e., there was a significant inferiority in the user experience compared to the competitor, 'zoom', not adopted by the organization. As a result, a manager who wanted to "see them all" switched to the "Zoom" app, thus compromising the implementation of the service. However, even if the needs of the manager are understandable and he can choose another service, this reduces the long-term implementation effectiveness and undercuts the effectiveness of digital solutions over time. Researchers Klein and others have examined the relationship between quality and characteristics of a digital service and its long-term implementation, but found only a weak link (2001, Klein et al), so we think there is still room for an improved organizational support message. It is our belief that department heads who are constantly involved in implementing technologies are better able to identify and manage these tensions.

Based on the corporate policy on the subject, a shared environment on the civilian Internet cannot address the needs of departments and processes with high classification requirements. Although it makes sense to discuss this as well, it is outside the scope of this article.

### ***3.6 Implement an absorption and assimilation framework***

In this case, the implementation of MIDI framework for digital management proved inadequate. The project management method suggested by the model was not workable, primarily because the system was already in existence.

Therefore, they were used as guidelines for tailoring support, both to the situation and to organizational structures.

### ***3.7 Is there anything else about the process worth getting to know? Communities***

"There are many fathers to success, but failure is an orphan" is truer than ever. In cases where organizational fit rates have improved, we can be certain that a significant networking organization is behind it. Communities are defined as groups of people with a common purpose that allows a person to feel less alone in dealing with the obstacles, problems, and complexities in the field of practice (Wegner, 2002; Etienne, 2002). Even if they are from different units, community members are interested and motivated to work toward a common goal, so they learn, are updated, and lend a hand to one another. This process was made possible by setting up a dedicated community for process leaders to realize the benefits of transitioning to digital, while at the same time, developing a community for users and implementation leaders to receive training in various issues involving recognition, recognition and solution development. Interestingly, we found the most vibrant community of the Teams was actually conducted on... 'WhatsApp'. While the Teams has a built-in chat capability, no app in the 365 environment has the option of multi-participant chat in one click.

## **4 Discussion**

### ***4.1 Uniqueness and inclusivity***

The characteristics of the military organization and the characteristics of the corona crisis may seem unique, but numerous conversations indicate that the findings we present are fairly similar to those found in other organizations that face similar crises; therefore, the discussion presented here could be generalized to other organizations.

### ***4.2 Success is a combination of motivation and ability***

**Motivation?** - Our research has characterized a wide scope of possible reasons for organizational change among commanders in units, apart from the need to continue operating effectively. Motivations included among others experimenting

with new technologies and tools then, identifying the situation as an opportunity for the commanders to bring about a change they wanted to make earlier, as well as curiosity about the new technologies. In addition to this, there is covert competition for positioning the unit at the "knowledge front" and promoting it as a more advanced and technological part of the organization, both among servicemen and within the organization as a whole.

**Ability?** - Although mastery of technology is not necessary for advancing and assimilating technology in the unit, we found that the commanders' attitudes and their sense of efficacy have a great impact on the infiltration of this technology in their unit. There are numerous factors determining willingness to adapt to change by units and leaders; willingness to take risk generally, when technology is only one expression of it; and tendency to adopt technology, as reflected in the accomplishments of the commanders in maintaining innovation processes and adopting technology. Sometimes these tendencies were perceived as contrary to conservatism within the unit; "The technological touch" - the understanding and technological skill of the commander; the sense of technological capability of the commanders in the unit - both their own sense and their sense of their unit's technological capability. This is partly explained by the fact that in a practical way, "motivation and ability" helps users and management to view a system through a positive lens and find solutions instead of despair.

#### ***4.3 One of the predictors of success - the link between assimilation (of product) and adoption (in departments)***

The more you adapt an existing product / service to users, requiring the product to change and be developed in order to better meet their needs, the harder it will be to assimilate it into their lives (Pillai, 1979).

Rogers (1983), who investigated processes of technological innovation infiltration in organizations, found that the better the product is adapted to the nature of use and the processes followed by users, the easier it is to integrate it. As it is evident, adapting a product to dozens of units and processes requires a lot of effort on the part of the product managers, and it is questionable whether there is the time and resources to accomplish this. A variety of existing technologies and solutions are used to develop products that are tailored to the needs of specific consumers. You can adapt a service that works with dedicated

software for analyzing and displaying data, for training units you can adapt dedicated and readymade training solutions, etc.

The use of a shelf product and user assimilation in this case was less successful. In units that have succeeded in adapting products to their needs through characterization processes and relevant representatives, they have been more successfully assimilated, for example in a greater number of operational processes and users. It also illustrates the importance of those technological leaders in the units, who were able to make the necessary adjustments to increase the likelihood of implementing the products in their units.

Gartner's technology adoption model known as the hype cycle supports this viewpoint (Gartner, 2019). When a product is introduced as the 'solution', there is a rapid rise in expectations and adoption among those who have waited for this and promoted it within the organization. It is when a product is put to use that its pros and cons become apparent and it enters the valley of disillusionment (underestimated expectations), units that were motivating or inspirational could cross the valley of sobriety and achieve maturity (the plane of productivity). Users learn how to use the product (implement) correctly, while at the same time the service learns to adapt itself to meet the needs of users.

#### ***4.4 What can we learn about implementation in general***

After detailing the key findings, we'll attempt to generalize what can be learned from the process carried out in the organization during this complex period to other organizations and routine periods when they prepare for situations and are not experiencing them.

##### ***4.4.1 An Implementation contingency plan - Would it be possible to turn a routine implementation into a crisis solution?***

Considering the implementation MIDI framework has helped a lot at the organization level. As a rule of thumb, it is recommended that an organization have at least a general, applicable contingency plan for implementation. The organization has handled crisis, light and material in a very short period of time. In an emergency, it is still necessary to implement systems in a relatively orderly manner in order to focus on time and other resources. We recommend keeping the central framework in place together with significant components, such as: delineating the concept and the system's objectives; identifying the user and

group management; risk management in terms of privacy and information security.

In a crisis situation, what remained of our absorption and assimilation model, the MIDI, were largely issues of support and training, whereas the organizational 'macro' stages, that demand careful planning up to months prior to the actual delivery to the end user, were not addressed, and the success of the assimilation was accordingly low.

#### *4.4.2 Should any system be implemented?*

The expected benefits of using a new information system should be evident right from the start. An organization's goals must be mapped out in advance in order to reap these benefits. In both the research literature and the popular management literature, there are dozens of different criteria that are used to ensure the adoption of a system. Some of these criteria relate to the actions of management, sociological and anthropological characteristics of the organization and its members, or to the relationship between investing time and money resources and the process (Christensen & Overdorf, 2000). Few refer to the system properties itself:

***Does the system "do what it's supposed to"? Is it effective in the sense that*** it allows for the existence of the processes and goals that led to its entry into the organization?

Is the system Technology ***reliable?*** without technical "crashes" or "bugs."

***Integration*** - Does the system integrate with other systems within the organization, or does it require a separate login / environment? Are data files and processes, managed by another information system already in use, available to the users?

***User-Friendly - What is the quality of user experience in the system?*** Is the 'user journey' pleasant and clear, and is the visual language helping the system to please the user and do what it is expected to do? Can the system generate a desire to work with it and explore its capabilities?

***Expandable and scalable*** - Will the system be able to handle the complexity of many users, processes, and timings? *Will the system hold limits if its' implementation will be even more successful than planned?*

#### *4.4.3 Centralization or decentralization?*

**The tension between decentralization and centralization** is expressed at two levels: first, upwards - at the level of project management at the top. This formulates the overall strategy created by the organization for the implementation of information systems and implementation management. Is there a centralized body responsible for the effort and does senior management oversee it? Is the implementation at the strategic level carried out with a high degree of decentralization in contrast to the degree of organizational centralization that characterizes the control of projects in the organization. The second level is the tension between the project management team and the leaders and knowledge officers deployed in units and bases. Considering the characteristics of the Corona period, there was considerable freedom granted, as a continuation of decisions taken before the Corona period and due to the inability to enforce tight regulation. The decentralization of these operations has been found to adversely affect the course of implementation, as the ratio of benefit to the investment in learning to use the system has shifted from positive to negative. In general, we recommend that the implementation efforts be more closely centralized in light of the relationship between decentralization and concentration.

**Organizational pace** - Organizations considering emergency deployment must take their internal pace into account. Based on the process we carried out, we recognize that the primary characteristic of the rhythm is the number of significant meetings led by leader of the organization (chief executive or senior manager). The slower this rate, the longer the implementation will take. Rapid implementation requires daily or frequent monitoring. Organizations that are not able to maintain administrative control at this frequency are likely to be left behind in the event of a crisis.

#### *4.5 What can we learn about implementation in times of emergency?*

If you are planning to implement a system in times of crisis, we recommend that the organization examines whether the system meets the expectations of the system as shown above, that it can set itself to action according to the organizational implementation model, and that the organizational pace will be appropriate. It is advisable not to move forward when the "prediction" of success

is not adequate, because it will be hard to invest the time and resources possible in a more relaxed situation.

## 5 Conclusions

The question arises as a result of the view that the implementation of an important information system is a significant organizational change - is a time of crisis the right time for such a change? The answer is intuitively no; however, some organizations utilize emergencies as an opportunity to acquire new capabilities, either through the acceleration of a preplanned initiative or a forced acquisition. Armies and other emergency organizations distinguish between deployment and implementation. No matter how successful a deployment may be, it does not lead to a successful implementation if the organization moves to a state where the embedded system is no longer needed, or if the organization readjusts to a state of crisis.

Our intention in this article was to learn from the IAF's adoption of collaborative work services during the Corona crisis how to assimilate shared work environments better. We believe that despite the uniqueness of this case, there are many lessons to be learned about the deployment of information systems, especially in times of emergency.

### Abstract

**Background:** Recent major health shocks like the 2014-16 Ebola outbreak, the Zika outbreak, and, last but not least, the Covid-19 pandemic have strongly contributed to drawing attention to the issue of resilience of health systems, because health authorities and organizations experienced severe difficulties in managing these crises. The concept of resilience is assuming a central role also in the scientific debate about healthcare management. Nevertheless, the lack of clarity on how to systematize and deal with this topic led to a highly fragmented scientific literature, which creates difficulties in the development and assimilation of incremental research in this relevant field. This study provides a comprehensive map of the extant literature and identifies the main themes and future research needs.

**Methods:** A systematic literature review was carried out. We used the database ISI Web of Science (WoS) to extract the dataset. The material search was conducted in December 2020, using keywords derived from the literature. The final sample, obtained from the

application of exclusion and inclusion criteria on the initial dataset, comprises 89 articles that are the object of this analysis.

**Results:** The 89 articles in the final sample range from 2001 to 2020. The research on resilience in healthcare appears fragmented and linked to different research streams. Hence, effective framing existing contributions could be beneficial and help at identifying the most investigated areas and the main gaps to fill. At this aim, we proposed a novel theoretical framework, to systematize the papers dealing with the topic of 'resilience in healthcare' and to provide a clear picture of the state of the art in this field.

**Conclusions:** The content analysis allowed identifying the significant dimensions defining the scope of investigation on the topic under analysis. Scrutinizing articles along these dimensions, several gaps emerge, which opens interesting paths for future research.

**Keywords** – Resilience, Healthcare, Flexibility, Literature review, COVID-19

**Paper type** – Academic Research Paper

## 1 Introduction

The concept of resilience is assuming a growing central role in the debates about healthcare systems (Blanchet et al., 2017; Biddle et al., 2020). Recent major health shocks like the 2014-16 Ebola outbreak, the Zika outbreak, and, last but not least, the Covid-19 pandemic have strongly contributed to drawing attention to such issue, because health authorities and organizations experienced severe difficulties in managing these crises.

However, these emergencies have just raised a problem that tends to be systemic in the healthcare sector (de Vries et al., 2011; Barasa et al., 2017). Indeed, the lack of flexibility of health systems implies a poor ability to adapt to conditions other than the standard ones and leads to a decline in health performance, as soon as an unexpected change occurs. Such vulnerability has an impact not only when a serious crisis occurs, but also when systems face routine stressors. In such a context, resilience is gaining momentum since it is the only answer for health authorities to this issue.

Numerous definitions and concepts of health systems resilience were proposed in the scientific literature, with different perspectives and aims (Blanchet et al., 2017; Fridell et al., 2020; Biddle et al., 2020), reflecting the rich facets that the term can take on in the healthcare environment. Since the presence of numerous different potential conceptualizations, resilience in health systems remains a very fragmented and broad concept (Turenne et al., 2019). The theoretical and

empirical cases in literature tend to be very different from each other, without also the use of a common terminology.

The lack of clarity on how to systematize and deal with this topic in managerial literature leads to a highly fragmented scientific literature, which creates difficulties in the development and assimilation of incremental research in this relevant field. This arises the need for an extensive review of the literature to systematize the managerial research referred to this topic.

The majority of available reviews in literature tend to be scoping reviews, thus not systematic ones, and generally have a narrow scope – e.g. answer to shocks, everyday resilience, Ebola outbreak in West Africa, developing countries (Biddle et al., 2020). In addition, they seem to look only at the articles that expressly refer to the resilience concept, without considering associated terms (e.g. flexibility, agility, readiness), which are often used to describe methods and concepts that are coincident or strongly related to health system resilience. Some limits also emerge considering the extent of the analyses that frequently consider a small number of articles (e.g. Fridell et al., 2020; Iflaifel et al., 2020). This lead to a shortage of a comprehensive framework able to guide the development of literature in the field. To fill this gap, this research aims to provide a clear picture of the current state of the art about resilience in the healthcare domain, by applying a systematic literature review methodology.

The contribution of this work, also in light of previous reviews in this area, is in being comprehensive of all the literature streams that have addressed the topic of resilience in healthcare and in proposing and placing papers in a multi-dimensional framework that can streamline such literature. In this effort to be broad, this review also examines contributions that describe methods and concepts coincident or strongly related to health system resilience though they do not expressly involve the term resilience. In addition, the content analysis was more extensive, both in terms of the number of articles analysed and in terms of dimensions assessed, which is highly needed to drive the further development of healthcare resilience literature.

## **2 Methodology**

To reach our purpose, we followed a systematic and transparent method based on Pittaway et al. (2004), meant to guide the literature review. As a first step, we aimed at identifying the intellectual core of a field (McCain, 1990), with the final

purpose of determining its underlying structure. This implies beginning from a broad dataset to be reduced progressively in later steps. The starting database was defined by combining the keyword health\*, searched in the title, with the keywords resilien\* or flexib\* or adapt\* or readiness\* or agil\*, searched in the topic, in the scientific database ISI Web of Science (WoS) Core Collection in December 2020. The choice of keywords is based on the conceptualization of resilience provided by Wiig et al. (2020), who stress that the definitions differ across disciplinary fields, complemented by the fact that different constructs are used with a similar meaning. However, despite variations, "some common core mechanisms of resilience have been identified as the ability that individuals, communities, organisational units or larger systems have to return to some 'normal' condition or state of functioning after a disruptive event; to cope with pressure and problems by being flexible without compromising system performance; or to adapt to a new normal state, where system functioning is reorganised or enhanced in some way in response to the disruption they face" (Wiig et al, 2020, p. 3). We added the keywords readiness\* or agil\* that are more used when speaking about routine stressors instead of disruptive events (e.g. ...).

This searching produced 29,306 results. After refining the query by WoS category (i.e. Operations Research Management Science, Economics, Management or Business), by document type (i.e. Article, Review, Early Access, or Editorial Material), and language (i.e. English), we ended up with 556 articles. However, while reading these articles and looking at forward and backward references to be sure we had captured all relevant contributions, we realized some contributions were missing. We noticed they were published in a bundle of journals pertaining to the WoS categories *Healthcare Sciences & Services* and *Health Policy and Services*. Consequently, we performed the search mentioned above within these categories, applying the same filters, thus obtaining 510 additional results.

As a second step, we read the abstracts, establishing specific exclusion criteria to leave not pertinent articles out of the analysis. In particular, when the concept of resilience was not considered at all or not with reference to a health organization or service, the article was excluded from the sample (e.g. resilience of the patient, health intended as improving air quality or reducing soil consumption). When collateral subjects (e.g. lean principles, complex adaptive systems) were the main topic of the article, we retained it only if there was mention of resilience in some way. We maintained the same criteria also for the

third step, i.e. full article reading of those contributions requiring further examination because the abstract was not sufficiently informative. After authors cross-checked the inclusion/exclusion of articles in the final pool during several sessions, we obtained 89 articles that are the object of investigation of this analysis.

As a final step, we analysed those articles carefully and mapped in a spreadsheet the main fields of interest, namely the purpose of the research, the methodology employed, the context of analysis, the research questions/hypotheses, the theoretical background, the main construct and associated definition (when provided), the key findings and future research.

While reading and mapping articles, we realized that other dimensions deserved particular attention because they were present in most articles, explicitly or implicitly, and they seemed to define the features surrounding the concept of resilience in healthcare, thus contributing to identifying the scope of investigation. These are the relevant dimensions we used to organize the literature, which is the main focus of the content analysis presented in the following section.

### **3 Results**

#### ***3.1 Descriptive analysis***

The 89 articles of the sample have been published from 2001 to 2020 (Figure 1). As shown in Fig.1, the biggest increase has occurred in the last 5 years (about 80% of documents sourced) and, in particular, in 2020, when the number of publications was more than double compared to 2019, and triple compared to 2015.

Figure 1: Annual scientific production

The variety of outlets that published articles on the topic of resilience in healthcare is wide (i.e. 51 journals). In Table 1, we show the scientific journals that published more than two articles in the sample. Among the 13 journals listed in the table, 8 belong to the first quartile of SJR classification and 3 to the second quartile.

The most productive journals contain approximately the 57% of the total number of documents retrieved (51 out of 89); they belong to different areas of research – including “Engineering, Industrial; Operations Research & Management Science”, “Development Studies; Economics, Health Policy & Services” according to WoS categories. The two top journals (i.e. Health policy and planning and BMC health services research) fall within the category of “Health Care Sciences & Services”. Table 1 reports, for each journal, the mean value of citations received by the manuscripts of our sample. In particular, “BMJ Quality & Safety” and “International Journal for Quality in Health Care” are the journals with the highest value of citations per document, i.e. 64.6 and 59.6 respectively.

Table 1. Most productive Journals

Scientific Journal	N. of Articles	SJR	Citations per document
Health policy and planning	13	Q1	14.4
BMC health services research	8	Q1	15.5
Safety Science	7	Q1	17.2
BMJ Quality & Safety	3	Q1	64.6
International Journal for Quality in Health Care	3	Q2	59.6
World Development	3	Q1	5.0

Australian Health Review	2	Q2	5.5
Disaster Prevention and Management: An International Journal	2	N/A	4.5
Health research policy and systems	2	Q1	3.0
International journal of health policy and management	2	Q1	28.0
Journal of evaluation in clinical practice	2	Q2	4.5
Journal of Health Management	2	N/A	0.5
Medical teacher	2	Q1	12.5

### 3.2 Content analysis

In this section, we propose a novel theoretical framework, to systematize the papers dealing with the topic of ‘resilience in healthcare’ and to provide a clear picture of the state of the art in this field. As recalled above, the research on resilience in healthcare is fragmented and roots back in different research areas and streams. Hence, an effective framing of existing contributions could be beneficial and help at identifying the most investigated areas and the main gaps to fill.

The framework proposed in this article is based on the dimensions listed below:

1. The typology of stressor to deal with;
2. The organizational level;
3. The geographical context;
4. The resilience strategy;
5. The resources to nurture resilience.

In the following paragraphs, the single dimensions will be detailed and discussed.

#### 3.2.1 The typology of stressor to deal with

*Resilience* is traditionally intended as the capacity of a system to respond to acute shocks, but it may refer also to the response to chronic stressors and everyday challenges (Barasa et al, 2017). In this regard, Gilson et al. (2017) introduced the concept of everyday resilience to indicate the capacity to cope with a different category of adverse events that may affect the system daily or in the long run. In this study, we have adopted a holistic view of resilience that focuses on both perspectives. Hence, we classified articles in the sample according to the typology of stressor under analysis (acute shocks vs. chronic

challenges). Most of the contributions dealing with *acute shocks* focus on infectious disease outbreaks. In this context, many authors analyzed the case of the Ebola outbreak (Gizelis et al., 2017; Ling et al., 2017), while, more recently, flourishing literature has started to appear about the COVID-19 pandemic, which has provided a fruitful case of analysis for scholars (Sharma and Sharma, 2020; Van Nguyen et al., 2020). Further examples of acute shocks are natural disasters, as earthquakes and tsunamis (Raven et al., 2018) and military conflicts (Odhiambo et al., 2020). The articles dealing with *chronic stressors* focus on different sources of uncertainties that may put the normal functioning of the systems at risk. Many contributions concentrate on internal sources of uncertainties, with the aim to minimize potential operational failures and/or harms on patients (Sujan et al., 2015; O'Hara et al., 2019). Others focus on external sources, as demand fluctuations (Restrepo et al., 2020), economic crisis (Thomas et al., 2013), demographic changes (Chen and Chen, 2015). Due to the high variability of the environment and the variety of chronic stressors that may occur, health systems have to develop appropriate strategies to respond and to be resilient every day, beyond disruptive events.

### 3.2.2 The organizational level

The contributions analysing the system response to a crisis event (shock or stressor) differ on the basis of the organizational level they focus on. On the one hand, some authors analyse the phenomenon from a *macroscopic* point of view, by focusing on the response of entire national health systems (Thomas et al., 2013; Van Nguyen et al., 2020) or of regional and urban health networks (Crowe et al., 2014). In this context, the policies undertaken by single governments or health organizations and/or the service reconfiguration strategies during a crisis are the most investigated aspects. On the other hand, there is a big quota of contributions focusing on a *microscopic level*, i.e. on the capacity of single organizations (i.e. hospitals, health units) to respond to adverse events (Sujan et al., 2015; Sharma and Sharma, 2020). In this case, the focus is on the internal processes and resources.

### 3.2.3 The geographical context

The crisis that put at risk the functioning of the health systems may range from events that have global impacts (i.e. pandemics) and those with local and limited consequences (i.e., natural disaster, epidemic). In this latter case, it is useful to

distinguish articles according to the geographical context they set their analysis on, to understand if there are threats affecting health systems in specific contexts.

It emerges that low and middle-income countries are affected by specific diseases (e.g. Ebola) and environmental conditions (e.g. military conflicts); hence, most of the studies on the developing countries focus on a specific class of adverse events (Gizelis et al., 2017; Raven et al., 2018). On the other hand, different difficulties have affected high-income countries, such as the 2008-2009 financial crisis that forced multiple health systems in Europe to reorganize to increase efficiency and make cutbacks in health budgets (Thomas et al., 2013). Further challenges are slowly emerging worldwide, causing progressive stress to systems; for instance, the continued threat of antibiotic resistance, which is predicted to become one of the largest challenges to health systems in the future, the climate change, that poses serious challenges to human health (Araos et al., 2016).

#### *3.2.4 The resilience strategy*

The approach towards resilience can be proactive or reactive, where proactive refers to preparedness and reactive refers to the recovery from turbulence (Chowdhury and Quaddus, 2017). Accordingly, we classified articles based on the undertaken strategy, distinguishing between:

- *proactive strategies*, aimed at reducing the likelihood of occurrence of adverse events and/or at anticipating the future threats, before they are actually experienced.
- *reactive strategies*, aimed at reducing the consequences of the adverse events, once they have already occurred.

Most of the articles focus on reactive strategies (Ling et al., 2017; Van Nguyen et al., 2020), being empirical studies focusing on the ex-post analysis of response to real crisis events, already occurred. Less attention has been devoted to proactive strategies. Some studies focus on the development of tools and management practices, which help to monitor processes and to recognize, anticipate and defend against the risk before adverse consequences occur. To cite a few, Crowe et al. (2014) develop Operations Research techniques for supporting strategic decisions concerning service reconfiguration during a crisis; Maunder et al. (2010) develop a computer-assisted course to train health workers and

improve their preparedness during pandemics, thus minimizing the stress and its negative impact on the health systems (i.e. absenteeism).

### *3.2.5 The resources to nurture resilience*

Complex health systems are comprised of both hardware and software resources (Sheikh et al., 2011). Hardware resources include infrastructure, medical devices, human resources and finances, while software resources include the tangible software of management knowledge and skills, organizational systems and procedures, as well as the intangible software of values and norms, relationships and power (Barasa et al., 2017). Most of the articles focus on hardware elements; specifically, on the pivotal role played by health workforce in the response to a crisis (Mauder et al., 2010); on the engagement of patients and families in the process delivery to minimize variability and risks (O'Hara et al., 2019); on the exploitation of digital technologies (Rubbio et al., 2019) and on the availability of equipment, materials and infrastructure (Kumar et al., 2020). The contributions focusing on the software elements are mostly devoted to investigate the impact of governance and leadership on the system response at different organizational levels (Thomas et al., 2013; Gizelis et al., 2017) or to the development of flexible and robust managerial tools that may support resource allocation decisions (Crowe et al., 2014).

## **4 Conclusions**

The purpose of this article was to carry out a literature review on the theme of resilience in healthcare in an attempt to systematize the existing, broad and fragmented literature into a multi-dimensional framework.

The content analysis allowed identifying the significant dimensions defining the scope of investigation of the topic object of study, namely the typology of crisis to deal with, the organizational level, the geographical context, the resilience strategy, and the selected resources to nurture resilience. Scrutinising articles along these dimensions made a number of gaps emerge, which opens interesting paths for future research, among which we would like to put attention on some main points. First, research on how to be prepared to prevent shortcomings of and deal with stressors and disruptive events, which means having a proactive approach towards resilience in healthcare, is still scant. Second, the resources required to foster resilience have disregarded software resources in favour of

hardware ones. In particular, intangible software resources related to relational aspects of agent interactions (e.g. norms, power, trust, culture) are unexplored. Instead, among the hardware resources, authors frequently mention information technology in general terms, whereas nowadays specific studies on how digital technologies may contribute to increasing resilience would be appropriate. Third, the interplay among these dimensions could be a stimulating evolution of this study. For example, looking at whether resilience at different organizational levels or different resilience strategies benefit from different resources or could reveal interesting insights.

Finally, beyond the dimensions, we had a further confirmation that authors still do not converge towards a shared definition of resilience in healthcare, which has relevant implications because using a multiplicity of definitions for a single construct or using constructs with a similar meaning as a basis for theorizing could lead to biases in the field, because the development of a consistent, strong and generalizable theory necessitates a base of well-defined constructs. This calls for the standardization of the definition of resilience in healthcare in an attempt to provide a common language to describe and explain resilience (e.g. Huey and Palaganas, 2020; Wiig et al., 2020).

From a theoretical perspective, this article contributes to the creation of a comprehensive framework able to guide the development of the literature in the field. But it has also a relevant practical contribution, as it provides a knowledge base supporting decision-making in healthcare. For a health care organization to be truly prepared for unexpected events, leaders can be supported and facilitated in their decision-making if they have solid knowledge and a basic understanding of the principles that can guide the resilient management of health care systems. Overall, the study offered a demonstration of the importance of developing specific knowledge for fostering a proper conceptualization of resilience in healthcare. In this regard, it calls for a new research agenda.

### Abstract

The mounting pressure from governments and investors has imposed companies to think “green”, “sustainable” and be “social compliant”. In this paper, an investigation to understand the joint impact that Sustainable Oriented Innovation (SOI) and Open Innovation (OI) may have on companies' performance is presented. In particular, the study aims to see if these practices, i.e. OI and SOI, impact in terms of innovation, sustainable and economic performance that have been described in the literature as different but often correlated outcomes. The model proposed a setting in which it is possible to test the joined effect of developing SOI and the sharing of knowledge considering open and closed OI strategies. Results show that the most convenient strategy is to develop SOI technologies, but the use of an open setting should be evaluated according to the life cycle stage and dynamicity of the technological environment.

**Keywords** – sustainability-oriented innovation, open innovation, agent-based model, performance, patent. (*max 5 words*)

## 1 Introduction

The mounting pressure from governments and investors has imposed companies to think “green”, “sustainable” and be “social compliant”. In the last years, sustainability-oriented innovation (SOI) has largely been considered as one of the most important drivers to cope with regulation and be competitive in the market. Although SOI is not a new concept, many large multinational corporations but also small enterprises are increasing their attention toward SOI practices. SOI is defined as “realized ideas that improve environmental and/or social performance compared with the current situation” (Arnold and Hockerts, 2011, 394) and it can be considered either a practice or an output of a process. It concerns several aspects of a company, ranging from the efficient use of resource inputs to the creation of totally new products and services that need to be aligned with the traditional business (Adams et al., 2016; Nidumolu et al., 2009). One of the main questions regards the impact that SOI may generate and its effect on the company’s final performance. Nowadays, SOI is seen also as a source of opportunities that drives businesses to gain a competitive advantage and simultaneously improve their performance (Hall, Wagner, 2012). However, for a long time, sustainability has been seen as a cost of doing business to be compliant with governmental laws and as an economic externality or as a cost infringed by effective legal enforcement (Porter and Van der Linde, 1995).

In this context, explorative studies suggest that sharing knowledge and resource can be fundamental for improving company’s results. The fact to share knowledge with others can be characterized as an Open Innovation (OI). This may support the development of a sustainable, timely, commercially viable innovation and improve company’s performance. Over the past decade, innovation literature emphasized the importance of going beyond the firm’s boundaries when creating and developing innovation in order to increase the firms’ performance (Chesbrough, 2003). For example, external technology acquisition positively affects firm performance. Moreover, the collaborative approach when developing SOI products or processes may enable the innovation team to harness the opportunities offered by adopting a sustainability strategy. It seems that a proactive SOI strategy harnessed the benefits of OI. As Keskin et al.’s (2013) study the “network” is a critical practice and sharing knowledge with other actors facilitates the engagement with like-minded external actors (such as industry experts, universities and formal innovation partners) (Adams et al., 2016). Thus,

collaborating with other actors may realize a synergic result (Slotegraaf, 2012) because OI creates a combined internal and external space for organizational practices, enabling an externally-oriented approach to their respective execution that reduces the risk and uncertainty of SOI. Nevertheless, it is not clear what the impact may be and sometimes also the sharing of knowledge does not lead to the expected results. Current studies are mainly based on a specific case study and, for example, empirical evidence suggests that SOI processes coupled with OI lead to more radical products without providing a more complete understanding (Kennedy et al., 2017) about how these two practices may work synergically and how they may impact companies' performance.

Relying on this background, the paper aims to understand the joint impact that SOI and OI may have on companies' performance and answer the following research question:

*How does the synergic use of SOI and OI impact on company's performance?*

In particular, the study aims to see if these practices, i.e. OI and SOI, impact in terms of innovation and economic performance that has been described in the literature as different but correlated outcomes. To answer the research question outlined above, many different methodologies can be applied. Among them, the agent-based models are very powerful tools as they let to create a sort of computational laboratory where to make experiments through simulations (Landolfi et al., 2012, Ponta et al., 2018, Albino et al. 2006). In this paper, the PABIM model and simulator have been enriched to address the research question underlined above (Ponta et al., 2020b). Results show that the most convenient strategy is to develop SOI technologies. However, the synergic use of an open environment should be evaluated according to the life cycle stage and dynamicity of the technological environment.

The paper is organized as follows: Section 2 presents the model, Section 3 shows the results of the computational experiments and Section 4 provides the discussions and conclusion of the study.

## **2 The model**

To investigate the main objective of the study outlined above, the agent-based model and simulator (PABIM) has been used (Ponta et al., 2020b).

The agent-based model developed is characterized by heterogeneous firms that are organized as a directed random graph. The graphical representation of the PABIM model in terms of firms and interactions is shown in Figure 2.

Figure 2 – Graphical representation of PABIM model in terms of firms (circles) and interactions (lines) at time step 0.

At the beginning of the simulation, all the firms have the same output node degree, defined as the number of outgoing arrows, and are endowed with the same quantity of cash and the same number of employees. During the simulation, the output node degree of each firm is directly proportional to the firm's size, i.e., it increases if the firm's size increases and decreases if the firm's size decreases, thus the number of employees, proportional to the firms' size, varies during the simulation.

Each firm  $i$  is characterized by an identifier  $id_i$ , a number of employees  $N_i$ , a list of its filed patents  $P_i$ , an amount of cash  $C_i$ , the turnover  $Tu_i$ , the percentage of turnover invested in R&D  $\alpha_i$ , an industrial sector  $IS_i$  and a probability to patent  $\rho_i$ .

The percentage of turnover invested in R&D research is different for each firm and proportional to the firms' dimension.

In this enriched version of PABIM, firms are also characterized by two R&D divisions: the SOI and NO SOI divisions. The SOI division makes research finalized to file SOI patents, whereas NO SOI division to file patent not specifically related to sustainability.

At each iteration step, each firm invests a fraction of the turnover in R&D research, that is divided between the SOI and NO SOI division, necessary to file patents. All the R&D expenses are finalized to patent.

The probability  $\rho_{i,s}$  of firm  $i$  to file for a SOI patent is set to depend on the cumulated R&D research investment  $Mc_{i,s}$  employed by the SOI division of firm  $i$  since the latest SOI patent filed, as follows:

$$\rho_{i,s}^t = 1 - \frac{1}{1 + \eta Mc_{i,s}^t} \quad (1)$$

where  $\eta$  is a shape parameter, homogenous across all firms, setting the sector innovation intensity, i.e., the higher is  $\eta$ , the higher is the probability to file for a patent, for any level of cumulated R&D research investment  $Mc_{i,s}$  employed.

The probability to make a SOI patent using shared knowledge between firm  $i$  and  $j$  (co-patent between firm  $i$  and  $j$ ) is given by Eq. 2

$$\rho_{ij,s}^t = 1 - \frac{1}{1 + \eta (Mc_{i,s}^t + Mc_{j,s}^t)} \quad (2)$$

If firm  $j$  cannot patent alone, it chooses from among all the firms' requests, to make a patent using shared knowledge with the firm with the greatest connection strength.

Analogously, the probability  $\rho_{i,ns}$  of firm  $i$  to file for a NO SOI patent is set to depend on the cumulated R&D research investment  $Mc_{i,ns}$  employed by the NO SOI division of firm  $i$  since the latest NO SOI patent filed, as follows:

$$\rho_{i,ns}^t = 1 - \frac{1}{1 + \eta Mc_{i,ns}^t} \quad (3)$$

The probability to make a NO SOI patent using shared knowledge between firm  $i$  and  $j$  (co-patent between firm  $i$  and  $j$ ) is given by Eq. 4

$$\begin{aligned} &\rho_{ij,ns}^t \\ &= 1 - \frac{1}{1 + \eta (Mc_{i,ns}^t + Mc_{j,ns}^t)} \end{aligned} \quad (4)$$

Thus, at each iteration step a firm can file a SOI patent and a NO SOI patent.

If a patent is not possible at time  $t$ , the firm can extend a patent issued at time step  $t-1$ . If firm  $i$  did not file for a patent at time step  $t-1$  no patent is extended.

The patent is characterized by an identifier, an IP class, one or more countries in which the patent is extended, the number of forward and backward citations. It is worth remembering that the backward citations are the patents cited when the new patent is issued, whereas the forward citations are the ones received by the patent. Moreover, a patent is characterized by a cost composed of a part that represents the cumulated (discounted) cost of filing and maintaining a patent and

another part that depends on the R&D investment done until the year of filing. Moreover, a patent is also characterized by an extensions cost which represents the cumulated (discounted) cost of extending and maintaining the extensions of a patent. Management costs have also been considered.

The value of the SOI and NO SOI patent, intended as the cumulated (discounted) turnover generated by the patent is defined by firms proportional to costs, through the multipliers  $\mu_{sp,i}$  and  $\mu_{nsp,i}$ , respectively, defined at the beginning of simulation and constant during the simulation.  $\mu_{sp,i}$  and  $\mu_{nsp,i}$  are a positive real number to consider both the case of success and failure of a patent. In particular,  $0 < \mu_{p,i} \leq 1$  represents the failure case, whereas  $\mu_{p,i} > 1$  represents the success case.

The revenues for firm  $i$  of a patent  $p$  filed at time  $t$  is:

$$R_{p,i,t+2} = \begin{cases} V_{p,i}^t & \text{if firm } i \text{ files a patent alone at time step } t \\ V_{p,i}^t \nu \frac{Mc_i^t}{Mc_i^t + Mc_j^t} & \text{if firm } i \text{ files a patent at time step } t \text{ using shared knowledge with firm } j \text{ (copatent)} \end{cases} \quad (5)$$

where  $\nu$  is a coefficient positive and less than 1, which simulates the management costs between firm  $i$  and  $j$ .

In general, a SOI patent is more expensive in term of research but also the revenues are larger (Whelan et al., 2016). Following Whelan et al. (2016), this assumption mimics the benefit of a SOI patent.

Furthermore, the turnover of firms is updated. and firms determine the number of employees to hire or fire at each iteration step, according to their revenues. In particular, if the variation of turnover,  $\Delta Tu_i$ , is larger than zero firm  $i$  will hire a number of employees directly proportional to  $\Delta Tu_i$ , whereas if  $\Delta Tu_i$  is smaller than zero firm  $i$  will fire. Furthermore, if  $\Delta Tu_i$  is equal to zero no hiring or layoffs are implemented.

Finally, at each time step, the economic and innovative performances are evaluated. It is worth remarking that at each time step  $t$ , each firm checks if it can make a patent alone, and if not, the firm can try to share knowledge with the connected firms.

At each iteration step, the economic performance  $Pe_i^t$  of firm  $i$  is evaluated as its turnover  $Tu_i^t$ . Concerning the firms' innovation performance, among the traditional measure based on secondary data, the number of patents is considered. Moreover, also the patents' features that combined define the Innovation Patent Index (IPI), have been taken into account (Ponta et. al. (2021),

Ponta et. al. (2020a). Finally, the sustainability innovation performance is evaluated measuring the number of SOI patents.

### 3 Computational Experiment

#### 3.1 Design of experiments

In order to investigate the research question described above four scenarios have been considered. In the scenario (i) each firm can only create knowledge about NO SOI, in the scenario (ii) the knowledge's share strategy is allowed about NO SOI, in the scenario (iii) each firm can only create knowledge alone about SOI and NO SOI and in the scenario (iv) the knowledge's share strategy is allowed for both SOI and NO SOI. Table 1 summarizes the characteristics of the four scenarios.

Table 8: Scenario description

Scenario	Description	Color
i	Firms can develop alone only NO SOI technologies	Blue
ii	Firms can develop alone the technology or share the knowledge only NO SOI technologies	Red
iii	Firms can develop alone SOI and NO SOI technologies	Green
iv	Firms can develop alone or share the knowledge for SOI and NO SOI technologies	Magenta

Simulations have been performed *ceteris paribus*, meaning that all the parameters are identical with the exception of the strategy. In particular, twenty firms, working in eight different sectors have been simulated. Each firm can file two patents maximum per year. The four cases previously described and summarized in Table 1, are explored with six different values of  $\eta$ , the parameter which controls the probability to translate the R&D investment into patents, see Eq. 1; in this way twenty-four different scenarios are obtained. The methodology used is based on Monte Carlo computational experiments: each scenario is simulated with fifty different seeds of the pseudorandom number generator. So, a

total of 480 simulations were considered in order to conduct the investigation. The computational results are presented in the form of boxplots. In particular, each boxplot shows the distribution of the time averages of relevant variables over a twenty-year time interval, concerning the twenty simulations characterized by different seeds. Boxes enclose the values from the first to the third quartile; they also include whiskers that extend up to the minimum and maximum data points that are not considered outliers; the horizontal segments inside boxes represent the median of the distribution. The analysis aims to investigate the impact of sharing knowledge and of sustainability on firm performance, considering economic innovation and sustainability performance. Table 2 summarizes the simulations' initialization data. The data used in the simulations were estimated from the Orbit Intelligence database provided by Questel<sup>1</sup>, collecting patents that are published by firms with a registered office in Italy, or by an inventor with a residence in Italy from 2000 to 2018.

Table 9 - Simulation Parameters

Symbol	Description	Value
T	Years	20
I	Number firms	20
ES	number economic sector	8
do	number of initial output connection	0, 2
$n_d$	Number of divisions	1,2
$T_u$	Initial Turnover	20000
$\eta$	Sector innovation intensity	0.00001 to 0.005
$\alpha$	% of turnover invested in R&D	[2 - 17]
$\mu$	Multiplicator	[0.5 - 2]
$\mu_G$	Multiplicator SOI	[0.9 - 1.7]
$v$	coeff management cost	0.9
$C_e$	patent extension cost	350
$C_f$	patent filed fixed cost	500

### 3.2 Results

Figure 3 shows the economic and innovation performance in scenario (i) (blue), scenario (ii) (red), scenario (iii) (green) and scenario (iv) (magenta). Scenario (i) is

<sup>1</sup> [www.questel.com](http://www.questel.com)

characterized by a no share of knowledge strategy for only NO SOI. Firms patent only alone and do not cooperate to achieve technological improvement more quickly. Scenario (ii) is characterized by the possibility to share knowledge for NO SOI research, that is, firms cooperate to reach the issue of a NO SOI patent. Scenario (iii) is characterized by the possibility to file both SOI and NO SOI patents but with no share of knowledge. Finally, in scenario (iv) both SOI and NO SOI patents are allowed and also the share of knowledge among firms. In particular, Figure 3 (a) shows the economic performance approximated with the turnover. It can be noted that for all the values of  $\eta$ , the turnover in scenario (i) and (iii) is larger than in scenario (ii) and (iv), meaning that firms can convert R&D investment into patents without sharing knowledge, and making patents alone saves the management costs. For a firm, it is more remunerative to reach enough knowledge to patent rather than to use shared knowledge. Moreover, for very large  $\eta$  the two scenarios are similar because, even in the case of shared knowledge, firms file for patents alone. Furthermore, in both scenarios, the maximum value of economic performance is reached for an intermediate value of  $\eta$  meaning that either a low or a large number of patents does not permit to reach the optimal value of economic performance. Moreover, it is worth noting that the economic performance is largest for scenario (iii) for all  $\eta$  meaning that SOI patents can produce higher economic performance. Figure 3 (b) shows the innovation performance evaluated with the number of patents. For all  $\eta$  the innovation performance is larger in scenarios (iii) and (iv), i.e. when firms can file SOI patents. Moreover, for small  $\eta$  the innovation performance is larger when firms share knowledge (scenario (iv)), whereas, for large  $\eta$  it is larger in scenario (iii), that is when firms do not share knowledge. This behaviour is also shown by the sustainability performance as clear in Figure 2 (c). In order to investigate innovation performance deeply, Figure 4 shows the five patent features mentioned in Section 2. In each subfigure, all scenarios are plotted for easy comparison. Figure 4(a) shows the normalized number of patents with respect the firm size. It is possible to observe that for all  $\eta$  it is larger in scenario (iv), i.e., firms that file also SOI patents and share knowledge are able to file for a larger number of patents compared to the no share case and the cases of NO SOI research. Thus, independently of the ability of firms to transform R&D research into patents, the possibility to use sharing knowledge increases the innovation performance of firms. It is even more evident in the case of SOI.

Figure 3 (b) shows the number of IPC classes. It is possible to observe that for small  $\eta$  the feature is larger in scenario (ii) whereas for large  $\eta$  in scenario (iv). Concerning the backward citations, as shown in Figure 3 (c) for all  $\eta$  the features is large in scenario (iv).

Finally, Figure 4 (d) and (e) show the number of extensions and the number of months between the publication date of the youngest and the oldest patent of the family. It can be observed that for larger  $\eta$  in scenario (iii) and in scenario (iv) these patents features are larger than in scenarios (i) and (ii). It is worth noting that in both scenarios the maximum number of these features is for  $\eta$  not very small nor very large. Summarizing the results of the innovation performance, in scenarios (iii) and (iv), i.e. when firms file also SOI patents, firms reach better performance compared to scenario (i) and (ii). Moreover, it is worth noting that if firms file also SOI patents the best innovation performance is reached if firms do not share knowledge, whereas if firms file only NO SOI patents the best innovation performance is reached if firms share knowledge.

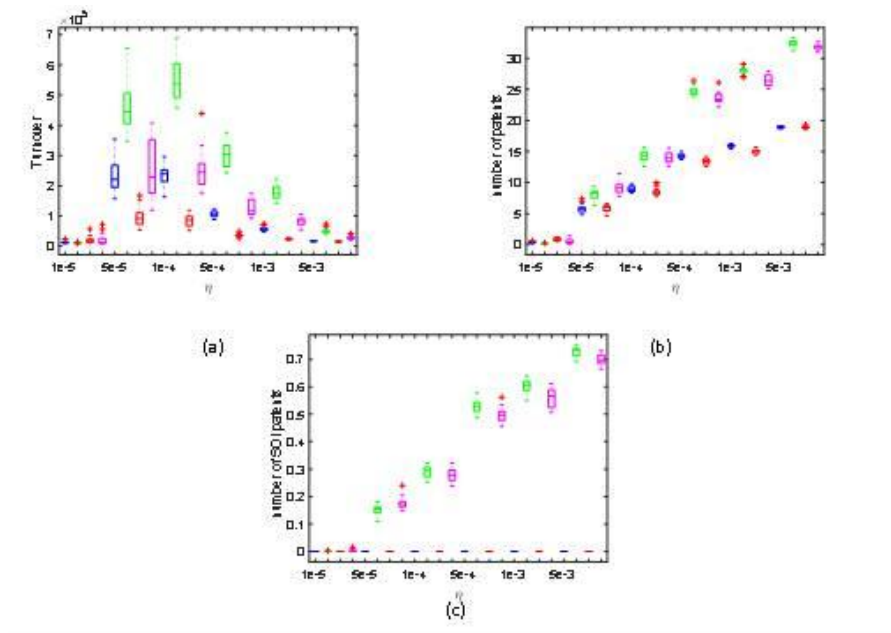

Figure 3 – Distribution of the economic (a), innovation (b) and sustainability (c) performance of firms for scenario(i) (no share of knowledge, NO SOI) in blue, scenario (ii) (share of knowledge, NO SOI) in red, scenario(iii) (no share of knowledge, SOI) in green and scenario (iv) (share of knowledge, SOI) in magenta.

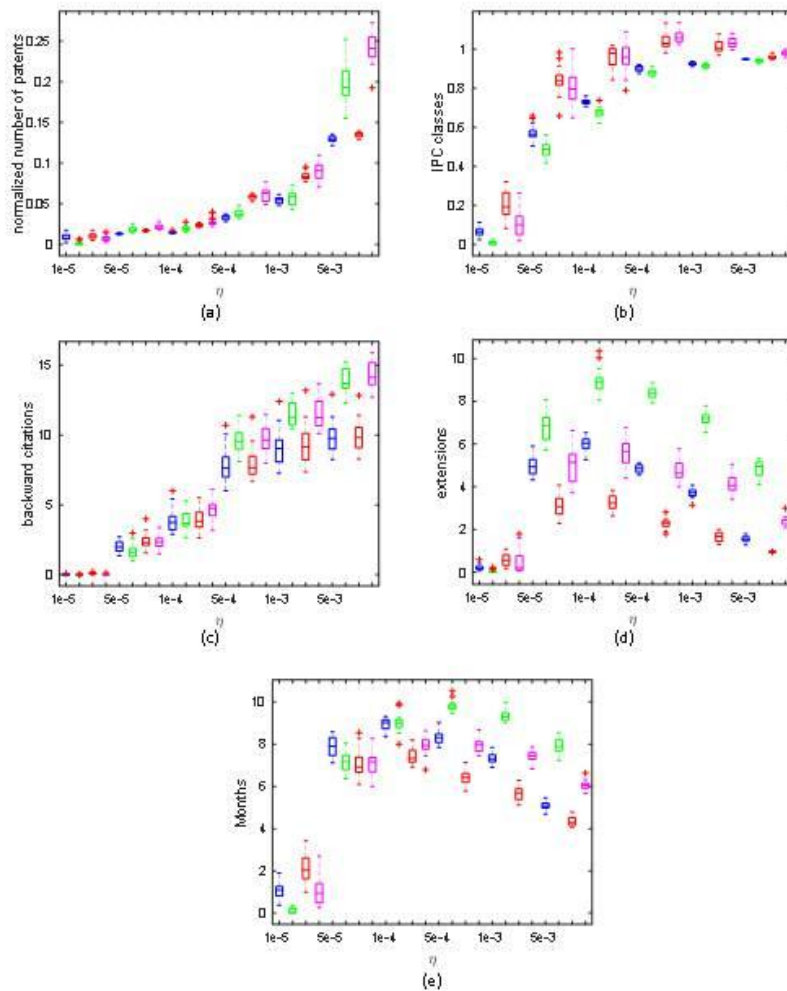

Figure 4 - Distribution of the following patents features: the normalized number of patents (a), the number of extensions (b), the number of IPC classes (c), the number of backward citations (d) and the number of months between the publication date of the youngest and the oldest patent of the family (e) for scenario(i) in blue, scenario (ii) in red, scenario (iii) in green and scenario (iv) in magenta.

#### 4 Discussion and Conclusion

This model contributes to both SOI and OI literature, trying to merge these two main paradigms beyond the innovation management literature. Recently, SOI has developed impressively, with a surprising steep rise and accounting for a variety of nuances, showing also high complexities and a large variety of actors and

interests involved in transformation processes. Moreover, the importance of sharing knowledge in challenging and uncertain environments to create a complete knowledge chain towards successful innovation (Kennedy et al., 2017) has always been a main point for scholars. The study suggests to innovation management scholars the importance of combining both practices (Van den Ende et al., 2015) to reduce issues and complexity and when the combination of these strategies maximize the value of the effort.

Thus, in this complex environment the model simulates the possibility to develop SOI or NO SOI leveraging two opposite collaboration strategies: i.e. open or closed (Chesbrough, 2003). The study suggests that the innovation process must be seen from different perspectives and performance should be measured with different indicators. The impact of SOI and knowledge sharing on innovation, economic and sustainable performance may be different according to the performance measured and assume different meanings according to the dynamicity of the environment. In particular, the sharing of knowledge leads to lower turnover results when developed with other actors. When managing the development of new products, and probably even more when developing sustainable related innovations, the collaboration and sharing of knowledge between firms presents challenges. Indeed, the turnover should be split among the companies that help in developing the technology (Wang et al., 2021). However, it should be noticed that for a low intensity of the external context, the turnover is more or less the same when collaborating or not, probably because the market does not lead to splitting the revenues among companies. Innovation performance differ according to the different scenarios. In general, for medium level of context dynamicity, the sharing of knowledge to develop new innovations may provide fruitful results. If the company aims to develop a high number of innovations, with respect to the number of employees (a measure of the efficiency of the firms (Ponta et al., 2021) an open strategy helps to split risks and costs. Moreover, this strategy lets also having a higher quality (measured in terms of backward citations) (Ponta et al., 2021) because it allows using the previous knowledge of multiple actors. In general, the sharing of knowledge is even more fruitful if the company is developing NO SOI innovation. Moreover, an open approach does not really help in entering new markets (number of extensions) probably because in this case it would be more helpful to search for partners that support the sales channels and that own higher marketing competencies instead of technical ones.

Based on the findings, the study delineates a practical guidance for firms. It suggests that SOI permits to achieve superior performance both using the two possible collaboration strategies analysed: open or closed. As Markad et al. (2012), sustainability has high relevance for society and industry, given the magnitude and pervasiveness of sustainability issues that we have to cope with today and we are beginning to understand the practical implications of the shifts in established socio-technical systems. Managers should invest in SOI-related performance because on average they permit having better innovation and economic performance. This implies making intentional changes to firms' culture, philosophy and values and consequently to products, processes or practices to be compliant with the social and external environment to finally generate higher economic returns (Adams et al., 2016). However, in highly competitive environments, probably, a high sharing of knowledge should be avoided. Then, when the environment is more stable, as suggested by the innovation cycle of Utterback and Abernathy (1975), companies can share the knowledge and managers should decide to have a more open collaboration strategy. It is also worth noting that probably companies should also think in terms of sales channels and invest not only in terms of technological development but they should also invest in competencies that allow making the new product, in particular the SOI one, valued by the market. In addition, the results suggest to both managers and policy-makers, how the innovation process should be conceived with a comprehensive view and has a continuous evolution that embraces different stages, including the understanding not only of the technical knowledge of the product or process produced (sustainable or not) but also the resources that need to be used or acquired to make it.

### Abstract

In this paper we address the limited understanding of how the amount of sales used by retailers changes the customers' propensity to plan purchases. We investigate the effects of shopping motivation, buying behavior, marketing skepticism, and marketing literacy on the propensity to plan purchases by customers and how they comply with this purchase plan. A classification of sales into short-, missile- and long-run is developed. Based on in-depth interviews and an online survey we identify the abovementioned factors perform differently depending on sales types. Overall, utilitarian shopping motivation that positively affects shopping planning and compliance with the shopping plan during sales, and sales buyers experience more hedonic value and have a higher level of marketing literacy at sales than non-buyers. It was also found that the less often the sale is held, the more unplanned purchases buyers make. During regular sales, buyers show a lower level of marketing skepticism than those who do not buy.

**Paper type** – Academic Research Paper

## **1 Introduction**

The sales volume for promotions in stores of the modern format in different categories is continually growing worldwide. Constant innovations, new trends, and events are changing customers' needs and increasing their interest in the shopping experience, raising the level of competition within and between retail formats, which have a significant impact on how retailers conduct sales in such an environment.

The demand from customers for promotional products is becoming more intense. The industry is actively responding to this request, and retailers are increasing their offer of products at discounts from year to year. As a result, the volume of promotions increases due to three key parameters: the number of product positions on the promo, the number of stores where promotions are held, and the discount price. The abovementioned customer reactions make companies organize sales promotions on a regular basis, and as those become predictable for customers that changes their shopping behavior.

In this paper we are trying to address the limited understanding of how the amount of sales used by retailers changes the customers' propensity to plan purchases. To address the research problem, this study aims to investigate the effects of shopping motivation, buying behavior, marketing skepticism, and marketing literacy on the propensity to plan purchases by customers. In addition, we want to check whether customers who plan their purchases tend to comply with this purchase plan.

## **2 Defining the effect of sales promotions on consumer behaviour**

### ***2.1 Three types of sales promotions and shopping planning***

Sales are one of the most popular tools for trade marketing. They are held for different purposes. The most popular goal is to increase sales and get rid of old products. However, this discount campaign can be called successful when it not only sells out inventory but also helps to improve the company's image or at least does not harm it (Gedenk, Neslin and Ailawadi, 2009). There is an extensive amount of research on sales promotion in the context of different sciences, such as economics, psychology, and marketing. Over the past 35 years, much research has been done to study the impact of promotions (Blattberg and Briesch, 2012).

The definition of the term “sales promotion” is quite complex due to the presence of many interrelated methods and tactics. In general, sales promotion refers to the actions of advertising activities in order to increase the interest of regular customers and attract new ones. They are temporary and most often focus on encouraging shoppers or retailers to take short-term actions (Cannon, Perreault and McCarthy, 2016).

For the purposes of the research, we consider only scheduled (known, predictable) sales and introduce a classification of all sales into three types based on their regularity and frequency: short-run, middle-run and long-run sales. Short-run sales are held to correct stock management and increase profit (Shyan, 2003). Middle-run sales are mainly seasonal sales. The purpose of these sales promotions is to attract as many customers as possible, in addition to selling off the stock (Shyan, 2003). Long-run sales are holiday or events based and normally can be expected only once a year. This type of sale is characterized by a short period, in which there is a rush of demand (e.g., Christmas sales or Black Friday).

Researchers who study the impact of sales promotion on the buying behaviour, not very often focus on the customers’ attitude to shopping planning and how they adhere to this plan. Lennon, Johnson and Lee (2011) showed that shoppers spend significant effort in preparing and shopping during Black Friday, such as making a plan for their purchases in advance. Buyers who plan their purchases experience the convenience and “smart shopper feeling”, which has hedonic and utilitarian aspects. Connection between the feelings of a smart buyer and planning is significant and represents a group of buyers who manage to get advertised products at discounts. Additionally, the results of the study showed that buyers who spend effort on planning their purchases are also prone to impulsive purchases. Authors explain this by the fact that buyers plan their activities during sales and fulfill their plan, after which they can take advantage of unplanned transactions on their shopping path.

Laroche et al. (2003) determined that there are buyers characterized by their expertise in shopping, their planning of shopping trips and expenses. They can also provide information about favorable offers to other customers. Moreover, customers who continuously make purchases in the stores they know will be better aware of the environment and the range of products in these stores. Thus, they will properly plan their purchases and buy what they need. Another study confirms that shoppers are engaged in strategic planning for shopping on Black Friday. Such planning on Black Friday is consistent with traditional holiday rituals

and can be the same as planning to buy gifts before Christmas (Thomas and Peters, 2011).

All these results of various studies indirectly confirm that people plan their purchases before going to the store and try to stick to their plan during sales. Further, we will focus on different shopping motivations and buying behaviors of customers, which can influence their shopping trip.

## ***2.2 Shopping motivation***

Sales promotion offers the benefits of various advantages to which the consumer responds (Shimp and Andrews, 2012). The various advantages offered by sales promotion affect the consumer's psychological assessment, after which the consumer evaluates and makes conclusions about how profitable this offer is. However, the evaluation of profitability is not the only thing that determines the buyer's decision to buy; it also affects the buyer's emotional and internal feelings (Sinha and Verma, 2020).

There are two significant shopping motivations and two types of buying behaviors. Each shopping experience allows customers a combination of compulsive and impulsive buying, as well as hedonic and utilitarian shopping values (Gohary and Hanzaee, 2014).

Hedonic purchases are usually motivated by a desire for fun and pleasure, sensory stimulation, and often include products that are thoughtless or luxurious. When we spend money on hedonic products or services, there is often an internal conflict between the necessity to save money and encourage our desires. It is happening because spending money on the second option reduces the monetary resources needed to meet basic life needs (Kivetz and Zheng, 2017).

In contrast, utilitarian shopping is based on the principle of rational purchases, which is usually based on the motivation of the need and regularly involve practical product. There are utilitarian goods and services without which it is impossible to do, and spending money on them has a natural justification. Babin, Darden and Griffin (1994) determined that utilitarian value can arise from a situationally engaged consumer who collects information as needed, so a purchase is not a necessary precursor to utilitarian purchasing value.

There is a direct link between shopping motivation and its consequences such as loyalty, retail satisfaction, and assessment of the utilitarian and hedonic value of purchases, which has been proven by research in retail (Arnold and Reynolds,

2003). It has also been confirmed that retailers can provide both hedonic and utilitarian values while the customer is shopping (Sherry, 1990). For instance, the customer may be motivated to buy a particular item and go shopping for it, and when s/he finds that item in the first store (utilitarian value), it can be at a reduced price (hedonic value) (Carpenter and Moore, 2009).

Drawing from the discussion above, it could be stated that:

*H1: Customers who take advantage of sales offers will be more prone to have a utilitarian shopping motivation than a hedonic one.*

*H2: A tendency to utilitarian shopping motivation has a positive effect on (a) a propensity for shopping planning, (b) compliance with a prepared shopping plan during sales.*

According to Beatty and Ferrell (1998), impulsivity is the degree to which an individual can make unintended, spontaneous, and non-reflexive purchases with no pre-shopping intentions either to buy a specific product or to perform a specific purchasing task. Most customers at least occasionally make purchases on impulse, which is essential for marketers, since this is a form of purchasing action (Prashar et al, 2015).

Price is a crucial factor that affects an impulsive purchase. The number of unpredictable purchases increases if a person's mood rises at the sight of unexpected savings. According to Liao et al. (2009), customer's impulsive behavior is especially evident when they are offered an instant-reward promotion, such as a reduced price or free goods. Thus, the impact of sales promotion strategies is significant on buyers' impulsive purchases.

Another buying behavior is compulsive buying, which is defined as the consumer's tendency to be concerned about a purchase. It can be manifested through the lack of impulse control over the purchase or regularly recurring purchases (Ridgway, Kukar-Kinney and Monroe, 2008). These people cannot control this behavior (Mowen and Spears, 1999), and the aforementioned is often due to internal stress or problems in which buyers have little regard for financial, social, or personal consequences (Flight, Rountree and Beatty, 2012). Also, compulsive buying can be associated with shopaholic or excessive purchases (Lim et al., 2020).

Drawing from the discussion above, it could be stated that:

*H3: Customers who take advantage of sales offers will be more prone to have impulsive buying behavior than compulsive buying behavior.*

*H4: A tendency to impulsive buying behavior has a negative effect on (a) a propensity to plan purchases, (b) compliance with a prepared shopping plan during sales.*

### **2.3 Marketing literacy and marketing skepticism**

Marketing skepticism and marketing literacy is the most popular and discussed topic in recent years. It is confirmed by an increase in the number of publications in this area (Golovacheva, 2016). Research in the field of knowledge about persuasion usually focuses on two factors that affect the perception of marketing messages. The first factor comes from people's knowledge of attempts to persuade, and the second factor is the distrust felt for the marketing message, which is also often called skepticism (Isaac and Grayson, 2019).

The knowledge about marketing persuasion is the basis for the formation of marketing skepticism and marketing literacy of consumers. In research, marketing skepticism is defined as distrust, which is sometimes experienced by the customers concerning the market and marketing tools (Isaac and Grayson, 2019). According to Obermiller and Spangenberg (1998), the factors that shape skepticism can be very different such as social interactions, customers' experiences related to the market, or media comments and discussions about how people are affected by marketing and advertisement.

It has been found that people who are skeptical of advertising are conservative about it and less likely to be convinced. Fong Yee Chan (2019) proved that people with a low level of skepticism and perceived credibility of advertising could positively affect the results of product promotion. On the contrary, a high level of skepticism leads to a more negative perception of the brand in advertising since such buyers do not like it when they are intentionally manipulated or sold something.

Marketing literacy not only applies to people whose education or professional activities are related to marketing or those who have studied marketing closely at university and conducted research on it. Today, consumers who are familiar with the ideas, goals, and marketing methods and advertising also belong to the group of marketing-literate consumers. It was determined that the consumers' expression of skepticism about the techniques used by marketers and their confidence in evaluating advertising statements and making judgments is proof

that consumers are becoming literate in the field of marketing (Macdonald & Uncles, 2007).

Drawing from the discussion above, it could be stated that:

*H5: Customers with a low level of marketing skepticism will be more prone to make purchases during sales than customers with a high level of marketing skepticism.*

*H6: A low level of marketing skepticism has a positive effect on (a) the propensity to plan purchases, (b) compliance with a prepared shopping plan during sales.*

*H7: Customers with a high level of marketing literacy will be more prone to make purchases during sales than customers with a low level of marketing literacy.*

*H8: A high level of marketing literacy has a positive effect on (a) the propensity to plan purchases, (b) compliance with a prepared shopping plan during sales.*

## **2.4 Conceptual model**

Earlier we introduced a typology of sales based on the frequency of sales holding per year. We assume that the above effects (formulated in hypotheses) will also differ depending on the type of sale. Purchase planning and compliance with the purchase plan will be adjusted during sales, depending on the type of sale. These outcomes are based on indirect indications about planning purchases, which were found during the literature analysis. Thus, we can make the following proposition:

*P. The effects mentioned above (H1- H8) will differ depending on the type of sales.*

Based on the literature analysis and research hypotheses, a conceptual model of the current study was formed (Figure 2.1). Shopping planning and compliance with the purchase plan were divided into two resulting variables, which will be influenced by factors such as customers' hedonic and utilitarian shopping motivation, impulsive and compulsive buying behavior, marketing skepticism, and marketing literacy. Since we assume that the main effects will vary under the influence of different types of sales, we have been marked this influence with dashed lines.

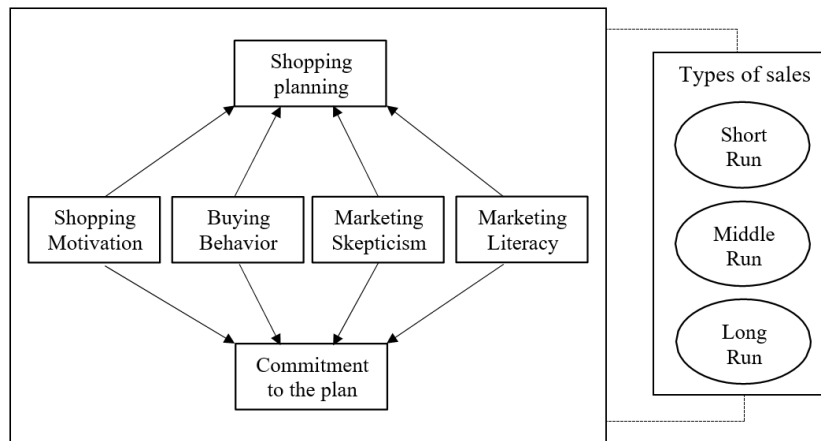

Figure 2.1 Conceptual model of the research

### 3 Empirical study

#### 3.1 Research organization

The empirical study was performed in a mixed format and consists of a qualitative and quantitative study. The qualitative study aimed to identify and confirm the factors that influence whether the customer will shop during short-, middle- and long-run sales and the process of planning purchases and compliance with the purchase plan during these types of sales. The quantitative study's objective was to identify the extent of the influence of factors that affect the behavior of buyers during the three types of sales identified at the stage of in-depth interviews.

As Study 1, a series of in-depth interviews were conducted to identify and confirm factors that determine the attitude and behavior of customers during sales periods. Black Friday sale was chosen as the main topic of the interview. Firstly, this sale was chosen as a "universal" sale, in which almost all Russian retailers participate and provide a different set of products at discounts. Secondly, this sale is not timed to any event or holiday and is designed to fit any category of customers. Thirdly, in-depth interviews were conducted in November 2019. In 2019, Black Friday in Russia was officially held for 3 days – from November 29 to December 1. Therefore, it was essential for us to understand how well Russian buyers are aware of this sale, whether they are going to take advantage of buying products at discounts and whether they are preparing for it by making a

shopping list. The respondents were selected from 18 to 55 years, as this category is not only the most active in terms of Internet use but also can independently make decisions about buying goods at sales. The interview guide included five groups of questions: (1) about different types of sales; (2) about Black Friday; (3) on taking advantage of discount offers during Black Friday the previous year (in 2018); (4) on taking advantage of discount offers during the upcoming Black Friday (in 2019); (5) specific questions for those who do not use discount offers during Black Friday sales.

As Study 2, an online survey was conducted. The survey was developed based on a conceptual research model and the results of in-depth interviews. The structured online questionnaire was used for the survey. The first part of the questionnaire was introductory and devoted to overall shopping planning behaviour and tendency to rely on discounts. The second part contained three sets of questions regarding shopping behaviour during short-, middle- and long-run sales. The third part of the questionnaire was based on scales from (Macdonald and Uncles, 2007) for (Obermiller and Spangenberg, 1998) for marketing scepticism and marketing literacy respectively, we also adopted impulsive/compulsive buying behaviour scales from (Flight, Rountree and Beatty, 2012) and shopping motivation scales from (Babin, Darden and Griffin, 1994). The questionnaire ended with socio-demographic questions. The data was collected in May 2020, and respondents were recruited among active users of two social online platforms popular in Russia according to "DIGITAL 2020: THE RUSSIAN FEDERATION" report, i.e. VK.com and Instagram (Datareportal, 2020).

### **3.2 Study 1. In-depth interviews**

The respondents were selected according to their personal desire to participate in the interview. All of them received a mini-questionnaire before the in-depth discussion, with questions that determined their age, marital status, having children, and their occupation. Respondents were chosen in such order that their age, marital status, and profession did not recur with other respondents to obtain the relevant information for the research.

A total of 13 respondents took part in the in-depth interviews. All interviews were recorded on a voice recorder with the verbal permission of the respondents. After that, the voice recordings were transcribed into written text based on which

the content analysis was performed. The results of content analysis are presented in the Figure 3.1.

Memory	<p>Most respondents participate in sales at least twice a year. However, they do not always remember when certain sales take place and react only to ads about them</p> <p>Most respondents do not remember what kind of impulsive purchases they made during the Black Friday sale</p>	<ul style="list-style-type: none"> <li>• "I participate four times per year, during seasonal sales, and such big sales as Black Friday and Cyber Monday."</li> <li>• "I do not remember, but it was probably some clothing..."</li> </ul>
Planning	<p>Some respondents were not going to shop without a pre-made list in the upcoming Black Friday sale</p> <p>Usually, respondents make a shopping plan of what they want to buy but do not adjust it to particular sales</p> <p>After completing the purchase plan, respondents can make additional "small" purchases</p>	<ul style="list-style-type: none"> <li>• "At the moment, I do not have a well-thought-out list of what I need. Although I might have looked at New Year's items or gifts, however, I think that if I go now without a list, I will spend more than planned on things that will later turn out to be unnecessary."</li> <li>• "I keep a list of what I need to buy, but it is not timed for sales..."</li> <li>• "When I was buying 3-5 shirts, I could buy a few extra ties that in non-sale periods I would have been unlikely to buy..."</li> </ul>
Attitude	<p>Respondents mentioned that they do not believe in Black Friday discount offers in Russia.</p> <p>Even though respondents are skeptical, they continue to monitor the prices of their favorite products on Black Friday sale.</p> <p>All respondents would recommend taking advantage of Black Friday discount offers for their friends because it can be profitable.</p>	<ul style="list-style-type: none"> <li>• "I feel more neutral emotions, closer to skepticism, because this event has gained popularity in Russia, there is a comment with which I agree that there cannot be quiet discounts of 70-80% for a group of some electrical equipment..."</li> <li>• "I really wanted LEGO, and I looked at the prices because I knew it would be Black Friday sale... Also, I followed the price of the cream that I use every day; maybe there will be a discount..."</li> <li>• "I will advise my friend to take advantage of discount offers during Black Friday sale because he can profitably buy the thing he likes."</li> </ul>

Figure 3.1 Findings from in-depth interviews

Thus, Study 1 confirmed shopping motivation, purchasing behavior, marketing skepticism, and marketing literacy among Russian buyers who make purchases at sales. It was also found that respondents remember many sales held by retailers, such as seasonal sales and regular sales, in addition to describing their shopping experience at the Black Friday sale. Based on these results and the literature review, a questionnaire for quantitative research was compiled.

### 3.3 Study 2. Online survey results

A sample of 553 responses was collected. After the screening we obtained a sample of 493 respondents. Sample profile is presented in Table 3.1.

In order to test the stated hypotheses first factor analysis was performed to check for validity and reliability of the scales utilised, as a result, utilitarian value and marketing literacy were divided into two factors each (see Table 3.2 for details). Further, an analysis was conducted for each type of sales, namely short-run, middle-run and long-run sales. A Mann-Whitney U-test, binary logistic regressions and multiple linear regressions were performed for each sale.

Table 3.1 Sample profile

Male 18.7%		Female 81.3%	
18–25 years old	31.6%	46–55 years old	18.5%
26–35 years old	20.5%	56–65 years old	5.3%
36–45 years old	23.1%	66–75 years old	1.0%
Secondary degree	3.9%	Unemployed	7.5%
Specialized secondary degree	7.3%	Students	21.3%
Incomplete higher degree	14.6%	Business workers	36.3%
Higher degree	72.2%	Budget institution workers	20.5%
Academic degree	2.0%	Entrepreneurs	8.7%
		Retirement	3.0%
Married	44.2%	No children	45.6%
Have a relationship	21.9%	1 child	26.2%
Single	21.5%	2 children	22.7%
Divorced	9.7%	3+ children	5.5%
Widowed	2.6%		
There is not enough money even for food			0.2%
There is enough money only to buy food			2.8%
There is enough money to buy food and clothing			47.1%
Buying durable goods does not cause difficulties			32.7%
There is enough money for a new car			12.2%
We have no financial difficulties			5.1%

Table 3.2 Scale reliability, and abbreviations further used in the analysis

Factors	CR	Alpha
Hedonic shopping motivation (HV)	0,913	0,914
Utilitarian shopping motivation associated with rational buying during shopping (UV1)	0,762	0,690
Utilitarian shopping motivation related to shopping productivity (UV2) ( <i>single item variable</i> )	N/a	N/a
Impulsive buying behavior (IB)	0,870	0,861
Compulsive buying behavior (CB)	0,797	0,750
Marketing skepticism (MS)	0,916	0,899
Marketing literacy concerning advertisement (ML1)	0,840	0,800
Marketing literacy demonstrated during shopping (ML2)	0,705	0,799

Based on the U-test results, buyers who take advantage of the **short-run sales** offers experience more shopping enjoyment during this type of sales than those who do not buy during these periods. Also, these buyers are less skeptical concerning commercials about upcoming sales or advertised products. Moreover,

buyers' level of marketing literacy is much higher than that of non-buyers at regular sales. These customers can find benefit deals while shopping. Linear regression results are shown on Figure 3.2. Summing up the results about short-run sales, there is a 55% probability that buyers will purchase products at regular sales. According to the analysis, they experience more pleasure from shopping with discounts during these sales, show less marketing skepticism about advertising. They are entirely marketing literate about shopping, which allows them to find the best price for the product and receive benefit offers.

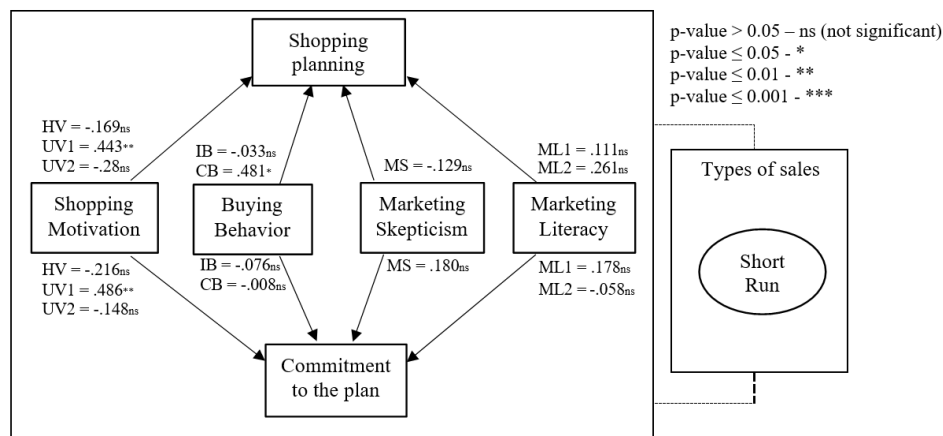

Figure 3.2 Model testing for short-run sales

For the **middle-run (or seasonal) sales**, there is a statistically significant difference between buyers and non-buyers in terms of hedonic shopping motivation, impulsive buying behavior, and marketing literacy regarding shopping. The U-test results showed that shoppers experience a higher level of shopping pleasure while shopping at seasonal sales. They are more likely to make unplanned purchases, and their level of marketing literacy regarding shopping is much higher than that of non-buyers. They know when most sales are held and can find the best price for the product. Linear regression results are shown on Figure 3.3. The analysis findings showed that, unlike non-buyers, buyers of seasonal sales experience the enjoyment of shopping and a tendency to unplanned purchases. They can find favorable offers for products during the seasonal sale, which shows their high level of marketing literacy regarding shopping.

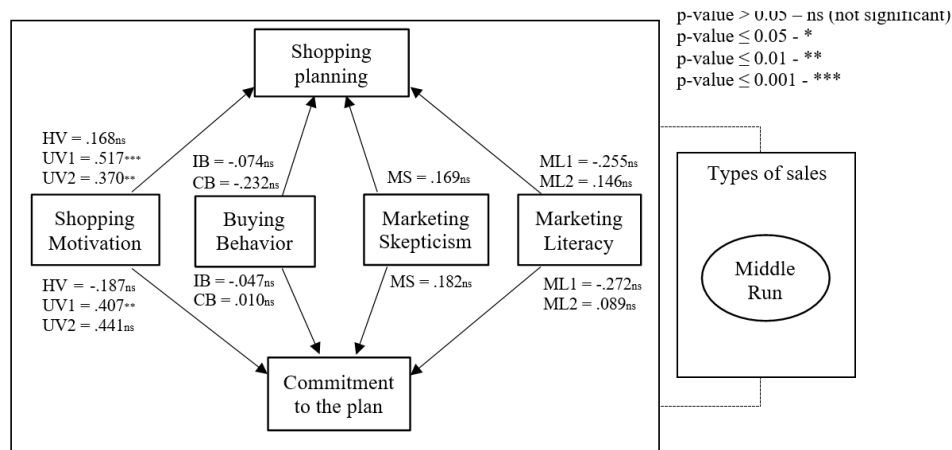

Figure 3.3 Model testing for middle-run sales

In case of the **long-run sales**, the U-test results showed that shoppers who use these sales are more likely to make unplanned purchases and more likely related to choosing the right product or brand at an attractive price. Their level of marketing literacy regarding shopping is much higher than that of non-buyers. They can find the best price for the product and make a profitable deal. Linear regression results are shown on Figure 3.4. It was found that buyers of these sales experience hedonic value from purchases and make more unplanned purchases under the influence of impulsive and compulsive purchasing behavior. Also, they are more marketing literate about shopping during these periods, in contrast to non-buyers. For buyers of event sales, unplanned purchases can happen on the spur-of-the-moment or depending on their emotional state. Despite this, they can find great deals and know when most sales are taking place. Utilitarian value influences the propensity to make a purchase plan, but at the same time, the hedonic value will be reduced. Following a shopping plan during event sales, customers are guided by the level of marketing literacy with the advertisement. They can determine the information provided by promotion. Additionally, utilitarian value has a role in the case of commitment, which is evident for such actions.

Overall, we may thus summarize that hypotheses 2 and 7 are fully supported, hypotheses 3, 5 and 8 are partially supported and hypotheses 1, 4 and 6 are not confirmed. The analysis results confirmed that shopping motivation, buying behavior, marketing skepticism, and marketing literacy have different extents of

influence during short-, middle- and long-run sales. Thus, the proposition made in this study can be confirmed.

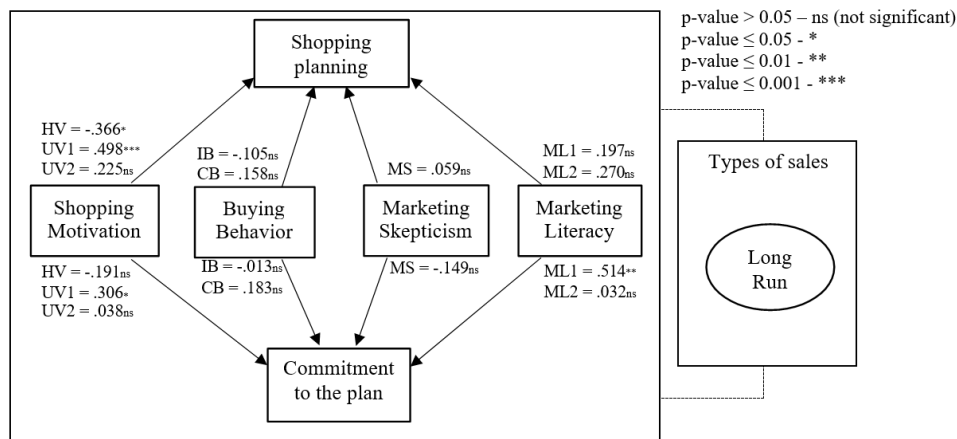

Figure 3.4 Model testing for long-run sales

#### 4 Conclusions and discussion

The results obtained are of interest to researchers and management practitioners to form a deeper understanding of consumers' behaviour during sales periods. As the results show, planning purchases for sales is a healthy choice of a rational buyer who wants to optimize the budget for everyday expenses. This research helps retailers understand how greatly shoppers plan their purchases and how fully they commit to their shopping plan during various types of sales.

Theoretically, the results of the current study contribute to an understanding of what are the behavioral patterns of customers' behavior that form the plan of purchases when it comes to sales.

As it was found, utilitarian shopping motivation affects the propensity to plan and comply with the shopping plan, which looks quite reasonable. Previously, other studies confirm that utilitarian value is acquired by completing a practical task (such as completing a shopping plan) (Babin, Darden and Griffin, 1994) and saving money (Chandon, Wansink and Laurent, 2000).

Also, shopping planning leads to a sense of convenience and smart shopper feeling, so this study confirms all the beforehand found results on utilitarian value by other researchers. It should be added that research conducted in the United States about Black Friday sale has determined that buyers receive hedonic and

utilitarian value when planning their purchases for this sale. The current study also confirmed that results that hedonic shopping motivation has its significance when customers plan their purchases (Lennon, Johnson and Lee, 2011).

It was found that the level of marketing skepticism does not affect the planning of purchases or compliance with the purchase plan. However, a statistically significant difference is observed between buyers and non-buyers of regular sales. Buyers who buy at this type of sale have a lower level of marketing skepticism than non-buyers. The same results were obtained in the study of Fong Yee Chan (2019), showing that people who have a positive attitude to advertising will be more likely to make purchases.

Moreover, since sales were classified into three types in this study, this typology can be used in further research and become a considerable contribution to the theory. In this paper, the proposition made that the effects of factors affecting buyers' shopping planning vary depending on the types of sales - were confirmed. Thus, this typology can be used for future researches and identify other differences between all market participants depending on the short-, middle- and long-run type of sale.

As for managerial implications, our findings can be used by retailers. According to the quantitative study, all buyers experience utilitarian shopping motivation during sales. However, the hedonic value is more substantial in shoppers who buy at sales than those who do not buy. Therefore, it makes sense for retailers to increase customer satisfaction by bringing them hedonic values. Moreover, hedonic motivation was also mentioned by respondents in in-depth interviews who said they enjoyed shopping during the holiday sales, as they are attracted to the beauty and festive atmosphere in stores.

Also, as the results of the analysis show, sales are a source of pleasure for customers, which is one of the factors of loyalty that affects the long-term relationship between the buyer and the retailer (Arnold & Reynolds, 2003). Therefore, retailers should not refuse to use promotions at all. They can initially include the cost of promotions in the product price that there will be an opportunity to reduce the price during sales periods.

If buyers and non-buyers of all three types of sales are compared, the less often the sale is held, the more unplanned purchases buyers make. Thus, buyers of seasonal sales tend to make purchases under the spur-of-the-moment, and buyers of event sales can not only buy under the influence of the situation but also because their emotional state pushes them to buy the product at a discount.

Therefore, retailers may consider event sales as a profitable opportunity to increase their sales.

In a regular type of sale, buyers show a lower level of marketing skepticism than those who do not buy. This may be related to a commercial that advertises regular sales or promotional goods. To attract new customers, it is necessary to reduce the level of marketing skepticism among those who do not buy at this type of sale. Retailers can do this by providing complete and truthful information about the benefits that customers can receive when choosing their store. Often, when conducting promo offers, it should be advertised not only a temporary price reduction of some goods but also the opportunity to get a gift, sweepstakes, etc. For example, if a customer purchases items in one store for a certain amount of money, they may receive a gift. In this case, the conditions for receiving additional goods for the purchase should be informative and explain clearly what kind of gift the buyer can get and on what conditions. It will help to reduce the level of marketing skepticism and attract new customers during regular sales.

Retailers may be offered a more technological approach to attracting customers to the store. Smart technologies allow the buyer to attract better and work more effectively for the benefit of the company. This way, retailers could use electronic price tags on their store shelves. It would be practical since it would allow retailers to quickly change prices for certain products or adjust them to a specific target group. Given all of the above, the results of the study can be applied by retailers and bring them significant benefits if implemented and maintained.

This study had some limitations that may be covered in future studies. The sample of the current research was significantly skewed towards female customers which may be due to the fact that stereotypically in the Russian culture women are responsible for family shopping. Future research could conduct in-depth comparisons of women's and men's shopping behaviour at sales, and examine their differences in planning their purchases and how they adhere to their shopping plan. Such results could provide new ways for retailers to attract target customers. Also, this study did not distinguish between purchases in an online store or a brick-and-mortar store. Further research may benefit from examining the relationships between shopping motivation, buying behaviour, marketing skepticism, and marketing literacy in both online and offline shopping. The research was carried out in May 2020 in Russia, amid the peak of the first

wave of COVID-19 pandemic and two months after the lockdown was announced. COVID-19 pandemic brought in a substantial amount of instability to customers everyday life which might have affected the judgements of the customers. Replication of the study and comparison with our results would shed light on possible effects of the pandemic on consumers' judgements related to shopping planning.

## Abstract

Food production represents today an environmental cost, boosting scientific community and food companies searching innovative solutions to reduce environmental impacts and wastes. Among all agri-food supply chains, 65% of global agricultural emissions of CO<sub>2</sub> equivalent are produced by livestock and connected activities. Dairy industry produces a multiplier effect of impacts, using a large amount of primary products to obtain relatively little quantity of cheese.

In this context, it is clear that food loss is not only a socio-economic problem, but also represents an additional environmental burden to be attributed to the production process. The adoption of circular economy strategies could represent the right way to reduce the issue of food waste and food losses, not only by reusing and/or recycling expired products but also extending the shelf life of edible products, that finally would mean reducing waste and increasing production efficiency (Stillitano et al., 2021).

However, the effort of adopting circular strategies risks to become vain if the degree of circularity achieved is not measured, so that a process of continuous improvement can be adopted in a circular design logic.

The aim of this study is to evaluate, from a circular, environmental and economic perspective, techniques for the shelf life extension (SLE) of Lacto-Fermented Mozzarella Cheese.

Life Cycle Assessment, Circularity Assessment and Life Cycle Costing methodologies were applied to evaluate the effects of SLE implementation, taking also into account the potential reduction of food loss and returned goods.

Results showed that despite a minimal increase of impacts and costs due to the introduction of the innovation, the SLE could allow reducing the share of losses up to 50%. Expressing results in terms of days of product shelf life, the innovative solution is more sustainable from both the environmental and the economic point of view and allows an improve

## 1 Introduction

Food represents the principal requirement for every biological activity of every organism, above all for human, who, in function of food resources, shaped the geographical conformation of the planet and influenced the history of humanity (Kiple and Ornelas, 2000; Diamond, 2002).

In a global scenario of exponential growth of the earth's population, food production system plays a continuous challenge to respond to food requirement of people, also providing an answer to other emerging needs linked to the food,

for example cultural or aesthetic ones (Notarnicola et al., 2017). The wild rush to produce ever larger quantities of ever better quality food, in particular in the rich countries, generated as a correlated issue the food losses, producing, according to FAO estimation, 1.3 billion of edible food wastes (Gustavsson et al., 2011; Corrado et al., 2017). Because of its close connection with natural ecosystems, the agrifood system, that represents the basis of food supply chain, can be defined as a syneresis of different economic activities which involve both natural processes managed by anthropic actions and industrial processes, fully under human control (Gulisano et al., 2018).

According to Garrone et al. (2016), food production, represents today an environmental cost, boosting scientific community and food companies searching innovative solutions to reduce environmental impacts and wastes. Food production sector is also recognised to be one of most impacting environmental sectors. About 65% of global agricultural emissions of CO<sub>2</sub> equivalent are produced by livestock and connected activities. The dairy industry produces a multiplier effect of impacts, using a large amount of primary products to make little quantity of cheese.

In this context, it is clear that food loss, in addition to being a socio-economic problem, represents an additional environmental burden to be attributed to the production process.

The adoption of circular economy strategies could represent the right way to reduce the issue of food waste and food losses, not only by reusing and/or recycling of expired products but also extending the shelf life of edible products thus reducing waste and thus increasing production efficiency (Stillitano et al., 2021).

However, the effort to adopt circular strategies risks becoming vain if the degree of circularity achieved is not measured, so that a process of continuous improvement can be adopted in a circular design thinking.

On the other hand, the modelling of circular strategies must necessarily take into account the environmental, economic and social impacts they produce, so that the sustainability of these strategies can be assessed.

According to the Ellen MacArthur Foundation (Goddin et al., 2019) the evaluation of circular strategies should be assessed considering as complementary elements of circularity other risk factors, such as environmental impacts resulting from the adoption of these strategies, proposing as reference methodologies those of life cycle thinking.

Life Cycle Assessment - LCA, Life Cycle Costing - LCC and Social Life Cycle Assessment – sLCA are the three reference tools for the assessment of the three pillars of sustainability: environmental, economic and social (De Luca et al., 2015).

These instruments used individually (eg. Nicolò et al., 2018; Strano et al., 2015; Iofrida et al., 2019) or in combination (De Luca et al., 2018) have been applied to the main agricultural and agri-food sectors, as well as for the evaluation of some circular strategies for the valorisation of production waste (Benalia et al., 2021).

The aim of this study is to evaluate, from a circular, environmental and economic perspective, techniques for the shelf life extension (SLE) of Lacto-Fermented Mozzarella Cheese.

Life Cycle Assessment, Circularity Assessment and Life Cycle Costing methodologies were applied to evaluate the effects of SLE implementation, taking also into account the potential reduction of food loss and returned goods.

## **2 Materials and methods**

### ***2.1 Case study description***

The object of analysis in this study is a new mozzarella cheese production technique that allows the shelf life of the product to be extended. The study represents a continuation of research presented in Falcone et al. (2017). The technique involves the use of an alternative governing liquid, so it is a solution that can be easily implemented in any dairy without new investment. The new technique has been tested in a firm located in Reggio Calabria, southern Italy, specialised in high quality cheese production. In particular, The lacto-fermented mozzarella cheeses were manufactured from cow's milk. About four mozzarella cheeses (weighting 125 g each) were then packaged in polypropylene trays with tap water (control) and an alternative governing liquid consisting of 0.6% calcium lactate (CL). The samples were stored at 5 °C and several microbiological and chemical-physical indexes were monitored to 18 days in order to assess the hygienic, physical, chemical and organoleptic quality characteristics of the product as its shelf life increases. All the analyses were conducted in triplicate and variance has been analysed through one-way ANOVA.

## **2.2 Environmental and economic assessment**

Once the technological feasibility of the innovative solution had been assessed, the sustainability of the innovative process was compared to the control scenario. The environmental analysis was made through the LCA methodology (ISO, 2006a and 2006b). The first methodological step concerned the definition of the functions of the system under study. Since the function of the system is linked to the production of high quality mozzarella, and since the latter is characterised by certain chemical, physical and organoleptic parameters, it was decided to evaluate the Shelf life of the product as Functional Unit (FU), understood as the time during which the product maintains its qualitative characteristics. So "1 day of shelf life of packaged product" was defined as FU, however, as the production function is a key aspect of any food production, the impacts were also assessed according to the mass produced, so "1 kg of packaged product" was chosen as secondary FU.

The study was extended from cradle to grave in order to include in the system boundaries also the unsold products (Figure 1) in accordance also with Gobbin et al. (2019) for the assessment of circularity.

Data were collected from different primary, secondary and tertiary sources. In particular data on upstream processes were directly collected from three different dairy farms which confer the milk to the cheese factory where the experimentation was made. Data on animal feeds composition were directly collected as well as data on feed production, water and energy consumption and waste production and treatment. Data on methane, ammonia, nitrogen and carbon dioxide emissions were taken from Agri-footprint (Blonk Agri-footprint BV, 2015) and Ecoinvent V3.3 (Frischknecht et al., 2007) database.

Data on core processes were directly collected from partner firm: energy use in the cheese factory were measured through Fluke 179 True RMS Digital Multimeter instruments; data on water use were measured through a Water Flow Meter and data on methane gas used for heating were measured through the Flow Meter installed to the plant.

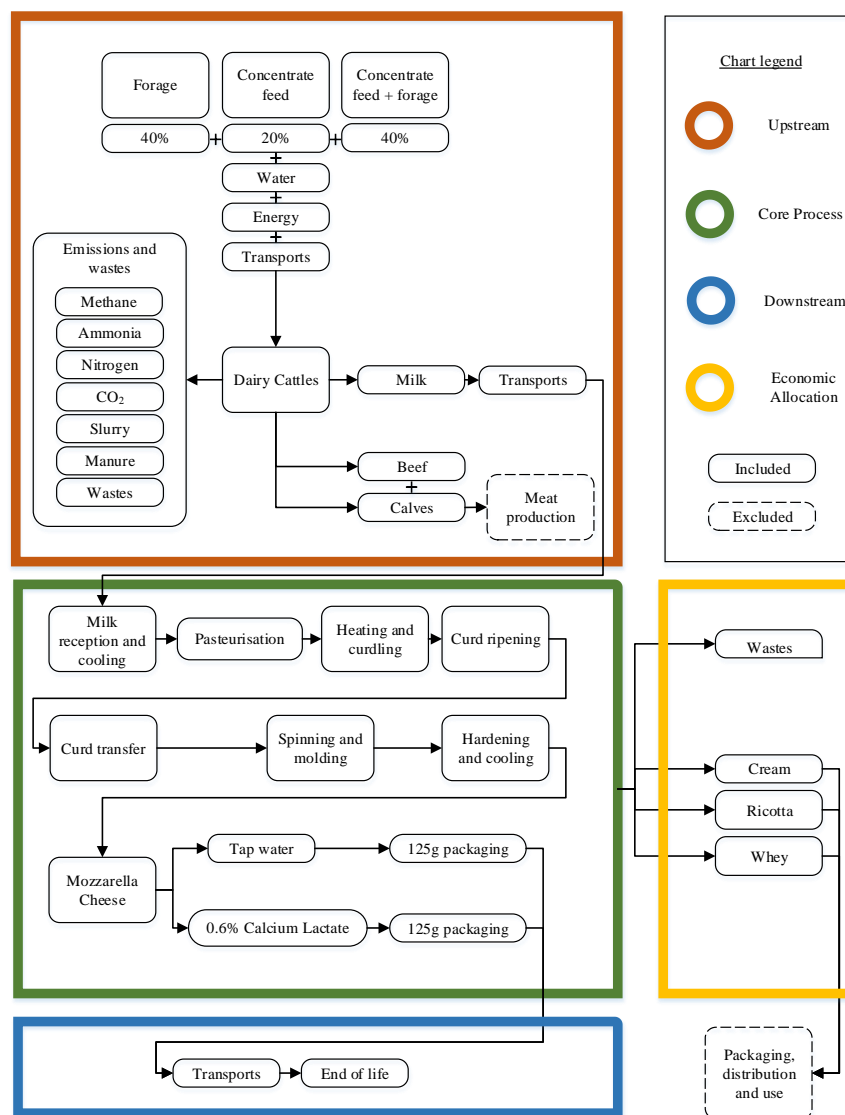

Figure 1: System boundary flow chart

Transports distances from cheese factory and selling locations were measured, and classified according to the typology of means of transport. Data on distance travelled by the final consumers were estimated. Wastewater treatment was included using the waste scenario included in Ecoinvent 3.3 and all the packaging was considered as waste disposed to the municipal landfill (both consumed and unsold ones). Input and output data from both dairy farms and cheese factory

were allocated in function of economic value of products (Thomassen et al., 2008). Data were processed through the ReCiPe midpoint impact method (Goedkoop et al., 2013).

Economic assessment was performed by Life Cycle Costing methodology following an approach LCA-based (Hunkeler et al., 2008) in which the same criteria described for LCA were used for LCC. All all material and energy inputs and outputs accounted for in the environmental analysis were monetised and some specific items of cost analysis were added to them, such as wages, the quotas and other duties, interests, land capital use and externalized services (Falcone et al., 2020). The computational framework proposed by Moreau and Weidema (2015) was implemented as described in Figure 2.

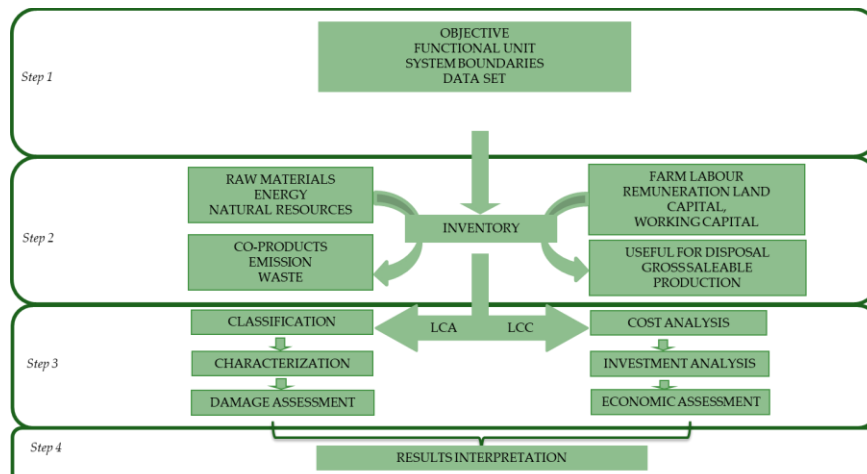

Figure 2. Methodological implementation  
(Source: Benalia et al., 2021)

The Added Value (AV) was determined for control and CL scenarios, by considering the same selling price for both. The cost related to the main FU determined per day of SL also considers the costs for unsold returned goods, as lost value (Buzby et al., 2014).

The circularity assessment was performed calculating the Material Circularity Indicator (MCI) by the Ellen MacArthur Foundation (Goddin et al., 2019) expressed by the following equation:

$$MCI_p = LFI-1 \cdot F(X)$$

where LFI represents the Linear Flow Index, i.e. the percentage of material flow originating from virgin sources and ending up as non-recoverable waste, while  $F(X)$  represents the utility factor of the linear component of material flows and is represented by the product of the intensity of use measure and the product life length.

For the calculation of circularity, it was considered that the whey obtained during cheese making is reused in dairy cow farming, representing a reused product share of 22%. This applies equally to both scenarios.

It was then considered that the product returned to the dairy can also be reused in animal feed (pig farming). This represents 9% of the realised product in the case of the control scenario and 3% of the realised product in the case of the CL scenario.

The utility factor was considered equal to 1 for the control scenario, while a Lifespan of 1.5x and a Functional Unit of 1.1x were considered for the CL scenario due to the longer shelf life and a higher amount of product being used (resulting in less loss). The MCI calculation was performed using the Dynamic Modelling Tool developed by the Ellen MacArthur Foundation and Granta Design Ltd.

### 3 Results and discussion

The results attested a shelf life extension of 6 days (+50%) in the mozzarella cheeses packed in 0.6% of Calcium Lactate (CL) solution ( $p < 0.05$ ) compared to the control scenario (12 days), with significant differences for the total microbial count, pH, NaCl% and textural properties. Analysing the findings related to the environmental impact of "1 day of shelf life of packaged product", the CL scenario resulted being better than the Control, with a ratio that overtakes the 45% (Table 1).

Table 1 – Characterisation of impacts per "1 day of shelf life of packaged product"

Impact category	Unità	Control	CL
Climate change	kg CO <sub>2</sub> eq	7.99E-01	5.36E-01
Ozone depletion	kg CFC-11 eq	4.58E-08	3.14E-08
Terrestrial acidification	kg SO <sub>2</sub> eq	9.92E-03	6.64E-03
Freshwater eutrophication	kg P eq	8.81E-05	5.91E-05
Marine eutrophication	kg N eq	2.16E-03	1.44E-03
Human toxicity	kg 1,4-DB eq	7.23E-02	4.88E-02
Photochemical oxidant formation	kg NMVOC	1.28E-03	8.93E-04

Particulate matter formation	kg PM10 eq	1.71E-03	1.15E-03
Terrestrial ecotoxicity	kg 1,4-DB eq	1.97E-03	1.31E-03
Freshwater ecotoxicity	kg 1,4-DB eq	4.92E-03	3.33E-03
Marine ecotoxicity	kg 1,4-DB eq	4.20E-03	2.85E-03
Ionising radiation	kBq U235 eq	3.07E-02	2.07E-02
Agricultural land occupation	m <sup>2</sup> a	3.64E-01	2.43E-01
Urban land occupation	m <sup>2</sup> a	6.21E-03	4.15E-03
Natural land transformation	m <sup>2</sup>	9.15E-04	6.11E-04
Water depletion	m <sup>3</sup>	2.42E-02	1.61E-02
Metal depletion	kg Fe eq	1.45E-02	9.77E-03
Fossil depletion	kg oil eq	1.19E-01	8.02E-02

The improvement over the control scenario can be attributed to each impact category and is easily explained by the significant shelf life extension generated by the new technology, which consists simply of adding calcium lactate to the governing liquid. The addition is very moderate and does not cause an environmental impact that would compromise the benefits generated by SLE.

This is easiest to understand when looking at the results for "1 kg of packaged product".

Figure 3 – Comparison of impacts per "1 day of shelf life of packaged product"

The improvement of the mozzarella shelf life corresponds, in fact, from an environmental point of view, to a minimal increase of impacts in all categories. However, this increase did not exceed the 1% (see the ratio CL/Control).

Table 2 – Characterisation of impacts per “1 kg of packaged product”

Impact Category	Unità	Control	CL	CL/Control
Climate Change	kg CO <sub>2</sub> eq	9.61E+00	9.63E+00	0.14%
Ozone Depletion	kg CFC-11 eq	5.21E-07	5.22E-07	0.33%
Terrestrial Acidification	kg SO <sub>2</sub> eq	1.18E-01	1.18E-01	0.05%
Freshwater Eutrophication	kg P eq	1.04E-03	1.04E-03	0.37%
Marine Eutrophication	kg N eq	2.58E-02	2.58E-02	0.04%

Photochemical Oxidant Formation	kg NMVOC	1.45E-02	1.45E-02	0.27%
Particulate Matter Formation	kg PM10 eq	2.00E-02	2.00E-02	0.12%
Terrestrial Ecotoxicity	kg 1,4-DB eq	2.36E-02	2.36E-02	0.01%
Freshwater Ecotoxicity	kg 1,4-DB eq	5.70E-02	5.71E-02	0.29%
Marine Ecotoxicity	kg 1,4-DB eq	4.85E-02	4.87E-02	0.34%
Ionising Radiation	kBq U235 eq	3.57E-01	3.58E-01	0.29%
Agricultural Land Occupation	m <sup>2</sup> a	4.37E+00	4.37E+00	0.01%
Urban Land Occupation	m <sup>2</sup> a	7.37E-02	7.37E-02	0.11%
Natural Land Transformation	m <sup>2</sup>	1.09E-02	1.09E-02	0.01%
Water Depletion	m <sup>3</sup>	2.91E-01	2.91E-01	0.08%
Metal Depletion	kg Fe eq	1.69E-01	1.70E-01	0.41%
Fossil Depletion	kg oil eq	1.51E+00	1.52E+00	0.37%

According with other studies (e.g. Falcone et al., 2017), milk production represents the most important hotspot, contributing for each impact category on average for the 50% of environmental burdens, whereas for Terrestrial Acidification, Marine Eutrophication, Terrestrial Ecotoxicity, Agricultural Land Occupation, Natural Land Transformation and Water Depletion generate over the 90% of total impact. However, according to Fantin et al. (2012), impact of milk production can vary effectively. For other impact categories as Ozone depletion, Urban land occupation and Fossil depletion transportations and energy used during cheese-making processes are the main causes of impact.

Also in term of costs, considering as FU “1 day of shelf life of packaged product”, the CL scenario achieves better results than Control one. The improvement corresponds to about 30% for all cost factors except the cost of returned products, which is 76% lower in the CL scenario. In fact, while for the control scenario the food loss is 9% by product weight, for the CL scenario it drops to 3% (Table 3).

Also from an economic perspective, milk represents the higher burden. Wages and packaging are also two important cost items, confirming the findings by Durham et al. (2015).

Table 3: Results of the economic analysis per “1 day of shelf life of packaged product”

<b>Cost factors</b>	<b>Control</b>	<b>CL</b>
Quotas and other duties	0.0559	0.0372
Milk	0.1604	0.1069
Rennet	0.0037	0.0025
Water	0.0013	0.0009
Electricity	0.0056	0.0037
Other energy sources	0.0377	0.0251
General cost	0.0013	0.0009
Wages	0.1153	0.0769
Externalized services	0.0103	0.0069
Packaging	0.0667	0.0648
Returned goods	0.0412	0.0098
Total	0.4994	0.3355

The analysis of results per kg of packaged product returns more obvious conclusions. In fact, the cost profile of two different scenarios differs only for the packaging, as the innovative solution is obviously more expensive (Table 4). The cost factor that tends to balance the results is the cost related to food losses represented as returned product, because, as already mentioned, the longer shelf life means that less food is lost. In this context, considering the same selling price for both solutions (6.5 €) the Control scenario had a higher added value (Figure 4).

Table 4: Results of the economic analysis per “1 kg of packaged product”

<b>Cost factors</b>	<b>Control</b>	<b>CL</b>
Quotas and other duties	0.6703	0.6703
Milk	1.9250	1.9250
Rennet	0.0443	0.0443
Water	0.0158	0.0158

Electricity	0.0668	0.0668
Other energy sources	0.4525	0.4525
General cost	0.0154	0.0154
Wages	1.3839	1.3839
Externalized services	0.1234	0.1234
Packaging	0.8003	1.1663
Returned goods	0.4948	0.1759
Total	5.9925	6.0396

Figure 4: Added value per "1 kg of packaged product" considering a selling price equal to 6.5€

The use of calcium lactate in the governing liquid corresponds, of course, to a higher production cost, however, the insignificant increase in cost generates a strong extension of the shelf life of the product. In this study, we have assumed that a 50% increase in shelf life generates a reduction of product loss of 9% to 3%, however, one could also consider a total reduction in food loss. In fact, considering a shelf life of 12 days, the company produces every other day and obtains a 9% waste, while with a shelf life of 18 days the company could produce every 3 or 4 days and bring the returned product to zero.

Evaluation of the circularity of the two scenarios returned an MCI of 0.24 for the Control scenario and 0.52 for the CL scenario.

The improved circularity performance of the CL scenario can be attributed primarily to the longer product life and greater intensity of use realized through increased shelf life (Figure 5).

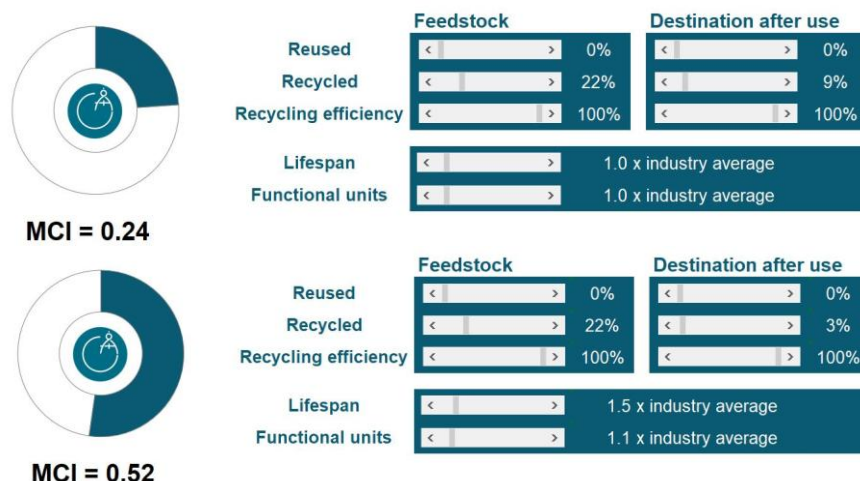

Figure 5: Circularity evaluation of Control (above) and CL (below) scenarios.

Regarding the percentage of resources deriving from reuse or recycling, there are no differences since the product differs only in the addition of a small quantity of calcium lactate in the governing liquid, which is however irrelevant for the purposes of calculating the MCI.

#### 4 Conclusions

The aim of this study was to assess how effective was a technological innovation to reduce food losses, from both an economic and an environmental point of view.

Using LCA and LCC methodologies, the technological innovation tested, based on a 0.6% calcium lactate solution, was compared with current technology in order to evaluate the effectiveness of the innovation.

It improved the shelf life of the product, lacto-fermented mozzarella, from 12 days to 18 days.

The innovation, with very small changes in the production process, does not require any investment, and generates both economic and environmental improvements without compromising product quality but helping to reduce product losses. Extending the useful life of the product allows its value to be maintained for longer, reducing product wastes and thus helping to make the production process more circular and mitigating the phenomena of increasing waste and food losses.

## Abstract

Due to COVID-19, telemedicine solutions, in general, have played a crucial role, with their ability to minimize physical physician-patient contacts, and to optimize healthcare system capacity, during demand surges, guaranteeing the taking in charge of the patients and the continuity of care.

The present study aims at investigating the feasibility and economic/organizational sustainability of an innovative telemedicine platform, as an example of telemonitoring care programs for patients with or without COVID-19, integrated with telerehabilitation and tele-supporting activities (whose name is T-CUBE), by addressing the following research questions: i) Which are the main benefits related to T-CUBE introduction in the clinical practice, from a clinical and an economic perspectives?; ii) Which are the key factors determining the intention to use T-CUBE in the clinical practice?

A Health Technology Assessment (HTA) was conducted in the year 2020, thus examining all the dimensions proposed by the Model for Assessment of Telemedicine (MAST), thus comparing T-CUBE implementation, with the usual care consisting of on-site monitoring and rehabilitative activities. The HTA was then integrated with an in-depth analysis of all the factors that could predict T-CUBE individual's acceptance, focusing on social and cognitive instrumental factors, and based on the Technology Acceptance Model framework.

Literature declared that telemonitoring and tele-supporting would improve the management of patients' with or without COVID-19, optimizing the care by detecting clinical deterioration at an early stage, caused both by COVID-19 or chronic cardiac or pulmonary diseases, thus also revealing a lower hospitalization rate, as well as a shorter length of stay with respect to usual care. Furthermore, the platform would lead to a reduction of 14.11% of rehabilitative hospitalization days, with a consequent increase in the overall accessibility to care (51.6%). From an economic perspective, considering 184,792 patients potentially treated with T-CUBE in Lombardy Region, an economic saving equal to 41% emerged on annual basis. With regard to T-CUBE acceptability, its intention to use is strictly dependent from its usefulness and ease of use perceived by the healthcare professionals involved, as well as by its capability to produce a relevant job and a high-quality output.

In conclusion, T-CUBE represents an ideal strategic leverage useful to manage the current pandemic emergency, thus being a relevant example in which digital technologies gives the possibility to solve a health problem in an efficient and effective way.

**Paper type** – Academic Research Paper

## 1 Introduction

COVID-19 pandemic, with the implementation of severe restrictions to better control the spread of the virus (McCloskey *et al.*, 2020), has severely impacted on healthcare services, requiring processes redesign to address deficits in quality of care and create more sustainable care processes. As a result, unique and innovative solutions are necessary to address both the critical and unmet needs of patients with COVID-19, but also of the other fragile patients, using healthcare services. In this view, people who are not infected with the COVID-19, especially those who are at greater risk of developing the disease, as well as those requiring a strict monitoring given their current chronic critical clinical conditions, should receive daily care without the risk of exposure to other patients in the hospital (Smith *et al.*, 2020).

In this respect, technological advances provide new options (Wax & Christina, 2020) due to COVID-19: telemedicine has played a crucial role, with its ability to minimize physical physician-patient contact, and to optimise healthcare system capacity during demand surges (Turolla *et al.*, 2020), guaranteeing the taking in charge of the patients and the continuity of care.

Any strategies, grounding on telemedicine services, digital technologies and artificial intelligence tools, have been a key part of the European and Italian response to this sudden health threat (Langabeer *et al.*, 2016; Lurie *et al.*, 2018), for the continuous monitoring of both COVID-19 patients and those who are not COVID-19 infected, but present chronic diseases.

Despite the relevance of the topic, many digital technologies have been only empirically proposed, without being effectively available for COVID-19 public-health response, in particular because of barriers to their implementation, including legal, ethical and privacy concerns, as well as organizational and workforce limitations (Budd *et al.*, 2020). In addition, recent literature has also highlighted significant challenges in deployment and scale-up, and limitations of clinical trials that are of varied quality and design (Piovani *et al.*, 2020; Murray *et al.*, 2020).

However, evidence of the effectiveness of any innovative technologies is needed for their wider adoption and implementation in the clinical practice: as the pandemic is ongoing, many digital technologies have not yet been peer-reviewed or undergone rigorous testing or been evaluated by digital evidence frameworks (IVB, 2019).

Although it is challenging, evaluation of the effectiveness of interventions is essential. Thus, in this paper, we propose the results deriving from the implementation of an innovative telemedicine platform as an example of telemonitoring care programs for patients with or without COVID-19, integrated with telerehabilitation and tele-supporting activities. This platform, whose name is T-CUBE, was designed to offer healthcare services and psychological support to people at home, using telemedicine solutions, to proactively monitor their health conditions, both after hospital discharge, during quarantine or isolation because of COVID-19 diagnosis infection, and in case of home isolation induced by the rules of social distancing for individuals needing continuity of care, even if they are not COVID-19 infected, but suffering from cardiac and pulmonary diseases.

Hence, the present study aims at investigating the feasibility and economic/organizational sustainability of the innovative platform T-CUBE, by addressing the following research questions: *i)* Which are the main benefits related to T-CUBE introduction in the clinical practice, from a clinical and an economic perspectives?; *ii)* Which are the key factors determining the intention to use T-CUBE in the clinical practice?

## **2 Methods**

For the achievement of the above mentioned two-fold objectives, a Health Technology Assessment (HTA) was conducted by means of the Model for the Assessment of Telemedicine – MAST (MethoTelemed Team, 2010), thus being the most acknowledged framework to be used for assessing tele-medicine solutions.

The assessment focused on the comparison between T-CUBE platform (based on tele-monitoring, tele-supporting and tele-rehabilitation activities) and the usual care, based on an on-site monitoring, supporting and rehabilitation activities.

Due to the multi-dimensional nature of the evaluation, the following aspects were deeply analysed: *i)* Health problem and application's characteristics; *ii)* Safety; *iii)* Clinical effectiveness; *iv)* Patient perspectives; *v)* Economic aspects; *vi)* Organisational aspects; *vii)* Socio-cultural, ethical and legal aspects, thus being consistent with MAST framework (MethoTelemed Team, 2010).

Three different methodological approaches were utilized for the deployment of the above dimensions.

1. Systematic literature review was carried out to collect evidence-based data with regard to the efficacy and the safety profile of using tele-monitoring, tele-supporting and tele-rehabilitation activities, with respect to the standard of care. In particular, the literature review was developed according to the following PICO (P: population; I: intervention; C: comparator; O: outcome) statements, being double because referring to two different Populations: on the one hand, literature review was conducted focusing on the chronic population not-infected with COVID-19; on the other hand, literature review was conducted focusing on the specific COVID-19 patients. For both populations, the "Intervention" was tele-supporting, tele-rehabilitation and tele-monitoring activities, that was compared to the "Comparator", represented by the standard usual care. The main Outcomes were hospitalities rate, number of hospital access, mortality rate and quality of life measures.
2. Health economics tools for the economic evaluation of both healthcare pathways and for understanding the ceasing/emerging costs related to T-CUBE were also considered. In this view, at first the economic evaluation of both pathways was conducted by means of an activity-based costing approach, thus collecting all the healthcare direct costs related to the proper taking-in-charge of the patients, according to real-life data derived from Lombardy Region (Northern Italy) database. Secondly, a budget impact analysis was developed, to understand the impact of T-CUBE technology within the specific Lombardy Region setting, according to the regional population potentially eligible to such innovative digital technology. The economic analysis was performed considering a time horizon of 12 months, and according to the Italian reimbursement tariffs of outpatients and hospital admissions, valid for the years 2020-2021.
3. Qualitative questionnaires, derived from the MAST model, were administered to all the healthcare professionals directly involved in T-CUBE use, thus retrieving their perceptions. The qualitative questionnaires were used for examining equity, social, legal and organizational aspects, considering a comparative approach of the two technologies under assessment (the presence or the absence of T-CUBE platform), in accordance with a 7-item Likert scale ranging from - 3 (less performant solution) to +3 (most performant solution).

In conclusions, the assessment of the MAST dimension was integrated with the analysis of the T-CUBE ecosystem acceptability, concerning the healthcare professionals' degree of T-CUBE intention to use, through Technology Acceptance Model – TAM2 core constructs (Davis, 1989; Venkatesh & Davis, 2000), thus being one of the most popular research models to predict use, person's intention to perform a particular behaviour, and acceptance of information systems and technology by individual users (Surendran, 2013; Nadri *et al.*, 2018).

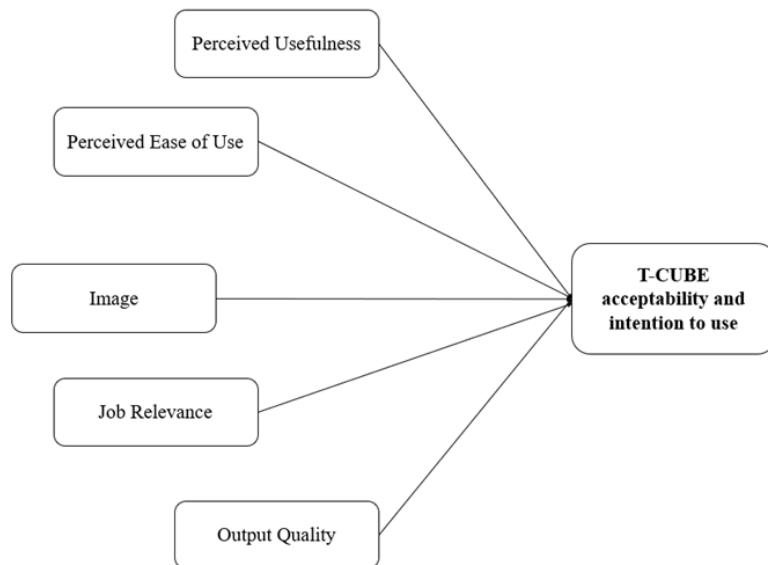

In this view, considering the importance of correctly assessing the impact of innovative healthcare technologies adoption on the existing clinical pathways, it is crucial to directly involve all the healthcare professionals in the ITs use (LeRouge *et al.*, 2007, Mantzana *et al.*, 2007). Despite the digital technologies' positive impact on the process efficiency improvement, their adoption is usually related to a professional resilience to change, because of digital technologies being perceived as disruptive innovations.

Based on the above, the following assumptions, derived from TAM 2 framework, were considered.

- Perceived usefulness has a positive impact on T-CUBE acceptability and intention to use (Davis, 1989; Holden *et al.*, 2010)
- Perceived ease of use has a positive impact on T-CUBE acceptability and intention to use (Davis, 1989; Bhattacharjee *et al.*, 2007)
- Image could have a positive impact on T-CUBE acceptability and intention to use (Venkatesh *et al.*, 2000; Holden *et al.*, 2010)
- Job relevance has a positive impact on T-CUBE acceptability and intention to use (Venkatesh *et al.*, 2000)
- Quality output has a positive impact on T-CUBE acceptability and intention to use (Venkatesh *et al.*, 2000; Yarbrough *et al.*, 2007).

In conclusion, for a more comprehensive framework, a set of control variables was investigated: i) healthcare professionals' gender; ii) healthcare professionals' working experience; iii) healthcare professionals' age; and iv) healthcare professionals' role.

A synthesis of the research framework is proposed in the following Figure 1.

*Figure 1 – Framework for assessing T-CUBE acceptability and intention to use*

Moving on from these premises, in October 2020, a qualitative questionnaire based on TAM2, was administered to clinicians, psychologists and rehabilitative professionals taking in charge both COVID-19 individuals and chronic patients, requiring strict monitoring and rehabilitative activities, in a rehabilitative research institute, normally working with chronic and fragile patients and currently using the innovative T-CUBE platform.

Besides the personal information related to each respondent (professional role, age, seniority and working experience) the questionnaire was composed by a qualitative section in which a 7-item Likert scale was implemented (7=completely agree; 1=completely disagree). In particular, the interview process aimed at getting the clinicians' insight concerning their intention to use the innovative technologies under assessment and the independent/moderator/control variables previously described that are perceived usefulness, perceived ease of use, image, quality output, and job relevance.

The above framework has been tested using inferential analyses, by means of a specific regression model, useful to define the main aspects useful to understand the factors impacting on such digital technology adoption in clinical practice. The Adjusted  $R^2$  was examined, in order to control the explanatory power of the model (Tabachnick and Fidell, 2007).

All the analyses were conducted using the Statistical Package for the Social Sciences (SPSS).

### 3 Results

#### 3.1 Results from literature review

As previously mentioned in the Methods Section, literature review was conducted according to the defined PICO and to the following search strategies, using different databases (Pubmed, Medline, Cochrane Database).

- “((NCDS) OR (NON COMMUNICABLE DISEASES) OR (chronic pulmonary diseases) OR (chronic lung diseases) OR (CHRONIC RESPIRATORY DISEASES) OR (post-COVID-19) OR (post-COVID) OR (post-SARS-COV-2) NOT (DIABETES) NOT (CANCER)) AND ((telerehabilitation) OR (tele supporting) OR (TELEMONITORING) OR (TELEMEDICINE)) AND ((USUAL CARE) OR (REHABILITATION) OR (AS IS SCENARIO)) AND ((QUALITY OF LIFE) OR (QOL) OR (COMPLICATIONS) OR (compliances) OR (PATHOLOGIES PROGRESSION) OR (DISEASE PROGRESSION) OR (ILLNESS PROGRESSION))” in order to collect evidence-based information with regard to the general chronic population, without COVID-19 infection.
- (“telemedicine”[MeSH Terms] OR “telemedicine”[All Fields] OR “mhealth”[All Fields]) AND COVID[All Fields] AND telemonitoring[All Fields]), in order to collect evidence-based information with regard COVID-19 infected patients.

The search for Mesh terms resulted in 181 records for the general chronic population, without COVID-19 infection and in 1,054 for the COVID-19 infected population. Out of them, only 16 and 21 were assessed for eligibility, respectively. In accordance with the above-mentioned search strategy and the PICO, only 13 articles met the inclusion criteria defined in the methodology section, focusing on the specific use of telemedicine services within the COVID population (Annis, 2020; Luwen, 2020; Martinez-Garcia *et al.*, 2020) or the chronic population not affected with COVID-19 (Hwang *et al.*, 2015; Chan *et al.*, 2016; Walker *et al.*, 2013; Franek, 2012; Gellis *et al.*, 2012; Martín-Lesende *et al.*, 2013; Hansen, 2020, Kessler *et al.*, 2018; Jodar Sanchez, 2013; Rehman *et al.*, 2017) comparing the innovative telemedicine solutions with the usual care.

The above scientific evidence was used to collect evidence-based information with regard to the efficacy and the safety profile of tele-monitoring, tele-supporting and tele-rehabilitation activities, compared to the usual care.

On the one hand, literature declared that telemonitoring and tele-supporting would improve the management of patients' with or without COVID-19, optimizing the care by detecting clinical deterioration at an early stage, caused both by COVID-19 or chronic cardiac or pulmonary diseases. A better perception of quality of life (48.4 versus 41.1) and fewer depression episodes (10.4 versus 18.7) were found in patients using tele-supporting activities (Gellis *et al.*, 2012).

Focusing on the chronic population not COVID-infected, but suffering from cardiac or pulmonary diseases, scientific evidence (Walker *et al.*, 2018) revealed a lower hospitalization rate for patients treated with telemonitoring for the worsening of their clinical conditions (79% versus 99%), as well as a shorter hospitalization stay with respect to usual care (1 day versus 4 days), on annual basis.

The same clinical benefits were found in COVID-19 patients: the use of telemedicine is associated with a hospitalization rate equal to 3.12% (Martinez-Garcia *et al.*, 2020), compared with 5.6% related to a condition in which such devices are not standardized (Italian Civil Protection Datawarehouse, 2020).

With regard to tele-rehabilitation, T-CUBE and usual care presented the same effectiveness and benefits for the patients (Chan *et al.*, 2016), thus presenting the same efficacy and safety profiles.

### **3.2 Results from the economic and organizational impacts**

From an economic perspective, the economic evaluation of both scenarios was conducted according to an activity-based costing approach on the basis of real-life Lombardy Region data. The following items of healthcare expenditure were deeply analysed and economically valorised: i) diagnostic and laboratory procedures; ii) drugs; iii) hospitalization; iv) rehabilitation activities; and v) specialist visits.

Table 1 reports the cost related to the management of COVID-19 or frail chronic patients (with or without COVID-19 infection), comparing T-CUBE implementation and usual care, in terms of clinical monitoring, rehabilitation and supporting activities, and considering the following populations:

- Currently COVID-19 patients.

- Post COVID-19 patients, in terms of negative patients, with a previous infection, requiring rehabilitation activities.
- Frail and Chronic patients, without COVID-19 infection.
- Frail and Chronic patients requiring an in-depth monitoring, without COVID-19 infection.
- Frail and Chronic patients, with COVID-19 infection.

Table 1 – Economic evaluation of the healthcare pathways

	COVID-patient (currently infected) Usual Care	COVID-patient (currently infected) T-CUBE	POST-COVID (COVID negative patients requiring rehabilitation) Usual Care	POST-COVID (COVID negative patients requiring rehabilitation) T-CUBE	Frail and Chronic patient, without COVID-19 infection - Usual Care	Frail and Chronic patient, without COVID-19 infection - T-CUBE	Frail and Chronic patient requiring an in-depth monitoring, without COVID-19 infection - Usual Care	Frail and Chronic patient requiring an in-depth monitoring, without COVID-19 infection - T-CUBE	Frail and Chronic patient, with COVID-19 infection - Usual Care	Frail and Chronic patient, with COVID-19 infection - T-CUBE
Clinical monitoring	295.88 €	444.94 €	- €	- €	- €	- €	2,113.03 €	1,731.65 €	2,408.91 €	2,784.55 €
Rehabilitation	- €	- €	4,331.48 €	993.32 €	2,066.22 €	1,085.83 €	- €	- €	- €	- €
Supporting Activities	137.74 €	40.64 €	137.74 €	40.64 €	92.79 €	48.35 €	92.79 €	48.35 €	230.53 €	89.00 €
<b>Total</b>	<b>433.62 €</b>	<b>485.58 €</b>	<b>4,469.22 €</b>	<b>1,033.96 €</b>	<b>2,159.01 €</b>	<b>1,134.18 €</b>	<b>2,205.82 €</b>	<b>1,780.00 €</b>	<b>2,639.44 €</b>	<b>2,873.55 €</b>
<b>Differences (%)</b>	<b>11.98%</b>		<b>-76.86%</b>		<b>-47.47%</b>		<b>-19.30%</b>		<b>8.87%</b>	

A budget impact analysis was then implemented to understand the impact of any innovative technology on the regional budget, thus defining the ceasing and the incremental costs related to its implementation, within a specific setting.

Considering 184,792 patients potentially treated with T-CUBE in Lombardy Region, an economic saving equal to 41% emerged on annual basis (Table 2). Despite marginal economic investment is required for T-CUBE adoption within the COVID-19 patients' management (+12%), significant advantages were reported in tele-rehabilitation activities devoted to negative patients (-77%).

Table 2 – Budget impact analysis

	COVID-patient (currently infected)	POST-COVID (COVID negative patients requiring rehabilitation)	Frail and Chronic patient, without COVID-19 infection	Frail and Chronic patient requiring an in-depth monitoring, without COVID-19 infection	Frail and Chronic patient, with COVID-19 infection	Total
<b>Number of regional patients</b>	81,024	23,136	33,426	45,926	1,280	184,792
<b>Total costs related to "Usual Care"</b>	35,133,626.88 €	103,399,873.9 2 €	72,167,068.26 €	101,304,489.3 2 €	3,378,483.20 €	315,383,542
<b>Total costs related to "T-CUBE introduction"</b>	39,343,633.92 €	23,921,698.56 €	37,911,100.68 €	81,748,280.00 €	3,678,144.00 €	186,602,857
<b>Difference (Euro)</b>	<b>4,210,007.04 €</b>	<b>- 79,478,175.3 6 €</b>	<b>- 34,255,967.5 8 €</b>	<b>- 19,556,209.3 2 €</b>	<b>299,660.80 €</b>	<b>- 128,780,684. 42 €</b>
<b>Difference (%)</b>	<b>11.98%</b>	<b>-76.86%</b>	<b>-47.47%</b>	<b>-19.30%</b>	<b>8.87%</b>	<b>-40.83%</b>

The above economic saving would also generate important organizational, social and environmental benefits, since T-CUBE would decrease the number of hospital visits and admissions, reducing the use of resources, optimizing healthcare organizational capacity. The platform would lead to a reduction of 14.11% of rehabilitative hospitalization days, with a consequent increase in the overall accessibility to care (51.6%).

With the decrease of hospital accesses, a significant social cost saving emerged: the potentially avoidable total cost by adopting telemedicine solutions could amount to € 14,858,731.33 € on annual basis. This would also result in an environmental benefit, in terms of CO2 emissions reductions (-3 thousand tons of CO2).

### **3.3 Results from the assessment of the qualitative MAST dimensions**

The analysis of the qualitative perceptions of the healthcare professionals involved (Table 3), considering a 7-item Likert Scale, ranging from – 3 to + 3, reported that T-CUBE platform presented higher values with regard to the social impact, as well as the equity impact, thus assuming the patients' perspective. T-

CUBE would be considered the preferable solution in particular because of its capability to decrease the patients' and the caregivers' productivity loss, due to fewer hospital accesses. On the other hand, T-CUBE would generate healthcare migration phenomena, thus being easily accessible at local level since it is based on telemedicine solutions.

From a legal perspective, legal efforts are required in particular with regard to the fulfilment of the safety requirements, as well as for regulating the use of such innovative platform.

In conclusions, from an organizational perspective, T-CUBE platform, at least in the short term, acquired a lower score than the usual care, since it required additional investments in training courses for all those who are involved in the procedure. Furthermore, an equipment updates is needed since T-CUBE grounds its application on telemedicine solutions. Despite the above drawbacks, T-CUBE implementation could significantly improve both the therapeutic and diagnostic pathway of COVID-19 infected patients and chronic patients requiring a strict monitoring and rehabilitative activities.

Table 3 – Qualitative perceptions (average values)

### 3.4 Results from the acceptability analysis

Table 4 demonstrates that T-CUBE acceptability and intention to use is strictly dependent from its usefulness ( $\beta=0.296$ ,  $p\text{-value}=0.003$ ) and ease of use ( $\beta=0.491$ ,  $p\text{-value}=0.021$ ) perceived by the healthcare professionals involved, as well as by its capability to produce a high-quality output ( $\beta=0.981$ ,  $p\text{-value}=0.016$ ), in terms of adequate care of patients, thus being the factors that most influence T-CUBE adoption in the routinely practice (Adjusted  $R^2=83.7\%$ ).

No statistically significant differences were found with regard to the seniority of the respondents, thus demonstrating that no digital divide exists. Furthermore, a negative relationship emerged between image and T-CUBE intention to use ( $\beta=-0.185$ ,  $p\text{-value}=0.035$ ). Healthcare professionals would not utilize T-CUBE for enhancing their "status symbol", but they voluntarily would use the innovative technology only if they are able to find a real usefulness and advantage for improving patients' health results.

#### 4 Conclusions

The use of telehealth has significantly improved the provision of health services during COVID-19 outbreak, with important consequence on hospital occupancy rate.

In this situation, remote diagnosis, treatment, and monitoring technologies have been used and developed in various countries with positive results. A Chinese study conducted on 4,589 COVID-19 patients (Liu *et al.*, 2020) who received remote diagnosis and treatment reported both a reduction in hospitals accessing and an improvement in symptoms and anxiety of patients, impacting at the same time the risks of overcrowding and contagion. An additional Spanish study, enrolling 313 patients, (Martinez-Garcia *et al.*, 2020) revealed the effectiveness in using a telemedicine approach in monitoring high-risk patients with COVID-19. A Brazilian retrospective study (Nascimento *et al.*, 2020) on 24,354 patients showed telemedicine was associated with a low rate of emergency room access and hospital admissions, suggesting a positive impact on the healthcare system.

According to the above, clinicians and patients are strongly recommended to apply telehealth tools as an appropriate option to prevent and contain COVID-19 infection.

As a result, T-CUBE has thus been created to monitor both COVID-19 patients as well as people who are not infected with the COVID-19, that should receive daily care without the risk of exposure to other patients in the hospital. Hence, the development of a monitoring decision-making algorithm, associated with the development of an integrated platform that allows the detection and recording of the vital parameters of patients, allows an efficient management of patients responding both to the need for safe care of patients and the need not to overload the hospital health system. In this view, due to the emergent occurrence of also depression and anxiety events (Xiong *et al.*, 2020), T-CUBE not only is based on tele-monitoring and tele-rehabilitation activities but could also offer tele-supporting services.

The results of the study have demonstrated that the sustainability of T-CUBE implementation of T-CUBE within the Lombardy Region setting, with important economic benefits, and an improvement in the overall accessibility to care for both COVID-19 infected patients and chronic population requiring a strict monitoring control. In this view, despite an initial investment in acquiring this platform, its routinely adoption would generate important economic savings, in particular for the proper management of frail patients (-47%) and COVID-19 negative patients requiring tele-monitoring and tele-rehabilitative activities (-77%). In addition, an improvement and an overall optimization of the patients' clinical pathway emerged, with important reduction in the onset of severe complications, thus also increasing the hospital admissions rate, freeing up economic and organizational resources that could be re-invested in taking in charge additional patients with important diseases to be managed.

On the other hand, once having demonstrated the efficacy and the sustainability of T-CUBE, it should be noted that its adoption would be accepted by all the healthcare professionals devoted to its use. To ensure the success of any digital technology, it is important to have the user's acceptance for that technology. Thus, healthcare professionals would effectively use the innovative platform T-CUBE, when it will be available, to guarantee the taking in charge and the continuity of care, for COVID-19 patients or chronic patients suffering from cardiac and pulmonary disease, both requiring tele-monitoring, tele-supporting

and tele-rehabilitative activities, thus promoting and improving the general wellbeing of the population.

In conclusion, T-Cube represents an ideal strategic leverage useful to manage the current pandemic emergency, thus being a relevant example in which digital technologies gives the possibility to solve a health problem in an efficient and effective way.

### Abstract

As a part of industrial revolution 4.0, digitalization has a major impact on organizational profitability and competitiveness (Viale and Zouari 2020). Digitalization is one of the biggest challenges organizations have been recently facing. Causing also organizations to respond to digitalization differently. Information technology plays a significant role in digitalizing organizational processes, also different automation solutions (Viale and Zouari 2020). Although RPA is a relatively new technology, it has recently gained a lot of attention among academia and industry (Gao et al. 2019; Cooper et al. 2019). Organizational management is getting increasingly interested in this new technological approach (Jimenez-Ramirez et al. 2019). While organisations have begun to implement RPA to improve process efficiency, the literature tends to examine this phenomenon from a technical perspective (Güner et al. 2020), instead of, for example, management perspective. The aim of this research is to study the required capabilities of RPA-based organizational value creation in the private healthcare sector, from an intellectual capital (IC) perspective. The practical outcome of this study will provide understanding of the IC components role

of capabilities of RPA utilization, that allow direct and indirect value creation in the private healthcare sector organizations.

The four evolution stages of IC (Secundo et al. 2017; Borin and Donato 2015; Dumay and Garanina 2013; Guthrie et al., 2012; Petty and Guthrie 2000) enriched by managerial data-driven approach (Secundo et al. 2017) are used as a framework to bring IC perspective. The research has been conducted by focusing on the enabling interest group, RPA consultants, having knowledge and experience in RPA implementations in organizations within different industries, also in the private healthcare sector. Several consulting companies in Finland were chosen for the study. This research was conducted using qualitative research methods and a case study research strategy. As an outcome, we will provide understanding on the role of IC components together with the required capabilities for RPA utilization and thus, value creation through examining different value functions in the private healthcare business industry. There are two practical outcomes of this study. First, this study will provide valuable information and understanding on the role of IC components together with capabilities required for RPA utilization in the private healthcare sector. Understanding what capabilities are required to use RPA efficiently would increase the ability of value creation in the private healthcare sector companies. Second, this study will provide information on the capabilities required for each value function.

## 1 Introduction

As a part of industrial revolution 4.0, digitalization has a major impact on organizational profitability and competitiveness (Viale and Zouari 2020). Digitalization is one of the biggest challenges organizations have been recently facing. Also, organizations respond to digitalization differently. Some of the companies are taking it top-down and developing a digital business strategy, whereas the others are focusing on uncoordinated digital initiatives to be developed ad hoc in local business functions (Osmundsen et al. 2019). Information technology plays a significant role in digitalizing organizational processes, also different automation solutions (Viale and Zouari 2020).

Even though RPA is a relatively new technology, it has recently gained a lot of attention, among both academia and industry (Gao et al. 2019; Cooper et al. 2019). Organizational management is getting more and more interested in this new technological approach (Jimenez-Ramirez et al. 2019). Even though organisations have begun to implement RPA to improve process efficiency, the literature tends to examine this phenomenon from a technical perspective (Güner

et al. 2020). Different RPA technologies are rather a part of so-called lightweight IT, than traditional or heavyweight IT (Osmundsen et al. 2019). During the last few years many organizations, especially in the Nordic countries, have implemented or considered different automations and robotics to enhance their business operations (Kedziora and Kiviranta 2018; Syeda et al. 2020; Cooper et al. 2019).

The aim of this research is to study the required capabilities of RPA-based organizational value creation in the private healthcare business industry. The purpose of the research is to understand the different combinations of capabilities of RPA utilization that allow direct and indirect value creation in the private healthcare sector organizations. We are especially interested in analyzing what are the capabilities in different value functions.

This study is putting together the required capabilities for RPA utilization and thus, value creation through examining different value functions in the private healthcare business industry. Understanding the potential of RPA utilization, and moreover the enabling capabilities, in enhancing organizational performance, can be considered important in private healthcare, but there are not many previous studies looking at this issue. By analyzing the capabilities that enable RPA utilization in the private healthcare industry sector, the research brings a significant novel value for the private healthcare sector companies, specifying the requirements for value creating RPA utilization. There are two practical outcomes of this study. First, this study will provide valuable information as well as deep understanding on the capabilities required for RPA utilization in the private healthcare sector. Understanding what capabilities are required to use RPA efficiently would increase the ability of value creation in the private healthcare sector companies. Second, this study will provide information on the capabilities required for each value function.

In the second chapter the aim is to show a conceptual basis for RPA, capability and value creation. Chapter 3 presents an empirical setting, introducing the methodology and empirical material. Chapter 4 is of showing the results of the presentation by answering to the interview themes, based on the modified Walter et al's (2001) by Ratia et al. (2018) framework, that can also be applied to evaluate value brought by RPA utilization. Finally, in chapter 5, the conclusions and discussion conclude the paper.

## **2 A holistic overview of RPA capabilities**

### ***2.1 RPA enhancing business processes***

Digitalization sets a growing challenge towards the traditional role of the central IT function (Osmundsen et al. 2019). The software-based business and workflow processes automation in the organizations has been an emerging trend during the past few years (Davenport and Kirby 2016). The software performs typical and relatively simple tasks of office workers (Osmundsen et al. 2019). The literature describes RPA as a combination of method, system, and tool, including computer software, to automate manual organizational processes (Fernandez and Aman 2018; Bataller et al. 2017). RPA, is a technology widely used in an automation process, being based on software and algorithms to enable automation or copying employers' action in the digital process and can replace human resource in performing a specific digital process. Also called as software robots, robot or digital workers, that are being used to underline the purpose of digitalizing the automation process (Lu et al. 2017; Willcocks et al. 2015a; Willcocks et al. 2015b; Lacity et al. 2015). So, basically RPA can be described as the automation of service tasks that were previously performed using human resources, enabling the automation of repeatable business processes, eliminating lower complexity tasks currently undertaken especially by back-office teams (Asquith and Horsman 2019; Osmundsen et al. 2019).

Even though RPA is roughly process automation, it has a few distinctive features that differ it from other automation tools. First, RPA can be configured easily, so implementing or using it does not require programming skills. Second, RPA software can be considered a non-invasive solution, so RPA software functionalities are applied on the top of existing systems, as the software is accessing systems in a human-like way. Thirdly, RPA is ideal for enterprise use, so, IT requirements such as security, scalability and auditability are easily met (Osmundsen et al. 2019; Lacity and Willcocks 2015). Even though significant cost savings can appear as well as agility and quality can be improved, not all processes are suitable for automation. The process has to be highly frequent, having a low level of exceptions, involving an enclosed cognitive scope and vulnerable to errors made by human resources (Jimenez-Ramirez et al. 2019).

When the process is digital, routine and requires a lot of human resources, utilization of RPA is justifiable (Lu et al. 2017). However, the process owner is

responsible to develop the process and initiate efforts for process improvement, also processes should be routinized and standardized, to be able to imitate human behaviour (Osmundsen et al. 2019; Güner et al. 2020). RPA is often used when using human resources is costly, inefficient or the amount of data to be processed is enormous (Lu et al. 2017; Güner et al. 2020). Organizations are seeking for effective solutions that can improve the quality of deliverables, enhance efficiency, help them to meet compliance requirements, make them more agile and improve customer experience, also being cost-efficient and easy to implement. RPA can be seen as one of the potential digital enablers (Kirchmer 2017; Güner et al. 2020). As there is still a lot of routine work in organizations, it is clear that as a technology, RPA is being found very interesting by the executives, especially in the industries with a lot of manual work and expensive labor, such as the private healthcare sector in Finland.

## *2.2 1 capability perspective*

Capability as a concept has several definitions, some of them being supplementary and some interchangeable. One of the available views towards capabilities, is organizational ability in implementing and utilizing available resources in organizational processes. Often, it is a combination of organization-specific information and different knowledge processes (Amit and Schoemaker 1993). The literature suggests different combinations of capabilities for a capability framework, for example human resources, technology and organizational processes (Cosic et al. 2015; Davenport and Harris 2007). Another approach is to group capabilities, forming strategy, social, technical, quality and impact -groups of capabilities (Cosic et al. 2015; Raber et al. 2012). In addition, other capabilities, such as governance, culture and people were mentioned. Also, a leadership aspect was added, or more specifically change management (Cosic et al. 2015). So, capabilities can be roughly described as a combination of different competences (Mikalef et al. 2018). Also, capabilities can be considered as a combination of organizational core resources that are under the control of the organization. Nevertheless, requiring strong and complex interactions between organizational resources and competencies to be able to build organizational capabilities (Amit and Schoemaker 1993; Mikalef et al. 2018).

As of their complex nature, capabilities are difficult to buy, and they have to be grown within the organization (Mikalef et al. 2018). However, even though organizational capabilities can be considered to be a puzzle to solve, the

competitive advantage brought to the organization can be significant. The right combination of required capabilities can create business value. For example leadership, technology, culture, process, data and talent capabilities can be mentioned (Cosic et al. 2015). So, successful RPA implementation is more than a technological capability approach but requires a holistic capability perspective to succeed in bringing business value to the organization. After all, the goal of RPA is not to disrupt existing enterprise softwares, but to digitalize or replace a manual process with an automated one (Viale and Zouari 2020).

### **2.3 Creating business value**

The concept of value creation is not novel either in academia or among business management practitioners. However, the concept itself is multilateral, with definitions that are rather complete that exclude each other (e.g. Ojala and Helander 2014). Often the concept of value or value creation, is being referred to in business discussions, leading to business value, consisting of several elements (Ojala and Helander 2014). There are several approaches to value creation framework. The literature suggests that value can be viewed from the perspective of trade-off between benefits and sacrifices, more specifically monetary and non-monetary ones (e.g., Ojala and Helander 2014; Hugos and Hulitzky 2011; Lapierre 2000). Monetary trade-offs could be for example productivity and resource utilizations, whereas non-monetary functions could for example different competence, position of organization on market, time and effort (e.g. Walter et al 2001; Ojala and Helander 2014; Myllärniemi and Helander 2012).

When it comes to RPA utilization, the suggested value could be monetary, such as increased efficiency in the organization, by reducing human labor in the routine business processes. However, some non-monetary functions also might appear, such as quality of the work, as fewer mistakes are made (e.g. (Ratia et al. 2018; Myllärniemi and Helander 2012). In this paper, as a framework for our analysis, we use Walter et al's (2001) model, modified by Ratia et al. (2018). The model introduces direct and indirect value functions, enabling measuring the created value in private healthcare. Whereas direct functions are way easier to measure financially, as being profit, volume and safeguard functions. Whereas indirect functions require the input outside of healthcare organizations, such as innovation, market, scout and access, and thus cannot be directly measured

financially. However, this model does not provide direct answers, but rather helps us to understand functions that can create value in the private healthcare sector.

Table 1. Direct and indirect RPA utilization value functions and their measurement in the private healthcare sector (based on Ratia et al. 2018 and Walter et al 2001)

<b>Value function</b>	<b>Description of the function</b>	<b>Measurement examples for private healthcare sector</b>
<b>DIRECT</b>		
Profit	The financial value of efficiency	<ul style="list-style-type: none"> <li>- Less manual administrative work</li> <li>- Less workforce needed</li> <li>- Expensive workforce, e.g., doctors can concentrate on value creation</li> </ul>
Volume	Amount of tasks performed	<ul style="list-style-type: none"> <li>- Scalability of work</li> <li>- Resource optimization between workforce and RPA</li> <li>- Volume of performed tasks</li> </ul>
Safeguard	Better service level	<ul style="list-style-type: none"> <li>- Better quality performance</li> <li>- Better customer service</li> </ul>
<b>INDIRECT</b>		
Development	Refocusing to development	<ul style="list-style-type: none"> <li>- Allowing to focus on development of process</li> <li>- Developing new ways of work</li> </ul>
Innovation	Creating new products and services	<ul style="list-style-type: none"> <li>- Creating new digital solutions and services internally and externally</li> </ul>
Scout	External sources	<ul style="list-style-type: none"> <li>- Utilization of RPA to collect information from external data sources</li> </ul>

Function-oriented value analysis shows that issues related to performance, optimization of workforce, scalability and better quality, were the main value creating functions within direct value functions. These were focusing on reducing manual work, optimizing expensive resources, scaling work and improving quality of performance. Whereas in terms of indirect value creation the focus was on development, innovations and utilizing external sources (Ratia et al. 2018).

Clearly, enhancing productivity and lowering costs seem to be one of the key drivers for RPA utilization. However, RPA utilization is more than a technological approach, but requires a holistic socio-technical approach that includes a combination of capabilities, enabling value creation. Furthermore, it is yet unclear what are the capabilities required.

### **3 Methods**

The purpose of this paper is to study the potential value of RPA utilization and required capabilities in the private healthcare sector. The study has been conducted by focusing on the enabling interest group, more specifically on RPA consultants. The targeted interest group was selected based on the results of previous research (Ratia and Myllärniemi 2017; Ratia et al. 2017), conducted from the point of view of business intelligence and business analytics (BI/BA) utilization and data-driven value creation. Just like other data-driven approaches, also RPA has enabled the potential for value creation in the private healthcare sector. As the capabilities required for RPA utilization have not been studied previously in the private healthcare organizations, the research is focusing on identifying the capabilities required for RPA utilization and thus, business value creation. By focusing on the interest group of RPA consultants, we enable the potential value of RPA enabled potential and its' enabling capabilities to emerge, showing the impact in the private healthcare organizations.

This research was conducted using qualitative research methods and a case study research strategy. To be more specific, multiple case research strategy was used, to enable studying complex and context-dependent research topics (Yin 2003). For this research in total eight RPA consultants, who were representing several different size RPA consulting companies that had operations in Finland, were chosen. The potential value enabled by RPA utilization was approached inductively with semi-structured, thematic interviews. Upon other methods, the qualitative research method was chosen, enabling explanations and understanding on the research questions, also allowing the adjusted questions and thus, gathering more information, than if used quantitative study. However, a semi-structured interview approach can be considered to be flexible and also, allowing gathering information effectively and conveniently (Qu and Dumay 2011).

The case organizations were a part of the technology consulting sector, and they were located all over Finland, having their consulting operations at least in RPA, some also in Business Intelligence or Business Analytics. Companies involved in this study were Finnish and international companies having permanent locations in Finland. These semi-structured thematic interviews were done by skype- and phone and were recorded and transcribed, so that they could be systematically organized and analyzed. These interviewees were technology consultants, moreover from RPA functions of their companies. The list of interviewees and their role in a company is described in Table 2.

Table 2. The list of interviewees and their roles in a company

Interviewee	Role
1	Consultant
2	Consultant
3	Consultant
4	Manager
5	Consultant
6	Consultant
7	Director
8	Consultant

The interviews were conducted during spring 2018. Themes of questions included introducing questions, follow-up and probing questions as well as specifying direct and indirect questions (Qu and Dumay 2011). However, none of the background related questions cannot be specified, to ensure anonymity of the interviewees. All of the interviews were carried out in a discursive atmosphere, however, including targeted discussion themes e.g. what is RPA, what benefits and value it brings to private healthcare, what kind of organizational processes can be automatized and what are the biggest challenges of RPA. In chapter 4 we analyze the result with modified Walter et al. 's framework (Ratia et al. 2018; Walter et al 2001).

#### 4 The value creating RPA capabilities

The primary objective of this paper is to study the potential value of RPA utilization and required capabilities in the private healthcare business industry. The data gathered from RPA consultants brought up two views of RPA

capabilities, the technological and the process ones. Nevertheless, the literature shows that there are also other capabilities that are required for business value creation (e.g., Cosic et al. 2015). However, the different descriptions of capabilities in the literature were not exclusive, but rather complementary, creating a holistic overview of capability perspective (e.g., Davenport and Harris 2007; Raber et al. 2012; Cosic et al. 2015). However, also, the value enabled by RPA utilization was multidimensional. Literature together with empirical research both suggest that there are several value creating benefits of RPA utilization, such as, increasing efficiency in organization by reducing human labor in the routine business processes, improving quality of the work as fewer mistakes are being made, and good scalability towards business processes (e.g. Ratia et al. 2018; Osmundsen et al. 2019; Güner et al. 2020). Being a highly scalable business technology solution, it is easy to implement in technical matters, as it does not require integrations etc., but is operating on top of existing software (Ratia et al. 2018; Osmundsen et al. 2019; Lacity and Willcocks 2015).

The following table shows, value that could be achieved by using RPA and capabilities required for that. The modifications to the measurements are done based on earlier research of the healthcare sector (Ratia et al. 2018; Myllärniemi and Helander 2012; Ratia and Myllärniemi 2017).

Table 3. Direct and indirect RPA utilization value functions and their measurement in the private healthcare sector along with suggested required capabilities (based on Ratia et al. 2018 and Walter et al 2001)

<b>Value function</b>	<b>Description of the function</b>	<b>Measurement examples for private healthcare sector</b>	<b>Capabilities</b>
<b>DIRECT</b>			
Profit	The financial value of efficiency	<ul style="list-style-type: none"> <li>- Less manual administrative work</li> <li>- Less workforce needed</li> <li>- Expensive workforce, e.g., doctors can concentrate on value creation</li> </ul>	Technology, leadership, process, talent
Volume	Amount of tasks performed	<ul style="list-style-type: none"> <li>- Scalability of work</li> <li>- Resource optimization between workforce and RPA</li> </ul>	Technology, process, governance, leadership

		- Volume of performed tasks	
Safeguard	Better service level	- Better quality performance - Better customer service	Leadership, culture, talent
<b>INDIRECT</b>			
Development	Refocusing to development	- Allowing to focus on development of process - Developing new ways of work	Process, culture, talent
Innovation	Creating new products and services	- Creating new digital solutions and services internally and externally	Technology, culture, talent
Scout	External sources	- Utilization of RPA to collect information from external data sources	Technology, data, talent

Function-oriented value analysis together with matching required capabilities, can show value that can be enabled using RPA in the private healthcare organizations.

This analysis of the value functions showed that issues related to performance, optimization of workforce, scalability and better quality, were the key players, when creating value through direct value functions, requiring technology, leadership, process, talent, governance and culture capabilities. So, direct value can be reducing manual work, optimizing expensive resources, scaling work and improving quality of performance.

When discussing the indirect value, the primary focus areas are development, innovations and utilizing external sources, as new and innovative ways to create value, requiring process, culture, talent, technology and data capabilities. As an example, an indirect innovation function can enable creation of new digital products and services, both internally and externally, creating value using RPA. However, this model is not an absolute and exhaustive list of value-creating functions, but rather helps us to understand the activities and functions enabling RPA based value creation in the private healthcare sector.

Also, some managerial implications could be drawn, as a result of this research. First, to enable the benefits in automation of routine business processes, such as administrative routine work, for e.g., HR and finance processes and simple customer service activities, several capabilities, such as technology, leadership, process and talent capabilities are required. Second, when utilization RPA brings value by enabling clinical staff to focus more on the patient or customer, for e.g., in visit records management, where inputting multiple records is being outsourced to be performed using RPA and doctors and nurses have more time for the patient or customer, it requires technology, process, governance and leadership capabilities. Third, it can create new products or services that can bring value, requiring technology, culture, talent and data capabilities. As a summary, value creation, utilizing RPA in the private healthcare sector, requires a combination of several capabilities to succeed.

## **5 Conclusions**

This paper is introducing a fairly novel approach of capability development in discussion of RPA utilization in the private healthcare business industry. As digitalization is one of the most significant challenges organizations have been recently facing, organizations tend to approach it top-down and develop a digital business strategy or focusing on uncoordinated digital initiatives to be developed ad hoc in local business functions (Osmundsen et al. 2019). The role of information technology has expanded in digitalizing organizational processes and in different automation solutions (Viale and Zouari 2020). The significance of automation and digitalization of business processes has been also timely in the private healthcare organizations. However, aiming to gain business value out of their automation practices (Ratia et al. 2018). We analyzed the required capabilities for RPA enabled value creation through Walter et al's (2001) framework modified by Ratia et al. (2018), to gain better understanding of direct and indirect value functions in the context of the private healthcare in Finland capabilities required.

This research is putting together the capabilities required for RPA utilization and value creating functions in the private healthcare business industry in Finland. The automation potential, especially RPA utilization, in enhancing operational excellence, can be seen as a considerable opportunity in digitalization of business processes in the private healthcare, for e.g., by reducing cost and enhancing

financial performance of the organization (e.g. Ratia et al. 2018; Fernandez and Aman 2018; Kirchmer 2017). By analyzing the required capabilities of RPA utilization in the private healthcare industry, the research brings a significant novel value for the private healthcare sector companies, specifying the required capabilities and value creating functions enabled by RPA. Clearly, RPA utilization can bring value to organization, as literature review and empirical research both showed, but requiring a combination of capabilities that enable value creation. As of direct value, the main examples can be considered to be financial value of efficiency, such as reduction of manual administrative work and allowing medical staff to concentrate more on patient work and thus, value creation, requiring several capabilities, such as technology, leadership, process and talent. Whereas indirect value appearing in the empirical study was focusing on development and innovations as well as utilizing external sources, requiring technology, data, talent and culture capabilities. However, indirect value functions allow private healthcare organizations to seek for new and innovative ways to create business value, such as enabling creation of new digital products and services.

There are two practical outcomes of this study. The first outcome of this study will provide valuable information as well as deep understanding on the potential of RPA in value creation of the private healthcare sector, as digitalization is one of the most significant challenges organizations have been recently facing (Osmundsen et al. 2019). Also, the healthcare sector is seeking for new opportunities to increase quality of their operations and reduce their costs to enable maximization of created value (Laurenza et al. 2018). The second outcome of this research will provide understanding on capabilities enabling RPA driven value creation. But, in order to get a more in-depth perspective on this issue, we need to gather more empirical data from the RPA consulting organizations. Also, we need to study more from the private healthcare organizations perspective, on different organizational levels, to be able to point out the relevance of RPA utilization in the value creation process.

### **Abstract**

Several studies have suggested that collaborative-based approaches are relevant to attain sustainability related goals in the Agri-food sector. These approaches take on even more significance in the light of the opportunities offered by the so-called *circular economy*, through innovative technologies and profitable business models based on the exploitation of agricultural wastes, byproducts and unsold products. The role of circular-based methods in conciliating social, environmental and economic objectives in the Agri-food sector is emphasized in several works, with a particular focus on approaches aimed at promoting rational use of resources and reducing food loss and waste. In this sense, Circular Economy represents an emerging and promising approach to manage the socioeconomic-growth of Agri-food Networks.

Starting from these considerations, the analysis of organizational and business models based on collaborative approaches as a tool for value chains creation in the agri-food sector seems to be a promising field to be explored. Unfortunately, the state-of-the-art picture of this field of study still appears fragmented and no specific model to design collaborative-based initiative in food sustainable chains are available. Thus, we analysed in depth the literature landscape of collaborative networks supporting the sustainable development through circular economy-based approaches in the agri-food sector, by means of a systematic literature review. Results of our systematic literature review led to the identification of a modelling framework consisting in four main elements, namely *Network structure, Participants behavior, Supply Chain Processes, Supporting tools, methods, and technologies*. We adopted this modelling framework to design a real experience of collaborative network based on the circular economy paradigm in the agri-food sector, namely MEC – Marketplace Ecosostenibile Calabria.

## 1 Introduction

Agri-Food is an industry where sustainability related issues are more evident and pressing (Krishnan et al., 2020). This is mainly due to factors as the overexploitation of natural resources, the strong dependence of rural communities on food production, the changes in consumers' needs, and the bargaining power of big players of large-scale distribution (León-Bravo et al., 2017). To face these economical, societal and environmental challenges, agri-food companies are addressing their choices towards process and organizational investments in sustainable innovation (Nazzaro et al., 2020). Several studies have suggested that collaborative-based approaches can make the difference towards the attainment of sustainability related goals (Ramanathan et al., 2014). Collaborative Networks paradigm in the Agri-food sector are characterized by a re-connection among producers and consumers and the re-vitalisation of territory identity, in order to offer agri-food companies the opportunity to return in taking an active role in the agri-food system, improving their revenue streams and developing new market niches (Volpentesta and Ammirato, 2013). These approaches take on even more significance in the light of the opportunities offered by the so-called circular economy, through innovative technologies and profitable business models based on the exploitation of agricultural wastes, byproducts and unsold products (Toop et al., 2017). Collaboration among

organizations in the Agri-food sector is considered mandatory for rural communities to achieve sustainability goals, since companies along the supply chain pursue different objectives, often conflicting with each other (Manteghi et al., 2021). The role of circular-based methods in conciliating social, environmental and economic objectives in the Agri-food sector is emphasized in several works, with a particular focus on approaches aimed at promoting rational use of resources and reducing food loss and waste (Principato et al., 2019). In this sense, Circular Economy represents an emerging and promising approach to manage the socioeconomic-growth of Agri-food Networks.

Starting from these considerations, the analysis of organizational and business models based on collaborative approaches as a tool for value chains creation in the agri-food sector seems to be a promising field to be explored. Unfortunately, the state-of-the-art picture of this field of study still appears fragmented and no specific model to design collaborative-based initiative in food sustainable chains are available.

In order to fill this gap, we analysed in depth the literature landscape of collaborative networks supporting the sustainable development through circular economy-based approaches in the agri-food sector, by means of a systematic literature review (Denyer & Tranfield, 2009). Results of our systematic literature review led to the identification of a modelling framework that was adopted as a base to design a real experience of collaborative network based on the circular economy paradigm in the agri-food sector, namely MEC – Marketplace Ecosostenibile Calabria.

## **2 A literature review on sustainable agri-food supply chains**

According to the methodological framework proposed by Denyer and Tranfield (2009), we carried out a systematic literature review to provide a complete, exhaustive summary of relevant literature addressing the characteristics of sustainable agri-food supply chains. We selected Scopus and Web of Science (WoS) as scientific databases where to perform our search. We defined two sets of keywords including, , terms related to the sustainability field of study and terms related to organizational approaches for agri-food supply chains, respectively. The search results must contain at least one keyword for each set. We limited our search to research works published in journal indexed on the following subject areas: "Business, Management and Accounting; Decision

Sciences; Economics, Econometrics and Finance". At the end of this process, we obtained a final set P of 287 papers.

We carried out a quantitative analysis based on the Latent Dirichlet Allocation (LDA) in order to identify main topics. The process led to the identification of four topics. Then, we carried out a human-based review of representative and relevant papers, to provide a meaningful description of each topic. In order to select relevant papers, we followed suggestions provided in Ammirato et al., (2020): we selected papers with a topic proportion value of 0,25 or higher that were published in journals ranked with a ISI Impact Factor greater than 0,7.

**Supply-chain governance.** Some works addressed the definition of governance rules, policies and principles driving the behavior of members in agri-food supply chains. The definition of appropriate policies aiming to govern the behavior of the members within an agri-food supply chains is fundamental to reduce their opportunistic and individualistic behavior (Schuster and Maertens, 2013). In this context, standards for food safety and quality have a huge impact on internal organization of firms, the organization of the whole supply chain, the distribution of profits and the welfare of all stakeholders (Hammoudi et al., 2009).

Another relevant aspect influencing supply-chain governance deals with transparency and trust along the food supply chain (Qu and Yang, 2015). The last decades' strive towards ecologically and socially sound supply chains emphasize the role of trust as an important asset in an exchange relationship between food supply chain members and between supply chain and consumers (Leon-Bravo et al., 2017).

**Organizational structure.** Several papers emphasized the need of coordination and collaboration in agri-food supply chains. This is mainly due to the high dynamicity of the food industry and the need to face sustainability challenges (Wiengarten et al., 2012). Some works systematized collaborative approaches based on territorial embeddedness and reconnection with consumers (Volpentesta et al., 2013, Sacchi et al., 2019). Such initiatives have been labelled either as Alternative Food Networks or Short Food Supply Chains (Mardsen et al., 2000).

Other studies faced the impact of the intensity of collaboration (i.e., the mutual engagement of participants) on agri-food supply chain operations (Marqui et al., 2013). Several authors (Moharana et al., 2012; Volpentesta and Ammirato, 2013) agree that collaboration in agri-food supply chains can be classified in four coalition types, ranging from a purely transactional approach to a long-term

partnership. As the level of integration among supply chain members increases, it increases the amount of common goal-oriented risk taking, commitment, and resources that participants must invest into the joint endeavor (Camarinha-Matos and Afsarmanesh, 2008). This implies mutual trust and thus takes time, effort and dedication of participants towards the achievement of shared goals.

**Actors and roles.** Some works are devoted to the identification of actors and the definition of roles within sustainable food chains. Sustainability issues in food supply chains call for integrative approaches including several types of partners, stakeholders and consumers (Singh et al., 2018). Successful experiences of sustainable food supply chains highlight the importance of identifying right participants in a collaborative setting (Sarpong, 2014). Volpentesta and Ammirato (2013) defined main actors and roles needed to build up an alternative agri-food network. The number and the type of participants depends on the strategic objectives of the networks, the competence needed to carry out network activities and the specific characteristics of the supply chain (e.g., fresh vs. processed food). Besides typical players that characterize food supply chain (e.g., growers, food processors, logistics service suppliers, retailers, and specialty shops), sustainable collaborative networks are characterized by the presence of trusted third parties able to manage typical issues in bottom-up networks. These entities usually play an intermediate role among networks members, as collaboration catalyst, technology intermediary and guarantee authority.

**Agri-food supply chain digitalisation.** Digitalisation led to a new phase in sustainable agri-food supply chains. A wide range of literature on the role of ICTs applications addressing several issues of agri-food chains, e.g., data monitoring (Coley et al., 2011), precision agriculture (Van Evert et al., 2017), traceability (Accorsi et al., 2018). Digital based solutions allow the monitoring of food supply chain more efficient, reducing delivery time, costs and waste due to food products expiring warehouses (Jagtap and Rahimifard, 2019) representing a suitable tool to make the supply chain capable of quick response and performance improvement (Thöni and Tjoa, 2017). Supply chain's actors can communicate at a faster rate, reducing variability and uncertainty in the system (Kataike et al., 2019). Recently, the adoption of electronic grocery (e-grocery) platform among food consumers is gaining momentum. Several benefits, such as shopping convenience, time savings, as well as 24-hour accessibility to a wide variety of products and virtual stores contribute in making the popularity of e-grocery platform increasing (Caniato et al., 2017). However, the real jolt to the

food distribution industry came from the COVID-19 pandemic that radically changed the way consumers approach food shopping (Ellison et al., 2021).

The critical reading of the results of our systematic literature review led to the identification of four topics that, from an operational perspective, represent main aspects characterizing organizational and business features of sustainable collaborative networks in the Agri-food sector. This framework represents a useful tool to characterize the foundational aspects, principles, and practices of Sustainable Collaborative Networks and thus can be useful to help practitioners in the analysis and design of Sustainable Supply Chains in the Agri-food sector.

Many works highlighted limiting and enabling context factors potentially affecting the establishment and performance of agri-food supply chain initiatives. In these studies, authors agree that the ambition of having a universal organisational model that is valid for any reference territory is almost unreal. We found that successful cases of sustainable agri-food supply chains strictly depends on the cultural, social and economic characteristics of a territory (Knickel et al. 2008). In order to taking into account economic, social and technological factors characterising a specific regional area, we identified some constrains whose satisfaction is necessary for the establishment of a sustainable agri-food chain:

- presence of a high number of agri-food companies aiming to overcome the large retail scale and directly control an alternative distribution channel;
- presence of a community of potential consumers manifesting the need to purchase local and 'secured' agri-food products;
- emergence of interorganizational relationships characterised by trustworthiness, fine-grained knowledge transfer and joint problem-solving arrangements.

### **3 A case Study: MEC - Marketplace Ecosostenibile Calabria**

In what follows we provide an application of the proposed modelling framework, as emerged from the literature review, to design a real experience of collaborative network based on the circular economy paradigm in the agri-food sector, namely *MEC – Marketplace Ecosostenibile Calabria*.

Calabria is a southern Italy region with socio-economic problems that are broadly characterised by geographical remoteness, low population density, low

income levels, limited employment opportunities, dependency on agriculture, poor service provision, poor development capacities. The region is very rich of agrifood products which are strictly connected to the territory. Most of them have characteristics which fit the nine attributes identifying a 'typical product' connotation: territory, commodity economics, legal regulation, industrial nature, time, tradition, specificity, identity and nutritional surplus (Volpentesta and Ammirato, 2013). In particular, the Metropolitan City of Reggio Calabria is a province located in the extreme southern tip of mainland Italy, accounting a population of over 550.000 inhabitants. Among the list of typical food products indexed by Italian Minister of Agriculture, the Metropolitan City of Reggio Calabria accounts for a total of 195 typical food product. According to Cafiero et al. (2020), 89 out 195 of those products are hosted only in the province of Reggio Calabria. In that area, traditional foods are mainly produced by small-sized producers who rarely engage with others in pursuing joint marketing activities. Most of their products are secured by Protected Designation of Origin and Protected Geographical Indication status for typical regional food; all of them belonging to the sectors wine, olive, fruit and vegetable and dairy productions.

The above socioeconomic scenario satisfies the constraints listed in Section 2. For this reason, the Calabria Region and in particular the Metropolitan City of Reggio Calabria was selected to develop the MISE funded project MEC.

### ***3.1 Towards a multi-side platform for MEC Network***

In what follows we aim to define the business and governance model of a multi-side platform providing a value proposition to the actors belonging to the MEC network. The definition of such a platform takes into account the four elements identified in the previous section, namely: actors and roles, supply-chain governance, organizational structure, digital platform.

On the one side, the platform provides value to agricultural producers (e.g., direct farmers) and food processing and distribution companies. MEC supports agri-food companies promoting the reduction of product losses and food waste and enhancing, from a commercial point of view, agri-food products with a strong local / regional connotation through product management and control systems that allow an improvement of the chemical, physical, organoleptic, and nutritional qualities of the products at the time of consumption.

On the other side, *MEC* provides value to a set of actors involved in various capacities with the use and consumption of agri-food products. Consumers (e.g., individual consumers, purchasing groups and restaurant / catering services) can be provided with high-quality local products characterized by a direct connection with producers, territory, and cultural values; not-for-profit associations can be easily receiving upcoming food for distribution to disadvantaged social groups; energy companies can access to food loss and waste to produce energy.

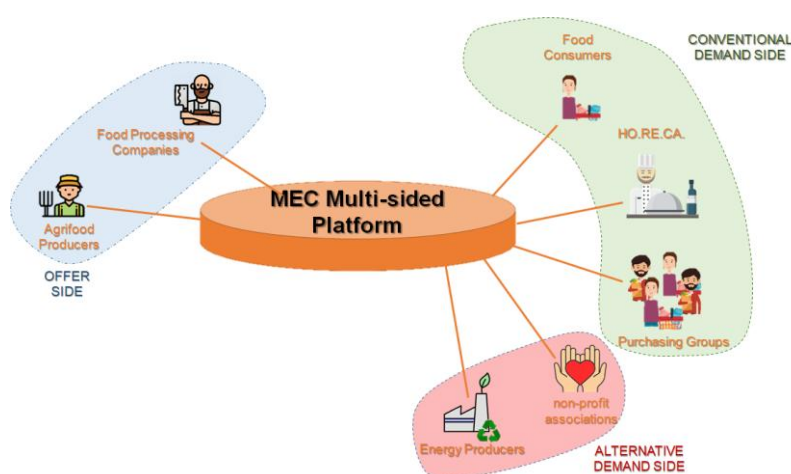

Figure 1 – Sides involved within the MEC Network.

A description of actors involved in MEC Network is provided as follows.

**Agrifood Producers:** A set of small and medium enterprises, producing high quality agri-food goods and operating in the four main agricultural sectors (wine, olive, fruit and vegetable and dairy productions).

**Food Processing Companies:** A set of small and medium enterprises specialized in the transformation of raw agricultural products into food.

**Purchasing Groups:** A set of final consumers, grouped in a self-organised non-profit purchasing group, who want to purchase agrifood goods at reduced prices. Consumers decide to share their 'shopping lists' to create a unique cumulative order for a heterogeneous bundle of products to be submitted to the platform.

**HO.RE.CA Operators:** A set of companies, operating in the Hotel, Restaurant and Catering Industry, that prepares and serves food and drinks to customers.

**Food Consumers:** A set of final consumers interested in purchasing local food product directly from producers.

**Non-profit associations:** A set of associations interested in receiving upcoming or unsold food for distribution to disadvantaged social groups;

**Energy producers:** A set of companies that are interested in accessing to food loss and waste to produce energy. Biogas, energy of organic waste captured through anaerobic digestion, can be burned to produce electricity and heat (cogeneration).

To enjoy diffused and equal trust from both agrifood producers and consumers, a Trusted Third Party (TTP) has the tasks to guarantee authority and collaboration catalyst. A technical staff within the TTP was invested by the role of technology intermediary and knowledgemediary, while another staff of the TTP has been charged with operational management of transactions. According to its role of collaboration catalyst, the TTP designed and proposed an organizational model shaping a blended form of a Collecting Buying Group and Collective farmer shops. From an operational viewpoint, the TTP, as transaction intermediary, collects and structures producers' offer by means of an e-catalogue; collects cumulative purchase orders from the demand side and processes them in order to form single purchase orders for each agrifood producer. As knowledgemediary, the TTP provides a web platform, which is based on the web 2.0 paradigms, and where web tools are available for sharing information and knowledge among users. In particular, by means of web 2.0 (social networking, photo and video sharing, mashups, podcast, etc.) tools, the TTP supports the development of virtual communities among MEC members. As matter of fact, such tools allow the creation and exchange of 'user-generated content', i.e. the blending of various kinds of media content, publicly available, that are produced by end-users. They are important in supporting the democratisation of knowledge and information, and their usage transforms MEC members from content consumers to content producers. In particular, agrifood consumers assume an active role as they get more involved in the production processes, becoming real prosumers. The virtual communities so created are based on a blending of technology and social interaction, which enables the co-creation of value for all communities' members.

The spread of the internet and the growing accessibility to technological solutions have revolutionized the lifestyle and habits of the population, not only as users but also as consumers. Grocery retailers are also adapting to the new type of customer and their needs, revising their business models with a view to a new type of trade and competition. In recent years, several traditional operators

in this sector have decided to activate new distribution channels by exploiting the potential of electronic commerce. In addition to this, several new players have entered this sector, basing their business exclusively on digital channels. In general e-grocery platforms can play a dual role. First, they can offer a new direct sales channel for individual retailers, allowing them to reach individual consumers, purchasing groups, but also business customers such as operators in the catering and restaurant sector. As previously stated, the internet has favored the entry into the market of operators who do not base their business on the direct sale of products, but act as intermediaries, facilitating the meeting between supply and demand, thus offering a two-category value proposition of actors:

- Agricultural producers and processing companies who manage to have a direct commercial channel with consumers. These operators have the advantage of not being forced to resort exclusively to large-scale retail trade and not investing money to create their own e-commerce platform.
- Consumers who have access to a large basket of products from different producers.

The MEC platform combines the above-mentioned conventional value proposition with a new value proposition that could refer to a new category of actors, interested in an alternative use of food, such as charitable / non-profit associations or companies capable of transforming food waste into energy.

The "conventional" flow therefore provides that the products coming from farms or from processing companies are collected at the logistics platform that will take care of breaking down the deliveries from the companies and reassembling them according to consumer orders.

Figure 2 – Conventional products flows within the MEC Network

In addition to this, other flows are enabled that we can call "alternative". For example, in order to reduce food waste, unsold or close to expiry products could be published on the platform and sold at a heavily discounted price, donated to non-profit organizations or sold to companies in the sector interested in alternative uses of food products. Likewise, expired food or production waste could be of interest to energy producers who could use these waste for energy purposes.

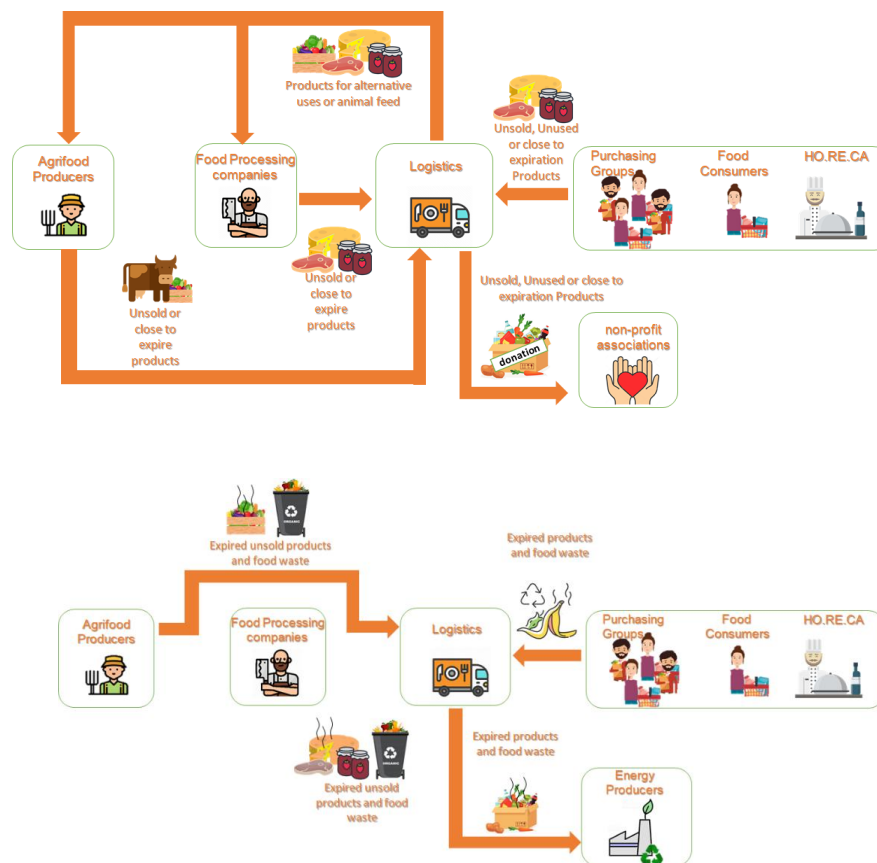

Figure 3 – Alternative products flows within the MEC Network

#### 4 Conclusions

The high dynamism and uncertainty of the reference context, force food supply chain operators to develop new skills, new methods, new structured approaches to face the challenges of the global market. We found in the literature a

significant amount of studies dealing with basic aspects of Sustainable food supply chain management. The attention of literature has so far concentrated mainly on the evaluation benefits of sustainability oriented strategies and advantages for involved parties, with a particular focus on how sustainability strategies have a positive impact on food quality, transparency and consumers' trust. However, less attention has been paid towards implications and issues of collaboration between different business organizations in sustainable food supply chains. Results of our systematic literature review led to the identification of four main topics dealing with collaboration in sustainable food supply chains.

. Sustainable change begins with recognition and modification of core values, assumptions and ideologies shared by members within organisations. Because of the complexities of the culture of change, many past projects of collecting farmers and consumers around agribusiness initiatives failed. In this paper, we presented some findings from the project MEC. In the case study, an instantiation of collaborative networks in agri-food supply chains within the Metropolitan City area of Reggio Calabria (Italy) has been proposed. Critical issues and lessons learned in the development of the project can be summarised as follows: the MEC Network plays a fundamental role as institutional framework, at all levels, for the development of the regional agrifood community. The establishment of a collaborative network where producers participated with public institutions and consumers, has been an important step in guaranteeing development and strengthening of the socioeconomic environment. This situation may clearly produce a catalysing effect for further organisations of producers (and/or consumers), encouraging the search for alternative markets for their products; since the early steps of the network establishment, commitment from local, public and private authorities is necessary.

In conceiving the MEC initiative, we first surveyed social and cultural specifics of small-scale producers, particularly their economic rationales (based on traditions and customs), which do not always coincide with the rationales of the greater organisations or institutions with which they usually interact. Participation of research and university centres is an enabling factor for the success of MEC establishment. The presence of a TTP contributes in providing an institutional framework guaranteeing neutrality and independence of interests; besides, this allowed intensive methodological thinking at the different stages of the process of building an agrifood learning community. Individualism of agrifood producers, lack of trust and spirit of coordination among stakeholders (consumers vs.

producers, producers vs. local authorities, producers vs. producers, etc.) and absence of a strategic vision (business vision of small producers is short-term, unlike the longterm view of agro industries) may hinder the establishment of a collaborative based initiative in the agri-food sector.

## Funding

This research was partially funded by MISE (Ministero Italiano dello Sviluppo Economico) under the project "MEC—Marketplace Ecosostenibile Calabria": CUP B31B20000520005.

### **Abstract**

Information and knowledge management is key to create added value for organizations no matter what field organization is acting. Covid -19 has shown the importance of accurate and right information to be available for those who need information to be able to act. Respectively we have seen the challenges and problems when information has not received on time, information is insufficient or not received at all.

For organizations and their many stakeholders, customers included, uncertain times are the ultimate test for processes. This can be seen strongly in information and knowledge management practices. If organization has strong organizational culture where communication and knowledge management have strong position it can assume that ability and willingness to use alternative methods for communication when those are needed are in good level. This ensures also that ability to create added value for stakeholders and customers are not in danger and agility to react changes occurring in operating environment is existing. Barriers in communication have many different levels in organization. Individuals have different ways to communicate and receive information and these individual differences are creating needs to better and diverse communication within organization to create better possibilities to be successful also in organizational level. Today as covid-19 has changed dramatically ways to communicate and manage knowledge technological barriers and ability to use new technology has been the most important challenge organizations have been faced today. To be able to continue their businesses and survive new technology must be adopt and take in use even in individual level might be some challenges to learn and adopt new ways of doing things. This study focuses on added value and how communication as well as knowledge management. Case study is presented through industrial organization and their customer satisfaction survey to see how knowledge barriers are affecting on customer satisfaction and organization's ability to create added value through minimizing knowledge barriers. Through theoretical review of knowledge barriers, case study organization's customer satisfaction survey and survey creation process are shortly presented. Results of the customer satisfaction survey are introduced and results are reflected against theory related to different knowledge and information barriers. This evaluation is to be done to present the challenges what organizations are facing in individual, organizational and especially in technological level and how these all levels are connected when communication tools and methods must be

changed quickly and knowledge management is suddenly most important mode of management.

**Keywords** – knowledge barriers, added value, customer

**Paper Type** - Practical Paper

## 1 Introduction

Covid-19 forced us, organizations and individuals to take digitalization and tools modern technology is able to provide in use as quickly as possible to ensure that our daily operations can be secured in situation where processes are partly or fully remotely operated. Barriers were suddenly existing, disturbing organization's performance at all levels. These barriers needed to be recognized and solved, processes re-structured accordingly to keep daily operations running, customers served internally and externally. Added value by minimizing barriers internally to ensure operational performance at all levels in organization gives possibility to influence in customer satisfaction.

## 2 Added value and Customer satisfaction

Companies are having a great success do not just satisfy their customers, they strive "superb" and delight them. To have and maintain superior customer value means creating continuously experiences that exceed customer expectations. This value is the strategic driver and element that utilize to recognize and differentiate themselves from the pack in the mind of customer. Value is defined by our customers all the time and enables, if organization's value is outstanding, turn buyers into lifetime customers. (Johnson & Weinstein 2004:3)

So Companies have to create value for their customers and face the possible problems related to success and also failure of it, like deterring market share, declining customer loyalty, decreasing profits and chaos which may be caused by these matters. Anyway customer value is a key element for organizations to give direction to unite different business functions with strategies and common goals, recognize the importance of the focus on customer's expectations and needs; implement and develop information, personnel, business and quality systems to ensure and deliver required customer value. Approach build by customer value perspective can be shown as a pyramid with strategies and goals at the top and

quality, personnel, information and business systems at the bottom. Figure 1. Duchessi 2002: 1-3)

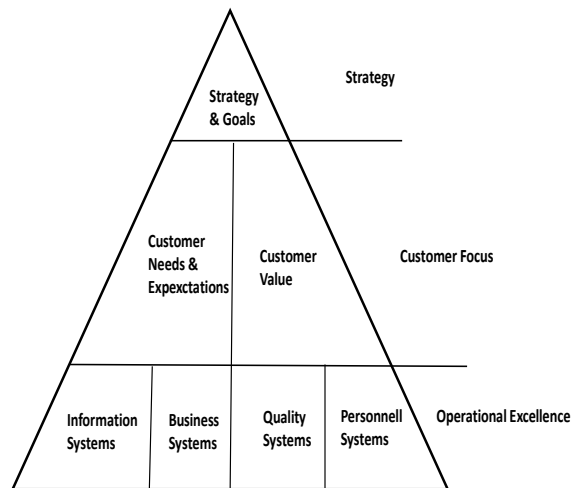

Figure 1. Customer Value Pyramid. ( Duchessi 2002: 1)

## 2.1 Definition of customer value

When defining customer value, customer value can be defined so that it represents the trade off between sacrifices and benefits from provider's relationship and product resources which customers think and believe to be facilitating their goals. At the same time we have to remember that quite often customer value is changing because customers are changing their own expectations. This aspect is a critical challenge for the providers because failing to meet customer expectations may lead to dissatisfaction and terminate the customer relationship. (Blocker et al 2011: 217-218)

Value as a term is used in many different contexts. For value definition customer perspective seems still be valid. Delivering and creating superior customer value to customers with high-value can be seen as increasing value of organization. There is a monetary worth in high-value customers as in individual customers to the organization which can be quantified, whereas organization's value quantifies the worth to its stakeholders. Still, customer value takes the perspective of the organization's customers. As a definition of customer value

and concept many different perspectives and meanings can be found and some of them are summarized in table 1. (Spiteri, Dion 2004:676-678)

Table 1: Definitions of Customer Value. ( Spiteri, Dion 2004:678)

<b>Researchers</b>	<b>Benefits</b>	<b>Sacrifices or costs</b>

Monroe, 1991	Quality and benefits	Relative for sacrifices
Zeithaml, 1988	Utility of what is received	What is given
Bagozzi, 1974	Maximise rewards	Minimize costs

### 3 Barriers in organization

Organizations are facing several challenges in their daily work in every organizational level. Challenges can be faced in individual as well as group or department levels while reaching the targets settled by management and owners.

Definition for knowledge has been often stated as a "justified personal belief." There are many classifications which specify various different kinds of knowledge. The most relevant and important distinction is between "tacit" and "explicit" knowledge. Knowledge is often tacit in nature and it has developed during long period of time. Some of it has merged in business activities processes and relationships that have been created over time when series of continuous improvements have implemented. Explicit knowledge is available for example in the form of sentences, words and documents words, different types of organized data, like computer programs. (King 2009: 6-8)

Creating knowledge is rather depending on tapping the tacit and quite often highly subjective insights, hunches and intuitions of individual employees and making these insights available for use and test for the organization. Personal commitment is playing a key role in terms of the employees' sense of identity

with the organization and its mission. Embodying tacit knowledge in actual technologies and products to reach actual personal commitment will require foremen and managers who are as comfortable with symbols and images as they are with numbers measuring productivity or market shares. (Nonaka 2007:7)

Knowledge management has become more important field of study as the technology has become important part of our daily life. We receive huge amounts of information through modern technology like internet, television and through different types of mobile applications. At the same time speed of information has increased and world has become smaller in that perspective. We get information quicker and at the same time we are asked to respond and act quicker to impulses we receive. This is happening at individual and organizational level. This phenomenon can be seen as a one side of globalization and networking with global business and economy. Knowledge management is partly and traditionally hardware and technology based research area. More and more it can be seen that research has more focus to human side of knowledge management. One of the reasons for turning focus for the human side of knowledge management might be that we have all needed information available, but the challenge is now that how we really can get best of it for individual and organizational use.

### ***3.1 Knowledge management within organization***

Knowledge management improves processes in organization, like collaborative decision making, innovation, collective and individual learning. These organizational processes create as process outcome better products, services and relationships and decisions as well as organizational behaviors and these issues and process outcomes lead to improved organizational performance as in Figure 1 presents. (King 2009: 6-8)

Figure 1. Knowledge process (King 2009: 6)

In knowledge processes in organizations we refine, storage, share, transfer, create, acquire and re-use information. Through efficient and good planning of knowledge management processes we increase and improve processes of innovation, individual and collaborative learning as well as decision making processes within organization. Through these actions and processes we improve our organizational performance by organizational behavior on the level of decisions, services, processes, relationships. Vital issue for achieving best possible result for improved organizational performance is to find causes for disturbance factors in knowledge management processes, organizational processes and also to find new ways and methods to improve ways we handle these processes within organization.

When bringing knowledge to product and service perspective in organization environment, it can be said that new products and efficiencies are difficult to sustain. By using knowledge we can provide a sustainable advantage. Competitors can always in period of time match the quality and price of a market leader's current service or product. When that happens, the knowledge intensive, rich, knowledge-managing company will have moved on to a new level of creativity, efficiency and quality. The knowledge advantage is sustainable because when efficiently used knowledge increasing returns and continuing advantages. Knowledge increases when used as ideas will breed new ideas knowledge which is shared stays with the giver and at the same time enriches the receiver. The potential key information for new ideas will be found from the stock of knowledge. And this stock is in any organization practically limitless if the people

in the organization are given opportunities to talk, think and to learn with one another. (Davenport 2014: 13)

Organization's performance is quite much depending on how managers are able to get activation done with individuals and teams turning knowledge into value-creating activities. Activities can take place through five different phases: 1) Initial sharing of experience, knowledge and practices among team members, 2) The effective creation of concepts for new products and services based on shared knowledge 3) the justification of these concepts are rooted in organization's strategy, focus interviews and market studies 4) Building a prototype of service offering and leveraging of concepts, prototypes and offering throughout the organization. (Von Krogh 1998: 133-134)

In the study of knowledge management in public organization Syed-Ikhsan and Rowland (2004:109), emphasized that to have good and successful strategy in knowledge management, organizations should always see it as total. All organization elements should be considered and analyzed when knowledge management is implemented. As technology play important role in sharing and developing knowledge, attention should also be paid to organizational context and culture in which people are encouraged to share knowledge. Technology may not stimulate the flow of knowledge and this is why organizational structure, people and technology should be considered together.

There seems not been any systematic knowledge management policy on strategic level in small and medium sized organizations. There are no goals included in the organizations strategy, or development, sharing or evaluation of the knowledge. On structural and cultural perspective there was hardly any systematic knowledge management policy on tactical level found in medium and small -sized companies. This brings out that there is no explicit policy on a tactical level in order to make the structure facilitating to development, locking of knowledge and acquisition of knowledge to make the culture motivating with a regard to utilizing and sharing and knowledge. Related to knowledge management policy on an operational level it appears that in small and medium-sized companies have different types of instruments used to evaluate knowledge and to determine the knowledge gap, to acquire knowledge, to develop knowledge and to share knowledge. These instruments are often not seen as an instrument for knowledge management within the companies but also, this does not necessarily mean that there is no knowledge management. (Uit Beijerse 2000: 15-18)

## **4 Knowledge sharing barriers**

There are many examples existing where knowledge sharing practices have not reach their goals- to manage organizations skills and assets. This occurs mainly because of potential knowledge sharing barriers. It has been agreed and acknowledged the biggest challenges within organization sharing practices is to maximize and protect the value which is derived from tacit knowledge. This tacit knowledge is held by organization's external stakeholders, customers and employees. (Riege 2005:3)

### **4.1 Definition of Barriers**

#### **4.1.1 Organizational Barriers**

When taking a perspective of organizational level, barriers are quite often tend to be linked for example lack of infrastructure and resources, the economic viability, the accessibility of informal and formal meeting spaces and physical environment. (Riege 2005: 23)

To have success in sharing knowledge within organization there must be a right organizational conditions and environment. There are many ways to share organizational, social or individual knowledge effectively. Barriers on organizational level can be outlined as:

- a) Size of the sites or business units are unmanageable to enhance contact and facilitate easiness in sharing knowledge and often they are therefore not small enough.
- b) Hierarchical structure in organization slows or inhibits most of the sharing practices.
- c) Layout of the working areas and physical work environment restrict effective sharing practices
- d) Knowledge flows and communication are restricted into specific directions.
- e) High external competitiveness within sites or functions and between subsidiaries.
- f) Deficiency of organization resources that can provide adequate sharing opportunities
- g) Lack of appropriate infrastructure which supports sharing practices.

- h) Lack of transparent recognition and rewards that would motivate people to share knowledge.
- i) Shortage of informal and formal spaces to generate, reflect and share new knowledge
- j) Lack of managerial direction and leadership how to communicate clearly the benefits and values of knowledge sharing practices.
- k) Sharing initiatives of knowledge management and integration of knowledge management strategy into organization's strategic approach and goals is unclear or missing. (Riege 2005: 25-26)

#### *4.1.2 Individual sharing barriers*

At employee or individual level barriers of sharing knowledge are often factors like lack of trust and time, differences in national culture, lack of social networks and communication skills as well as overemphasis of position status. Barriers at individual level can be listed as:

- a) Difference in ethnic background or national culture and beliefs as well as values associated with it.
- b) Lack of trust in credibility and accuracy of knowledge due to source
- c) Lack of trust in people because there may be occurring misuse of knowledge or taking unjust credit for it
- d) Taking ownership of intellectual property because of fear of not receiving accreditation and recognition from colleagues and managers
- e) Difference in levels of education
- f) Differences on genders
- g) Age differences.
- h) Insufficient evaluation, feedback, capture, communication and tolerance of the past mistakes that would enhance organizational and individual learning effects
- i) Dominance in sharing explicit over tacit knowledge such as experience and know-how that requires observation, hands- on learning, dialogue and interactive problem solving
- j) Low realization and awareness of the benefit and value of possessed knowledge to others
- k) Apprehension of fear that sharing may jeopardize or reduce people's job security

- l) General lack of time to identify colleagues in need of specific knowledge and general lack of time.(Riege 2005:23)

When going further and deeper for individual perspective individual sharing barriers can be described as uncertainty, loss of power, motivation and revelation. Uncertainty can be seen especially as a feeling among the less experienced and younger people, because they are not able to judge if their working results represent knowledge which is valuable. Their knowledge cannot be estimated if it is too well known or general or if the knowledge is too specific for special situation and therefore useless for colleagues in other cases. The positioning on the scale of specific to general is not trivial at all and thus it creates uncertainty. (Disterer, G 2001: 2)

Loss of power is quite common feature of individual level as knowledge can be used to enforce spheres of influence and to take action, to pass knowledge to colleagues may grant some of these potentials. The ones who do not own this knowledge are deprived to influence respectively. This applies to knowledge about procedures, competitors, suppliers' methods, formulas as well as customers from business perspective. By this perspective someone who will pass the knowledge to colleague will lose the exclusiveness of her or his influence and this might have suggested some respect and job security. "Knowledge is power" where experts with rare knowledge have monopolies of knowledge and reputation causes knowledge hoarding instead of knowledge transfer. In situations where job security is low power of knowledge becomes vital for the individual and knowledge can be seen as an insurance against losing job. (Disterer G 2001: 2)

Motivation can be also one reason for barrier at individual level as transferring knowledge can be seen as additional work. This is due the extra time needed for communication and documentation etc. Employees may not expect reciprocal benefits from transferring their knowledge because they do not experience it or they not believe these benefits. Even if people do expect some kind of reward for their contributions the question "what's in it for me "is not clear always to employees which are suffering from the lack of motivation. The need for self-motivated creativity is existing in order to foster knowledge sharing. Quite often the benefits of the contribution to a knowledge database is received by a different stakeholder at a later point of time, the benefits are quite often earned by colleagues of the provider, not provider itself. Knowledge sharing can be

beneficial only if everybody provides his knowledge unselfishly. (Disterer G 2001: 2)

A Revelation can be felt when putting results of the work or passing knowledge to colleagues, because it proclaims that this knowledge has certain rareness and value. Embarrassment may happen if this assessment is not shared by other users of the database and quite often some hasty colleagues will hurriedly suggest their necessary improvements just to emphasize their own expertise. (Disterer G 2001:2)

#### *4.1.3 Technology barriers*

At Technology level barriers are occurring with difficulties in integrating, building, and modifying technology-based systems. Barriers also correlate with factors like unrealistic expectations of ERP/IT-systems, unwillingness to use applications because of mismatch with need requirements. (After all there can be found various reasons why people hoar their knowledge and the contexts are often multi-dimensional). (Riege 2005: 23)

Knowledge sharing is also a technology issue and challenge. There is a little doubt that technology can be a facilitator to support and encourage knowledge sharing and its processes by making sharing more effective and easier. At the end, the key issue is to implement and choose technology which is most suitable and provides a close fit between organizations and people. Potential barriers for sharing can be.

- a) Lack of communication and demonstration of all possible advantages of new systems compared to existing one.
- b) Reluctance to use IT-systems due to lack of experience and familiarity with them
- c) Lack of training when employee is to be trained to be familiar with new IT-system
- d) Mismatch between integrated IT systems and processes restricts sharing practices and individual's deed requirements.
- e) Unrealistic expectations of employees on what technology cannot and can do
- f) Lack of integration of IT processes and systems impedes on the way people do things

- g) Lack of technical assistant and support as well as maintenance of integrated IT systems communication flows and obstructs work routines. (Riege 2005: 28-29)

## **5 Case study**

Creating added value for their internal processed as well as their customers. Case study is presented through industrial organization and their customer satisfaction survey to see how knowledge barriers are affecting on customer satisfaction and organization's ability to create added value through minimizing knowledge barriers. Through theoretical review of knowledge barriers, case study organization's customer satisfaction survey and survey creation process are shortly presented. Results of the customer satisfaction survey are to be introduced and these results are reflected against theory related to different knowledge and information barriers. Through this reflection weaknesses are revealed in customer added value creation and proposals for improvements are presented. Additionally, changes in organization's operating environment caused by covid-19 is evaluated through business perspective as well as through knowledge and communication perspective in general level. This evaluation is to be done to present the challenges what organizations are facing in individual, organizational and specially, in technological level and how these all levels are connected.

Customer were selected from 3 different segments so that all customer segments were covered. Totally 38 customers were requested to participate in the survey. Question patterns were discussed and prepared in a sales meeting January 2019 to have insights from customer interface and additional information from customers. At the first phase customers were approached via email; to give a gentle overview from the purpose, timing and information about the survey and how it will be done as a process. Survey itself was done by telephone interview during January 2019.

Analysis of empirical data revealed that there were clearly four themes which were continuously appearing when development needs were asked: Deliveries to be more accurate in time, in full and reliability and all functions, proactivity, more focus on innovations and product development and improving customer service.

For product development more activity and proposals were needed to create more added value to customer's product development function which would support customer's needs at their own development needs received from end customer. Reaction and response times related to information needed was experienced slow and more standardized and systematic methods in processes at customer interface was needed.

It was clearly stated that needs for better understanding of customer's needs through product development and new product innovations are expected.

*" One development need is to participate customer's R&D process. To offer new product innovations to customer"*

When experiences related to deliveries and quality were asked, deliveries were experienced to have big variations and some of the customers were very disappointed because of long delivery times or being uncertain that deliveries are delivered as promised. These failures in delivery quality have had serious influences on customer's own performance.

*" There are differences in quality of deliveries. One is having deliveries on time and in full, but another one is having big problems"*

*" In our weekly meetings you are always mentioned because of some problem."*

*" Act Systematically: Every order must have order confirmation and deliveries should be done accordingly. Deliveries should arrive as promised – too much post-deliveries"*

Role conflicts within organization clearly has reflections to relationship and how customer is served and informed.

*" Lead-times are okay. Customer service should be fixed first, meaning that there should be person who is in charge. Of course when you are familiar and know persons it helps, but sales assistant is missing. They have customer service manager, but person who is between production and customer is missing"*

When it was separately asked from customer that what are the main development areas where Company should focus more in future answers were divided as follows; Product Development 53% environmentally friendly solutions 50%, and lead-time 50%

After services was indicated to be something to be improved and harmonized as one site is acting differently than other. This is indication gaps in information and communication between sites.

*" Same things what we do with other sites; follow up on claims and other projects- what is the status and what will be done next etc."*

This has clearly indication that barriers have major effect on customer satisfaction and therefore minimizing barriers and focus improvements internally have direct influence how organization can improve their own performance on the markets.

Table 2. Summary how barriers at individual, organizational and technical level are influencing customer's experience.

<b>INDIVIDUAL LEVEL BARRIERS</b>	<b>CUSTOMER PERSPECTIVE</b>
Poorer understanding of customer requirements in production than earlier, as contact level is missing.	Information missing related to deliveries, not known who is in charge
<i>Difference in levels of education, causing e.g. shortages in language skills.</i>	Information missing related to deliveries, not known who is in charge.
<i>Insufficient learning loop and tolerance of past mistakes</i>	Lack of Research and development.
<i>Lack of trust (towards other units)</i>	Lack of Research and development, long lead-time..
<i>General lack of time</i>	delays, long lead-time

<b>ORGANIZATIONAL LEVEL BARRIERS</b>	<b>CUSTOMER PERSPECTIVE</b>
Communications break-down between sales, operative and development functions.	Lack of Research and development
Knowledge sharing problems between the unit and the corporation level	Information missing related to deliveries, not known who is in charge
Unclear roles and job descriptions	<i>not known who is in charge</i>
<i>High competitiveness between other subsidiaries</i>	<i>different methods within claim handling and follow up</i>
<i>Deficiency of resources</i>	delays, long lead-times

<b>TECHNOLOGICAL LEVEL BARRIERS</b>	<b>CUSTOMER PERSPECTIVE</b>
Data and information are incoherent and splattered into different information systems	delays, long lead-times
Information systems are not used comprehensively	delays, long lead-times
<i>Unrealistic expectations of employees about what technology can do or can't do</i>	delays, long lead-times
<i>Lack of integration of IT processes and systems</i>	delays, long lead-times
<i>Lack of technical support</i>	delays, long lead-times

## 6 Conclusions

Barriers occur in organizations and to improve processes and efficiency those existing barriers must be identified and recognized by all organization levels. By identifying organization can evaluate what is the influence of each barrier. By involving customer satisfaction to organizational barriers importance of minimising barriers and their effect on organizational success in markets is way to raise importance of barrier-studies in organizations. Case study clearly indicated how much specially, lead-times were effected by technology barriers by technological level barriers. As the short lead-time is one of the biggest advantages for organization to compete in the markets and acquire new customers, it is a must that organizations are doing all possible actions to be as flexible and as fast as possible to serve their customers in globally markets. Individual and organizational level barriers were clearly effecting to customer's perspective on organization's capability to do research and development. If organization wants to be competitive now and in future it is similarly important to be able to provide new products and services and in that way show customers that organization is worth to have long term business relationship as added value can be created through new ideas and development projects. Winning organizations should continuously identify and monitor their processes and minimize barriers at all levels. Through these actions organizations have clearly positive effect on their customers through better service. This achieved better service level will be seen as improved customer satisfaction and better business results.

### Abstract

**Purpose** — The purpose of this study was to examine how knowledge management should be implemented in medium-sized manufacturing companies in order to ensure adequate B2B communication and knowledge sharing of explicit knowledge with distributors in the sales channel in times of impeded and limited access due to COVID-19 pandemic. Manufacturers traditionally manage their sales channel partnerships inefficiently, and especially SMEs do not often make use of consequent knowledge sharing. This leads to the fact that converting leads into sales becomes an on-going challenge and calls for new ways of inter-organizational knowledge sharing of explicit knowledge internationally.

**Methodology and approach** — To explore the complexity of business partner knowledge sharing in the B2B sector, a qualitative approach has been applied. Building on the purpose of the research, a single case study research as the research strategy provided in-depth information on the manufacturer-distributor knowledge sharing in times of crises. The contemporary phenomenon of SMEs within the real-life context of B2B communications primary data was collected in form of a self-administered questionnaire from international business partners in the sales channel of an industrial manufacturer of machine building industry in Germany.

**Findings** — The rising importance of knowledge being the fourth production factor generating values require companies to constantly transfer and share knowledge – not only inter-, but also intra-organizationally, especially when it comes to sales channel collaborations. The findings of this research highlight that the use and positioning of knowledge sharing among business partners in the sales channel is crucial and enable collaborations to improve B2B working flows cross-organizationally. Explicit knowledge such as specific product-related information material, prices or logistical information should be trained on the product, catalogues or via internet-mediated means and should furthermore be stored in a commonly used knowledge management tool. Tacit knowledge

should be transferred in a pre-agreed language, predominantly through joined customer visits and training on the product.

**Practical implications** — This research does not only enhance practical implementations in the case organisation but also can be conferred upon those organisations that rely on a manufacturer-distributor relationship in their sales channels. It provides insights regarding a proposed knowledge management in SMEs and it links the theoretical understanding of knowledge sharing with real-life practices in manufacturer-distributor relationship-related processes. Thus, this research generates new knowledge by combining knowledge management theory with practice to develop a framework that provides insights on observing, improving and preventing knowledge-based bottlenecks.

**Keywords** – Knowledge sharing, Knowledge sharing among collaborations, Manufacturer-distributor knowledge transfer, Small and medium-sized enterprises

**Paper type** – Academic Research Paper

## 1 Introduction

Nowadays, the fourth factor – knowledge – can be identified when looking at wealth-generating variables in organisations. In knowledge-based economies, firms that participate in the creation and utilisation of knowledge are able to gain a sustainable advantage from their business strategy (Ibrahim and Heng, 2013). In contrast, medium-sized companies do not often make use of knowledge sharing in order to become more competitive (Massaro et al., 2016; Wong and Aspinwall, 2005). In particular, manufacturing companies of this size traditionally manage their sales channel partnerships inefficiently via phone-calls, E-mails, presentations, face-to-face meetings and etc. While all these implying work-intensive communication and knowledge sharing processes lead to the fact that converting leads into sales becomes a difficult task, sales channels have received rising attention as a determination of business performance (Sharma and Mehotra, 2007; Jiang, Henneberg and Naudé, 2011; Parvinen and Pöyry, 2016).

The problem becomes more complicated, when external distributors of the sales channel are not on the same level of explicit knowledge because the sharing process lacks a concept of informing all international distributors from every location at once. Medium-sized manufacturing companies are at risk to lose potential and existing customers. There is a need to answer the question of how knowledge management can be implemented in order to ensure adequate B2B communication and sharing of explicit knowledge among channel collaborations.

This study investigates into a medium-sized engineer supplier for the machine building industry based in Germany.

## **2 Literature Review**

### ***2.1 Knowledge management capability in sales channel collaborations***

A company's knowledge management capability refers to the amount to which the company creates, shares and applies "*knowledge resources across functional boundaries*" (Liao, Chuang and To, 2011, p. 729). These KM activities enable the company to use new information, assimilate it and utilise it in order to create new knowledge (Wong and Wong, 2011). They "*co-exist, co-vary, and overlap with each other,*" (Liao, Chuang and To, 2011, p. 729).

When focusing on an entrepreneurial environment, the differentiation between tacit and explicit knowledge is as essential as distinguishing between individual and organisational knowledge. Making tacit knowledge explicit carries the risk of losing sustainable competitive advantage. The more tangible the knowledge, the greater the risk of other firms to imitate this knowledge (Lubit, 2001). Nonaka and Toyama (2003) state that the only way to acquire tacit knowledge is to share experience by spending time together (Holste and Fields, 2010). In the opposite to tacit knowledge, explicit knowledge can be transmitted by using interaction between physical objects (Collins, 2010). It can be codified and/or verbalized (Takeuchi, 2013; Grover and Davenport, 2017) and expressed by data, numbers, formulas, pictures, manuals, and patents (Takeuchi, 2013). The specific characteristics of both, tacit and explicit knowledge have not really changed over the years apart from the fact that knowledge nowadays can be exchanged via digital solutions. Successful intra- and inter-organisational knowledge management is dependent on the willingness to share explicit and tacit knowledge in order to benefit the business partners. Therefore, a company is advised to keep a spirit of community among all employees and collaborative partners to encourage them to keep the knowledge growing (Al-Busaidi and Olfman, 2017).

Looking at supply chain knowledge management capability, the company's ability to learn from its partners is affected by the ability to transfer it internally among organisational members as knowledge (Spekman, Spear and Kamauff,

2002) in an organizational routine that generates memory from external collaboration partners.

## **2.2 Knowledge sharing methods**

Knowledge sharing is “the exchange of knowledge between and among individuals, and within and among teams, organisational units, and organisations” (Paulin and Suneson, 2012, p. 83).

Even if there is willingness to practice knowledge sharing it remains difficult to transfer knowledge adequately. While it may be simple to codify explicit knowledge, tacit knowledge requires intense interaction and can only be shared in small group settings (Dyer and Nobeoka, 2000). The phenomenon of failing to contribute is called free-riding problem – for individuals it is rational to use knowledge systems without adding to them because it would not carry any benefits (McCarthy and Riegelsberger, 2004). Different methods supporting tacit and explicit knowledge sharing are e.g. community of practice, storytelling, training, mentoring (Bryant, 2005; Bryant and Terborg, 2018; Dyer and Hatch, 2006) and knowledge sharing networks technologies. In the following, methods that are applicable for the manufacturer-distributor relationship are explained:

- Organisational **storytelling** contains information about past management actions, employee interaction or organizational events that are communicated informally. According to Ferneley and Sobreperez (2009) such stories can be fictional, factional, anecdotal or scripted. Storytelling includes several tools, each suitable for various business purposes (Denning, 2006). If the objective is to share knowledge, the story has to focus on mistakes made and shows in detail how these mistakes were corrected or solutions worked.
- **Training** is a company’s planned exertion to help its employees in the learning process of work-related competencies (Fong et al., 2011). As a medium motivating knowledge sharing it gives employees the chance to gather and share new knowledge. The evidence found in the link between team-based training activities and the level of commitment to learning supports the importance of training encouraging the creation of teams that are committed to learning (Jerez Gómez, Céspedes Lorente and Valle Cabrera, 2004).

- The most common **knowledge sharing network technologies** for explicit knowledge and information sharing include phone, video and audio conferencing, chat, e-mail, instant messaging, webinars, etc. By these ways, knowledge and information can flow digitally within seconds. When product-related information has to be shared, the concept of collaborative writing systems can be applied (Ruggles, 1997; Nabelsi, Gagnon and Brochot, 2017). Word processors provide support by allowing users to track changes and make annotations when collaborating on a document. Another technology could be wikis in order to share knowledge among members of a broader community by openly editing content that facilitate collaboration (Nabelsi, Gagnon and Brochot (2017). In order to share knowledge, a groupware or collaboration tools enable the knowledge flow and knowledge-sharing activities among different parties.

### **2.3 Knowledge sharing in sales channel collaborations**

According to Frohlich and Westbrook (2001, cited in Redaelli, Paiva and Teixeira (2015)) performance monitoring is the manufacturer's constant overseeing of their distributors' actions. Performance monitoring is the step right before cooperation, which helps to build trust and improve performance (Alsharo, Gregg and Ramirez, 2017; Redaelli, Paiva and Teixeira, 2015) and it is also consistent with tacit and explicit knowledge sharing among collaborations.

One way of doing this is to base the manufacturer-distributor relationship on regular visits of distributors' staff to the manufacturer's units and vice versa for knowledge-sharing activities. Another way is the direct transfer of the manufacturer's personnel to the suppliers/distributors. Siguaw, Baker and Simpson (2003) state that maintaining a good relationship with the distributor, increases their commitment and trust and therefore their willingness to share knowledge. Hence, Modi and Mabert (2007) suggest that direct involvement is a key strategy to make knowledge sharing possible because the manufacturer's staff can teach the distributor's staff and this allows the transfer of good practices (Dyer and Hatch, 2006).

Explicit knowledge acquisition can be related to the activities developed by the manufacturer in order to "*formally transfer information and knowledge to the distributor*" (Redaelli, Paiva and Teixeira, 2015, p. 426). Activities such as trainings on the product, technical courses, sales promotion campaigns etc. are supportive

mechanisms to transfer explicit knowledge to explicit (Nonaka, von Krogh, and Voelpel, 2006; von Krogh, Nonaka and Rechsteiner, 2012). Guenzi and Storbacka (2015) state that by monitoring the distributor's performance, the manufacturer has the possibility to identify failures and provide accurate knowledge. Nowadays, it is required that supply chains act flexibly in order to be able to remain competitive in increasingly multifaceted business environment (Blome, Schoenherr and Rexhausen, 2013). According to Parvinen and Pöyry (2018), the relationship of the manufacturer and the distributor consists of two parties, each wanting to get the most out of this relationship. Vázquez, Iglesias and Álvarez-González (2005) add that this relationship is based upon the will to maintain successful collaborative relationships. It is said that B2B partnerships base upon diverse factors (Jiang, Henneberg and Naudé, 2011) such as trust (Maheshwari, Kumar and Kumar, 2006; Vázquez, Iglesias and Álvarez-González, 2017), equitable interdependence, flexibility and information flow (Parvinen and Pöyry, 2018). Redaelli, Paiva and Teixeira (2015) resume these aspects by stating that the sharing of knowledge between the manufacturer and the distributor is the key for strong cooperation, trust, effectiveness and longer-lasting supplier-reseller partnerships.

The knowledge flow between supplier and distributor is of notable importance and might be one factor for achieving a sustainable balance and a successful relationship between the two parties (Parvinen and Pöyry, 2018). Knowledge transfer must occur within the manufacturer's plant (intra-firm knowledge sharing) and then spread to the distributor as interfirm knowledge sharing (Dyer and Hatch, 2006). Once the knowledge has spread to the distributor, Yilmaz, Sezen and Tumer Kabadayi (2004) agree that this kind of communication has become a key factor for quality business relationships. Further, Kotabe, Martin and Domoto (2003) confirm that the transfer of knowledge can be associated with an improving supplier performance and results in longer lasting relationships. Developing knowledge and sharing it between separate organizations has a positive effect on the development of mutual advantage (Durst and Edvardsson, 2012). A manufacturer that shares its knowledge adequately is likely to establish a long-lasting relationship between both parties and eases the development of innovations linked to distribution (Vázquez-Casielles, Iglesias and Varela-Neira, 2013).

Although literature demonstrates an agreed importance of collaborative relationships between manufacturer and distributors (Kianto et al. 2018; Parvinen

and Pöyry, 2018; Vázquez, Iglesias and Álvarez-González, 2013) as well as the importance of interfirm knowledge management, integrating it into the domain of B2B management has received less attention (Jayaram and Pathak, 2013). In addition, research is missing that combines the collaborative relationships between manufacturer and distributors with knowledge sharing concepts of small and medium-sized organisations.

## 2.4 Research question and objectives

The research assumed that small and medium-sized businesses do not manage knowledge efficiently and due to this, collaborating with the distributors does not work at its best. Therefore, the case study research aimed at investigating which means of knowledge sharing on what information bases are recommended to mitigate the potential risks of losing customers in the sales channel. Therefore, the overarching research question for this qualitative explanatory research was:

*How should knowledge management be implemented in medium-sized manufacturing companies in order to ensure adequate B2B communication among channel collaborations?*

The conceptual framework of this research illustrates those conditions of the distributor and the manufacturer that had to be figured out by answering relevant questions before elaborating on the need of knowledge sharing and the integration between channel members (figure 1).

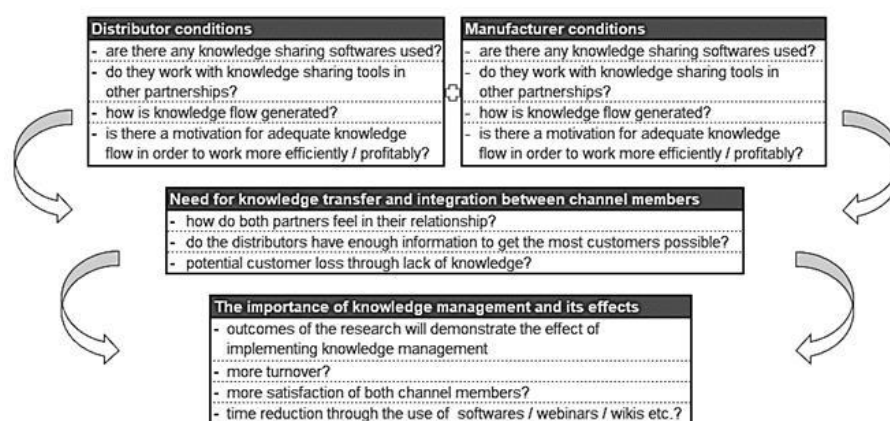

Figure 1: Conceptual research framework

### **3 Research Method**

#### ***3.1 Single case study qualitative research***

Processing data of a single case and studying the existing problem in order to explain the relationship between knowledge sharing and the potential loss of customers, while results are not pre-given, lead to an explanatory and inductive research approach in a case study research design (Yin, 2018). This was also reinforced by the wish to bring light to the complex problem of conceptualising and harmonising the knowledge sharing process between a medium-sized manufacturer and the external distributors of the sales channel. The suitable approach was the qualitative research methodology since the research aimed at analysing the complex phenomenon of business partner communication in the B2B business. As recommended by Yin (2018), small samples were used in a single case study research that was concerned with extending existing theory, since little research has been undertaken regarding knowledge sharing among B2B partners in sales channel of SMEs.

This single case study research focussed on two embedded units of analysis which were the distributors' employees who were involved by filling in questionnaires and the senior sales managers of the case organisation who reviewed the outcomes of the inquiry during interviews in order to interpret the research outcomes. The case organisation was a medium-sized mechanical engineer supplier for cables, connectors and cable assemblies for more than 15 years, a business that is exclusively dependent on customer's needs. Recently, the firm released a completely new product line of luminaires that required to establish a new way of distributing the new product line on the European and North American market through a network of distributors in Europe and in Canada. The headquarter is located in Germany employing roughly 150 people in both commercial and technical areas. Facilities for the series production of cable assemblies are located in Germany and Eastern Europe. The company's customers are predominantly working in the area of machine and plant engineering.

#### ***3.2 Sampling and data collection***

The sampling methods were narrowed down to purposive homogeneous sampling. Bryman (2016) add that the use of the purposive sampling strategy is

most applicable when there is a wish to select cases that are particularly informative. The focus on one specific sub-group, in this case the sales representatives of the distributors' firms, enabled the researchers to study this group in-depth. Participants were selected by finding contact person in a mailing list of the 20 distributors who were working as commercial and technical experts in the branch of industrial luminaires.

The tool used for creating and distributing the questionnaire was Google Forms. It was most suitable to use a self-administered mail questionnaire with open and pre-configured questions, aiming at qualitative data collection. The use of questionnaires was also simplifying the access to the distributors during the external circumstances of the pandemic Covid-19 combining pre-configured and open questions in a faster way than by interviews (Maylor, Blackmon and Huemann, 2017).

In addition, as already mentioned, 2 expert interviews were conducted with the senior sales manager and the international sales manager of the case organisation. Nevertheless, the findings are based on the online inquiry. Ethical issues were paid attention to by informing participants about their rights in advance. The data collection took place from March – April 2020. The questionnaire was answered by 12 out of 20 participants (60% response rate). 5 of them were technicians (product managers) and 7 of them were commercials (sales managers).

## **4 Findings and Discussion**

### ***4.1 Knowledge sharing in the sales channel***

Firstly, distributors' overall satisfaction with the collaboration with the case organisation has been examined. The calculated average of 0.325 demonstrates that the distributors are slightly satisfied, however when splitting the commercials and the technicians into two separate groups, the commercials are less satisfied (0.14) than the technicians (0.20). In order to be able to differentiate the knowledge sharing with the distributors, nine factors were evaluated: availability of contact persons for product-related support, reliability of statements given, language (mother-tongue, English), personal perception of manufacturer, onboarding programs, trainings on the product, transparency of processes, and provision of case studies.

Figure 2: Importance vs satisfaction of knowledge transfer factors

Splitting up the participants into the two departmental groups, differences were visible (figure 2). While the commercials rated the average importance with Ø2.80 (slightly important), the technicians evaluated it with Ø1.70 (moderately important). In relation to this, the commercials were less satisfied (Ø2.8) than the technicians (Ø1.40). Especially noticeable were the specific differences e.g. when it comes to English as the spoken language, the trainings on the product and the provision of case studies. According to Paulin and Suneson (2012), knowledge sharing is knowledge exchange between and among individuals. Therefore, the language manufacturer and distributor talk in to one another plays an important role. The findings show that speaking the mother tongue of each distributor is rather unimportant (Ø3.92), which makes English the more important basis for a mutual language (Ø2.42). Case studies could be seen as a form of business narrative and therefore be related to storytelling, since stories turn information into meaningful units and expound tacit knowledge (Leblanc, Leblanc and Hogg (2006), Whyte and Classen, 2012).

Apart from the fact that explicit knowledge also has to be provided, the current academic debate does not explicitly mention which kind of knowledge should be provided in a manufacturer-distributor relationship. However, the authors assumed that the following four aspects would be helpful for a working relationship: specific product-related information material (data sheet, drawing, manual CAD, etc.), prices (list prices, graduated prices, discounts, etc.), logistics (availability of articles, delivery dates, etc.) and general technological information

material (working principles/glossary). The overall satisfaction concerning the four explicit knowledge categories was evaluated as following (figure 3).

Figure 3: Explicit knowledge categories

Giving each participant the possibility to choose as many options as they like the following ranking has emerged: 1. specific product-related information material and prices (both at 100%), 2. logistics (75%), and 3. general technological information (50%).

#### 4.2 Knowledge sharing in manufacturer-distributor relationships

This section aimed at finding out where the knowledge shared is rooted in and how satisfying each means was. Company-related knowledge of relevance for the distributors was provided through the following media: Advertising campaigns, online catalogue, printed catalogue, homepage, emails, phone, social media, joined customer visits and trainings on the product. These media are predominantly enabling to transfer explicit knowledge, that can be easily codified and/ or verbalised (Nonaka and Toyama, 2003; Holste and Fields, 2010).

In general, these media were seen as moderately important (Ø2.40) and also moderately satisfying (Ø2.20). The most important knowledge bases, herein, were the trainings on the product and congruently the satisfaction rate was also the best. Nonaka and Toyama, (2003, p. 4) explains this as the means of "shared direct experience". Albeit, joined customer visits and trainings on the product perfectly allow for transferring tacit knowledge its universal application possibilities are limited in times of pandemics when personal contacts are prohibited. Video-

conferencing tools and virtual trainings, however, could substitute the personal contact during live trainings. Nevertheless, both knowledge media represent parts of the knowledge creation process based on Nonaka and Toyama's SECI-model (Kahrens and Früauff, 2018) whenever tacit knowledge is amplified by sharing it with the distributors.

When considering the commercials' group, they define trainings on the product, joined customer visits and information via telephone as the three most important factors. This correlates also with their satisfaction ranking. The overall ranking by the technicians is better because the most important information bases for them are firstly the homepage, followed by the catalogue and thirdly the trainings on the product.

Figure 4: Importance vs satisfaction of knowledge bases

Information technology is only a tool (Wong and Aspinwall, 2005), but it works also as a facilitator for knowledge management (Wong, 2005) and generates several sub-tools, such as wikis and clouds that ease knowledge sharing. The participants were asked which knowledge sharing tools they already use e.g. in other (inter-)national collaborations. While none of the participants worked with platforms and shared workspaces, they predominantly used clouds (83.33%), succeeded by mailing lists (58.33%), instant messaging services and video calling applications (50.00%). Nabelsi, Gagnon and Brochot (2017) reveal that the use of wikis facilitates collaboration. This study further demonstrates that wikis are not as common among channel collaborations as the use of e.g. clouds. While commercials already use clouds for (inter-)national collaborations, followed by

video calling applications, mailing lists and instant messaging services, technicians, instead, used mailing lists and instant messaging services besides cloud services (figure 5). In order to communicate, most participants tend to use instant messenger services (Ø83.33%), 70% of those using WhatsApp, which could again underline Dyer and Nobeoka's (2000) statement of speed and ease with which knowledge sharing network members can communicate and share their knowledge. This may furthermore lead to the fact that in times of crisis, staying in contact via instant messenger services is helpful in keeping the closeness between manufacturer and distributor.

Figure 5: Perceived effectiveness of knowledge sharing network technology

To evaluate whether knowledge sharing can improve B2B communication and therefore potentially increase sales, it was necessary to find out whether due to a lack of knowledge customers could be lost. All participants agreed on factors such as lack of availability of the contact person or reliability of the statements. This was followed by the personal perception of the manufacturing firm. The least probable aspect to lose a potential customer, was seen in the fact that organisation's contact person does not communicate in the distributor's mother tongue.

According to Holste and Fields (2010), Levy (2011) and Paulin and Suneson (2012) and the findings, the following downwards spiral could emerge: The lack of product trainings would imply the lack of knowledge sharing. This affects trust that must arise when collaborating and hinders the knowledge sharing process. Overall, the technicians saw more potential in losing customers due to the lack of

knowledge. This underlined that one of the participants has already lost potential customers due to fact that personnel was not available for questions, statements given were not reliable, and there were insufficient trainings on the products. As a result, the probability of occurrence to lose a potential customer due to the lack of knowledge is given.

## **5 Conclusion**

This research project explained how knowledge sharing should be implemented in medium-sized manufacturing companies to ensure adequate B2B communication among channel collaborations. Taking the findings, the overall collaboration with the case organisation was perceived as slightly satisfying, but the reason for this did not deal with knowledge sharing or anything that has to do with knowledge in a broader sense.

Knowledge sharing through case studies, transparent processes or the language were important factors, that at the same time were satisfying for the distributors. Explicit knowledge that should be transferred was specific product-related information material, and the prices of the products. Logistical aspects, such as delivery or production times were still (but less) important and general technological information material were not required.

Furthermore, the knowledge bases provided, showed that the one that is most important for the distributors, was the most satisfying at the same time (trainings on the product). Strikingly, the printed catalogue is more important and more satisfying than the online version of it. Summing up, the two ways of transferring tacit knowledge, i.e. joined customer visits and product trainings are useful methods to share knowledge among manufacturer and distributor.

Nearly all of the above-mentioned aspects were far better rated by the technicians than by the commercials. While it was slightly probable to the commercials to lose a customer due to the lack of knowledge, it was moderately probable to the technicians. The highest probability of losing a potential customer was seen in the lack of reliability and the unavailability of the contact person. This could have been put into a more complete picture on the knowledge types and knowledge sharing activities. Thus, this research touched upon several aspects that might have the potential of future research. An interesting topic would be to analyse the cultural aspects that influence international B2B in sales

channel collaborations. Further, it would be interesting to repeat the study after being in a pandemic for more than one year.

### **Abstract**

Research on entrepreneurial ecosystems has gained significant interest throughout the academic community in recent years. In this context, the role of digital transformation and particularly digital platforms for improving the communication and collaboration of various actors in such ecosystems is increasingly being discussed. In this paper, we conceptualize how excubation platforms (XPs) can support the interaction among the actors in entrepreneurial ecosystems contributing to 1) an improved matchmaking between entrepreneurs and entrepreneurship supporters, 2) a better coordination of the multitude of support programs available, 3) novel approaches for quality control enabled by one digital solution used by all actors and 4) a more structured exchange of competence and experience between the individual entrepreneurs. We illustrate these potentials by the case of the Norwegian entrepreneurial ecosystem, where a pilot for an XP is currently being developed.

**Keywords** – Entrepreneurial Ecosystem, Excubator, Incubator, Business Model, Entrepreneurship Support

**Paper type** – Academic Research Paper

## 1 Introduction

Digital Platforms (DPs) and Multi-Sided Platforms (MSPs) gained significant research interest in recent years (e.g. Abdelkafi et al., 2019; Hagiwara & Wright, 2015; Täuscher & Laudien, 2018). In the context of open innovation and entrepreneurship, they are evaluated as drivers of value creation or as specific components of business models (BMs) (e.g. Helfat & Raubitschek, 2018; Nambisan et al., 2018; Nambisan et al., 2019). Besides the increasing importance of such platforms in general, they received an additional boost during the COVID-19 pandemic (JHCRC, 2021; Zhu et al., 2020) due to the need to switch towards digital and online formats (see, for example, Dwivedi et al., 2020; Kuckertz et al., 2020).

However, while these potentials of DPs and MSPs as part of the outcome of entrepreneurial activities are increasingly being discussed (e.g. Cenamor et al., 2019; de Oliveira & Cortimiglia, 2017; Srinivasan & Venkatraman, 2018), we argue that their role as connectors between entrepreneurs and their supporters (coaches, incubators, etc.) in the entrepreneurial ecosystem has received insufficient attention so far. This is in line with Elia et al. (2020) arguing that more research is needed on the digital organization of entrepreneurial ecosystems' design and implementation. Especially in times of the current COVID-19 pandemic, where many entrepreneurship support programs based on physically coming together in incubator spaces are deprived of their working basis, the relevance of digital solutions is increasing (e.g. EBN, 2020; Giones et al., 2020; Lose, 2020). In this context, we are currently experiencing a shift from primarily physical incubators with accompanying digital programs to a holistic accompaniment of entrepreneurs that often runs digitally only and supports the entire entrepreneurial lifecycle. Such programs are often referred to as *excubators* (Carman, 2013; Deeb, 2014), an approach that has been in practice for about a decade but seems to not playing a role in the academic debate yet (see Scopus, 2021).

Consequently, this paper aims to provide a first conceptualization of excubation platforms (XPs) as a new infrastructure enabling entrepreneurial ecosystems, thereby exploring the question how an XPs can create value for the actors within these ecosystems. Therefore, we develop a model depicting the key components and actors of an XP based on the DP, MSP and entrepreneurial ecosystem literatures. We then illustrate how an XP could look like in practice by discussing its current and future role in the Norwegian entrepreneurship ecosystem. We thus contribute to the ongoing academic debate on entrepreneurial ecosystems by providing a conceptualization of how the XP as a novel digital platform solution can organize the support of entrepreneurs in a better and more comprehensive manner.

## **2 Background**

### **2.1 About Platforms**

When discussing platforms in the context of business or entrepreneurship, we typically refer to digital platforms (DPs) and Multi-Sided Platforms (MSPs). DPs can broadly be defined as “technical elements (of software and hardware) and associated organizational processes and standards”, while MSPs add the notion of “mediating different groups of users, such as buyers and sellers” (de Reuver et al., 2018, p. 127). Investigating what DPs and MSPs do, Parker et al. (2016) describe that they enable the interaction among third-party producers of complementary goods and services, thereby seeking to create value for all participants. The participants can be distinguished in several kinds of actors – typically platform owners and platform providers, complementors and consumers – together forming the platform ecosystem (Abdelkafi et al., 2019; de Reuver et al., 2018; Van Alstyne et al., 2016).

Van Alstyne et al. (2016) illustrate this using the example of the Android platform: Google (today Alphabet) is the owner of the platform, mobile devices running the Android system are the platform provider, third party app developers are the complementors, creating complementary, digital products for this platform and the users of the mobile devices are the consumers not only using the devices themselves, but also the apps offered via the platform. This underlines that these platforms create value for the involved actors, by enabling goods to be exchanged and by creating matches among different users.

In the entrepreneurial context, we see that DPs and MSPs are frequently discussed as an outcome. For instance, platforms are described as parts of new ventures' business models (de Oliveira & Cortimiglia, 2017; Hagiwara & Wright, 2015), as local enablers of entrepreneurial activity (Freire-Gibb & Lorentzen, 2011) or entrepreneurship itself is described as a platform for contributing to the solution of societal challenges (Markman et al., 2016). More generally, the role of digital transformation is discussed in the context of entrepreneurial ecosystems (Elia et al., 2020; Sussan & Acs, 2017), an aspect that is further elaborated in the following section of this paper.

However, despite the multitude of governmental programs using significant resources on the support of entrepreneurial activity (Dahle et al., 2020), few studies seem to investigate the use of platforms to organize such support. Here, the *excubator* could deliver a foundation for a particular kind of platforms addressing this challenge. Carman (2013) distinguishes *excubators* from accelerators and incubators stating that while these would "typically last for just three months of the year, the *excubator* is designed to support startups from the very beginning with ideation to the very end of what hopes to be a successful exit".

## **2.2 Entrepreneurial Ecosystems**

Entrepreneurial ecosystems gained substantial popularity during the last years. After its introduction by Isenberg (2010) and Feld (2012), the concept was widely adopted outside of academia, leading to "a situation where research is led by policy rather than policy being guided by rigorous academic research (Stam & Bosma, 2015; Stam & Spigel, 2018)" (Wurth et al., 2021, p. 1). This development is summarized in a recent, comprehensive literature study and research agenda by Wurth et al. (2021). They highlight that the concept of entrepreneurial ecosystems has the potential to synthesize a variety of research streams in the field and that future ecosystem research should specifically discuss how it could be an enabler of entrepreneurship.

The purpose of entrepreneurial ecosystems is to provide a fruitful environment to support the growth of start-ups (Spigel & Harrison, 2018). The key actors within the ecosystem include individual entrepreneurs as well as entrepreneurship supporters providing resources including trainings, networks, talented workers and financing. Further actors include academic institutions, financial institutions, existing firms and the government (Brown & Mason, 2017; Spigel & Harrison,

2018). According to Spigel and Harrison (2018), successful entrepreneurial ecosystems are characterized by engaged entrepreneurs who benefit from the resources in the ecosystem and who use opportunities to interact with other actors in the ecosystems. Hence, a well-functioning interplay of entrepreneurship supporters and entrepreneurs is crucial for the entrepreneurial ecosystem's success. In the last two decades, various highly specialized entrepreneurship supporter types have emerged to address the diversity of entrepreneurial needs, e.g., along the entrepreneurial life cycle, pre-seed, seed and growth phases (investors, incubators, accelerators).

Yet, due to the specialization of entrepreneurship supporters, there is a challenge for them to find the right entrepreneurs for the programs they offer. Additionally, entrepreneurs can struggle to find the right support program for their needs at a certain development stage of their initiatives. This indicates a need for better coordination of how actors within the entrepreneurial ecosystem communicate and find each other to cooperate. Digital entrepreneurial ecosystems can enable a more efficient connection of actors and activities within the ecosystem (Elia et al., 2020). This is linked to the idea of XPs, which represent a specific digital organization of an entrepreneurial ecosystem and thus can be a significant driver of entrepreneurship support. For instance, an XP could improve the interactions among the actors in an entrepreneurial ecosystem by providing an overarching platform to connect a variety of different support offerings, making it easier for entrepreneurs to find the right helpers for the stage they are in and making it easier for the entrepreneurship supporters to find the right entrepreneurs who would benefit most from the support they offer. The following section expands on these thoughts by providing a comprehensive conceptualization of XPs and their role within the entrepreneurial ecosystem.

### **3 Conceptualization of an Excubation Platform**

We define an XP as a digital and multi-sided platform that can be used by entrepreneurship supporters for offering comprehensive support programs to entrepreneurs throughout the whole lifecycle of entrepreneurial initiatives. To conceptualize the role of XPs within the entrepreneurial ecosystem, we use the concept of *entrepreneurial activity systems* (Amit & Zott, 2015; Zott & Amit, 2010). It describes the activity of entrepreneurs from a systems perspective distinguishing three main system elements: The *governance*, describing the actor

who carries out the activity, the *content*, describing what the activities involve and the *structure*, describing how one activity is interrelated with one or several others.

Regarding the *governance*, we can identify the essential roles of platform actors highlighted in section 2.1 for XPs in the entrepreneurial ecosystem. The institution governing the respective XP (e.g. a regional government) is the *platform owner*. Its task is to strategically plan how, where and for what purpose the XP is offered. The *platform provider* would typically be a consortium of technology providers selected to develop the XP. Their responsibility is the technical and methodical development and provision of the XP as well as the operational support of all processes that are handled via the platform. Entrepreneurship supporters (e.g. incubators, accelerators, etc.) are the *complementors* of the XP, offering concrete programs that help entrepreneurs in developing their initiatives, founding their businesses etc. Finally, the entrepreneurs are the *consumers*, participating in programs selected via the platform.

Regarding the *content* and *structure*, we can identify several activities for each actor in the system that are interrelated when going through an XP. This is set out in Figure 1.

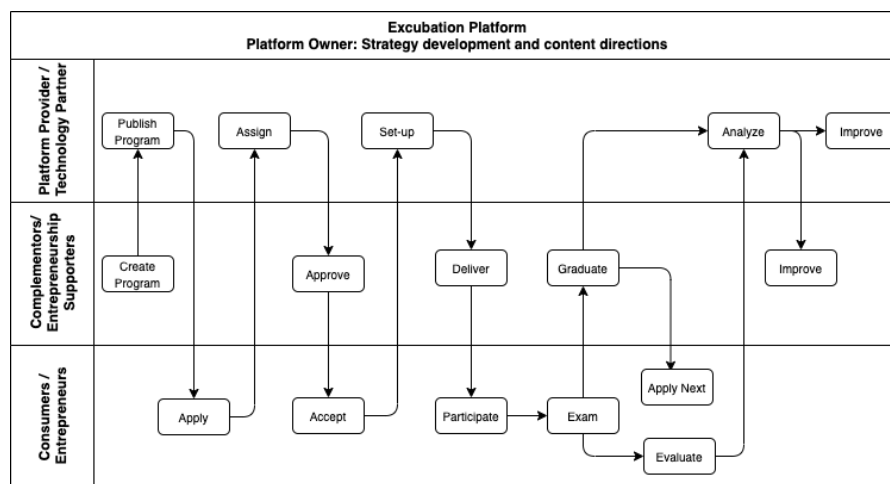

Figure 1: EPs in the Entrepreneurial Ecosystem

Here, all *complementors* design their support program before the *platform provider* (on behalf of the *platform owner*) quality assure and then publish the

program. The *consumers* then apply to a subset of the programs available on the platform before the *platform provider* assign the *consumer* to the most relevant program. The *complementors* and the *consumers* accept the match before the program is set up and delivered. Finally, the *consumers* finish the program with an exam, which is evaluated by the *complementors*. If the *consumers* graduate from one program, they can apply for the next level of programs. The evaluation of the program, together with the activities performed, is analyzed by the *platform provider* as a starting point for improvements to be made jointly with the *complementors*.

## **4 Illustrating the Excubation Platform – The case of Norway**

### **4.1 State of Play – Norway’s Entrepreneurial Ecosystem today**

National, regional, and local levels of the Norwegian government spend millions of Norwegian Kroner annually on a multitude of different government support programs for entrepreneurs (e.g. MTIF, 2016). In addition to this, commercial actors like consultancy firms, banks, investors, and co-working spaces provide entrepreneurial support, and academic institutions have their own offerings in the form of special courses, technology transfer offices and makerspaces. Together, all these programs provide funding, financial grants, incubation, mentoring, education and networking for entrepreneurs in all stages of their development.

Examples of complementors providing such programs would be *Innovation Norway*<sup>1</sup>, that provide funding for high-growth entrepreneurs, SIVA (Norwegian Association for Industrial Growth) that manages more than 150 incubators of various kind across Norway, The Norwegian Culture Council providing entrepreneurship support for Arts Entrepreneurs, 356 municipalities responsible for the initial support of start-ups and 10 regions coordinating the entrepreneurship support in their areas.

As highlighted in Section 2.2, entrepreneurial ecosystems can be defined as “a set of interdependent actors and factors coordinated in such a way that they enable productive entrepreneurship within a particular territory” (Stam & Spigel, 2018, p. 407). Consequently, we argue that the sum of all these support organizations and

---

<sup>1</sup> The national innovation support organisation of Norway

the entrepreneurs using them jointly constitute the Norwegian Entrepreneurial Ecosystem (NEE).

#### **4.2 Observed Challenges regarding the Norwegian Entrepreneurial Ecosystem**

The NEE undeniably provides significant value to entrepreneurs, making Norway an attractive location for entrepreneurial venturing. Still, there is clear room for improvement, causing *Innovation Norway* to take the initiative for a further coordination of the different actors in the Ecosystem in 2021 (Innovation Norway, 2021). We identify four specific and practical areas of potential improvements for the NEE in the future:

- (1) It could be easier for the individual entrepreneurs to find the program most suited for them, depending on their vertical industry, life phase and special need – while the programs struggle to recruit the right entrepreneurs for their individual programs.
- (2) The programs could be better coordinated. This means that they would benefit from having better communication between each of them, and also that the business development methodology the different programs used could be more similar. This would enable a smoother transition of entrepreneurs between the programs, and a better division of tasks between different programs.
- (3) There is a need for a better effect measurement and quality control for the programs, enabling the allocation of resources to the programs benefiting entrepreneurs the most.
- (4) There could be a more structured exchange of competence and experience between the individual entrepreneurs, creating better entrepreneurial networks.

#### **4.3 Piloting the Excubation Platform Concept**

We argue that the XP conceptualized in section 3 of this paper constitutes a suitable tool to implement these improvements. The new role of *Innovation Norway* as a coordinator within the NEE suggests that they could act as the potential *platform owner*, developing a strategy for enabling entrepreneurship in Norway by means of an XP connecting the multitude of individual support

offerings (then *complementors*) in the ecosystem. A chosen consortium of technology providers could develop the platform, supporting *Innovation Norway* in the process. Finally, the Norwegian entrepreneurs would take the role of the platform's *customers* receiving a better-coordinated and more comprehensive support on their way through the individual phases of the entrepreneurial process.

In the context of its role as a coordinator in the NEE, *Innovation Norway* funded an initial pilot program to develop a platform supporting Norwegian entrepreneurs, taking the anticipated role of the *platform owner*. Therefore, a coordination of the programs from five different *complementors* is currently being set up. The platform provider for this particular pilot is *Entrepreneurdy AS*, a Norwegian methods and tech provider within the entrepreneurship space. In addition to the *complementors* offerings, the *platform provider* is setting up a residual program to create an offering for entrepreneurs not fitting into the other programs. Table 1 provides an overview of the support programs in this pilot.

Table 1: Entrepreneurship Support Programs in the Incubation Pilot

Complementor	Program	Description
Norwegian Culture Council	Ovasjon	30-week virtual program for Arts Entrepreneurs.
Norwegian Unemployment Agency	NAV	36-week virtual program that allows unemployed people to develop an entrepreneurial initiative while keeping their benefits.
The region of Møre & Romsdal	Hoppid	4-week hybrid program for startups, combining grants, mentoring and training
The region of Vestland	Driftig	4-week hybrid program for startups
The region of Nordland	Nordland	8-week hybrid program for startups
EIKA Bank Group	Lokal	12-week hybrid program for growth phase companies
Innovation Norway	Program # 13	Virtual incubation program utilizing only MOOC-based learning.

The services provided within this platform pilot include the 1) program marketing and recruitment for all six programs as well as an automatic assignment to one of the six platforms based on geography, life phase, vertical industry, and entitlement to support, 2) the application and an automated approval for the assigned program, 3) the program design and implementation

utilizing an Entrepreneurship Management System (EMS), 4) the program evaluation and analysis based on both the input in the EMS and the direct feedback from the consumers and the complementors and 5) in-cohort communication as well as in-program and in-ecosystem communication, enabling the consumers and the complementors to interact with each other and share experiences and knowledge.

#### 4.4 Indications for Value Creation from a Pre-Study

We are accompanying the design of the XP for the pilot program initiated by *Innovation Norway*, supporting this process from an academic perspective. In the current phase, we are aiming to identify suitable indicators for the entrepreneurs' level of engagement in the course of the support programs, to reason whether the XP can add value by addressing the challenges described in Section 4.2. Therefore, we measure the number of interactions for three programs that will be part of the complementors in the XP but have previously cooperated individually with a digital platform provider. Thus, there is data on entrepreneurs' engagement before the introduction of the XP. These three programs are *Ovasjon* (run by the Norwegian Culture Council), *Hoppid* (run by the region of Møre and Romsdal) and *Driftig* (run by the Region of Vestland). The number of cases, i.e. entrepreneurial initiatives supported and captured via the digital platform, is 317 from *Ovasjon*, 405 from *Hoppid*, and 92 from *Driftig*, adding up to 814 cases. The measured, average number of interactions per case is set out in Table 2.

Table 2: Entrepreneurs Interactions before the Pilot Platform

	<b>Ovasjon</b>	<b>Hoppid</b>	<b>Driftig</b>
Purpose	14	9	9
Resources	16	9	10
Business Idea	30	17	17
Business Model	41	18	19
Objectives	20	11	14
Tasks	20	12	13

As soon as the pilot program of *Innovation Norway* described in Section 4.3 has been running for a sufficient time, we plan to measure this number of interactions again. The hypothesis is that the increased quality control within the programs, the improved consumer-program match and the increased interaction among the

platform participants will drive up the average number of interactions within each of the three programs. This empirical study on the XP concept will be a part of our future research on the subject.

## 5 Conclusions and Future Research

This paper conceptualizes how excubation platforms (XPs) can support the interaction among the actors in entrepreneurial ecosystems contributing to 1) an improved matchmaking between entrepreneurs and entrepreneurship supporters, 2) a better coordination of the multitude of support programs available, 3) novel approaches for quality control enabled by one digital solution used by all actors and 4) a more structured exchange of competence and experience between the individual entrepreneurs.

On this basis, we derive three propositions: We propose that entrepreneurs as *consumers* of an XP will display a continuum of ability and willingness to engage with their ecosystem, which will affect their ability to benefit from the resources it provides. Moreover, we propose that entrepreneurship supporters contributing to an XP will be enabled to develop novel services, advance servitization and co-create with other *complementors* to develop new solutions. Finally, we propose that governmental bodies acting as *platform owners* of an XP will benefit from the opportunity to store data on the supported cases for quality control and continuous improvement and that they are enabled to create scalable systems with an improved coordination of the support process.

We contribute to the academic debate by framing the role of Digital Platforms (DPs) and Multi-Sided Platforms (MSPs) beyond the outcome of entrepreneurial activities as part of entrepreneurship support within the entrepreneurial ecosystem. We therefore transfer the excubation approach widely used in entrepreneurship practice to an academic foundation in a platform context by defining the XP concept. We discuss and illustrate the potential effects and procedures of implementation for such XPs in the context of the Norwegian entrepreneurial ecosystem, thereby providing a basis for further investigation of holistic and digital entrepreneurship support approaches.

For entrepreneurship practice, we highlight opportunities for entrepreneurship support beyond physical meetings and map their potentials and challenges. We show how entrepreneurial supporters can enhance the engagement of their customers (the entrepreneurs) using digital platforms and comprehensive

accompaniment throughout the entire entrepreneurial lifecycle by means of the XP concept.

As this paper is conceptual in nature, setting out the fundamental structures and potentials of XPs, future research should explore further use cases and seek empirical evidence for the potentials of value creation through these kinds of platforms in the entrepreneurial ecosystem. As set out in section 4.3, our own research will involve the empirical investigation of a respective initiative in Norway that is currently in an early stage of development.

### Abstract

**Purpose** – This paper explores the moderation effect of knowledge complexity and social integration mechanisms on the relationships between the absorptive capacity (ACAP) components in southern Brazilian firms.

**Design/methodology/approach** –Our sample includes 174 ICT firms from ten clusters of technology-based firms located in Southern Brazil. Hypotheses were tested using structural equation modelling (PLS-SEM) supported by the software ADANCO 2.0.1.

**Originality/value** –We found that knowledge complexity matters for absorptive capacity. Depending on knowledge complexity, social integration mechanisms may be both: a blessing and a curse for absorptive capacity. Specifically, we found that in the paths from acquisition to assimilation, and from acquisition to transformation, high levels of social integration mechanisms help acquire complex knowledge, but they may constraint the absorption of simple knowledge. Our findings contribute to the KBV of the firm by improving our understanding of the role of knowledge complexity as an antecedent of absorptive capacity' components.

**Practical implications** – By identifying the role of knowledge complexity on the efficiency of both social integration mechanisms and ACAP, this study brings valuable information to

managers of both Brazilian firms and foreign organisations willing to establish their operations in Brazil, for the efficient allocation of firm resources for improving the firm innovative performance.

**Keywords** – Knowledge Complexity, Absorptive Capacity, Social Integration Mechanisms, Brazil, ICT.

**Paper type** – Academic Research Paper

## 1 Introduction

For the knowledge-based view (KBV), firm competitiveness is a function of how firms integrate the specialised knowledge that workers possess into the final products (Grant, 1996). In the current scenario, much valuable knowledge to innovate may be located outside the physical boundaries of the firm (Asimakopoulous, Revilla & Slavova, 2020). For this reason, knowledge absorptive capacity – the ability to acquire, to assimilate, to transform and to apply external knowledge to create value – emerged as a critical organisational competence (Cohen & Levinthal, 1990; Zahra & George, 2002). The antecedents of knowledge absorptive capacity have been analysed by several studies from different research streams (Apriliyanti & Alon, 2017). One of the factors proposed as fundamental for the development of absorptive capacity is the social integration mechanisms (e.g. Zahra & George, 2002; Enkel, Groemminger, Heil, 2017; Von Briel, Schneider & Lowry, 2019), the routines and processes that stimulate social integration between group members (Von Briel, Schneider & Lowry, 2019). Nevertheless, both conceptual and empirical views on the relationship between social integration mechanisms and absorptive capacity are divergent. Some authors posit that social integration mechanisms affect only the transition from knowledge assimilation to transformation, and that this influence is always positive (Zahra & George, 2002), while other authors argue that social integration mechanisms affect all relationships between the components of absorptive capacity and this influence may be either positive or negative, depending on contextual factors (Todorova & Durisin, 2007). From the empirical side, the findings are contradictory as well. The moderation effects of social integration mechanisms on the transition from what Zahra & George (2002) called the potential absorptive capacity (acquisition and assimilation) to realised absorptive capacity (transformation and exploitation) have been found as positive (Leal-

Rodriguez, Roldán, Ariza-Montes & Leal-Millán, 2014), negative (Armstrong & Lengnick-Hall, 2013) or not significant at all (Gluch, Gustafsson & Thuvander, 2009). These differences may be explained by the complexity of the knowledge which is being acquired, assimilated, transformed and applied. Managing knowledge may be easier or harder, depending on the nature of the knowledge involved, which may be more or less complex (Kim & Anand, 2018).

Knowledge complexity has been theorised as an antecedent of absorptive capacity (Vega-Jurado, Gutiérrez-Gracia, & Fernández-De-Lucio, 2008), or as a moderator of the effect of social integration mechanisms on absorptive capacity (Todorova & Durisin, 2007). Drawing on the 'weak ties' theory (Hansen, 1999), Todorova & Durisin (2007) stated that the complexity of knowledge will affect the efficiency of social integration mechanisms for enhancing absorptive capacity components, and ultimately, innovation performance. For Todorova & Durisin (2007), when knowledge complexity is high, strong social integration mechanisms are more efficient for enhancing absorptive capacity. On the other hand, when the knowledge is simple, weak social integration mechanisms are better to absorb this knowledge. Despite this, the effects of knowledge complexity, and its joint effects together with social integration mechanisms, on absorptive capacity have not been properly explored. Wang and Han (2011) analysed absorptive capacity as a moderator between properties of knowledge —tacitness, ambiguity, and complexity— and innovation performance. Other studies explored knowledge complexity and absorptive capacity as antecedents of uniformity (Minguella-Rata, Rodríguez-Benavides & López-Sánchez, 2012). Thus, to the best of our knowledge the joint effect of knowledge complexity and social integration mechanisms—two antecedents of absorptive capacity — remains unexplored. In this context, some questions emerge: How may the complexity of knowledge affect absorptive capacity' components? How may the complexity of knowledge affect the intensity and efficiency of other absorptive capacity antecedents, such as social integration mechanisms? What is the joint effect of knowledge complexity and social integration mechanisms on absorptive capacity' components? In line with studies of Dittlo (2004) and Winkelbach and Walter (2015), for addressing these research questions, the present authors chose firms from a knowledge-intensive sector such as ICT, because this sector has firms that are used to managing knowledge with a broader range of complexity.

## **2 Social integration Mechanisms and Absorptive Capacity**

The term “social integration mechanisms” have been used to describe a variety of such initiatives that contribute to building connectedness, socialisation and shared meanings among employees of an organisation, and thus influence various knowledge processes (Zahra & George, 2002; Armstrong & Lengenick-Hall, 2013). For instance, these mechanisms contribute to building channels for both distributing information and gathering interpretations across the organisation, and by doing so, they improve knowledge-processing capabilities (Armstrong & Lengenick-Hall, 2013). Social integration mechanisms overcome the challenges related to the information exchange within an organisation (Zahra and George, 2002), and they aim to facilitate the externalisation of tacit knowledge (Nonaka, 1994). They promote the efficient circulation of information flows within the firm (Fosfuri & Tribó, 2008), and they make interunit knowledge transfer more intensive by building up interpersonal networks (Peltokorpi, 2017).

Previous research broadly agrees that social integration mechanisms are important for absorptive capacity (Zahra & George, 2002; Todorova & Durisin, 2007; Spithoven et al., 2010). Some scholars have theorised that these mechanisms may affect the relationships between the different components of absorptive capacity, but they disagree on whether this moderating effect is positive or negative, and whether it holds for all relationships between absorptive capacity components, or just for some of them. For instance, scholars like Zahra & George (2002) or Easterby-Smith, Graça, Antonacopoulou & Ferdinand (2008), posit that social integration mechanisms moderates the transition from assimilation to transformation, and that this moderation effect is always positive. On the other hand, Todorova & Durisin (2007) state that social integration mechanisms moderates all the relationships between the different components of absorptive capacity, and that these moderations may be positive or negative depending on specific circumstances.

From the empirical side, the results are still very limited and inconclusive. Most studies have focused on analysing the moderation effect of social integration mechanisms on what Zahra & George (2002) called the transition from potential to realized absorptive capacity (assimilation to transformation), but with different results: while Leal-Rodriguez, Roldán, Ariza-Montes & Leal-Millán (2014) found that social integration mechanisms moderate positively the transition from potential to realised absorptive capacity, Armstrong & Lengenick-Hall (2013) found

this moderation to be negative, and Gluch et al. (2009) found no significant effects at all. Following Todorova & Durisin (2007) we posit that these contradictory results regarding the role of social integration mechanisms for absorptive capacity may be explained by including knowledge complexity in our equation. Besides, in line with several scholars (Todorova & Durisin, 2007; Patterson & Ambrosini, 2015; Björkman et al., 2007) we posit that social integration mechanisms may moderate all relationships between the components of absorptive capacity, and not just some of them.

### **3 The role of knowledge complexity for Absorptive Capacity**

Complex knowledge is a source of competitive advantage because it is difficult to imitate, and its management inside the organisation is challenging (Kim & Anand, 2018; Vuori et al., 2019). Li, Shi, Li & Wang (2015) stated that complex knowledge uses to be tacit, highly specialised and is difficult to formalize. In this line, Hansen (1999) posited that complex knowledge is usually uncoded, and it possesses a high number of elements and interdependencies among these elements (Simon, 1962). These attributes of knowledge complexity are related to the individual specialised knowledge used for performing a specific task, and ultimately, it differs from what Louadi (2008) called 'knowledge heterogeneity', a term related to the extent to which the old and new knowledge existing in the individuals and organisational units is different.

Since absorptive capacity promotes organisational innovations (Cohen & Levinthal, 1990; Zahra & George, 2002), and knowledge complexity has been linked to radical innovations (Pérez-Luño, Medina, Lavado, & Rodríguez, 2011), it is important to understand the relationship between knowledge complexity and absorptive capacity. We posit that knowledge complexity may affect the effect of social integration mechanisms on the different components of absorptive capacity in several ways. First, tasks that need a higher level of cognitive processing tend to need greater time for recovering from interruptions (Golden & Gajendran, 2019), and social interactions may be a source of interruptions for people performing individual tasks. Besides, knowledge complexity may affect some KM processes. For instance, some scholars stated that complex knowledge is more difficult to codify, and ultimately, to share (Hansen, 1999; Li et al., 2015). Thus, other studies have proposed that when the knowledge is more complex, information flows and information processing may become more biased (Kim &

Anand, 2018) and this may cause difficulties for efficient knowledge sharing (Heiman & Nickerson, 2004; Li et al., 2015). When the knowledge is complex, the efficiency of knowledge application depends on the level of cross-functional integration (Pérez-Luño, Bojica, & Golapakrishnan, 2019), which may be provided by social integration mechanisms. Knowledge complexity may also affect the reuse of knowledge, by hampering the needed level of interaction between the author and the user for developing a shared perspective (Boh, 2008).

Based on Hansen (1999), Todorova & Durisin (2007) proposed that knowledge complexity may affect the efficiency of social integration mechanisms for enhancing absorptive capacity components, and ultimately, firm outcomes. Hansen (1999) posit that when knowledge is simple, weak ties tend to be more efficient for enhancing information flows during search processes, by minimising the existence of redundant knowledge, and ultimately, by reducing search costs. Social integration mechanisms make the ties among employees stronger. Thus, Todorova & Durisin (2007) stated that when the knowledge is simple, weak social integration mechanisms are better to absorb this knowledge. On the Other hand, when knowledge complexity is high, strong social integration mechanisms are more efficient for enhancing absorptive capacity. Then, Todorova & Durisin (2007) stated that the moderation effect of social integration mechanisms on the relationships between the different components of absorptive capacity may be positive or negative depending on knowledge complexity. This proposition of Todorova and Durisin (2007) has not properly discussed yet. Thus, to the best of our knowledge the joint effect of knowledge complexity and social integration mechanisms—two antecedents of absorptive capacity — remains unexplored. Based on the propositions of Todorova & Durisin (2007), we posit that the more complex is the knowledge the firm is acquiring, the higher level of social integration mechanisms is required for enhancing the transition from acquisition to assimilation of knowledge. On the other hand, when the knowledge is simple, weak ties are better for the efficiency of the transition from acquisition to assimilation. In other words:

*H1. The moderation effect of social integration mechanisms (SIM) and knowledge complexity (KC), on the relationship between acquisition and assimilation of knowledge, is positive.*

Similarly, we developed these hypotheses for analysing how social integration mechanisms and knowledge complexity moderate the other paths inside absorptive capacity:

*H2. The moderation effect of social integration mechanisms (SIM) and knowledge complexity (KC), on the relationship between acquisition and transformation of knowledge, is positive.*

*H3. The moderation effect of social integration mechanisms (SIM) and knowledge complexity (KC), on the relationship between assimilation and exploitation of knowledge, is positive.*

*H4. The moderation effect of social integration mechanisms (SIM) and knowledge complexity (KC), on the relationship between transformation and exploitation of knowledge, is positive.*

## **4 Methodology**

### **4.1 Sample**

To address these research questions, this study used a sample that comprises 174 technology-based firms located in the three states of Southern Brazil: Paraná, Santa Catarina and Rio Grande do Sul. The three states hold innovation ecosystems that are leaders in Brazil, and together, these states possess and together they have 46 technological parks and 73 incubators (Conceição Neto et al., 2018; INNOVA.RS, 2019; ACATE, 2020). After sending invitations to these groups, ten technological clusters from the three states participated in our study. They are the Santa Catarina Technology Association, Deatec Chapecó, Polo Inovale, Tecnoparque – Hotmilk of the Catholic University of Paraná, Itaupú Technology Park, Maringá Technology Incubator, Pato Branco Technological Park, Biopark of Toledo, Tecnovates, Feevale TechPark and Technological Park of the Catholic University of Rio Grande do Sul. A total of 708 firms belong to these clusters. Data was collected between December 2019 and February 2020, by mailing the companies' CEOs. As a result of collection efforts, we collected 174 usable responses, representing a response rate of 24.6%, which is superior to other studies in the Brazilian context (i.e. Dávila, Andreeva, Varvakis, 2019).

### **4.2 Measures**

We use an online survey that integrates scales of absorptive capacity, knowledge complexity and social innovation mechanisms. For measuring the four components of absorptive capacity –acquisition, assimilation, transformation and

exploitation–, we used the scale developed by Flatten, Engelen, Zahra & Brettel (2011), composed of 15 items and that was built considering different research streams and models for ACAP (Todorova & Durisin, 2007; Zahra & George, 2002). We measured Social integration mechanisms by using a scale developed by Distel (2019). The scale for measuring Knowledge complexity was based on Li et al. (2015).

The wording and structure of all scales were validated in a pre-test for assuring that they are adequate and easy to understand by Brazilian managers. All scales used in this study are presented in Table 1. All items used in the survey have a five-point Likert scale with values ranging from 1- strongly disagree to 5 - strongly agree.

### **4.3 Analysis**

For analysing the moderation effects of knowledge complexity and social integration mechanisms on each path of absorptive capacity, we used partial least squares structural equation modelling (PLS-SEM), supported by ADANCO software version 2.1.1. We chose PLS-SEM because it is best suited to relatively small datasets and it does not rely on the assumption of normality (Henseler et al., 2016). For modelling the moderation effects, we used the two-stage approach proposed by Henseler (2017). In the first stage, we estimated the model without the interaction, and we created an interaction term by extracting the construct scores. In the second stage, we estimated a new model that includes the interaction. We decided to test four models instead of just one model with the moderation effects of both knowledge complexity and social integration mechanisms on the four components of absorptive capacity, to avoid multicollinearity created by the use of the same component to test moderation effects along the 'absorptive capacity circuit'. For analysing the results, we followed the best practices suggested by Ringle, Sarstedt, and Straub (2012).

## **5 Results**

Before analysing the measurement model and structural model, we applied some remedies for avoiding common method bias.

We used some procedural remedies suggested by Podsakoff et al. (2012). The online survey was managed and performed by the associations to which firms belong. By doing this, we provided to respondents the same data collection

standards they use to deal with (e.g. ethics, privacy, communication style and channel), and we increased the probability of honest answers. We chose respondents that were familiar with innovation and business management issues. On the statistical side, we compared the answers of early and late respondents for testing nonresponse bias, by using discriminant analysis (Armstrong & Overton, 1977) and no significant differences were found. Besides, we tested a model that included additional unmeasured latent factors to represent CMB, and as suggested by Liang, Saraf, Hu, & Xue (2007), we confirmed that the loadings on the unmeasured latent factor were lower than the loadings on the construct factors. In addition, we checked that variance inflation factors (VIF) for each construct factor in each latent variable were lower than 3.3 (Kock, 2015). These procedural and statistical procedures taken together decreased the risk of CMB being a serious concern in this research.

### 5.1 Measurement model.

We confirmed good reliability in latent constructs by calculating scores (above 0.65) as recommended by Nunnally & Bernstein (1994) for Cronbach's Alpha, composite reliability, and rho A tests. The AVE scores above 0.5 for all latent variables as suggested by Fornell & Larcker (1981), and the loadings of all indicators above 0.6 (Hair, Black, Babin, Anderson, & Tatham, 2006) evidenced an adequate convergent validity (see table 1).

Table 1. Scale items, scale reliability and validity

Indicators		Factor loadings	Dijkstra-Henseler's rho ( $\rho_A$ )	Jöreskog's rho ( $\rho_C$ )	Cronbach's alpha ( $\alpha$ )	AVE
<b>Acquisition</b>			0.782	0.854	0.771	0.596

As suggested by Fornell & Larcker (1981), we assessed Discriminant validity by checking that the square root of AVE in each latent construct is higher than the correlation between the construct and the other ones (see table 2). Descriptive statistics show that firms in the sample tend to use medium levels of social integration mechanisms (mean of 3.54) and these firms use to deal with simple and complex knowledge (mean of 3.32). Besides, assimilation and exploitation are the most representative components of ACAP most frequently performed by the firms in our sample (means of 4.24 and 4.22).

Table 2. Descriptive statistics, correlations and Fornell-Larcker criterion

Construct		Mean	StD	AC	AS	TR	EX	SIM	KC
AC	Acquisition	4.08	0.67	0.60					
AS	Assimilation	4.24	0.63	0.30	0.65				
TR	Transformation	4.08	0.72	0.24	0.35	0.78

Squared correlations; AVE in the diagonal.									

### 5.2 Structural model.

To analyse the moderation effects of both knowledge complexity and social integration mechanisms acting together on each path between components of absorptive capacity, we tested four models. For each model, following the suggestions of Henseler et al. (2016), a bootstrapping procedure was performed (with 4999 bootstrap samples) to obtain and present confidence intervals about each construct and path in the model. Table 3 summarizes the results of the four models tested.

Table 3. Results of the path analysis

Paths	Coefficients $\beta$ (p-values in brackets)				
	Model 0 (no mod)	Model 1	Model 2	Model 3	Model 4
Acquisition → Assimilation	0.57 (0.00)	0.46 (0.00)	0.57 (0.00)	0.57 (0.00)	0.57 (0.00)
Acquisition → Transformation	0.50 (0.00)	0.50 (0.00)	0.35 (0.00)	0.50 (0.00)	0.50 (0.00)
Assimilation → Exploitation	0.29 (0.00)	0.29 (0.00)	0.29 (0.00)	0.27 (0.00)	0.28 (0.00)
Transformation → Exploitation	0.44 (0.00)	0.44 (0.00)	0.44 (0.00)	0.44 (0.00)	0.41 (0.00)
Acquisition x Social Integration Mechanisms (SIM) x Knowledge Complexity (KC) → Assimilation		0.18 (0.00)			
Acquisition x SIM x KC → Transformation			0.25 (0.00)		
Assimilation x SIM x KC →				0.05	

Exploitation				(0.53)	
Transformation x SIM x KC → Exploitation					0.07 (0.40)
<b>SRMR</b>	0.07	0.07	0.07	0.07	0.07
<b>Adjusted R-squared</b>					
Assimilation	0.32	0.33	0.32	0.32	0.32
Transformation	0.24	0.24	0.28	0.24	0.24
Exploitation	0.42	0.42	0.42	0.42	0.42

\*  $p$ -values are reported in brackets after  $\beta$  coefficients.

The results indicate that the paths from acquisition to assimilation, from acquisition to transformation, from assimilation to exploitation, and from transformation to exploitation were positive and significant, as Todorova and Durisin (2007) predicted. All models showed an estimated SRMR value of 0.07, which is acceptable according to Henseler et al. (2016). The adjusted- $R^2$  values for assimilation, transformation and exploitation vary between 0.24 and 0.42. This explanatory power is in line with previous studies that explore absorptive capacity, where explained variance varies from 0.18 to 0.81 (Saraf, Liang, Xue & Hu, 2013; Ali & Park, 2016; Aliasghar, Rose, & Chetty, 2019).

Model 0 is a baseline model that excludes any moderations. Model 1 aimed to test the joint moderation effect of knowledge complexity and social integration mechanisms on the relationship between acquisition and assimilation components, which was positive and significant ( $\beta = 0.18$ ,  $p = 0.00$ ). Then, hypothesis 1 was confirmed. Model 2 confirmed hypothesis 2, as it tested the joint moderation effect of knowledge complexity and social integration mechanisms on the relationship between acquisition and transformation. This moderation effect is positive and significant ( $\beta = 0.25$ ,  $p = 0.00$ ). Hypothesis 3, regarding the joint moderation effect of knowledge complexity and social integration mechanisms on the relationship between assimilation and exploitation components, tested in model 3, was not confirmed ( $\beta = 0.05$ ,  $p = 0.53$ ). Finally, model 4 tested the moderation effect of social integration mechanisms on the relationship between transformation and exploitation components (hypothesis 4), and this effect was not confirmed ( $\beta = 0.07$ ,  $p = 0.40$ ).

## 6 Conclusion

We found that knowledge complexity matters for absorptive capacity and depending on that complexity, social integration mechanisms may be both: a blessing and a curse for absorptive capacity. Specifically, we found that in the paths from acquisition to assimilation, and from acquisition to transformation, high levels of social integration mechanisms help acquire complex knowledge, but they may constraint the absorption of simple knowledge. Taking together, our findings help to explain why some firms are more efficient at leveraging innovation than others with the same levels of absorptive capacity, and the same use of social interaction mechanisms.

This study contributed to the KBV of the firm by improving our understanding of the role of knowledge complexity as an antecedent of the efficiency of absorptive capacity' components. Besides, our findings contributed to organisational learning literature by providing a better understanding of how we can improve both absorptive capacity' components and outcomes, taking into consideration the knowledge complexity that firms use to deal with.

On the practical side, we demonstrated that maximum levels of social integrations mechanisms are not always beneficial for organisations. Since simple and complex knowledge requires different levels of social integration mechanisms for being transformed into organisational innovations, we posit that managers in ICT firms should evaluate to deploy different organisational units for absorbing simple (for exploitation projects) and complex knowledge (for exploration of new opportunities).

### Abstract

The health system's role for the welfare of the community and the growth and development of nations is widely known, and Business Economics scholars have paid great attention to the study of the sector. This paper focuses on a particular aspect of health care and aims to analyse the intellectual capital (IC) in the healthcare system regarding telemedicine's contribution at Covid-19.

The healthcare sector is "knowledge-intensive". For this reason, the study of IC becomes central in Business Economics studies that are increasingly oriented towards enhancing the intangible resources used and created by organisations. Recent scholars have investigated the development of knowledge-based activities as a significant factor in adopting innovation in healthcare organisations and institutions. However, scholars have paid little attention to the contribution of telemedicine to the generation of IC.

This paper aims to bridge the gap focusing on a particular aspect of health care and analyse the IC in the healthcare system regarding telemedicine's contribution at Covid-19.

Notably, we focus on how digital transformation and the knowledge management system used by telemedicine could contribute to the intellectual capital in the healthcare sector. To comply with the paper aim, we use a qualitative research method based on a case study particularly suitable for IC in health care studies. More precisely, we analyse a non-profit organisation that for over 15 years has offered a free multi-specialist teleconsultation service to answer medical questions from the most disadvantaged places in the world.

The findings show that telemedicine can develop and share knowledge in disadvantaged areas of the world . The IC makes the new business model capable of contributing to the improvement of the health conditions of the entire population, including the most fragile. Thus this research provides an original contribution to the literature on IC at the time of Covid-19.

**Paper type** – Academic Research Paper

## 1 Introduction

The health system's role for the welfare of the community and the growth and development of nations is widely known (EC, 2009), and Business Economics scholars have paid great attention to the study of the sector. The healthcare sector is knowledge-intensive, and this creates value and growth for organisations.

In the past two decades, extensive literature has turned the interest to exploring intellectual capital in the healthcare industry (Habersam and Piber, 2003; Zigan et al., 2008; Evans et al., 2015; Cavicchi, 2017). Recent scholars have investigated the development of knowledge-based activities as a significant factor in adopting innovation in healthcare organisations and institutions (Huang et al., 2021). Knowledge-based capital (KBC) comprises a variety of non-tangible assets. These assets are "the largest form of business investments and a key contributor to growth in advanced economies" (OECD, 2013:24) because they create future benefits for businesses. Still, these assets often cannot be accounted for because not referable to substantiated rights or expenses.

Even as the elements of a knowledge-based capital might take many forms and significance (Borchet al., 1999; Hitt et al., 2000), are fundamentally distinct in how they accumulate and distribute knowledge—namely, through individuals (human capital), relational ties (relational capital), and organisational systems (structural capital).

Following the OECD definition (OECD, 2013), KBC could be classified into three distinct groups: (1) computerised information (e.g. software and databases); (2) innovative property (e.g. patents, copyrights, design, trademarks, research & development); and (3) economic competencies (brand equity, human capital such as worker training and management consulting) or networks and people and

institutions and organisational know-how that increases enterprises' efficiency (OECD, 2013; Corrado et al., 2005; Paoloni et al., 2020).

IC becomes a crucial tool, especially in the health care sector, which has "knowledge intensive" features, especially telemedicine.

Telemedicine is a care pattern for patients that uses technology for both healthcare communication and delivery. This care application has been around for decades, and it has had an extensive development because it is easy to use for the patient, like a call to own physician for advice and treatment.

Due to recent advancing technology (e.g. streaming, video and text messages), telemedicine has quickly and widely extended its scope and capabilities. These effects have expanded during the Covid-19 era because of the need to maintain social distance (Colbert et al., 2020). However, scholars have paid little attention to the contribution of telemedicine to the generation of IC (Kraus et al., 2021).

This paper aims to bridge the gap focusing on a particular aspect of health care and seeks to analyse the intellectual capital (IC) in the healthcare system with specific regard to telemedicine's contribution at the time of Covid-19 by answering the following research question:

*How digital transformation and the knowledge management system used by telemedicine contribute to the intellectual capital in the healthcare sector?*

To comply with the paper aim, we use a qualitative research method based on a case study (Yin, 2014) particularly suitable for studies on IC in health care (Paoloni et al., 2020). More precisely, we will analyse a non-profit organisation that for over 15 years has offered a free multi-specialist teleconsultation service to answer medical questions from the most disadvantaged places in the world.

The findings show that telemedicine can develop and share knowledge in disadvantaged areas of the world. The IC makes the new business model capable of contributing to the improvement of the health conditions of the entire population, including the most fragile. Thus this research provides an original contribution to the literature on IC at the time of Covid-19.

The remainder of the paper is organised as follows: Section 2 examines the relevant literature on the IC, focusing on its application to the telemedicine sector. Section 3 outlines the research methodology. Section 4 presents the findings and discussion from the pilot case study. Lastly, section 5 presents the conclusions of the paper and future research directions.

## 2 Literature review and theoretical framework

The healthcare sector is "knowledge-intensive". Thus, the study of IC becomes central in Business Economics studies that are increasingly oriented towards enhancing the intangible resources used and created by organisations. Recent works have highlighted the growing interest in IC in the health sector (Paoloni et al., 2020). Some authors investigate knowledge generation and sharing as a fundamental intangible resource in creating a competitive advantage (Baum et al., 2000; Dyer and Nobeoka, 2000) by reducing costs (Cegarra-Navarro and Cepeda Carrion, 2013).

Kamaluddin and Rahman (2009) focused on IC's components (relational capital (RC), organisational capital (OC), and human capital (HC)) as value creators (Cavicchi, 2017).

HC concerns the organisation's human aspect and is represented by blending human skills, qualifications, and expertise (Bontis, 1998; Bontis et al., 1999). In this vein, HC refers to the value of the knowledge and talent that is embodied in people who form the organisation, expressing intangible resources as know-how, capacities, knowledge, skill, competence, attitude, intellectual agility, creativity (Edvinsson and Malone, 1997; Kaplan and Norton, 1996; Marr and Schiuma, 2001; Hamzah et al., 2018).

Youndt et al. (2004) define OC as the knowledge, skills, experience and information institutionalised, codified, and used by patents, systems, databases, routines and processes and includes other not evaluable intangible assets (Edvinsson and Malone, 1997).

RC refers to the internal and external relationships of the organisations (Paoloni, 2021).

All three components of the IC take on interesting connotations in telemedicine.

In the current context, still strongly pervaded by the emergency generated by the pandemic, an essential role in the provision of health services can be played by telemedicine (Leite et al., 2021; Bahl et al., 2020; Haleem and Javaid, 2020). The term "telemedicine" identifies a sector of the communication technologies sector (Information and Communication Systems, ICT) applied in the context of carrying out health care activities. The term is used to describe the computer and telecommunication systems that allow people to work together in time and space

and refer generically to the use of information technology in medicine (Craig, 1999; Rajani and Perry, 1999, EC, 2009).

Alonso et al. (2019) show that telemedicine and e-health allow offering predictive, personalised, preventive and participatory medical services. Thus, telehealth provides various benefits for patients with different illnesses and is vital for improving medical services. Bartel et al. (2014) underline that telemedicine is supported by greater patient participation in diagnosis and medical procedures. In this vein, the inquiries on the value creation process need to concentrate on the capabilities of general practitioners or the performance of digital devices (Huang et al., 2021). Simultaneously, these investigations should extend attention to what is happening to the knowledge sharing process (Mura et al., 2012; Radaelli et al., 2014), including the active role of a patient, who seems to be more integrated into intellectual capital exploitation (Piri and Asefzadeh, 2006).

Telemedicine resumes three knowledge-based activities in the healthcare ecosystem. Human capital develops capabilities for each health stakeholder. Relational capital promotes innovation and improves the effectiveness of the medical service. Structural capital is formed by a digital servitisation strategy (Huang et al., 2021).

The characteristics of telemedicine make it an exciting sector for studies on IC under different profiles: i) knowledge management (human capital), ii) dissemination of knowledge through the use of innovative digital and communication technologies (organisational capital), iii) cooperative work as a network of medical expertise (relational capital). Added to these aspects is iv) the social value (social impact) created by telemedicine to reach populations in disadvantaged areas of the territory where there would be little or no possibility of treatment (territorial intangible).

Regarding the latter aspect, the OECD (1991) defines the impact as the set of positive and negative, intentional or unintentional variations produced directly or indirectly by a development intervention. Different tools and measures of the social performance of non-profit organisations have been introduced since the late 1990s to provide a more holistic and sophisticated assessment of the results achieved in terms of impact and change (Arvidson 2009; Gibbon and Dey, 2011). Some scholars have adopted a qualitative (Kaplan and Norton, 1992; Paton, 2003) and universalist perspective. The most debated questions have always concerned which instruments were best suited to measuring (Marr and Schiuma, 2003), given the impossibility of using the known Tayloristic (individualistic) tools for non-

profit organisations that rarely offered comparable measurements (Nicholls, 2009).

This study will lay the foundations for analysing all the aforementioned profiles to bring out the telemedicine business model's fundamental contribution to efficient and effective healthcare management.

### **3 Research methodology**

To achieve the research goal, we choose to use a qualitative research method based on a case study (Yin, 2014), particularly suitable for studies on IC in health care (Paoloni et al., 2020). More precisely, we will analyse a non-profit organisation that for over 15 years has offered a free multi-specialist teleconsultation service to answer medical questions from the most disadvantaged places in the world.

Our analyses are mainly based on interviews with the organisation's director and project managers and secondary sources (websites, specialist literature, newspapers, financial statements, databases).

For the analysis of relational capital, we apply the C.A.O.S. model (Paoloni, 2011; 2021), which is widely used in the national and international literature to comply various purposes linked to RC studies (Paoloni and Dumay, 2015; Paoloni et al., 2018; Dal Mas and Paoloni, 2019; Paoloni et al., 2020; Cosentino et al., 2021).

C.A.O.S. model is part of the Strategic Management studies. Notably, it fits the reflections on the sources of competitive advantage as a development of the Knowledge-based View (Nonaka and Takeuchi 1995; Hung *et al.*, 2014) that led to the Relational-based View (RBV) (Dyer and Singh, 1998; Lavie, 2006; Chung et al., 2019). RBV introduces the possession and dissemination of knowledge as well as the economic and social relationships between company and environment as value drivers, extending the boundaries of study on competitive advantage (Li et al., 2021).

This model analyses how the types and intensity of the relationships woven by small and medium-sized enterprises can be framed during a given phase of their life cycle through a relational matrix. In this study, we propose an original application of the model to non-profit organisations in which the contribution of relational capital is particularly significant (Kong and Farrell, 2010; Eng et al., 2020).

## 4 Results and Discussion

### 4.1. Knowledge management (Human Capital)

The activities are carried out by a group of computer technicians and volunteer doctors who offer their professionalism free of charge to colleagues located above all and in developing countries, particularly in sub-Saharan Africa. During the health emergency, various activities were carried out on the Italian territory too. As the director said:

*'We offer teleconsultations in various specialist branches such as cardiology, neurology, infectious diseases, neurology, haematology, radiology, internal medicine, paediatrics. To date, we have delivered 15,924 number of consultations'*

The contribution of the HC is evident since it is only services rendered by highly specialised personnel. Furthermore, in the case analysed, since the activities were provided free of charge, it was possible to detect a solid intangible contribution (Quarter et al., 2003; Mook et al., 2009; Cosentino, 2020). The volunteers make their time and energy available - all of a high professional level, in the case examined - to favour the achievement of social objectives.

*'Multidisciplinary medical teleconsultation service uses a pool of Italian and European specialists who provide their consultancy free of charge. Retired doctors are a great wealth'* (director)

The services rendered can be valued according to the replacement cost criterion for each function (UN, 2002) which provides for the determination of an adequate shadow wage, capable of expressing the remuneration corresponding to the service rendered by the voluntary worker. In principle, it would be appropriate to consider a salary equal to the average or median wage if there are significant deviations between the minimum and the maximum. The market recognises workers employed in the same activities in which the volunteers were engaged. This remuneration should then be corrected to consider the difference in productivity and skills, which may exist between paid and voluntary workers (Cnel and Istat, 2011).

The value attributable to voluntary work constitutes "notional income" that cannot be accounted for according to the techniques of accounting practice. This income allows covering 'ideally' the so-called figurative costs or the costs that the organisation would have incurred in the absence of the services provided free of charge by the volunteers. (Cosentino, 2020).

#### **4.2. Innovative digital and communication technologies (Organisational Capital)**

The instrumentation of each remote health centre is modular and can include sophisticated and innovative health equipment (e.g. electrocardiograph, oximeter, HD webcam, ophthalmoscope, X-ray scanner).

The organisation uses ad hoc software whose IT assistance and development can never connect the specialists. An Italian software house guarantees the assistance.

*'We operate through a web-based platform created by our partner, which has able to work even offline. This software capability is a relevant item for health centres with poor internet access'* (Director).

Each teleconsultation is "sorted" automatically to the doctors available based on different points: i) language, ii) urgency, iii) specialised branch required. The corresponding doctors are felt via SMS, e-mail or other alerting procedures, and they can consult the answer from software or online through any device, even smartphone.

The mechanism is simple. As described by the director:

*'The facility in Africa sends the clinical question through a dedicated platform to which instrumental tests such as an electrocardiogram, an electroencephalogram, other tests performed locally can be attached. According to the speciality, the volunteer doctors participating in the project respond by giving diagnostic suggestions, therapeutic indications, and other documents explaining how to treat the highlighted pathology'.*

To support the process, two remote units (Service Centre and Health Help Desk) supervise and, if necessary, intervene to ensure each teleconsultation's success and correct timing. The technical help desk assists each operator with any technical problems.

The association has created a technological platform that connects about 200 Italian and European specialists with hospitals and health centres in various developing countries.

In 2020, the non-profit organisation reached 12,000 teleconsultations, coming from thirty-nine centres in Africa, Peru and Brazil.

### 4.3. Network of medical expertise (Relational Capital)

For this part of the research, the analyses were conducted in the conceptual framework of the C.A.O.S. (Paoloni, 2011; 2021), which is part of the line of studies on relational capital (Dyer and Sigh, 1998; Lavie, 2006; Sulistyo, 2016; Fernandez-Olmos et al., 2020).

The model summarises some qualitative variables concerning four different elements (Table 1). We adapted the original model, considering its implementation to a non-profit organisation rather than a small/medium enterprise to which the model has been applied so far.

C.A.O.S. is an acronym and summarises the qualitative variables observed with respect to personal Characteristics (C) of the entrepreneur (founders in this study), territorial Ambience (A)<sup>1</sup> where the organisation investigated works, Organizational and managerial aspects (O). Lastly, a specific phase in the corporate life cycle investigated by the researcher (S). In the authentic model, the letter "S" corresponds to "start-up." In this research, we intend it as "sustainability", namely the organisation's capacity to survive in the dynamic context.

Table 1 - Description of the factors of the C.A.O.S. (Paoloni, 2011; 2021)

Acronym	Variables	Description
C	Personal element	→ Characteristics of the founders
A	Macro element	→ territorial operative Ambience (environment)
O	Micro element	→ Organisational aspects and management style
S	Time element	→ Sustainability (cycle life in which the organisation is analysed)

#### 4.3.1. Characteristics (C)

Ten years ago, the organisation was founded by a group of IT technicians and volunteer doctors to offer their professionalism free of charge and answer medical questions from the most disadvantaged places globally.

The association was born as a spin-off of the "Dream" project of the Community of Sant'Egidio to fight AIDS in Africa. Later, the telemedicine service was also installed in other health centres in developing countries. To date, the association can count on a network of about 200 specialists from different

<sup>1</sup> The letter "A" of the acronym derives from the Italian "ambiente", which translated becomes "environment". In the research, we keep the authentic letter to stay faithful to the original model.

European structures connected, through an ad hoc technological platform, with hospitals and health centres in developing countries.

#### 4.3.2. Environment (A)

The activities turn to different categories of stakeholders. Firstly, to health cooperation programs located in disadvantaged places that desire to enrich their work with a specialist teleconsultation. Secondly, to specialist doctors who aim to become part of the network by making their experience available and actively contributing, free of charge, to health cooperation projects. Thirdly, to governmental and non-governmental rural hospitals, in countries or countries areas in particular poverty. Finally, to the biomedical device industry in the hope of introducing new devices to make peripheral workstations more economical, complete and competitive.

The survey on the ten most requested types of consultations shows a prevalence of teleconsultations in cardiology, followed by internal medicine (Figure 1).

*Figure 1 – First ten clinical categories required (all countries)*

*Source: Our elaboration on Association's data*

In Italy, the most numerous teleconsultations are internal medicine, followed by ambulatory and infection disease ones (Figure 2).

Figure 2 – First ten clinical categories required (Italy)  
Source: Our elaboration on Association's data

#### 4.3.3. Organisation (O)

The organisational structure is very complex.

Figure 3 summarises the organisation chart. Relationships are not hierarchical but collaborative.

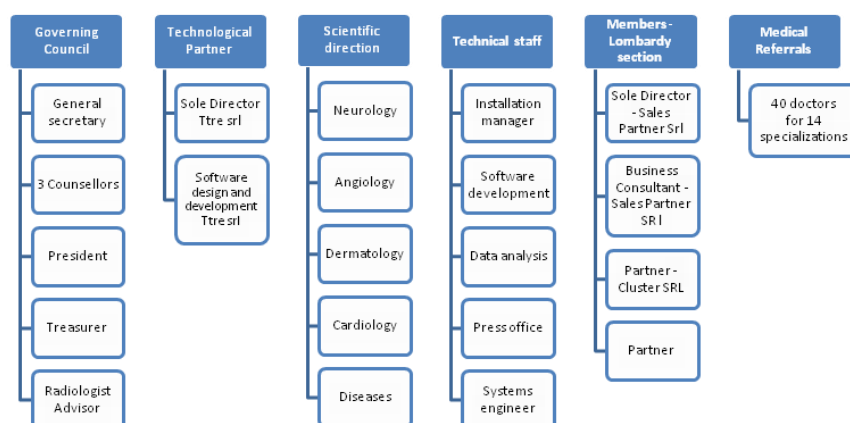

Figure 3 – Organisation chart  
Source – Our elaboration on Association's data

#### 4.3.4. Sustainability (S)

Since the beginning of the pandemic, the association with a traditional partner has activated a new telephone line for the most vulnerable people in Rome. In addition to providing social help, it also offered the possibility of a multi-specialist teleconsultation. These services are helpful for the people who, due to the Covid-19 emergency, struggle to turn to the traditional health system.

New telemedicine service is waiting to be launched in Southern Italy, in the Calabria region, to support fragile people in a depressed peninsula area.

We have analysed the association's activities in the last three years to highlight what effects the pandemic has produced on the volume of activities and the recipients of production.

In 2020, total activities decreased by 6.4% compared to the previous year, while for the current year, the consultations provided are just under half of those in 2019 (data referring to half year).

Focusing attention on Italy, where the association, doctors and partners are based, we notice that the contraction of activities abroad corresponded to a more than proportional increase in Italy, with a growth of 600% and 102 consultations in 2019 and 739 in 2020.

This is a consequence of pandemic. In the last year, in fact, many activities have been suspended, particularly training for doctors in disadvantaged areas of the planet. However, activities in Italy have increased due to the growing demand from patients who have had difficulty accessing traditional facilities, overcrowded by the pandemic.

The situation appears re-established in the current year, and the activities toward Italy are less than half of those carried out in 2019 (42).

Figure 4 shows the general data relating to the activities carried out in Italy (Rome), the Mediterranean, Africa, Peru, Brazil compared with those carried out in Italy. The data referring to 2021 are updated as of 30 June 2021.

Figure 4 - Number of teleconsultations  
Source: Our elaboration on Association's data

#### 4.4. Social and economic impact

Table 2 summarises some results relating to the economic and social impact generated by the activities.

The analysis does not consider complex methodologies usually used for impact measurements such as SROI (SROI Network, 2012), SEIE (Zamagni et al., 2015) or others (Grieco et al., 2015) that require ad hoc in-depth analysis.

To offer a first representation of the impact, we used some data from the interviews with the association's director and the website.

Table 2 - The impact generated by the activities

Social Impact	Economic Impact
23 medical specialties	150,000 Euros/year the platform cost
15,924 total teleconsultations since 2001	12,000 Euros the equipment cost for the implementation of a telemedicine centre
200 European volunteer specialists involved	
39 centres located in Italy (Rome), Mediterranean, Africa, Peru, Brazil	

## 5 Conclusions

This research has shown how telemedicine represents a successful new business model even in times of crisis.

The organisational model makes it possible to i) offer cutting-edge specialist assistance, ii) contain costs (Cegarra-Navarro and Cepeda Carrion, 2013), iii) reach disadvantaged areas of the planet easily, iv) strengthen the skills and autonomy of the most backward countries through a knowledge-sharing process (Mura et al. 2012; Radaelli et al., 2014), v) pushing the structures operating there to interact with those of the advanced countries (Corrado et al., 2005; Paoloni et al., 2020).

A well-structured organisation, such as the case study analysed, require: a) highly specialised and motivated human capital (Bontis, 1998; Bontis et al., 1999), b) orienting towards technological innovation (Youndt et al., 2004), c) strength by a vast network of formal and informal relationships both with other non-profit organisations and with institutions (Paoloni, 2011; 2021). Finally, it can generate value for the social stakeholder (Cavicchi, 2017).

The aforementioned characteristics formed the IC (Kamaluddin and Rahman, 2009; OECD, 2013; Huang et al., 2021) and make the new business model capable of contributing to the improvement of the health conditions of the entire population, including the most fragile (Huang et al., 2021). Thus, it becomes a new way of doing high-impact and low-cost cooperation. Thus, in the current context, still strongly pervaded by the emergency generated by the pandemic, an essential role in the provision of health services can be played by telemedicine (Leite et al., 2021; Bahl et al., 2020; Haleem and Javaid, 2020).

### **5.1. Originality, Value and Future step**

This research contributes to studies on IC in health care by focusing on the contribution of telemedicine to the creation of IC.

Notably, the present work underlines the telemedicine capacity to develop and share knowledge in disadvantaged areas of the world (Mura et al., 2012; Radaelli et al., 2014). Furthermore, in the current context, still strongly permeated by the health emergency generated by the pandemic, the importance of those forms of assistance and diagnosis is growing. On the one hand, in a crucial moment for humanity, they favour adequate health services. On the other hand, they allow professionals located in different territorial contexts to arrive at a more precise diagnosis and ensure a proper level of performance in areas not easily reachable.

Telemedicine is part of this, and its application has made it possible to manage complex processes at the time of Covid-19, overcoming all the constraints imposed by the restrictions on the movement of individuals and by the rules on social distancing put in place by governments to contain the spread of the virus.

Although the conclusions we have reached align with the prevailing literature, they require future investigations that include analysing other organisations, public and private, profit and non-profit, to compare results and impacts.

### Abstract

The main purpose of this work is to systematically reconstruct the context of industrial symbiosis initiatives with relation to the networks of actors, the roles they play, the factors that determined the initiative, the obstacles that hinder (or have hindered) their implementation, the expected and/or achieved benefits, and the development prospects through the presentation of an original database of 18 case studies.

**Keywords** – industrial symbiosis, sustainability, business models

**Paper type** – Academic Research Paper

### 1 Introduction

In the operational context, the term "industrial symbiosis" appears in the nineties and goes back to Christensen (1992), manager of the eco-industrial park of Kalundborg in Denmark who defines industrial symbiosis as "a cooperation between different industries by which the presence of each ... increases the

viability of the other(s), and by which the demands [of] society for resource savings and environmental protection are considered."; quickly, the concept spreads in the scientific literature with the seminal studies of Frosch e Gallopoulos (1989), Ehrenfeld e Gertler (1997), Lowe (1997) e Schwarz e Steininger (1997).

The concept of industrial symbiosis, based on the opportunities to use the flows of resources of any kind within networks of industrial actors, is therefore related to the problems posed by the exhaustion of resources, the management of waste and by-products and the pollution; as such, the principles of symbiosis play an important role in the transition towards sustainability, here assumed - in line with the widespread scientific perspective and the general perception of the concept (Barile and Saviano, 2018; Saviano et al., 2017) - such as the ability, in economic activities, to balance social, economic and environmental objectives at different levels: micro-level within individual companies; macro-level related to the business networks involved in the symbiotic initiative; meso level as the network of formal or informal contracts between the companies involved, within the market, between civil and social institutions; at the meta-level, considering the society or the territory as a complex interactive and holistic living system (Barile et al., 2016; Simone et al., 2018). The application of the principles of industrial symbiosis is therefore aimed at configuring industrial eco-systems intended as a community or network of companies and other organizations in a region who choose to interact by exchanging and making use of byproducts and/or energy in a way that reduces resource inputs, increases energy efficiency, and reduces the volume of waste products Lowe (1997).

Closely linked to the concept of industrial symbiosis are, but not limited to, its concretizations in industrial agglomerations (industrial parks) in which companies seek (and carry out) exchanges of residues of any kind, thus configuring eco-industrial parks to which literature and operational practice devote increasing attention (Caroli et al., 2015).

## **2 Literature review and paper positioning**

The laying of the discussion along with a series of dimensions - not always coinciding - is not new, it is found, among others, in Benedetti et al. (2017), in various contributions from the University of Linköping and Massard et al. (2014). However, contributions aimed at specifying these dimensions in the various types of initiatives are not found in the literature and/or in the main databases

available: apart from the uniqueness of the single eco-industrial park, each of them can be considered as part of a homogeneous category, using one or more of the taxonomies designed to classify drivers, barriers, expected or achieved benefits, to outline development prospects, etc. The issue of identifying similarities and differences in industrial symbiosis initiatives, in particular in their concretization in eco-industrial parks has produced in the literature a series of finalized classification proposals, through the definition of homogeneous classes of characteristics and of problems, to the identification of the methodologies (from the scientific point of view) and of the operational approaches (from the practical point of view) most suitable for interpreting their characteristics and functioning. One of the first taxonomies is due to Lowe (1997), who classifies eco-industrial parks into two types: co-located eco-industrial parks and virtual eco-industrial parks: the former are systems in which companies are located in the same site or the same region; virtual ones do not require the co-location of companies in the same region but are still based on the exchanges of by-products and waste between companies. In co-located parks, the proximity of companies simplifies exchanges and obtaining benefits, especially through the reduction of logistics, transport and storage costs; virtual ones produce, according to the author, significant environmental benefits precisely because the exchanges of waste, materials and energy, taking place in a wider territorial context, having a greater impact on the socio-economic-environmental milieu of the region. Subsequently, Chertow (2000) distinguishes five types of industrial symbiosis by proposing a taxonomy to which the literature still refers widely: through waste exchanges; within a company; between production units co-located in a defined eco-industrial park; between non co-located companies; between companies organized "virtually" in a wider region. Another classification is due to Boons et al. (2015) along with the three different characteristics of the process, residues, and place: the process-oriented industrial symbiosis refers to a network of companies that collaborate concerning a specific industrial process; residue-oriented symbiosis refers to a cooperative network around a flow of residues; place-oriented symbiosis refers to a cooperative network linked to a specific geographic location. In the Authors' work, the basis for subsequent classification proposals based on the characteristics of the network can be found, namely the size, heterogeneity and intensity of the links between the participating actors. Domenech et al. (2019) focus their attention on the aspects related to the birth of the symbiotic initiatives distinguishing: self-organized symbiotic activity,

which emerges as a result of direct interactions between industrial players; networks that are formed with the support of an intermediary who coordinates the activities of the participating companies; planned networks, which result from a plan or program of the central or local Authorities, generally for a specific industrial area, therefore of a top-down nature, aimed at configuring coordinated economic activity systems in terms of infrastructures, services and flows of any type between the actors. Zhang et al. (2016), noting that the various classifications existing in the literature were of the qualitative type, propose, based on a network analysis conducted on 8 case studies, classification of quantitative nature into three distinct types: with a modest degree of completeness, in which the links are few in number and there are nodes (participating companies) outside the network; a high degree of completeness in the form of "tenant" mutualism - in which there are few "dominant" firms and the other actors are in a situation of dependence from them; high degree of completeness in the form of "equality-oriented" mutualism, in which the participating companies are roughly equal in importance or there are many with dominant roles so that the relatively high number of leading companies leads to the development of relationships and roles of more homogeneous responsibilities. From the point of view of operational practice, the dimensions of the classification contained, albeit implicitly, in Massard et al. (2014) and the papers of the MAESTRI project: Massard et al. (2014) classify, in fact, the 302 industrial parks they surveyed in industrial, combined (industrial and residential), and strictly urban, referring to the term urban symbiosis as the possibility of using urban by-products (in particular waste) as alternatives in industrial processes: similar to industrial symbiosis, urban symbiosis is therefore based on synergistic opportunities between businesses and local communities. As part of the MAESTRI project "Energy and resource management systems for better efficiency in the process industries" of the Center for Industrial Sustainability of the University of Cambridge in the context of Horizon 2020 of the European Union, a classification based on the state of progress of the initiatives are introduced, as implemented, underdevelopment, planned, at the feasibility recognition stage. Following the dimension of the typology of the main actors involved (whether only firms participate in the initiative or if urban settlements are involved as well), it is possible to distinguish industrial, combined or exclusively urban parks. Concerning the level of completeness of the symbiotic initiatives, parks can instead be distinguished in parks that have already been fully exploited (implemented) or are only partially exploited (planned) or both. This

approach, in the case of firms involved in the initiative, provides a possible measure of their propensity to innovation and of their sensitivity to two of the cornerstones of sustainability (social and environmental sustainability) which are to be placed side by side with the third, consisting of the economic goals. Finally, concerning the characteristics of the decision-maker, it is possible to distinguish whether a park is centralized in a single large dominant subject (generally one of the companies that play a central role in the network), polarized between a few important companies, or even widespread in a sort of equal responsibility or management of the network. This work deals with this latter aspect through a network analysis of a sample of eco-industrial parks, which characteristics have been deduced on a quantitative basis constituted by the density of the network and the degree of centrality of the actors, taking into account the nature of the park (whether industrial, urban, or combined) and the role of either provider or user of the exchanged flows of the main actors.

### **3 Materials and methods**

The scientific literature, in particular the contributions pertaining, mainly, to the field of industrial ecology, is rich in case studies of existing eco-industrial parks, on the innovative initiatives taking place within them, on the planning after the identification of symbiotic opportunities between companies located more or less close to each other. Most of the existing databases and summary documents aimed at scientific speculation on the subject are based on case studies found in the literature, of which bibliographic references are promptly provided. This work also makes use of secondary sources consisting of the data and information contained in the main databases available, in the scientific literature based on the study of single or multiple cases integrated with what can be found on the parks' websites, press news, multimedia material of scientific and informative nature available on the main social networks. The case studies were selected drawing on the following sources:

- The database developed during the activities within the MAESTRI project "Energy and resource management systems for better efficiency in the process industries" carried out by the Center for Industrial Sustainability, University of Cambridge. The database, containing 46 case studies, consists of a narrative section organized along the dimensions "main challenge (triggering)", "main barriers",

"approach", "discovery process", "prerequisites (precondition)" and a section in which symbiotic enterprises and the type of resources exchanged are qualified (Benedetti et al., 2017).

- "The project of the Industrial and Urban Symbiosis Research Group of the Environmental Management and Technology Division at Linköping University" containing various case studies not all previously covered in the literature. The cases are organized according to "key players," "main resources exchanged", "enabling factors", "economic and environmental benefits", "key drivers and barriers", "possible future synergies".
- The database narratively exposed by Massard et al. (2014) in which, 168 eco-industrial parks where significant incentives for innovation can be found are examined. The cases are treated along the dimensions of "genesis", "objectives", "success factors", "development prospects".

The criteria for selecting the cases examined was essentially the evaluation of the abundance, relevance and accuracy of the available data. The selected cases included the eco-industrial park of Kalundborg in Denmark which, being one of the best known and most important examples of the application of the principles of industrial symbiosis, is the subject of continuous interest by scholars (Doménech & Davies, 2011; Ehrenfeld & Gertler, 1997; Jacobsen, 2006) and managers to appropriate the good practices therein. A sample of 18 case studies was obtained, preliminarily classified according to the level of completeness and type (Table 1):

Table 1: Selected case studies

<b>Identifier</b>	<b>Country</b>	<b>Completeness level</b>	<b>Type (according to Massard 2014)</b>
The eco-industrial park of Kalundborg, Denmark	Denmark	Implemented	combined
Symbiosis in the industrial park of Ulsan, South Korea	South Korea	Implemented	combined
Symbiotic exchanges in the Landskrona area, Sweden	Sweden	Partially Implemented	combined
Industrial symbiosis in the area of the municipality of Norrköping and the island of Händelö, Sweden	Sweden	Implemented	combined
The urban and industrial district of Liuzhou, China	China	Partially Implemented	combined

The industrial and urban symbiosis in the Kawasaki area, Japan	Japan	Implemented	combined
The production settlements of the Kymijoki River area in Kuusankoski (now Kouvola), Finland	Finland	Implemented	industrial
Production settlements in the Humber region, United Kingdom	United Kingdom	Partially Implemented	industrial
The Guitang Group in Guanxi Province, China	China	Implemented	industrial
Nanning Sugar Co. Ltd, China	China	Implemented	industrial
Industrial symbiosis and waste recovery in the Mysore area, India	India	Implemented	industrial
The chemical site of Bussi sul Tirino, Italy	Italy	Partially Implemented	industrial
Plastic Alfa, Caltagirone, Sicily, Italy	Italy	Implemented	industrial
"Green" project, Emilia Romagna, Italy	Italy	Planned	industrial
The British Sugar case in the UK	United Kingdom	Implemented	industrial
The productive settlements of Taranto, Italy	Italy	Partially Implemented	industrial*
Industrial settlements in the Chamusca area, Portugal	Portugal	Planned	industrial**
The aluminium industrial district in Gladstone, Australia	Australia	Partially Implemented	industrial***

\* urban participation planned for the reception of steam

\*\* urban participation planned for the delivery of waste

\*\*\* urban participation planned for the supply of lubricating oils

## 4 Discussion

### ***The production settlements of the Kymijoki River area in Kuusankoski (now Kouvola), Finland***

Founded in 1872 in Finland, the UPM Kymi paper mill has gone through alternating periods of high and low production and given the need to adapt to changing market conditions it has always adopted symbiotic approaches, such as Industrial Symbiosis. Symbiotic relationships in the district began more than a century ago when the paper mill started the production of chemical pulp to meet the growing demand for the product from the Russian market. On that occasion, a new chemical plant was installed that supplied chemicals for the production of paper and received waste energy from the mill. The main prerequisite for the

creation of symbiotic exchanges was the production of pulp and paper which led companies to adopt a 'symbiotic way of operating' in Finland and Sweden. Since the founding of the paper mill, waste has been used for the production of paper as rags, instead of wood, were often used as raw materials.

### ***Production settlements in the Humber region, United Kingdom***

The Humber region is one of the largest port complexes in the UK. The industrialization of the region began in the 1960s and the dominant industries are chemicals, oil and gas, food processing, furniture, iron, steel and other metals. The Humber Region Industrial Symbiosis Program started in 2000 and was the first regional program for IS in the United Kingdom. The Program was launched following an initiative by a large global oil and gas company that aimed to create a cogeneration plant in the region, involving neighbouring industrial companies from the planning stage.

In addition, the companies involved had to pay a certain percentage of the profits obtained from this cooperation for the creation of a coordinating body. The development of the project was initially hampered by the reluctance of local companies due to the lack of competence in this type of agreement and the limited participation of these companies as many of them were competing in the same market segment. Since 2003, HISP has been integrated into the NISP and encompasses the entire Yorkshire and Humber region. It currently works with hundreds of companies that use public funding.

### ***The Guitang Group in Guanxi Province, China***

The Guitang Group, located in the Guangxi Zhuang Autonomous Region, was founded by the state in 1956. The group that runs one of China's largest sugar refineries has exploited its by-products through internal symbiosis. The main objective that guided the implementation of the Industrial Symbiosis in the Guitang group district was to maintain its competitiveness despite the high prices of sugar cane imposed by the local government by using the by-products and reducing disposal costs to have more economic benefits and reduce pollution. In regards to the technological barrier, the company has implemented collaborative projects with local universities and its own Technology Center. The Guitang group has devised various processes for using its by-products as inputs.

### ***Nanning Sugar Co. Ltd, China***

In recent decades the company has directed its development strategy towards the realization and permanent integration of Industrial Symbiosis and has managed to create a large district led by a single industrial sector aimed at the production of sugar and at the same time diversified between producers of alcohol and fertilizers, agro-industries, cement factories, pulp and paper, wood and chemical companies. The pressing need to survive a competitive market was the main challenge that led to the implementation of the Industrial Symbiosis in the case of Nanning Sugar Co. Decided to implement diversification by reusing part of its waste materials they began to incorporate the Industrial Symbiosis in its development strategy by reorganizing the entire company structure. The main factors that allowed the implementation of the Industrial Symbiosis were the industrial policies that started to push towards sustainable development and the absence of problems associated with the negotiation between the affiliated companies since the company founded the majority of them.

### ***Industrial symbiosis and waste recovery in the Mysore area, India***

In Southern India, the cities of Nanjangud and Mysore are home to a large group of industrial companies and multinational companies that make up the Nanjangud Industrial Area, of which the main representatives are food and beverage producers, agri-food industries, chemical companies and producers of pulp and paper, concrete and wood-based products. To implement industrial symbiotic exchanges, a process based on interactions and negotiations between the participating companies has been initiated which has given rise to a completely self-organized symbiotic industrial system. In India, no regulation binds the management of waste, in particular dry non-hazardous waste, so companies autonomously organize exchanges of internal waste and, more rarely, with external companies.

### ***The chemical site of Bussi sul Tirino, Italy***

In this district, Industrial Symbiosis has never been implemented, only a first attempt to identify symbiotic opportunities and their feasibility is reported. The reason that led the local government in 2008 to finance this exploratory research project, managed by the University of Chieti «G. D'Annunzio », was the need to

revitalize the industrial area from an economic and social point of view. The main prerequisites for the launch of the Industrial Symbiosis implementation project were determined by the fact that in the region several plants are operating in complementary industries with good logistical connections and the companies of the chemical site of Bussi already shared some facilities and services.

In addition, companies in the sector were involved in the project. The commitment of local companies has also been strengthened by a regional regulation that defines the discipline of Ecologically Equipped Estates. The strong opposition of the local community deriving from a lack of knowledge on the theme of Industrial Symbiosis, strong resistance to change and previous bad management of hazardous waste in the chemical site of Bussi was immediately the main obstacle to the project.

#### ***Plastic Alfa, Caltagirone, Sicily, Italy***

As part of the "BIO4BIO" project, several new symbiotic exchanges in the Sicily region were identified and evaluated and various companies producing fruit juices, feed, biofuels, plastic products and agricultural industries that had an interest in industrial symbiosis were involved; they wanted to enter new markets and increase their competitiveness while preserving the surrounding environment. The main obstacle that the companies faced to exploit the waste from local agro-industries and create new symbiotic exchanges was the high effort required in terms of time and resources to develop, test and expand the new technologies needed for waste treatment.

#### ***"Green" project, Emilia Romagna, Italy***

Numerous companies took part in the project such as food industries, agricultural industries, fuel or electricity producers, producers of plastic products, chemical companies. Here, ENEA has, first of all, illustrated the scope and purpose of the project, as well as the data collection tool and in a second phase sent to all the participants in the focus group structured spreadsheets for the start of the data collection. Subsequently, the ENEA researchers conducted a matchmaking activity aimed at identifying potential exchanges.

### ***The British Sugar case in the UK***

British Sugar, one of the largest sugar producers in the UK, was acquired by AB Sugar in 1991. Continued benchmarking with other sugar producers around the world has also made it possible to find new symbiotic opportunities. The process of implementing symbiotic exchanges has been almost entirely led by British Sugar over the years as its management was very focused on business growth and development.

### ***The productive settlements of Taranto, Italy***

In Southern Italy, in Taranto, there is an industrial district centred on the Ilva steel mills which include oil refineries, power plants and construction and cement companies, but also small agricultural industries and a large brewery. The district was born in the 1960s following the national strategy for the industrial development of the South. Since the founding of the district, industrial symbiosis experiments have been launched by the Ilva plant and the cement factory to reduce costs and increase competitiveness. Starting from the recognition of the high risk of environmental crisis, various stakeholders have made efforts to support companies in preventing pollution and its consequences. The study was commissioned to the University of Bari and was an attempt to highlight the potential of Industrial Symbiosis for solving environmental problems. The process began with the collection of data regarding the environmental performance of the companies involved. Finally, the results were presented to the companies and a series of interviews made it possible to assess their willingness to collaborate on broader and easier Industrial Symbiosis projects.

### ***Industrial settlements in the Chamusca area, Portugal***

The Relvão Eco-Industrial Park in Portugal is a project launched in 2006 thanks to various stakeholders, including the Portuguese government, the municipal government of Chamusca, the Technical University of Lisbon, together with industrial companies and entrepreneurs. Currently, the Industrial Park includes pulp and paper companies, chemical companies, waste treatment plants and agricultural industries. When the Relvão EIP project started, the Chamusca region had already started a plan for the treatment and disposal of hazardous waste and some companies in the centre had already established some spontaneous

synergies. However, the project envisaged a remarkable sustainable development of the region and triggered all efforts for the implementation of Industrial Symbiosis. In just four years, more than twenty companies have joined the network for the waste management and recovery industry. The objectives of the Relvão EIP are to develop knowledge of the characteristics and quantities of waste materials among the companies in the region and thus to identify potential IS to be implemented.

### ***The aluminium industrial district in Gladstone, Australia***

Gladstone, Queensland, is a large geographic area and is one of the major mineral industrial clusters in Australia. The companies in the district have decided to implement spontaneous symbiotic exchanges to pursue economic, as well as environmental and social benefits. However, after the Center for Sustainable Resource Processing, a national initiative created with the participation of associations of mineral processing companies, research centres and the national government, began to explore new possibilities for achieving greater resource efficiency, new exchanges have been identified and implemented in the area. The CSRП initially carried out a detailed analysis of the flows of waste materials, energy and water and used the data obtained for the construction of a database, thus facilitating the identification and mapping of by-products. This has allowed not only the achievement of a spontaneity of the implementations of Industrial Symbiosis coordinated by the CSRП but also a greater awareness of industrial development and the issues related to the efficiency of the Gladstone area.

### ***The eco-industrial park of Kalundborg, Denmark***

The Kalundborg Industrial District Symbiosis Network is one of the best-known examples of a long-term collaboration between different industrial sectors resulting in mutual economic and environmental benefits. The symbiosis network of the Kalundborg industrial district in Denmark was born thanks to a series of interactions between local companies and was the strategy followed by the participating companies to ensure the survival and expansion of local businesses. The basis for the development of Industrial Symbiosis in the Kalundborg area was mutual trust between companies, open communication between employees, the relative geographical isolation of the companies, the pre-existence of common

infrastructures and the awareness of the consequent economic and environmental benefits, deriving from the synergies of the network. The Kalundborg Symbiosis Institute created in 1996 now comprises nine public and private companies in the Kalundborg area, including the world's largest industrial producers such as the insulin-producing 'Novo Nordisk' and the enzyme-producing 'Novozymes'.

### ***Symbiosis in the industrial park of Ulsan, South Korea***

Ulsan Industrial Park in South Korea is one of six parks involved in the project run by the Korea National Cleaner Production Center affiliated with the Korean Institute of Industrial Technology in collaboration with the Korean Ministry of Commerce, Industry and Energy since 2006. The project involves the Korea Industrial Complex Corporation, the Ulsan eco-industrial park centre in charge of promoting industrial symbiosis, the Ulsan city government and various research and development centres. Strengths for the development of Industrial Symbiosis are the support of the government in the promotion and coordination of the project, the positive attitude of the participating companies that contributed to the coordination of the industrial complex and the financial gain.

### ***Symbiotic exchanges in the Landskrona area, Sweden***

The Landskrona Industrial Symbiosis Project, launched in 2003 in the industrial city of Landskrona in southwestern Sweden, involved 21 companies of different sizes and from different industrial sectors and the Technical and Environmental Departments and the Trade and Industry Office of the Municipality by Landskrona. The project promoters aimed to establish and implement long-term symbiotic relationships between the companies involved through exchanges of materials, adequate human resources and knowledge to cut costs and increase competitiveness by improving image and impact. environmental.

### ***Industrial symbiosis in the area of the municipality of Norrköping and the island of Händelö, Sweden***

The 'twin cities' of Norrköping and Linköping and the entire Östergötland region in Sweden, in collaboration with the University of Linköping, promote the development of clean technologies and establish more collaborative networks

between businesses to implement industrial ecology schemes. In the municipality of Norrköping and Linköping, collaboration networks were created between different actors and organizations which led to the establishment of a well-established and well-developed industrial symbiosis. The main companies in the network come from the forestry industry, agro-industry and the electricity/gas generation sector. To guarantee a continuous supply of electricity and heat at competitive prices to companies, a thermal and power plant has been created on the island of Händelö, opposite the city of Norrköping, which has led, over the years, to the creation on the island of an industrial symbiotic district focused on the production of energy and fuels. Later, the process also included exchanges of waste raw materials for the production of new usable products. To date, the entire Östergötland region promotes the development of clean technologies and establishes collaborative networks between companies to implement industrial ecology schemes.

#### ***The urban and industrial district of Liuzhou, China***

In the Guangxi province of southern China lies Liuzhou, an industrial city home to a large industrial district, consisting mainly of heavy industries such as steel, automotive, cement, chemicals and power generation companies. In recent years, the national and local government has also involved companies and researchers to identify new potential exchanges to be implemented in the district. Since 2001, the Chinese government has launched several initiatives to encourage the implementation of the circular economy in cities. To overcome constraints, the construction of efficient energy structures has been proposed that channel funds and savings towards the construction of transport structures and the development of new technologies as well as awareness-raising activities, such as periodic newsletters and workshops. Material flow analysis was used to identify potential new trades and their profitability. Finally, new scenarios were described based on new potential symbiotic exchanges and their feasibility and profitability were assessed.

#### ***The industrial and urban symbiosis in the Kawasaki area, Japan***

The city of Kawasaki, located between Tokyo and Yokohama, is one of the most productive industrial areas in Japan, hosting 74 industrial plants that come mainly

from the steel, cement, chemical and paper sectors. The Kawasaki Eco-Town project, launched in 1997, promotes the effective use of commercial and industrial waste generated in the city and its recycling into raw materials that can be used by industries located in the city. Eco-Town's objectives were aimed at creating a resource recycling company and revitalizing the coastal area by reducing the impact of industrial activities on the environment. To overcome this barrier, the Japanese government has financed the creation of several waste recycling plants in the region, to allow the reuse of municipal and industrial waste in the area. The main factors that have enabled Eco-Town's success have been the political support and incentives provided by the national government and the presence of relatively large iron, steel and cement industries which have proved to be suitable consumers for a wide range of flows of different waste.

## 5 Conclusions

Concerning the systematic study of symbiotic initiatives, in particular of existing or developing eco-industrial parks, the need to define homogeneous categories was highlighted, to build theoretical reference frameworks adapted to each category that allows the governing bodies (Golinelli, 2000; Barile, 2009) to select the strategies more suitable for maintaining the conditions of equilibrium in compliance with the principles of autopoiesis and homeostasis to guarantee the survival of the systems (Barile et al., 2013). In this context, it was concluded that the traditional dimensions along which the classifications existing in the literature have been proposed must be accompanied by quantitative aspects of the density and centrality of the graphs that these parks represent.

### Abstract

The pandemic from Covid 19 brought changes in the PA and the actuality of the topic of smart working (SW) in PA has exploded since March 2020. In a very short time the use of digital has increased more than it has been attempted in many years.

The PA has reacted swiftly to ensure the provision of services to citizens and to respond to the needs generated by the pandemic, understanding the importance and the need for a profound renewal based on cultural change, digital transformation and the enhancement of women and men.

Of course we can not consider the SW an innovation or a new mode of work as the Law n. 191 of 1998 has been in force for more than 20 years.

The paper wants to reflect on the decisive role of human action within organizations and tries to answer research questions trying to understand the reasons that motivate employees of the PA to want to continue working in SW even after the pandemic and if this can be considered a new way of working.

All this is part of the introduction of an innovative mode of work organization, based on the use of flexibility, on the assessment by objectives, on the recognition of the needs of employees, all in the light of the need to reconcile work and personal time. Text of the abstract

**Paper type** – Practical Paper

## **1 Introduction**

The pandemic from Covid 19 brought radical changes in people's lives by restoring to the institutions that centrality that, not always, over the years had translated into innovation.

The actuality of the topic of smart working (SW) in PA has exploded since March 2020 with the emergency related to the Covid-19 pandemic.

Organizations during the health emergency experienced an artificial way of working.

In the short span of time of two to three months, the virus has managed to push digital adoption more than it has been attempted in many years.

For this reason, the PA is more than ever at the center of the digital change process that gives it the role of leader becoming the pillar on which to build the solidity of the country.

All this was seen at the time of the emergency when the PA reacted quickly, sometimes even without adequate preparation, in order to ensure the provision of services to citizens and respond to the needs generated by the pandemic.

The pandemic was an element of acceleration of the processes of technological and organizational transformation on which it had long been reflected.

The PA has been able to really understand the importance and the necessity of a deep renewal based on the digital transformation and on the valorization of women and men.

The PA has been promoter of the development and diffusion of the ICT for the application of a system of SW accompanied from a cultural change that has carried a great number of dependent to manifest the will to continue the activity in SW after the overcoming health emergency.

Of course we can not consider the SW an innovation or a new mode of work as the Law n. 191 of 1998 has been in force for more than 20 years.

This law provided for the possibility for Pas to use forms of distance work. For this reason it is possible to install the computer equipment and the necessary telephone and telematic connections and allow employees to work in a place other than the workplace, for the same remuneration.

The Ministry of Labour and Social Policy defines SW or Agile Work as a mode of execution of the employment relationship characterized by the absence of time or space constraints and a phased organization, cycles and objectives, established by mutual agreement between employee and employer.

With the Directive n. 3 of 2017 on agile work officially begins the season of "agile work" in the PA providing for the introduction of new and more agile measures to reconcile work and life times of its employees.

The stated aims refer to the introduction of the most innovative ways of work organization, based on the use of flexibility, on the assessment by objectives, on the recognition of the needs of employees, all in the light of the need to reconcile work and life.

At the base of the SW there is a cultural, organizational and process revolution passing to a culture oriented to the results to an evaluation linked to the actual performances.

The SW becomes a new management philosophy based on the return of flexibility and autonomy to people in the choice of spaces, times and tools to be used in the face of greater responsibility for the results to be achieved.

The context in which SW has developed and the new managerial trends have made it possible to interpret the theme of agile work from a perspective of complexity that takes into account the multiple dimensions at stake and the different cultural references with the aim of clarifying the basic aspects of this new organisational approach.

From the various studies it emerges that the implementation of the SW in PA undoubtedly leads to advantages for both the workers and the organization.

Since February 2020, due to the spread of the health emergency for COVID, a series of measures have been enacted to simplify access to the SW and disseminate the maximum use in PA.

The paper, aware of the decisive role of human action within organizations, starting from the latest results published by the National Observatory of Agile Work in PA established by the Decree of 4 November 2020, would like to answer the following research questions:

- What are the reasons why PA employees want to continue working in SW even after the pandemic?
- Can we consider SW a new way of working?

This theme is particularly relevant as the concepts of flexibility, autonomy, empowerment and results orientation summarize the philosophy behind the SW and can be productive of benefits not only within companies, but also in the public administration.

The increase in the quantity and quality of time due to the lack of home-work travel allows people in condition to experience new daily forms of resynchronization of work commitments with family and personal needs.

## **2 Literature review and Methodology**

In literature we find many definitions of SW each of which highlights different characteristics, peculiar to this new work culture.

Autonomy and collaboration in a working context are key themes of the SW and to be reached must be used in the correct way ICT and appropriate physical spaces.

The term SW describes a new, more open working environment that breaks the physical barriers of the office as we know it and this allows a workplace that allows you to maximize the leverage of dynamic creativity of employees and their emotional relationship to work (Osservatorio 2014).

In the literature, we find many definitions of SW each of which highlights different characteristics, peculiar to this new culture of work.

However, it is possible to grasp the similarities and cornerstones on which this new managerial thinking is based: collaboration, flexibility of working conditions, reconfiguration of spaces and innovation; without neglecting the cultural characteristics of the organization, the degree of autonomy in the choices and empowerment of the staff (Verbeke, Schulz, Greidanus, and Hambley, 2008; Nidumolu, Prahalad, and Rangaswami, 2009).

The evolution of organizational models and human capital management systems are strategic levers to focus on.

In this context, the growing attention to SW is inserted: an innovative approach to work organization that integrates and overcomes the concepts of telework and mobile work, questioning the traditional constraints (physical space, working hours and tools).

The Observatory on SW of the Politecnico di Milano in fact states that "SW implies the development of a new culture of work that does not involve carrying out activities in a traditional way with the addition of new technologies and with the support of redesigned offices.

It's about new ways of working using new tools, new processes, and new approaches to management and teamwork".

And we can still say that the transition to SW is much more than a project of technological innovation; because it involves questioning stereotypes relating to places, times and work tools.

SW sets itself up as a new organizational paradigm in which technologies play a key role in discovering, sharing, co-creating and distributing knowledge.

Technology allows remote working blurring geographical, cultural and functional boundaries in a complex and dynamic environment (Padroni, 2010).

ICT solutions make it easier for workers to share files, information, data and ideas (Chudoba et al., 2005). In this way, all employees can interact in real time flexibly and effectively in a SW environment.

Another important element is innovations in HR practices and in the organisational model.

One of the essential drivers to build and develop a SW model is represented by ICT (Mann, 2012), also essential to enable new ways of working, but that must be supported by a strong cultural change that must lead people to be active protagonists of this change, where ICT is the tool and not the end.

It is peaceful to assert that more and more often the SW is considered a instrument of business increase and this takes the start from the theory of the Resource-based view (RBV) that evidences the business resources like means in order to maintain and to increase the competitive advantage.

In the light of RBV resources are a set of tangible and intangible factors with which the organization interacts directly or indirectly in its processes.

For the RBV, intangible resources and human resources are the most critical and therefore the most difficult to imitate.

According to the RBV the competitive advantage is not consequence of investments aimed to discourage the competitors but from a greater efficiency and the possession of rare resources, a set of competences and activities to added value that resizes the role of the "organizational structure" on performance.

The SW can be a valuable tool available to the PA to increase the effectiveness and efficiency of employees even in particular situations such as the one we are experiencing.

The field survey, also taking into account institutional policy, responds mainly to the purpose of monitoring the propensity of the PA to implement innovative models of work organization oriented to technology, with sustainability objectives.

In particular, the paper, through the reading of the results of some qualitative research, carried out at national level will focus on the identification of the strengths and weaknesses found by employees in the implementation of the SW.

### **3 Results and Practical Implications**

The paper responds to research questions by investigating the perception that PA employees have of SW to understand whether it can be considered an alternative way of working or just a way to manage the emergency related to COVID because in some research (La PA oltre il Covid e Strategie individuali e organizzative in risposta all'emergenza) carried out by FPA in 2020 has shown that employees are in favour of continuing to work in SW even after the pandemic phase has been overcome.

The Research involved some Italian Public with the aim of bringing out the critical issues from employees in the implementation of the SW and the related actions to be taken for its correct implementation taking into account that the evolution of organizational models and management systems of human capital represent strategic levers.

This new way of working has suddenly involved a large number of workers, regardless of the characteristics of the work carried out and regardless of the companies in which they operate.

Among the peculiarities of SW we can highlight the strengths and weaknesses both for the company that adopts it, but also and above all, for the worker himself.

The strengths of the protagonists of the SW show greater flexibility for working hours, allowing to work in the home environment, increasing the time to spend with the cohabiting and the opportunity to carry out work activities at the same time as domestic and family care activities.

Another strong point highlighted is the time savings used in travel, critical element for those who face daily traffic; Workers say that they concentrate more in the home environment and that they also incur lower costs when it comes to moving or eating out of the home.

It is common ground that many workers restrict travel and this also has an impact on the environment.

Table 1 summarises the main strengths of the SW emerging from the research.

Table 1

<b>Strengths of the SW</b>
The flexibility of working time
The possibility of working from the home
The opportunity to carry out at the same time work activities and domestic and family care
Saving time on travel
The increased concentration capacity allowed by the domestic environment
Lower costs due to travel, meals away from home
The opportunity to spend time with cohabiting relatives while working

Turning to the points of weakness we highlight the reduction of sociality and relationship with their colleagues in the office.

Obviously, by working at a distance, they are unable to engage in direct dialogue with the other team members or with those responsible, and this could become a problem.

Other respondents argue that with SW, if on the one hand it brings workers at ease to work in the home, on the other, many have the feeling of being confined within the domestic environment with an impact on the psychological state.

In fact, having the feeling of never disconnecting could lead these individuals to psychologically distance themselves from their own work, due to the feeling of never quitting and never ending.

Other disadvantages are the loss of the division of the day into time for work and time for leisure; and the fragmentation of work and domestic and family care activities.

In addition to these disadvantages, a number of technological difficulties may also arise.

Table 2 shows the main weaknesses of the research findings.

Table 2.

<b>Weaknesses of the SW</b>
The loss of sociality with office colleagues
The feeling of being confined to the domestic environment
The loss of the subdivision of the day in time worked and free time
Fragmentation of work and domestic and family care
The slowdown of work activities without deadline

The difficulty of performing complex operations with one or more remote working groups
The complexities of distance dialogue with colleagues and managers
The difficulty to act in a remote technical environment, without any assistance support in presence

The widespread and sudden introduction of SW required organizational interventions.

The introduction of SW may be accompanied by the definition of more specialised organisational roles and units in which objectives are identified with more specific and measurable results; or a redesign that aims to make more autonomous and less interconnected between them, the different organisational units and the different roles that take place within the enterprise.

In many cases, these companies, in order to ensure and ensure that the SW is adopted and used effectively, have chosen to go and redefine in detail the coordination and planning mechanisms regarding the timing and mode of use; in addition, they have intervened on the methods used for the management of human resources, so as to enhance the work and the results obtained by smartworkers.

From the research of FPA "Strategie individuali e organizzative in risposta all'emergenza" carried out in 2020 involved 5,225 people of which 4,200 civil servants of which 92.3% are resorted to SW.

73.5% of these from home throughout working hours, 18.8% with some re-enters in the office or work suspensions with vacation days, recoveries or leave.

Those excluded from the SW were just 4.7% (2% for personal choice, 1.2% because in essential sectors or services, another 1.2% because he works in institutions that have not activated).

88% of the employees judged the experience of success and 61.1% believed that this new culture, based on flexibility and cooperation within institutions, between institutions and in relations with citizens and businesses, will prevail even after the end of the emergency phase.

93.6% would like to continue working in smart working even after the health emergency.

The research "La PA oltre il Covid" through a survey conducted in collaboration with the Istituto Piepoli in 2020 on a sample of 1000 people representative of the

Italian population and a second survey of over 2000 people who make up the Panelpa of the FPA community, compares the views of users and public employees on the role of the PA in the emergency and in the recovery sees the SW theme present in both investigations.

In the first second the majority of Italians, (53%), the SW is an opportunity for a more efficient and modern administration, a share well above 29% that considers it a risk for absenteeism and opportunistic behavior (13% considers it irrelevant).

In the second the SW was positive, but civil servants do not yet see a new orientation to results.

For 42.8% the practice of evaluation has not changed, for 44.6% there are still changes in this sense but signs of improvement, only 12.6% see a real change.

With distance work there is a greater need for a constant and effective sharing of objectives and strategies, but for the majority the internal communication is not improved but there are signs of change (40.6%) or there is no improvement and seems insufficient (36.1%).

If in June 2020, over 60% of respondents said that the SW would bring a positive change in the PA, now thinks it will take more time as there are still several technological and cultural limits that have limited the spread of SW in the PA.

Among them the lack of digitalisation, the perception that many activities in public bodies were not compatible with remote work, the complex bureaucratic procedures and the lack of awareness of the benefits obtainable (already listed above).

In trying to define and interpret the implications of SW it is good to analyze both the employee and the company actors.

From the point of view of the employee there is a decrease in stress, a better balance between private life and work, and a higher consideration of self and their daily work, managing the work at bestlife balance, making the most of the time available, reducing travel costs.

For the employer the greatest benefits arise from a greater attractiveness of their organization in the world of work and a greater efficiency linked to a decrease in costs.

Among the main strengths it is possible to summarize:

- rationalisation in the use of resources and increased productivity.

- promotion of the use of the most innovative digital technologies and use of smart working as a lever for digital transformation and the development of digital knowledge;
- the reduction of gender differences through a diversity management policy;
- the reduction of forms of “physiological absenteeism”.

In order to justify the affirmative answer to the question of search and to bring out the motivations of the dependent of the PA we refer to the Institute of Research on the Population and the Social Policies that has elaborated and described the results of the survey “Smart Working e questioni di genere negli enti di ricerca”.

The survey was carried out through an online questionnaire given to the workers of the main Italian research institutions, from April 2020 until June 2020; The questionnaire was completed by 2,721 employees of different Italian research institutions, including researchers, technologists, technical staff and administrative staff.

Among the respondents to the SW questionnaire, 45.20% are men while 54.80% are women and most workers have carried out SW activities throughout the period of the health emergency, and a small percentage, alternated SW to work at its place of work.

From the various answers it has emerged that in greater percentage the women regarding the men, have preferred to dedicate their free time to the home reorganization, to the experimentation in the kitchen, to the sport practiced to house etc.

Men, on the other hand, in higher percentages than women, preferred to read, participate in in-depth online courses, read, watch movies and TV series and the online shop.

More or less in the same percentages, both men and women have devoted themselves equally to the care of physical well-being and rest.

Table 3 lists the main activities of employees working in SW.

Table 3.

<b>Complementary activities carried out</b>
Follow in-depth online courses
Reading, music and cinema

Perform large house cleaning and tidy papers and documents
Experiment in the kitchen
Caring for personal well-being, both physical and spiritual
Assisting relatives and friends in need
Shop online
Reserve a higher dose of rest
Home sports

For these reasons most workers would be willing to continue working in SW even after the health emergency, because they feel that it can give much more benefits than disadvantages.

A small minority, on the other hand, want to go back to work at their workplace and sit at their desk, because there, they are more efficient than at home.

No one can give a precise answer to this question, but certainly a large number of workers, having been forced to use this method of work, have greatly revalued it and indeed, have also begun to appreciate it and to prefer it compared to classical work.

Other workers, however, perhaps those in a higher age group, will continue to prefer work in the office for personal comfort, because they do not know how to use a computer or because they do not feel safe to work with it.

Despite this, however, we can say that the COVID-19 emergency has allowed workers to discover a whole new world and a way to work, where there are no more schedules, and continuous supervision, a more "free" job; and surely this new way of working has won over many workers, especially the younger ones.

In conclusion, we can say that the SW, in this time of pandemic, cannot be considered a simple and immediate solution to the problems that have arisen before us since March 2020.

On the one hand, the SW makes it possible not to create gatherings in workplaces and to limit movements, on the other hand, workers find themselves catapulted into a whole new way of working where they no longer have certain limits of space and time.

For some all this is very favorable and can be much more productive, for other workers instead, the opposite case occurs and it is for this that investments are necessary on the organizational structure that is necessary to adopt.

For these reasons the SW can be considered a lever of change for the PA and its workers because it allows to go beyond compliance, favors collaboration, planning, management of results.

The SW thus becomes a new mode of work that goes beyond the emergency situation related to the pandemic and in this way it is interpreted the willingness of employees to continue to work in SW.

### Abstract

This paper presents the profile of the professionals at the Oswaldo Cruz Foundation who work in scientific research, with the aim of understanding within a perspective of decolonization and understanding the central actors of collaborative research networks. The methodology used was through reinforce the theoretical framework and data extraction in platforms that compile data from researchers and technologists who conducted research at Fiocruz are working in Science and Technology. In the conclusion, this initial project allowed an approximation of understanding about the profile of Fiocruz research professionals and analyze data to mapping of both scientific collaborative networks, their central nodes, and links.

**Keywords** – Researches, Scientific collaboration networks, Knowledge Management.

**Paper type** – Practical Paper

### 1 Introduction

The 21st century is characterized, among many aspects, by the configuration of the network society, a global interdependence, which was facilitated by the development of information and communication technologies. This environment has allowed not only the creation of new forms of relationship between organizations, people and the world, but also the development and availability of new innovative products and services.

Given this scenario, the enormous, complex challenges of networking in the health sector, especially those of public health in the country's health research institutions such as the Oswaldo Cruz Foundation (Fiocruz), assume a strategic role in the establishment of more projects, integrators and collaborative arrangements, which allow monitoring and generating more efficient and coordinated actions.

It is widely known that research groups that work in an integrated and coordinated manner produce more effective results, achieve goals quickly and have greater visibility. In fact, the greater the size and diversity of teams, the greater these effects. Therefore, it is extremely important for an institution with dozens of units within a diverse administrative structure like Fiocruz to map out and characterize the profile of collaborative networks and the professionals that make them up, as well as obtain data to analyze what critical knowledge is being acquired, retained, shared and disseminated in order to facilitate the entire process of development and monitoring of research projects whose effective results are for society.

Fiocruz is one of the few institutions that brings together the main elements of the innovation chain (generation, conversion, and dissemination of ideas) from the laboratory bench to advanced, biomedical, and social research activities. In a way, everyone has some level of collaborative environment. However, there is a weakness that needs to be improved and solidified through the integration of institutional strategies in research, development, and innovation that promote an agenda of priorities enabling a generation of new technologies that address public health problems and, consequently, the country's economic development. Given this scenario, the first stage of this innovation project sought answers to the following guiding questions: What is the profile of researchers and technologists who conducted research at Fiocruz? How are Fiocruz's scientific collaboration networks composed?

This project aims to investigate Fiocruz's scientific collaboration networks, the profile of its actors, and its main areas. As an innovative management product, this project is intended to create, from this data, a virtual platform of the mapped networks. This allows for a better visualization of the Fiocruz community and provides a translation to society of the institution's scientific production, bringing more transparency to the work of its scientific collaboration networks. The main focus is to strengthen the group's competitive intelligence, and thus accelerate

the dissemination of results obtained in health research and increase the visibility of the group and the institution.

## **2 Scientific Collaborative Networks**

Information and knowledge management plays an important role among collaborative research networks; it can support Fiocruz's innovation policy and assist in the management of the Institution's research projects. Fiocruz already has some expressive collaborative environments, such as Virtual Campus, Observatory of Science, Technology and Innovation in Health, ARCA - Institutional Repository and Data Repository, Agora Platform, among others, but the Institution still does not know how its groups collaborate internally and externally. Thus, the online platform for viewing networks can help manage the Institution's policies and research, in addition to understanding the organizational knowledge and intelligence generated by these collaborative practices, in favor of more effective results in scientific activity.

According to Castells (1999), we are in a network society and, for Benkler (2006), we live in the networked information economy. This may mean that it is not just an economy based on information, knowledge and culture, but above all, it is a network of decentralized information and communication links.

To meet current demands, it is necessary to develop skills and competences that allow the conscious, creative, and beneficial use of information, data, and knowledge. In this sense, Vitorino and Piantola (2009) state that to be competent in information, it is necessary to know how to recognize when information is needed, and to locate, evaluate and, effectively use the information. Furthermore, it is essential for scientific development that information and knowledge are shared, communicated, and debated.

Some authors help with the theoretical support of the research, as their studies address such points of view about interactions in research and collaborative networks, among them: Katz (1997), Carr (2010), Lastres & Ferraz (1999), Barnes (1954), Kudashin (2004), Portugal (2011), Fialho (2018, 2020) and Barabási (2016). All of these authors direct us to critical thinking about the analysis of social networks. Finally, Latour (2017) supports us on the "actor-network" relationship.

For Portugal (2007), in the social sciences, network analysis has always been an interdisciplinary field par excellence. In the view of Guimarães (2014), there is a

space for fluxes and that trust relationships are maintained indirectly, in general, mediated by communication devices through which trust is built.

Finally, Wellman and Berkowitz (1991) are useful to complement some analyses. According to them, social structures act as networks--as sets of "nodes" and ties that represent the interconnections, the flow of relations, the transfers, and structural relations between the "nodes." Kudashin (2004) perceives the social network as a set of relationships that can be mapped.

### **3 Coloniality of Power**

The research project intends to investigate the profile of researchers who work in networks--and thus provoke a reflection on the importance of diversity in research groups--and assess the gender and race quantitative of researchers and technologists who work at the forefront of Science.

According to Leone (2017), the insertion of women in economic activity in Brazil began to intensify in the 1970s, in a period of economic expansion, at the height of an urbanization and industrialization process that configured a favorable period for the incorporation of new workers into the labor market.

Despite the evolution of female work over the years, and the changes in values related to the role of women in Brazilian society, it is essential to understand whether these changes happen in the environment of collaborative scientific networks, especially those sexual in nature as it is what defines the place of men and women in this context.

Considering the transformations of work went from a logic of reproduction and repetition to a logic of knowledge and innovation--especially with regard to collaborative scientific networks--the most important thing in a process of cooperative creation is the knowledge generated by these groups: immaterial work.

According to Foucault, the subject is born from the relationship of other subjects constituted by social practices of power and control. It is in this relationship of power and control, for the maintenance of capitalism, that the Eurocentric culture strengthens the erasure of other cultures, the kidnapping of ancestors, and the construction of inequalities in the dimensions of power, knowledge, and being.

Racism is a power system that is born from the racialized production of the other for the permanence of concentrated wealth. According to Fanon (2009),

colonial relations were naturalized and do not end with the end of colonialism. In this relationship, eugenics establishes relations of power and a state of domination as for someone to live it is necessary for someone else to die.

From the privilege of establishing states of domination, people are placed on the sidelines or excluded from hierarchical structures and, therefore, are not subject to the same rules and the same opportunities. Thus, in these static and hierarchical structures, we can observe these power relations and the hardships of racism that affect these relations.

#### **4 Metodology**

To achieve the proposed objectives, it was essential to analyze and identify the profile of actors (researchers and technologists) who work in scientific research at Fiocruz. This research was quantitative and qualitative, with data collection techniques such as data extraction in the General Administration System to identify researchers and technologists and their respective race/ethnicity and gender. After the first collection, data were extracted from the Lattes Platform of professionals in relation to their training (postgraduate).

In the next stage of the project, the academic production of professionals and their scientific collaboration--that is, the dynamics of collaborative work between scientists--will be extracted from the Lattes Platform, through a system called ScriptLattes. The selection of scientific and academic production will be from 2000 to 2020; and we will analyze how this academic production is related and whether the identified research networks help the institution to be strategic. The case study methodology helped to draw an overview of the researchers' profile so that we can later use the social network analysis methodology to facilitate the understanding of the relationships and links of the areas involved in the process.

#### **5 Results**

For the authors Li, Liao and Yen (2013), one way of accumulating cognitive capital is through the diversity of the collaboration team, because while there is interaction between professionals, the chance of applying new knowledge increases. It can also lead to the deepening and sharing of knowledge, and possibly an expansion of the network. It is in this sense that the first analyses were interested in understanding the profile of professionals who work in research at the institution, taking 2020 as the base year and understanding this diversity.

According to the graphs below, it can be seen that the Institution's scientific profile, regardless of position, is mostly female. Graph 1 shows that in a population of 2,428 researchers and technologists, in relation to gender, it is 61.4% female and 38.6% male.

Graph 1: Gender x Servants, Fiocruz 2020.  
Source: Prepared by the authors (2021)

Graph 2 shows that the position of technologists and the female gender has the highest number of professionals, and this predominance of gender is also present in the position of researcher.

Graph 2: Gender x Position. Fiocruz, 2020.  
Source: Prepared by the authors (2021)

The data extracted from the Lattes Database, created by the National Council for Research and Technological Development (CNPq) and compulsory for all researchers in the country, is self-declaratory and dynamic. It can be concluded in Graphs 3 and 4 that the professional research staff regardless of gender is highly qualified, and that most of them have doctorates and post-doc.

Graph 3 : Graduate x Female Researchers. Fiocruz, 2020  
Source: Prepared by the authors (2021)

Graph 4: Graduate x Male Researchers. Fiocruz, 2020.  
Source: Prepared by the authors (2021)

We found that even the Institution that positions itself in the struggle for a fairer and more equitable society, that is committed to the diversity of the Brazilian people and their demands, and that carries out actions aimed at that their workers can face all forms of discrimination and exclusion, as the group of Black researchers and technologists is 2.6% compared to the white race, which is 75.9%.

Graph 5: General Race x Servants. Fiocruz, 2020  
Source: Elaborated by the authors (2021)

## 6 Conclusions

This initial project allowed an approximation of understanding about the profile of Fiocruz research professionals, who are responsible for the production of knowledge that makes up the essence of the mission of the Institution. The next phases of the project intend to be more analytical than descriptive, as they will have other data sources and will require the contextualization of the acquired information and will present a mapping of both researchers and scientific collaborative networks, their central nodes, and links.

Gender and ethnic-racial diversity may favor increased productivity and even reflect the transparency of deliveries to the Brazilian people, in addition to meeting their multiple demands and democratically proposing the generation of

new science, technology and innovation public policies based on different perspectives that will consequently promote the growth and development of this society.

In this case, we conclude that the profile of researchers who work in scientific research in health is mostly female and white, which reinforces the advancement of women's insertion in the labor market but demonstrates that the coloniality of power and racism prevail.

# Rediscovering Urban Intelligence within Sustainable Cities

---

Mauro Romanelli

Department of Business and Economics  
University of Naples Parthenope  
Via G. Parisi, 13 Napoli 80132, Italy

## Abstract

Cities are rediscovering the importance of becoming as intelligent communities and facing the challenge of advancing as smart, inclusive and sustainable cities in order to promote urban communities as engines of social and economic growth and societal development. Intelligent cities drive the urban community towards sustainability for ensuring social and inclusive growth. The future of sustainable urban development relies on intelligent cities which are able to promote future urban development and support social and economic growth of urban areas, developing urban intelligence to solve problems and drive towards the urban community towards urban sustainability. Intelligent cities identify possible itineraries of urban development in terms of social and economic growth within urban environments. Cities construct a pathway to develop urban intelligence as a source for sustainable urban future, promoting a smart vision to urban development as a key driver for enhancing the urban community and driving collaboration and cooperation among the urban private and public actors as a framework for innovation, knowledge and value creation processes.

**Keywords** – Intelligent and sustainable cities, smart city and community, collaboration.

**Paper type** – Academic Research Paper

## 1 Introduction

Today, cities are rediscovering the importance of intelligent communities as engines of smart, inclusive and sustainable growth and cities in order to promote urban communities as drivers of social and economic growth and societal development. Intelligent cities drive the urban community towards sustainability. Urban sustainability is becoming both a source and goal leading to cities working to promote sustainable urban development relying on urban intelligence. Cities contribute to sustaining value creation processes, becoming sustainable and intelligent communities that develop smart-driven and collaborative processes in

order to develop knowledge, support learning and innovation using the potential of information technology to support change in a significant way. Developing cities as sustainable communities helps cities to actively play a key role in promoting urban value creation and contribute to achieving urban sustainability too (Haapio, 2012). Cities identify a path for sustainability that helps improve and extend the wealth of community promoting social and technological change (Williams, 2010). Cities construct a truly smart and sustainable city moving from techno-centricity to post-anthropocentric approach (Yigitcanlar *et al.*, 2019). Cities become intelligent urban communities that develop a smart approach as cultural vision to urban development, strengthen the community to develop the potential of information technology in order to drive an intelligent urban growth and mobilise the organisation sustaining the cooperation among the helices of urban landscape (Lombardi *et al.*, 2011). Information technology helps cities to adopt a smart mind set constructing a dialogue with civil society in order to drive urban innovation and advance to build a sustainable city (European Economic and Social Committee, 2015). Smart cities should use technology to develop democratic and participatory governance capacities as necessary means for creating public and sustainable value (Deakin 2014). Cities adopt a smart city vision to support sustainable urban growth (Deakin *et al.*, 2012). Cities need to be intelligent communities in order to continue to live (Schnore, 1971) and become spaces for social and inclusive innovation (Newman and Jennings, 2008).

The pathway leading to urban sustainability relies on cities rediscovering urban intelligence as a key source that enables the city to develop as an organisation which contributes to value creation and wealth within urban spaces and environments. Cities are building a city as sustainable organisation, meeting the needs of communities without compromising the wealth of future generations. The future of sustainable development relies on intelligent cities of the future which are able to promote urban development and support social and economic growth of urban areas, developing urban intelligence to solve problems and drive towards the urban community towards urban sustainability. Intelligent cities identify possible itineraries of future urban development in terms of social and economic growth within urban environments, being able to see which intelligence are involved in the process of urban development (Santangelo, 2016). Intelligent cities use the potential of information technology to make the city more innovative, smart and efficient and have to develop technology to stress the need

for integration among innovation actors, connected communities, digital application that support the urban intelligence (Kominos, 2011).

While there are studies that focus on the role of the intelligent city, there are few studies that investigate which are the drivers that lead the city to becoming an intelligent city. Cities need to adapt to social and economic change, driving innovation, by becoming more smart and sustainable cities than the past cities. The aim of this study is to elucidate how cities develop sources to build urban intelligence. Smart city vision, smart-enabled community development, collaboration enable the intelligent city.

Smart and sustainable communities construct a vision of the urban future, identifying dialogue, partnership and collaboration as a way to take social and economic advantages and advance the city to become a sustainable urban community (Eger, 1997). Smart city and smart community become an urban vision and means that enable urban communities to develop urban intelligence and promote smartness in services management, urban mentality and governance as sources to build the city of the future as an entity that continuously develops innovation for change. This study analyses how cities construct urban intelligence for sustainability, and become intelligent and sustainable cities. The study is theoretical and relies on a literature review and analysis related to the concepts of sustainable and intelligent city, smart city and community as drivers of development and enablers of collaboration and cooperation. The selected contributions are interpreted in a narrative synthesis in order to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods, Agarwall, Young, Jones and Sutton, 2004).

The paper is articulated in the following way. After introduction and methodological section, in the second and third paragraphs, the role and meaning of intelligent cities and communities, and sustainable cities is elucidated. In the fifth paragraph, building urban intelligence relies on promoting a smart vision to urban development, rediscovering the community and enabling collaborative processes for knowledge, innovation and learning. Finally, discussion and conclusions are outset.

## **2 Becoming intelligent cities and communities**

Intelligence refers to the ability to learn and apply knowledge in new situations. As organizations, cities have to develop intelligence as the ability to drive change,

facing the uncertainty emerging from external pressures and environment (Brătianu, Vasilache and Janu, 2006). Intelligent cities contribute to facing and solving problems, and identifying solutions to urban development, focusing on collaborative innovation. (Komninos, 2009). According to Briggs (2005) a sustainable city is a dynamic and intelligent system which is able to adapt to change to proceed towards long-term health and success, and the «city intelligence is the capability of this network of organizational systems to function effectively, and successfully, over a period of time» (p. 39). According to Komninos (2006) intelligent cities are territories where high capacity for learning and innovation emerge in relation both to creativity of population and institution of knowledge creation, and digital infrastructure. Cities employ technology becoming spaces that construct strategic collective intelligence which is cooperative (Komninos, 2006). Hollands (2008) elucidates that the intelligent city brings together information technology and people to enhance innovation, learning, knowledge and problem solving. «Digital collaborative spaces and intelligent cities sustain a particular form of collective intelligence, in which information collection, assessment and dissemination rely on the combined action of a group of people, a community, or a network of companies and organisations» (Komninos, 2009, pp. 348-349). According to Santinha and de Castro (2010) the intelligent city provides high-quality economic services and supports the development of an organizational and technologically innovative environment capable of promoting competitiveness among firms and creativity. As intelligent communities, cities develop new collaborative opportunity for economic growth and social welfare. Urban spaces open up to possibilities of public collaborative and multi-actor innovation by involving civil society and citizens (Sørensen and Törfing, 2018). The intelligence of a city refers to collaboration and involvement of citizens, companies and public authorities as an organizational framework that enables urban innovation (Komninos, 2015). The role of both *smart* and *intelligent* cities is to integrate the physical, institutional and digital dimensions of urban spaces. Even if the concepts of *smart* and *intelligent* cities tend to be overlapping, the *smart* city stresses the importance of technologies and interactive media that support knowledge diffusion and interaction, *intelligent* cities focus on collective and collaborative intelligence, leading to innovation systems and web based collaborative spaces (Stratigeia, 2012). Intelligent cities adopt a smart approach to urban development but also integrate digital city dimension into the social space of the city and enable digital

spaces to enhance collaboration, social networking and collective intelligence in order to make the city as innovative and inclusive community (Kominos and Tsarchopoulos, 2013). Intelligent cities as communities contribute to both ensuring better quality of life of people within urban spaces and enabling value creation processes in long term horizon. Cities emerge as platforms that promote co-production of social value, capabilities and innovation, building a strategic urban intelligence (Ravetz and Miles, 2015).

### **3 Towards sustainable cities**

Cities contribute to creating social organisms and communities, promoting social interaction, creative processes, by improving the wealth of people in urban spaces (Camagni, 1996). Cities provide services and become social incubators for social change and innovation (Evans, 2005). Cities of tomorrow should be sustainable cities which are able to design an urban and sustainable development within global and competitive economies and open societies. A sustainable city should be able to reform the way in which the city tends to interact with global economy and environment (Haughton, 1997). Sustainable cities build an inclusive and learning urban prosperous future (Osborne, Kearns and Yang, 2013). Cities of tomorrow can assume a holistic model of sustainable urban development, promoting place- and people-based approaches, shaping governance and cooperation infrastructures and ensuring spatial development and efficient use of resources (European Union, 2011). Sustainable cities employ human, social, organizational and technological capability to drive change (Williams, 2010), promoting evolving partnerships among heterogeneous actors (Bayulken and Huisingh, 2015), transforming knowledge resources and reinforcing knowledge assets and intellectual infrastructures (Knight, 1995). As organizations, cities should encourage the use of knowledge in order to achieve social, economic and environmental issues, and advance towards sustainability (Leon, 2013). Following a knowledge-based view, cities are shaping the city as a sustainable entity which is able to establish key priorities, long-term urban planning, by integrating knowledge management processes (Chang *et al.*, 2018).

Building sustainable urban development relies on improving the quality of life for people in a city, preserving ecological, cultural, social and economic elements without a burden can occur on the future generations. Sustainable cities contribute to promoting sustainable urban development improving and

extending the wealth of people within a community (Trindade *et al.*, 2017). Sustainable cities develop the city as a community encouraging cooperation and collaboration between city government, people, business, research and education centers by promoting social and economic innovation, providing services, creating knowledge for continuous learning in order to ensure high quality of life. As urban communities designing long-terms policies for change and continuous innovation, sustainable cities should promote trust-based relationships by sustaining citizen participation in policy choices. Cities have to adopt a model of sustainable city development. In particular, «cities need to adopt an integrated approach to planning and development, integrating the social, economic, environmental and territorial dimensions of urban development» (European Union, 2011, p. 60). Intelligently-sustainable cities are responsible to ensure sustainable urban metabolism, by developing sustainable environment, economy and society (Gargiulo Morelli *et al.*, 2013). Sustainable cities should continuously develop the city as a future-oriented and innovation-driven smart community. In particular, sustainable cities adopt a demand-driven approach meeting the needs of people living in urban environments and promoting a smart city vision that enhances the importance of information technology as a source to support urban future, knowledge and innovation (Angelidou, 2015).

#### **4 Building urban intelligence within a city willing to be a sustainable city: smart city, community and collaboration**

Cities have to invest in smart city vision, community and collaborative processes in order to become a sustainable city. Cities investing in technology aim to become smart. According to Giffinger *et al.* (2007) smart cities employ strategically information technology to drive innovation and support service management in order to improve the quality of life within urban communities. Technology is opening up cities driving innovation in services, business, economy and governance, becoming smart cities in order to support social and economic growth and enhance the quality of life within urban communities (Nam and Pardo, 2011a; Shapiro, 2006). Smart cities contribute to shaping a sustainable city, by integrating technological, organizational and social infrastructures and capabilities, promoting sustainable economic growth and participatory governance (Albino, Berardi and Dangelico, 2015; Caragliu, Del Bo and Nijkamp, 2011). In particular, advanced ICT offer a potential for planning the city building

capabilities for shaping urban sustainability. The adoption of information technology is leading to cities becoming smart and sustainable communities (Bibri and Krogstie, 2017). Smart city vision and applications contribute to sustainable urban development and driving place-based collective intelligence (Angelidou *et al.*, 2017). Adopting a smart city perspective drives open innovation, leading to smarter, inclusive and sustainable cities (Paskaleva, 2011). Smart city visions contribute to improving urban sustainability, tracking a pathway for sustainable future (Ahvenniemi, Huovila, Pinto-Seppä and Airksinen, 2017).

According to Kourtit and Nijkamp (2012) smart cities concern human, technological and social capital as drivers of sustainable urban growth, and help to improve the urban performance of a city. Information technology enables cities to identify a smart vision to building satisfying conditions for urban development, promoting smartness as a source for sustainable urban spaces and growth. Smart and sustainable cities use information and communication technology, identifying new ways to address urban development, preserving capabilities and meeting the needs of future generations (Höjer and Wangel, 2015). A city should be sustainable to be a smart city too. According to Bifulco, Tregua, Amitrano and D'Auria (2016) the role of information technology in smart city framework is to promote sustainable urban development of cities. ICTs contribute to sustaining smart strategy, improving services and quality of life towards sustainability (Bifulco, Tregua, Amitrano and D'Auria, 2016).

Cities of the future will build a smart community in the knowledge-based economies, playing a central role for improving urban competitiveness and development (Begg, 1999, Eger, 2009). Promoting community, technology and policy as drivers of urban sustainable development help cities to adopt a smart strategy (Yigitcanlar *et al.*, 2019). Cities develop smartness by enhancing the collaboration as a source that enables urban development and innovation (Meijer and Bolívar, 2016). Cities becoming smart communities and sustainable cities tend to ensure efficient service delivery and infrastructures improving quality of life and well-being of its citizens, ensuring economic growth and employment opportunities (Dhingra and Chattopadhyay, 2016).

Information technology helps to support the sustainability of cities by making more smart the urban community (Walters, 2011). Promoting smartness helps cities to become smart communities able to drive urban change (Deakin, 2011). As communities using the potential of information technology, cities develop technologies as a means that empowers citizens as co-designers and co-

producers of public services, sustaining innovation, citizen-centricity, knowledge and sustainability (Granier and Kudo, 2016).

Intelligent cities use the potential of information technology to make the city as a smart city and community, rediscovering the opportunities for innovation development, social and participatory growth of the urban community as decision-maker of the urban future, by using information technology to make real smart city as a city which enhances democratic practice, enabling citizens to decide what kind of city want to live in (Hollands, 2008).

Sustaining smart city and community development helps to empower individuals and groups to use skills and information for change within communities (Stratigeia, 2012). According to Komninos and Tsarchopoulos (2013) the advent of digital and smart cities helps cities to produce collective and collaborative intelligence. «The digital life of cities starts at the hyperspace, but it soon becomes part of the social life and the physical environment of cities, empowering people and advancing citizen's capabilities by collaborative, collective, and embedded intelligence» (p. 151). Cities adopt a smart approach becoming platforms for engendering innovation by investing in human capital and involving people to interact and cooperate to build collaborative processes between people, business and government within community as means that leads to urban public value and innovation (Hollands, 2008; Paskaleva, 2011). Cities are drivers of economic growth and main actors of open innovation, encouraging multi-level and sector interactions between private and public organizations involved in the co-creation, co-design and co-implementation of integrated and innovative solutions (European Commission, 2017). Cities are becoming smart cities by involving universities, industry, government and civil society as one of the main key actors in order to promote the development and performance of cities (Lombardi *et al.*, 2011).

Technology helps to drive urban innovation in management, governance, and policy (Nam and Pardo, 2011b) leading cities to improving urban quality of life as a means for sustainable development (Bătăgan, 2011) by making urban communities, cities and human settlements as inclusive, safe, resilient and sustainable as requested by the goals 11.b3 of *UN 2030 Agenda for sustainable development*. Building a smart community means to develop and implement cooperation and collaborative processes as a way to drive urban sustainable development (Eger, 2005). The smart community develop collaboration, cooperation and partnership among voluntary, education, private and public

organizations, and citizens within urban space (Lindskog, 2004). As smart communities, cities proactively are using information technology to promote sustainable wellbeing for people (Lara *et al.*, 2016). Cities adopt a human-centred vision to smart city development in order to develop collaborative processes that drive urban innovation processes (Andreani *et al.*, 2019).

## **5 Discussion and conclusions**

Cities drive urban, social and economic development, selecting a pathway for urban sustainability, by identifying the sources for urban intelligence. As sustainable ecosystems and engines of economic growth, cities of tomorrow should select a strategic agenda by involving different stakeholders who will be working together in designing and implementing collaborative and cooperative smart and human-oriented processes that enable the opportunity for breeding new urban knowledge and innovation. Smart city vision, smart community and collaboration are at the heart of the city becoming an intelligent city which develops in order to promote a sustainable urban future and contribute to wealth of urban communities. Information technology is emerging as a source that supports cities to drive social and economic growth and innovation, and evolve as a community becoming smart rediscovering the cooperation among urban stakeholders and collaborative processes as engines of development. As following a smart approach to urban development, cities tend to design a pathway for sustainability and learn how to build the organisational processes and patterns that drive cities to act and evolve as smart communities which design and implement collaborative processes within urban spaces.

Cities should become intelligent communities that adopt a smart urban view as strategic and cultural vision for growth, promoting collaborative and collective intelligence by using the potential of information technology, leading to cooperative patterns that involve local government, business, research centres and citizenry that learn how to breed social and economic urban innovation, contribute to new value and knowledge. Cities design a pathway to urban sustainability, rediscovering the importance of the urban community as engine of social, inclusive and economic growth, strengthening the collaborative processes as drivers and key sources that shape the city's intelligence as a means that opens to future and sustainable urban development.

The future of cities should be sustainable. Cities are rediscovering the importance of developing urban intelligence and defining intelligent solutions to facing and solving urban problems that influence social and economic development of urban environments and communities. Cities of the future should face and win the challenge of sustainability as source for creating public value and benefit the economic and urban development. Cities should learn how to become intelligent urban communities that evolve using the potential of information technology and digital, interactive applications in order to drive urban growth and promote value creation and enable the city as an intelligent actor which supports a continuous orientation towards urban sustainability and innovation. Intelligent cities become drivers and engines of sustainable urban development and contribute to shaping the city as a sustainable community. As intelligent urban communities, cities should develop a smart-enabled vision a cultural and strategic approach to urban design mobilizing the organisational pattern for cities as engines of innovation and knowledge, following technological evolution that leads to considering cities not only as services providers but enablers of innovation, learning and knowledge. Future research perspectives imply to investigate how European cities are tracking a pathway to urban development becoming intelligent cities, by employing technological and social capabilities to promote smartness and community as drivers of urban sustainability.

### Abstract

In dynamic business environments with uncertainty and risks entrepreneurs make efforts to customize new products to latent user needs. In a product development process, user/customer integration (an approach of giving users an active role in an innovative product design) relates to challenging processes of collaboration and knowledge sharing with and within an entrepreneurial team. The paper research is focused on a model that comprise knowledge conversion and knowledge sharing barriers in an entrepreneurial team working in collaboration with innovative and "ordinary" users at early stage of product design. The key barriers to knowledge sharing in collaborative entrepreneurial team were formulated and assessed based on qualitative research (observation, questionnaire, and in-depth interviews). At the early stage of product design, in the model of knowledge conversion in collaborative entrepreneurial teams, the role of exploratory prototyping is identified.

**Paper type** – Academic Research Paper

## 1 Introduction

Today knowledge (individual and collective, internal, and external, explicit, and tacit) has become one of strategic assets of an organization. The experienced knowledge management (KM) has potential to produce sustainable competitive advantage (Bollinger & Smith, 2001; Murray & Peyrefitte, 2007; Constantinescu, 2008; Liyange et al., 2009, Lee, 2016; Ferreira, 2020; Marchegiani, 2021). There is growing flow of research devoted to KM not only in large but also in small organization and entrepreneurial entities (Hutchinson and Quintas, 2008; Presutti et al., 2011; Gaimon and Bailey, 2013; Alvarez et al., 2016; Bandera, 2017). KM practices in small and large organisations differ significantly (Hutchinson and Quintas, 2008; Zieba et al., 2016). In this regard, it takes the sense to extend research and study if and how small and micro companies, including entrepreneurial teams, manage their knowledge. KM in entrepreneurship is based on research of endogenous growth (Romer 1994), knowledge spillover (Cuervo et al. 2007; Audretsch and Keilbach, 2007; Acs et al. 2013; Caizza et al. 2020), strategic entrepreneurship (Agarwal et al. 2010; Audretsch et al. 2015; Ghio et al. 2015; Tavassoli, et al. 2017) and open innovation (van deVrande et al, 2009; West et al. 2014; West and Bogers 2014). Adoption of digital technologies and knowledge spillovers changed the entrepreneurial environment (Li et al. 2016; Hoffman and Yeh 2018; Kuratko et al. 2020). The modern social and network infrastructure creates new opportunities for nascent entrepreneurs, and a great interest in how nascent entrepreneurs can access and share knowledge via collaboration and co-creation with external partners (customers, users, suppliers, etc.) with the aim to new/innovative product design (Ahumada-Tello et al., 2017; Welter et al. 2019, Belitski et al.2021).

Entrepreneurial teams that challenge invention of innovative products come through stages with various priority goals on a way to sustainable business development. The first stage of product design is full of uncertainties and poorly formalized. This is pre-development (early) stage, so-called fuzzy front-end (FFE), where a concept of product and its feature set are determined and validated (Kim and Wilemon, 2002; Koen et al., 2014; Pereira et al., 2017). Entrepreneurial teams act at this FFE stage as creative design teams having in mind some extra-long-term goals/objectives related to business-model (scalability features of start-up operations) that are built around innovative product later. The teams face two critical questions at the FFE. How to evade useless efforts by creating an

innovative product/service that does not have value for customers. And how to verify success of an innovative product/service that will meet customers' expectations before running out of resources that entrepreneurs currently have. Users/ customers with their own innovative initiatives can demonstrate new opportunities for entrepreneurial team to make valuable market offerings (Witell et al. 2011) by participating in product/service/business model development with specific degree of participation in design process, i.e. "design for", "design with" and "design by" (Kaulio, 1998).

The necessity of external collaboration, to get competitive advantage, is challenging for entrepreneurial teams as external stakeholders are not the ones that get through HR requirements to comply with levels of professional education, experience, and soft skills match. In this sphere formulation of issues/problems and search of solutions lies in cross-section of the three domains: collaborative management, knowledge management, and entrepreneurial management.

In the knowledge management domain, we focus in this research on knowledge sharing (Yeşil and Hırlak, 2016; Kucharska and Kowalczyk, 2016; Zammit et al., 2016; Mathrani and Edwards, 2020) through which knowledge, skills, and expertise are exchanged among entrepreneurial team members and external stakeholders.

The collaborative management domain in this research is associated with choose of the methods and management of user/customer integration in IPD, whereby entrepreneurial team members attain tacit knowledge from use/customer and internalize that knowledge into IPD (Lilien, et al., 2002; Füller and Matzler, 2007; Bartl, et al., 2012; Bretschneider and Zogaj, 2016).

The entrepreneurial management domain is an "approach to management" which is characterized by "the pursuit of opportunity without regard to resources currently controlled" (Stevenson, 1983, Stevenson and Jarillo, 1990). Entrepreneurship as opportunity-based management behavior most fit in design of innovation solution. In this research entrepreneurial teams use Lean Startup techniques, iterate "hypothesis – build – measure – learn – new hypothesis" in feedback loop and improve PD to be competitive in shorter product life cycles (Blank, 2013). Authors of this paper define an entrepreneurial team as a cross-function collaborative team that attain knowledge, generate, and test hypotheses in an uncertain environment in collaboration with customers/users, iterate and learn with the aim to create valuable product/service and effective business

model. This definition refers to foundations of entrepreneurial management practices.

The goal of this research is to study the model of knowledge conversion and knowledge sharing barriers in entrepreneurial team working in collaboration with innovative and “ordinary” users at early stage (FFE) of product design (Co-PD). The research questions are formulated as follows: what are main barriers to knowledge sharing in collaborative entrepreneurial teams in FFE of Co-PD process? How exploratory prototyping influences knowledge sharing in FFE of Co-PD process?

The paper is structured in the following way. Section 2 presents theoretical background on collaboration, user/customer integration and knowledge sharing. Section 3 describes the process of collaborative product design by entrepreneurial team. Section 4 defines the research design, describes how the study was planned and executed. Section 5 presents SEI model of knowledge conversion and barriers to knowledge sharing in collaborative entrepreneurial team. The results are summarized in the Conclusion.

## **2 Theoretical background: collaboration and knowledge sharing**

### ***2.1 Collaboration and user/customer integration in Co-PD***

Collaboration is investigated from various direction, in particular, as a process for cross-organizational linkage (Emden et al., 2006), cross-enterprise processes (Deck and Strom, 2002; Bodas Freitas and Fontana, 2018; Sinkovics et al., 2018), as well as customer co-creation of innovation in corporations and SME's (Vrandea et al., 2009; Frow et al., 2015; Kleber, 2019). Collaboration can provide benefits of speed and resources savings in the IPD processes, through the effective and efficient sharing and combination of knowledge (Mathrani et al., 2011; Mathrani and Edwards, 2020). However, when communication between stakeholders of PD processes breaks down, the collaboration could act as a backward step. Geographical proximity plays an essential role in knowledge sharing into early stage of PD (Davids and Frenken, 2017).

Users/customers knowledge is impossible to replace in PD process (Sawhney et al., 2003; Su, et al., 2006). The model of user/customer integration in PD significantly depends on many factors such as stage of PD, degree of future product innovativeness, industry, type of market and users/customers, etc. (Enkel

et al., 2005; Lau et al., 2010; Sandmeier et al., 2010; Bretschneider and Zogaj, 2016). Thus, being integrated into the PD process, user/customer bring not only information regarding their needs/wants but also provide various solutions concerning different activities within the PD.

In this research entrepreneurial teams used Lead Users model (Lilien, et al., 2002; von Hippel, 2002) for integration of innovative users ('leading-edge user') (von Hippel and Katz, 2002) in Co-PD and were enriched with knowledge from "ordinary" users (market majority) by focus groups and user testing exploratory prototypes. The ability of innovative users to be effective in FFE of PD is explained by combination of superior knowledge of the user domain (so-called, use-experience) and sufficient technological knowledge.

## **2.2 User/customer knowledge sharing and barriers**

Dissemination of knowledge, understanding of a subject gained through study and experience, is an essential entity of modern competitive environment with rapid change of customer requirements and shortening product life cycles (Wang & Noe, 2010).

Knowledge is an irreplaceable resource for PD process and is crucial for creation innovative product. "It includes experience, values, insights and contextual information and helps in evaluation and incorporation of new experiences and creation of new knowledge" (Barney, 2001; Indira et al., 2012). User/customer knowledge includes both explicit and tacit one. Explicit knowledge is type of knowledge that the individual holds consciously in mental focus, that can be easily explained and can be communicated to others, which means it can be symbolic and documented, eg., user manual of for employee or user (Nonaka and von Krogh, 2009; Agan et al., 2018).

Tacit knowledge represents internalized knowledge, engrained with actions and experience, while including cognitive and technical elements, e.g., mental models, skills, ingenuity (Nonaka and Takeuchi, 1995; Agan et al., 2018). User/customer tacit knowledge is difficult to articulate and communicate, other than by direct interaction, telling metaphors and storytelling (Leonard and Sensiper, 1998; Hernandez-Serrano, et al., 2002).

SECI (Socialization—Externalization—Combination—Internalization) model of knowledge conversion illustrates how two types of knowledge are converted to one another (1-from tacit to tacit, 2- from tacit to explicit, 3- from explicit to

explicit, 4- from explicit to tacit) and create new knowledge model (Nonaka and Takeuchi, 1995; Nonaka et al., 2000).

In response to expanding importance and demand of knowledge sharing both in society and in business environment, the study of knowledge sharing barriers at different organizations took place (Barson et al., 2009; Kaps, 2011; Lilleore and Hansen, 2011; Santos et al. 2012; Athar and Evans, 2015; Zammit, 2015; Riege, 2005; Yeşil and Hırlak, 2016 Akgün et al., 2017).

Innovation activities stimulate research of tacit knowledge sharing barriers (Haldin-Herrgard, 2000; Cumberland and Githens, 2012; Park, 2012; Bretschneider and Zogaj, 2016; Kucharska and Kowalczyk 2016; Mathrani and Edwards, 2020). The process of user/customer tacit knowledge sharing is not well understood, but can provide ideas for breakthrough innovations (Mascitelli, 2000). Considering this, the authors of the paper showed interest and focused the research on study of knowledge conversion in collaborative entrepreneurial team and barriers to knowledge sharing in FFE of Co-PD process.

### **3 Early Stage of Collaborative Product Design by Entrepreneurial Team**

The result of the 2019/20, nine entrepreneurial teams of four-six members were plunged into collaborative product design (Co-PD) projects with user/customers at innovation lab organized in design thinking style with flexible creative spaces and prototyping equipment (3D printers, CNC milling and laser machines, scanners, etc.) during 2-2.5 months. The teams managed Co-PD projects through all stages of the creative problem identification and problem-solving design process within FFE: identification of customer/market/technology opportunities, development product ideas to meet customer demand and product concepts (Kim and Wilemon, 2002; Koen *et al.*, 2014) (see Fig.1). The teams developed and validated product concepts, i.e. minimum viable products (MVPs) (Blank, 2013) in the field of packaging of various categories of goods and business models. Design thinking and TRIZ approach were used throughout the Co-PD process.

Fig. 1. Early stage (fuzzy front-end, FFE) of product design.

Collaboration and knowledge sharing were organized by integration of users/customers in Co-PD process. The models for integration depend on types of users. Entrepreneurial teams used Empathic Design and the Lead User method (<http://www.leaduser.com/>) for integration with innovative user within the early stage (FFE) of Co-PD. Empathic Design method supposes that users are observed while using prototypes in natural environment (Evans et al., 2002). Lead User method is based on participation in Co-PD of innovative ('leading-edge') users (individuals or companies) that are experiencing "pain"/needs that are ahead of existing targeted market. Often, they develop solution to satisfy their own leading-edge needs ("magic pill" to relieve their own "pain") that after adaption can be attractive commercially (von Hippel and Katz, 2002; Lüthje and Herstatt, 2004; Ebel, 2013).

The "ordinary" users (market majority, use solutions existing on the market) is integrated in Co-PD process by Focus Groups, Concept Testing and Empathic Design methods (Bretschneider, 2016).

In some Co-PD projects, the end users of the future product are individuals (B2C) and the customers are organizations/companies (B2B). In this case, the leaders of the entrepreneurial teams established communications with key decision-makers in the organization, potential customer of the future product. Key success factors of knowledge/information sharing are soft skills in communication and negotiation, and the method of Dialogue (Zhang et al., 2012).

The nine collaborative entrepreneurial teams worked independently from each other and iterated "hypothesis – build – measure – learn – new hypothesis" feedback loop in 3 phases of FFEol domain based on knowledge sharing and experimentation with users/customers (see Fig.1). On the first phase (Ph.1)

"Opportunity" entrepreneurial teams were involved in the design research (user in-context interview and observation). Interviews and observations were conducted in the everyday user context which gave deep and reach view of the details of use-cases, "pains", insights, and user behaviours. In parallel teams study the trends in the certain areas and searching lead users and experts. Entrepreneurial teams used design tools (knowledge wall, persona profile, empathy, and trend mapping). Set of photos, videos, interviews, storyboards are working material for further discussion in a team with identified lead users and experts. The project team interviews lead users to gain deeper insight into emerging needs. Point of view (design task) is formulated at the end of this FFE phase. On the next phase (Ph.2) "Product Idea", entrepreneurial teams organised series of workshops with lead users to share knowledge/experience and finding solution for market. At this phase, the first exploratory prototypes appear in a form of sketch and mock-ups of the future product to start visual communication for representation specific and details within and outside the collaborative teams. Value propositions of a future solution are created and validated with users. In the third phase (Ph.3) called "Product concept" the teams prototyped and tested several minimum product feature sets (MPF). MPF is a "product" which has just enough features to gather validated learning about the product and its continued development (Blank, 2013). Validated MFP goes to the next stages of product development process.

## **4 Research design and process**

### **4.1 Qualitative research**

Due to the exploratory nature of the research, a qualitative type of study was chosen. This approach suits the goal of this research and let us to study the model of knowledge conversion and knowledge sharing barriers in entrepreneurial teams working in collaboration with lead and ordinary users at early stage (FFE) of product design (Co-PD). The authors used qualitative approach of the study with the focus on both individual (member of entrepreneurial team) and team, by observations in a natural environment and in-depth interviews with identification of insights of the respondents. We conducted a case study using the flexibility of this research format, because it did not require a strict pre-planned structure (Yin, 2013). This gave us to use three various data

collection tools (semi-structured interviews, questionnaire, and observation) when needed. We conducted research in a real time when Co-PD process and team activities were in progress.

#### ***4.2 Research process and data collection***

Authors started this research by reviewing the relevant literature around five main areas: knowledge management, innovative product design, collaboration, user/customer integration in product design and entrepreneurial management. Through this study, authors discovered Co-PD process, types of users involved in Co-PD, key joint activities of entrepreneurial team members and user/customers in the different stages of the innovation process. The research questions were formulated based on some gap in theories. Through this research we are going to discover specific feature of model of knowledge conversion and knowledge sharing barriers in entrepreneurial team working in collaboration with lead and ordinary users at early stage (FFE) of product design (Co-PD). For that we conducted a case study within nine entrepreneurial teams working in collaboration with lead and ordinary users at early stage (FFE) of product design (Co-PD).

The process of data collection started with observation of stakeholders and team work to better understand the situation with Co-PD in real time. Given the walking distance, the researchers regularly attended seminars organized by entrepreneurial teams and innovative users, as well as work areas where a concept of new product was created. We used the "shadow" method and observed the details of interactions between members of entrepreneurial teams and innovation users and ordinary users. The accumulated insights made it possible to prepare the survey and interviews with the members of the project teams more effectively. That provided us with an opportunity to better understand the context in which the innovative solution has been developed.

The next step after the start of the observation, which was continued by the researchers throughout the entire process, was the questioning of the members of the entrepreneurial teams (49 people) at the start of the project work to get an idea of their background. The response rate was 95,9%. The next questionnaire was repeated towards the end of the project activity. The response rate was 91,8%.

Previously we created an interview guide including questions concerning the focus areas. In advance, we arranged date/time and familiarized the respondents with the structure of the interview. From experience, it is important that the interview is conducted "not on the run", and the respondent allocates enough time for this activity. The interviews continued at around 1.5 hour each, based on a specific agenda upon the main fields of research. In case of exceeding the time, we arranged an addition meeting. Often, several follow-up questions were sent to responder through e-mails and that allowed to complete incomplete answers of the questionnaire. The interviews were recorded and transcribed afterwards. The aim of the interviews and questionnaire was to identify of the aspects that are covered behind the facts.

## **5 Research results and discussion**

### **5.1 Entrepreneurial team**

There are numerous differing definitions of the term "entrepreneurial team" in existing literature and one of the commonly used is formulated as follows: *"An entrepreneurial team consists of two or more persons who have an interest, both financial and otherwise, in and commitment to a venture's future and success; whose work is interdependent in the pursuit of common goals and venture success; who are accountable to the entrepreneurial team and for the venture; who are considered to be at the executive level with executive responsibility in the early phases of the venture, including founding and prestart up; and who are seen as a social entity by themselves and by others."* (Schjoedt and Kraus, 2009).

In this research we study nine entrepreneurial teams which iterate through "hypothesis – build – measure – learn – new hypothesis" feedback loop in FFE of Co-PD process in order to create a value proposition, user acceptable product concept and business model concept during 2-2.5 months. To have the access to user/customer knowledge, entrepreneurial teams organised collaboration with innovative and "ordinary" users by different models of their integration in FFE of Co-PD.

The integration model depends on the role of a particular category of users in the FFE of Co-PD process because users play different roles in Co-PD. "Ordinary" users are the providers of information about the "pain"/problems/needs of users/customers of the existing market, as well as provide valuable feedback on

user testing of created product concept. Innovative users are co-creators of the new commercial product concept and participate more-less in all phases of FFE of Co-PD (see. Fig.1) with the entrepreneurial team.

Model of knowledge conversion in collaborative entrepreneurial team and knowledge sharing barriers are discussed next section.

### **5.2 SEI model of knowledge conversion in collaborative entrepreneurial team**

The results of our observation in the real context of teamwork, questioning (45 respondents) and interviews (22 respondents), were the raw material for analysis how knowledge was converted within collaborative entrepreneurial teams using knowledge conversion model (Nonaka and Takeuchi, 1995; Nonaka et al., 2000).

#### *5.2.1 Socialization - conversion of tacit-to-tacit knowledge*

Socialization is based on the informal interactions and hands-on experiences obtained inside the team and through collaboration with "ordinary" and innovative users. The common language should be arisen and taken by all collaborative team members for effective transfer and shared tacit knowledge. This is one of the key issues identified in the study. Often innovative users have a different background, level and scope of knowledge and competencies, as well as cultural characteristics. At the very beginning of the joint project activity with selected innovative users, the entrepreneurial teams arranged a series of prof workshops (1-2 times a week) and informal events on weekends ("Friday night") outside the office. This allows not only to come to a common language of communication, but also to quickly establish personal communication, which is very important for the transfer and sharing tacit knowledge.

#### *5.2.2 Externalization -conversion of tacit to explicit knowledge*

Regular prof meetings (on/offline) and workshops (1-2 times a week) one of the tools to convert the accumulated tacit knowledge into explicit. But the research revealed inconsistency between spending resources on preparation of high-quality documentation of the event materials in small team with the frequency of their use by team members. The team members did not spend time reading post-meeting documents. One of the solutions, tested by collaborative teams, of effective knowledge conversion (tacit to explicit) was regular representations in different forms (sketches, storyboards, mockups, exploratory

prototypes, etc.) of the current project results in combination with storytelling and scenario of use (use cases). This format of knowledge converting (so called, intangible to tangible) was developed teams in the practical teams work and shown effectiveness (value/price) for product concept development. Such format of knowledge sharing was also very much accepted by innovative users, since the visualization of solutions was a very understandable form for them to give clearer feedback, comments on changes in the concept design.

#### *5.2.3 Combination - conversion of explicit-to-explicit knowledge*

Research revealed that limited resources (time, people, money) that are under the control of the small entrepreneurial teams do not allow them to accumulate explicit knowledge systematically, documented it and create a new set of systematic explicit knowledge. Unwillingness of team members to develop and save documentation of meetings and workshops in a proper way leads to limitations in new explicit knowledge accumulation and add risk for further success in product development. In this case the mode "Combination" of knowledge conversion model in small entrepreneurial teams is almost "empty" and can be eliminated for such cases.

#### *5.2.4 Internalization - conversion of explicit to tacit knowledge*

Research shown that internalization in entrepreneurial team working in collaboration with innovative takes place mainly through learning by doing. Collaborative team members and integrated users communicate each other and, in many cases, orally learn about the implicit (or explicit) knowledge and further directly assimilate it through learning by doing.

Fig.2 shows the SEI (socialization, externalization and internalization) model of knowledge conversion in an entrepreneurial team working in collaboration with innovative and ordinary users at early stage (FFE) of Co-PD.

Fig. 2. SEI (socialization, externalization and internalization) model of knowledge conversion model.

### 5.3 Barriers to knowledge sharing in collaborative entrepreneurial team

The results of our questioning (45 respondents) and interviews (22 respondents) were the raw material for analysis barriers to knowledge sharing in entrepreneurial team working in collaboration with innovative and ordinary users at early stage (FFE) of Co-PD. Based on the analysis of the materials of the questionnaire and interviews, as well as the literature review, the key barriers to knowledge sharing in collaborative entrepreneurial team were formulated, see Tables 1,2. Authors asked the team members (45 respondents) to rate the significance of the barriers and the frequency of their occurrence during activities in the FFE of Co-PD process. The assessment was carried out using the 4-point Likert scale (from "not a barrier" to "extreme barrier" and from "never" to "very time"). Tables 1,2 show the number of respondents who chose this or that significance of barriers in knowledge share and frequency of their occurrence in FEE of Co-PD.

Table 1. Knowledge sharing barriers in collaborative entrepreneurial team: significance

Nº	Barrier	Extreme barrier	Moderate barrier	Somewhat of a barrier	Not a barrier
<b>Individual level</b>					
1	lack of time to share knowledge	16	15	10	4

Source: author's elaboration based on own research and adaptation (Riege, 2005).

The study showed that large number of respondents defined the barriers associated with trust, communication, language, time, awareness, and distance as "Extreme barrier" to sharing of tacit knowledge (Haldin-Herrgard, 2000; Cumberland and Githens, 2012) (see Table 1). Tacit knowledge is sharing from person to person and having trust within this connection reduces risk and uncertainty. Cultural relations between individuals allows to build trust and indicates ability of tacit knowledge sharing. Tacit knowledge is most effectively shared through face-to-face interaction. Our empirical research supports notion that distance is a relevant barrier to the transfer of tacit knowledge. According to this research, more than half of the respondents meet such category of barriers in collaborative product design (see Table 2).

## 6 Conclusions

We found that knowledge conversion in entrepreneurial team working in collaboration with innovative and ordinary users at early stage (FFE) of product design can be described by 3-mode SEI (socialization, externalization, and internalization) model. SEI can be considered as a special case of the general SECI model of knowledge conversion (Nonaka et al., 2000). Elimination of "Combination" mode relates to the lack of converted "explicit to explicit" content

of knowledge due to limit of resources (people, time, money) of small collaborative entrepreneurial teams. We revealed that exploratory prototyping and systematic representation were the main tool that provides conversion of tacit to explicit knowledge in "Externalization" mode for collaborative entrepreneurial teams in a situation of limited documentation.

The key barriers to knowledge sharing in collaborative entrepreneurial team were formulated and assessed based on the analysis of the materials of the questionnaire and interviews, as well as the literature review. The study showed that large number of respondents defined the barriers associated with trust, communication, language, time, awareness and distance as "Extreme barrier" to sharing of tacit knowledge.

The limitations of this study are related to its qualitative nature and limited sample size. At the next step, we will include a quantitative part of the research considering the accumulated data. The further direction of the research will be associated with development of new models of knowledge sharing in an interdisciplinary entrepreneurial teams that creates an innovative product in collaboration with various categories of stakeholders.

### Abstract

The paper aims to propose a theoretical framework that brings together all the determinants behind VC investment decisions in startups, assessing the relevance of determinants in uncertain times. Specifically, we explore whether these determinants are subject to change during periods of high uncertainty, such as that generated by the covid-19 pandemic. We conducted a literature review drawing a taxonomy of VC determinants. In the literature review, we have recognized 4 determinants: localness, networking, startup industry and entrepreneurial team. Later this we have developed semi-structured interviews to test the relevance of identified determinants. Interviews are directed to 5 VC experts. Results show a relevant emphasis for the entrepreneurial team and networking determinants, while a moderate relevance for the localness and industry.

**Keywords** – Venture capital, determinant, investment decision, uncertainty

**Paper type** – Academic Research Paper

## **1 Introduction**

In accordance with Mason (2020), the economic crisis created by the COVID-19 pandemic will cause a contraction in the supply of venture capital since investors will focus on supporting their existing investee companies and much less on new investments. This suggests that venture capitalists (VC) could change or revise the startup deal-sourcing process, introducing new determinants or giving the existing ones a different priority. The paper aims to investigate which determinants behind investment decisions are relevant for VCs in uncertain times.

A wide literature faces the issue of venture capitalists' (VC) ' investment determinants, however, to the best of our knowledge nobody has explored VC investment decision criteria during or after a crisis. The goal of our study is to generate a theoretical framework that brings together all the determinants behind VC investment decisions in startups, assessing the relevance of determinants in uncertain times. Specifically, we asked whether these determinants are subject to change during periods of high uncertainty, such as that generated by the covid-19 pandemic.

To answer our research question, we conducted a literature review drawing a taxonomy of VC determinants. In the literature review, we have recognized 4 determinants: localness, networking, startup industry and entrepreneurial team. Later this we have developed semi-structured interviews to test the relevance of identified determinants. Interviews are directed to 5 VC experts. Results show a relevant emphasis for the entrepreneurial team and networking determinants, while a moderate relevance for the localness and industry.

## **2 Theoretical background**

Venture Capital has been defined as one of the key figures in generating growth and innovation. Since World War II, the trend has taken hold in the United States, resulting in the entrenched growth of an outsized innovative entrepreneurial fabric. The role and functions played by venture capitalists in the development of entrepreneurship have been widely documented. Realities such as those in Silicon Valley (Ferrary and Granovetter, 2009), Route 128, etc., have been carefully studied and unpacked to understand the dynamics of such disruptive innovation, highlighting the added value brought by the VC. The literature showed that the main motivations behind investment decisions could be incorporated into four macro-categories that we defined as (1) Localness, (2)

Networking, (3) Startup Industry and (4) Entrepreneurial Team. Each of them will be examined in detail in the following paragraphs.

## **2.1 Localness**

Proximity between individuals increases the probability of establishing relationships of friendship and marriage (Bossard, 1932). Similarly, it has been postulated that as distance increases, in terms of spatial proximity, the likelihood of meeting and, therefore, establishing a social relationship decreases (Lazarsfeld and Merton, 1954; Blau, 1977; Blau and Schwartz, 1984).

Processes related to social networks can be borrowed to describe the structures of economic exchange relationships in physical and social space (Granovetter, 1985; Burt, 1992). Information about potential investment opportunities is closely linked to geographic and industrial spaces (Gupta&Sapienza, 1992; Norton&Tenenbaum, 1993; Langeland, 2007; Sorenson&Stuart, 2001). According to Sorenson and Stuart (2001) it is precisely the highly circumscribed flow of information to such "natural boundaries" that contributes to VCs' geographic and industrial investment location choices. This evidence can be linked to pre and post-investment activities: location, in fact, facilitates the discovery and evaluation of opportunities, as well as the possibility for VCs to join boards of directors (Lerner, 1995). Spatial proximity allows VCs also to monitor the companies they have invested in, provide additional services, and train the management team (Chen et al. 2010). Geographic proximity reduces the time costs of monitoring, considering that VCs spend half of their time monitoring and consulting (Sahlman, 1989; Gorman and Sahlman, 1989).

Cumming and Dai (2010) report that some VCs make their investment decisions based on the "20-minute rule", i.e. if a startup company seeking venture capital is not within a 20-minute drive of the VCs' offices, it will not be funded.

Studying venture capital clusters in three metropolitan areas (San Francisco, Boston, and New York) Chen et al. (2010) find the reasons behind agglomerations in three main factors: first-order agglomeration externalities (among venture capital firms), second-order agglomeration externalities (among the types of firms in which venture capital firms invest), and the historical artefact of the location of early venture capital firms in these cities.

Moreover, there are other relevant aspects related to "Localness", as we meant it. These are all those variables linked to a given Country's political, economic,

social, and cultural characteristics. Many scholars focused on macroeconomic aspects defined as sources of a country's attractiveness. These relate to: economic activity, capital market depth, taxation, investor protection and corporate governance, human and social environment and entrepreneurial culture (Groh et al., 2010).

VC firms also depend on the presence of a number of institutions to operate. VCs invest in countries characterized by technological, legal, financial, and political institutions that create innovative opportunities, protect investors' rights, facilitate exit, and ensure regulatory stability, respectively (Guler & Guillén, 2010; Powell, Koput, Bowie, & Smith-Doerr, 2002; Nahata, 2014).

Li and Zahara (2012) also argue that a nation's formal institutions influence the level of its VC activity; the more developed these institutions are, the more likely they are to reduce transaction problems and encourage VC funding. Where formal and informal institutions are weaker, as in the case of emerging countries (Jeng and Wells, 2000; Groh, & Wallmeroth, 2016), different levels of VC presence and investment will be inferred. There are other elements that influence investment decisions, such as the effect of M&A investment volume, the legal rights index, corruption, and innovation (Groh & Wallmeroth, 2016).

Another key aspect is the cultural difference; high differences in ethnicities (Bengtsson and Hsu, 2015), languages, values, and beliefs tend to decrease the likelihood of investment in a given country (Li et al. 2014; Buchner, et al., 2018; Nahata et al., 2014).

Cultural distance often increases agency problems and can negatively affect levels of trust, reputation, financial contracts, and business performance (Li et al., 2014 ; Nahata et al., 2014 ).

Other studies, however, emphasize that cultural differences can add value as it has been shown that VCs are likely to engage in a more intensive screening of potential investments for selection when investing in culturally distant nations, particularly in emerging economies, and that careful deal selection contributes significantly to VC success. In addition, the impact of local investor participation, which serves to mitigate problems arising from institutional and cultural disparities between countries, has been investigated by scholars. While the presence of local investors in VC consortia has a positive impact on firm success in developed countries, it does not affect firm success in emerging economies (Nahata et al., 2014).

## **2.2 Networking**

VCs develop strong ties with other VC firms, and within the industries they repeatedly invest (Sorenson & Stuart, 2001). The importance of networks to entrepreneurial success is widely documented. Scholars investigate the strength of established social relationships as a key to investment success with respect to VCs.

Venture capitalists develop strong ties with other venture capital firms and within the industries in which they repeatedly invest. Interpersonal relationships serve as the primary pathway that structures the transmission of information; the composition of social and professional relationship networks determines which actors learn of promising investment opportunities (Sorenson & Stuart, 2001). In addition, the direct and indirect network ties of financial intermediaries mitigate the effects of distance and local investment preference (Jääskeläinen, & Maula, 2014). Moreover, the centrality of the VCs' position within the network is also essential. Positional characteristics influence the likelihood of venture capitalists to invest not only locally but also outside their local industry and geographic boundaries. Central VC firms can leverage relationships to identify and evaluate distant investment opportunities.

Proximity within networks facilitates cross-border transactions, suggesting that distance from the network is a relevant dimension of distance in addition to its geographic and cultural dimensions.

Indirect ties mitigate the problem related to opportunity identification, which is important for IPOs. On the other hand, direct ties appear to serve as a conduit for information transfer, reducing the problems of assessing the quality of entrepreneurs and consequently facilitating IPO exits to markets to which the firm is connected.

Investors, who can connect to non-local markets despite distance, have less social distance from these markets and consequently can obtain better information from them. In addition to mitigating the local bias based on geographic distance, network ties also mitigate the bias based on cultural distance (Guiso et al., 2009). Again, it emerges from the literature that in cross-border investments, entrepreneurial firms supported by international and local VC unions are more successful than those supported by either one or the other. This suggests that an investment criterion could be based on the complementarity of local and international VCs (Chemmanur, Hull & Krishnan, 2016).

The relevance of interpersonal relationships is further highlighted by the need to establish trust mechanisms within networks (Bottazzi et al., 2016).

### **2.3. Entrepreneurial Team**

Before deciding to invest in a new venture, VCs thoroughly examine the personality and experience of the entrepreneur to ensure that the entrepreneur has the characteristics and qualities required to thrive in the competitive business world (Dhochak & Sharma, 2016).

In a study of a sample of Indian VCs, what emerged was that Indian venture capitalists focus on the personality of the entrepreneur as it reflects their commitment to the project; they also evaluate the entrepreneurs' leadership skills and track record (Dhochak & Sharma, 2016).

In addition to the entrepreneur's leadership skills and personality, an interesting analysis conducted by Warnick et al (2018) , highlights the importance of entrepreneurs' passion, in terms of product passion and entrepreneurial passion. The likelihood that an investment by VCs will be made increases due to passion for the product rather than entrepreneurial passion. Another important factor is the role played by openness to feedback in elevating the attractiveness of perceived passion for the product and entrepreneurial passion in the eyes of investors. The latter element mitigates investors' concerns that unbridled passion will result in entrepreneurial ego, rigidity, or resistance from the investor, the market, and other key stakeholders (Warnick et al, 2018).

### **2.4. Startup Industry**

VCs tend to specialize in specific industries, thus developing expertise in a particular field that allows them to generate more value for the startups and for the VCs themselves (Zhong et al., 2018).

Firms' market sectors are important factors when evaluating investment deals (Tyebjee and Bruno, 1984). Indeed, "industry" spaces represent the natural boundaries where a large information flow about potential investment opportunities develops.

Some VC firms, in fact, specialize in making investments within a particular industry, while others diversify their investments across industries, adopting a

more generalist approach. In general, the performance of specialized VCs appears to be better (Gompers et al., 2009; Hochberg et al., 2015).

In addition, specialization in a particular industry grows experience in parallel, which causes a VC specializing in a specific industry to extend the network of personal contacts among entrepreneurs and other investors in that sector. With a large number of contacts, VCs can identify new investment opportunities (Sorenson & Stuart, 2001). In addition, the more experience the VC has within the target industry, the more industry-specific experience and industry-specific social capital the VC can provide.

### **3 Methodology**

#### **3.1 Method**

We apply the expert interview methodology. The interview is an attempt to obtain systematic and complete information by an expert who possesses certain valid pieces of knowledge and information that is not available to the researcher (Bogner and Menz, 2009). More precisely we conduct a systematizing expert interview to have access to exclusive knowledge possessed by experts (Gläser and Laudel, 2004; Bogner and Menz, 2009) concerning investment determinants and their degree of importance in uncertain times. Interviews are conducted at the level of investment executives upwards, including assistant directors and directors of VC funds. We select 5 VC experts from qualified VC companies with national experience. We in fact started to explore the phenomenon in the Italian scenario. Interviews are semi-structured, and questions are constructed on the basis of available literature, which focuses on the following determinants: localness, networking, entrepreneurial team and startups industry.

##### *3.1.1 Sample of experts*

Table 1 shows a systematic overview of experts. Each of them has a broader national experience. Their company provenance is variegated.

Expert 1 is the CEO and founder of Vertis SGR spa, a dynamic and independent (private) asset management company. His company operates through six closed-end investment funds, reserved for qualified investors, taking on investments in research projects, spin-offs, startups and SMEs and is the reference for investments in innovative Made in Italy. The firm deals with private equity and

venture capital. Venture capital invests with the "Vertis Venture", "Vertis Venture 2 Scaleup", "Vertis Venture 3 Technology Transfer" and "Vertis Venture 4 Scaleup Lazio" funds.

Expert 2 is a strategic and financial advisor for startup, private and public funds. He has a long standing experience in Italian VC funds, particularly seed capital funds. He has been following the Southern ecosystem of startups for years and collaborates with universities, research centers, trade associations, regional finance companies, accelerators and incubators in the main central and southern regions.

Expert 3 is an investment analyst in CDP Venture Capital SGR. The company aims to expand direct and indirect investments, overseeing existing funds while encouraging the emergence of new funds to support the Italian ecosystem startups. More specifically the interview analyst deals with bringing together companies, investors and startups for exchange of high tech ideas and pursue new opportunities.

Expert 4 is a procurement and innovation manager for an Italian Corporate Venture Capital fund. The manager is an expert in seed startup and later stage venture capital. The fund invests in the most promising digital startups with a strong fit with the business strategy.

Expert 5 is an investor manager at LUISS Alumni 4 Growth, the Investment Club of Luiss graduates managed in advisory mode on individual potential club deals, by a company wholly owned by the Luiss Guido Carli University. The Club promotes four to six annual micro-seed investments in Luiss-related startups. Investments prevalently concern Italian startups, however the founder team could be composed by foreign students

Table 1. Sample of expert

Expert ID	Expert position	Company	Interview duration
1	Founder and CEO	Vertis SGR spa	45 minutes
2	Strategic and Financial Advisor	Various banks and incubators	90 minutes
3	Investment analyst	CDP Venture Capital SGR	60 minutes

4	Procurement and Innovation manager	Corporate Venture Capital	30 minutes
5	Investor Manager	LUISS ALumni 4 Growth	30 minutes

## 4 Results and Discussion

Results of expert interviews are illustrated in table 2. The table reports key quotations grouped in four determinants (localness, networking, industry sector and entrepreneurial team), as well as quotes on Covid pandemic issues.

Table 2. Quotations

Expert ID	Determinant	Quotations
1	Localness	<i>"[...]the geography impacts on competencies"</i> <i>"There is a Nord-Sud gap. [...] the Sud gap enables a discount rate for investor"</i>
	Networking	<i>"[...]be part of a network, particularly be part of an accelerator, or in order to facilitate the VC approach to the startup"</i>
	Industry sector	<i>"Distinctive technology rather than the sectors is a key determinant"</i>
	Entrepreneurial team	<i>"The founder competencies and experience is a leading determinant"</i> <i>"[...]having had experience in successful consultant companies such as McKinsey means be prepared to face constantly challenge"</i> <i>"Being a serial entrepreneur is a positive signal"</i>
	Others	<i>"Covid has stressed the relevance of the entrepreneurial team. The particularly mature team have been more agile to face the crisis"</i> <i>"[...] Covid has downsized the startup evaluation"</i>
2	Localness	<i>"The localness is relevant, however the entrepreneurial team prevails [...]"</i> <i>"The legal framework is key aspect...it is a crucial aspect of the Italian context where investment are slow and complex"</i> <i>"The localness impacts on the education and on professional experience [...], in the Southern Italy there isn't top business schools, or top consulting companies, or big companies"</i> <i>"Localness is relevant for the seed capital investment"</i> <i>"National sub-culture impact on the deal process [...]"</i>

	Networking	<i>"the network is crucial to build a trust relationship" "[...]having a business angeli is a pre-condition to access at a first round of investment"</i>
	Industry sector	<i>"The industry sector is relevant for specialized funds, otherwise there are other core elements: the products/services, the traction, the market and the competitive advantages"</i>
	Entrepreneurial team	<i>"People lead the investment choice [...]" "Team competencies and experience are relevant, however soft skill such as speaking in a concise and persuasive way is really important", "The entrepreneurial team should know the right manner to interface with VCs" "Education background and professional experience make the difference"</i>
	Others	<i>"Covid has addressed new investment in covid related firms to re-launch promising businesses[...]"</i>
<b>3</b>	Localness	<i>"We believe in people before their idea[...]" "[...]few startups propose really an innovative idea, thus people make the difference" "The localness impact on the funds reasoning process, but not particularly in the VC deal processing, first of all if the fund is an institutional fund" "The localness could be a relevant determinant for private investors, not institutional" "The fiscal framework is a limit for the italian startup and VC scenario"</i>
	Networking	<i>"Being part of an incubator is relevant [...]particularly for deep tech startups" "After the team, we look at the startup network [...]" "There is another determinant from our point of view: the fundraising. Before investing, for us is relevant that other people believe in the team and in the idea"</i>
	Industry sector	<i>"The industry is relevant for private investors, institutional investor tend to trigger horizontal process in the startup ecosystem"</i>
	Entrepreneurial team	<i>"Education background and professional experience is not so relevant" "We observe the team credibility and their soft skill"</i>
	Others	<i>"Covid has accelerate the decline of sick startups...however it has encouraged some funders and some investors in starting a new path for the growth"</i>

4	Localness	<p><i>"Proximity is essential... it is necessary to easily organize meetings and strengthen relationships and trust"</i></p> <p><i>"The context in which the startup is located is certainly relevant to its success. A successful startup is unlikely to be placed in an unfavorable context."</i></p>
	Networking	<i>"The networking is not a priority...for us is more important the market, not the network"</i>
	Industry sector	<i>"A great idea can be independent by the sector [...]"</i>
	Entrepreneurial team	<i>"People are fundamental, indeed the team is fundamental. If the idea is proposed by an individual it will never be selected. "</i>
	Others	<i>"Covid has not influenced particularly trends or industry, but it has stressed the relevance of the proximity to the firms"</i>
5	Localness	<p><i>""Geographic proximity to target companies influence our investment decision"</i></p> <p><i>"Being proxime to other VC funds is important"</i></p> <p><i>"The economic and financial market are relevant for investment outside our target market (Italy)"</i></p> <p><i>"The legal system influence investment decisions, particularly the fiscal system is very important"</i></p> <p><i>"The level of innovativeness of the region in which startup is located influence affect our decision"</i></p>
	Networking	<p><i>"Founder personal relationship affect our investment decision"</i></p> <p><i>"From our point of view is very important that the investor and the entrepreneur attended the same educational institutions, or the same professional and trade association"</i></p>
	Industry sector	<i>"The industry proximity between investor interest and startup is relevant in the deal process"</i>
	Entrepreneurial team	<i>"The passion of the entrepreneur is moderately relevant, while the leadership and management skills are really important"</i>
	Others	<p><i>"The political stability is relevant for investment during the Covid period"</i></p> <p><i>"The Covis pandemic brought out new trend, i.e sustainability"</i></p> <p><i>"Entrepreneurial team influence investment decisions by a VC fund particularly during the Covid pandemic"</i></p>

Expert interviews confirm the relevance of some of the determinants identified. Particularly the entrepreneurial team and the networking are considered relevant respect to industry sector and localness. Experts in fact appear to agree on the relevance of the entrepreneurial team. Differently from Warnick et al (2018), rather than passion for the idea, investors consider really relevant the personality of the entrepreneur, leadership skills, the track record (Dhochak & Sharma, 2016) and the educational and professional background. However a difference concerning the team background may happen depending on the nature of the fund, private or public.

Networking is a further key determinant. Similarly to Chemmanur, Hull and Krishnan (2016) an investment criterion could be based on the complementarity with other startups' investors such as business angel, incubators, seed capital funds. More than networking some interviews suggest to use as a determinant the fundraising, thus the network of investors. In addition the need to establish trust mechanisms within networks (Bottazzi et al., 2016) is confirmed.

The localness and the industry sectors are considered less relevant than others. Differently from Gupta and Sapienza (1992) or Sorenson and Stuart (2001) the localness is seen as a moderator of the entrepreneurial background. Experts agree in considering localness as a driver for founders competencies, but less as a driver of the investment choice. However, the regional location of the startup could affect the fiscal system, thus may encourage or discourage mainly private investors in their decision.

The industry sector turns out to be the least relevant. Some experts assume the industry is a key determinant for specialised funds or private funds, not for institutional funds. Instead industry experts suggest other determinants such as the competitive advantage and the value proposition.

Concerning the relevance of certain determinants in uncertain times, experts agree that the Covid pandemic has even more increased the importance of the team. Particularly their ability to react and organize the startup with an agile approach.

## **5 Conclusions**

Our paper contributes two folds: i) it enriches the strand of literature investigating the VC role in ecosystems by providing an original perspective about the VC decision making process in uncertain times; ii) propose a taxonomy

of VC determinants. Furthermore, the study may reveal implications for entrepreneurs that intend to receive a VC investment.

Several limitations affect the paper and concern mainly the tiny sample dimension and the national experience of experts. However, in the near future we will enlarge the sample involving international experts and revise some dimensions adding a determinant for the startups' value proposition.

### **Abstract**

Since the last three decades Creative industries (CIs) have seen a sharp rise in their development. They became a central element of modern economy. Nowadays, discourses on CIs are mainly led by their distinctive contribution to different spheres of social and

economic activity: economic growth, new jobs, social cohesion, innovation and competitiveness of companies. Paradoxically, despite compelling calls for the promotion of CIs, their integration success remains rather elusive. In fact, on the one hand knowledge transfer from CIs to other industry sectors is underused, potential unexploited and synergies between CIs and other sectors arriving at innovation limited. In addition, low cross-sectoral collaboration and engagement of CIs in co-creation activities are linked with lack of awareness from both sectors, differences in communication and working methods. On the other hand, traditional industry sectors, such as maritime or production industry record low innovativeness, suffer from pressure resulting from environmental impact and necessity to provide sustainable solutions. In the face of the European Green Deal objectives to be reached by 2050 and contribution to the Agenda 2030 of the United Nations, sustainable innovation and development become the epicentre of the European future related discourses. In this light, the paper addresses research-to-practice problem pointing to the missing theoretical and practical foundation for cross-sectoral collaboration partnerships and tangible results thereof within the regional geographical nexus in which creative economy and CIs are getting an increasing importance. In particular, using real-life innovation prototyping projects as implemented in the South Baltic Sea Region (SBSR) in the frame of the cross-border project "CTCC – Creative Traditional Companies Cooperation" (July 2017–June 2021) that is part-financed by the European Regional Development Funds (ERDF), 32 traditional industry Small and Medium-Sized Enterprises (SMEs) from blue (ports, shipping, shipbuilding and tourism) and green (nutrition, renewable energy, recycling) economy sectors engaged both in formal and informal collaboration modes with CIs. The present research delivers particularly managerial contributions by showcasing how enterprise managers and innovation developers can engage into cross-sectoral innovation development through real-life prototyping along with CIs, what tools and processes help them to chop their way through the undergrowth in the frame of innovation development project as well as how tangible results can be achieved and ramped up. From the theoretical perspective, the research gap on cross-sectoral collaboration with CIs and co-creation for innovation is decreased as well as the focus on CIs as innovation brokers and intermediaries on a firm-level strengthened.

## 1 Introduction

By no doubt creativity is key source of competitiveness, innovation and growth. Recent developments and discourses touched upon sustainable development, inclusion, resilience and recovery brought creativity and thus Creative Industries back on stage. For this reason, the United Nations Conference on Trade and Development (UNCTAD) has dedicated 2021 as the International Year of the

Creative Economy for Sustainable Development, with high potentials of Cultural and Creative Industries (CCIs) contribution to the achievement of the Sustainable Development Goals (SDGs) of the United Nations (UN). Similarly, new institutional arrangements were introduced to support better proaction and reaction to faced complex societal, environmental and global problems, such as the New European Bauhaus Initiative launched in 2021. With fancy words as co-creation and co-design, new European ways are searched for to fix and reinforce sustainable development and find new avenues for Europe's competitiveness and way out of the lockdown.

Bearing this in mind it becomes clear that new tangible and hands-on instruments and solutions are needed to reignite and inspire key economy drivers – Small and Medium Sized Enterprises (SMEs) in Europe. This seems, however, to be a Sisyphean task on the European level. A more dramatic picture arises comparing the calls for CCIs (re)ignition on the longitudinal axis: EU underpins growing role of CCIs for innovation, sustainability and inclusion from 2010 onwards, in particular with the release of the Green Paper "Unlocking the Potential of Cultural and Creative Industries" (EC, 2010). In the Council Conclusions as of 2015 on CCIs cross-over effects aiming at innovation, economic sustainability and social inclusion it is stressed that "(...) there is a lack of awareness of the potential of combining arts, culture and creativity with technology, science and business, as well as insufficient exchange of good practices. In particular, the *catalytic effect* of culture and the arts on innovation in all sectors is still underestimated and thereby underused; (...) sectors and policies are still often organised in silos, thus limiting the scope for synergies and the emergence of innovative solutions (...)." (2015 / C 172/04, p. 13). The policy supports that there is a growing need to establish brokering and collaboration networks between CCIs and other sectors to drive innovation, parse market potentials and perceive creativity as an asset in the entire ecosystem (EC, 2018, p. 1; EC, 2019, p. 25).

Acknowledging this potential, CCIs shall play more crucial role in the future. This is already articulated by different institutions on the European level, national, transnational, cross-border, regional and local. To start with, the new EU Communication on "A New Industrial Strategy for Europe" (2020) addresses the challenges and points out that the way things are designed should be revolutionised, apply circular economy principles, and co-create via Public-Private Partnerships to help industry to develop technologies to meet their goals. In

addition, with the European Innovation Council that has started in 2021, a new place-based innovation and innovation should be encouraged. This would allow regions to develop and test new solutions with SMEs and consumers, drawing on their local characteristics, strengths and specialisms (EC, COM (2020) 102 final, p. 10). Similarly, the call for sustainable products' design was reinforced with "A new Circular Economy Action Plan for A Cleaner and More Competitive Europe" that amplifies the need for addressing aspects of products' sustainability and sufficient design in terms of circularity already at the design and value chain management stages (EC, COM (2020) 98 final, p. 3).

Against this background, the present research postulates itself somewhere on the crossroads of traditional innovation development and a growing interest on CCIs catalyst and brokerage effects in the regional nexus – would they act as drivers, connectors or integrators for the purpose of sustainable innovation development and search of problem / idea solutions of economic agents (Colombo et al., 2015; Gassmann et al., 2011; Bonetto et al., 2014; Halevy et al., 2019; Obstfeld, 2017; Sdrali, 2020). In contrast to a series of research papers, this research focuses on revealing potential of Creative Industries (CIs) only, meaning that only design, architecture, advertising and software and games are under scrutiny as key CIs sectors according to the taxonomy of the EU, leaving sectors of culture, such as museums, film, etc. outside the research nexus. More specifically, the researchers address the research gap following Bakhshi & McVittie (2009) and raises the research question (RQ) on how CIs can practically engage into innovation with traditional businesses (blue and green regional SMEs) and develop tangible innovation solutions' prototypes via co-creation and cross-collaboration?

In order to answer this question, the research utilises the action research and uses 33 innovation prototype journeys involving both CIs and traditional blue (marine resource-based) and green (ecology and circular economy driven) SMEs from the Interreg South Baltic Sea Region (SBSR). During a 17-month prototyping phase, 33 innovation prototypes were developed in the field of product, service, business modelling and marketing. All of them make a sound contribution towards improving regional performance of involved SMEs from Germany, Lithuania, Poland and Sweden. Against this, this pioneering project serves as a result-rich pilot establishing a bridge between CIs and traditional industry sectors in Europe and paves the way for hands-on actions leading to sustainable innovation development and regional growth. Therefore, this study contributes to

policy-driven managerial discourses supporting practical co-creation and cross-sectoral collaboration for innovation via formal and informal cross-sectoral collaboration modes as well as reduces the research gap on CIs potential for regional economy on macro (regional) and micro (firm level).

Following this endeavour, the paper starts with comprehensive positioning of the research in the theoretical domain, continues with the overview of the methodological journey and presents the achieved results – how practically both sides – CIs and traditional industry SMEs can deliver innovation outputs. Next, research achievements are elaborated on in the topical context and future research trajectories delineated.

## **2 Laying the groundwork: A cross-perspective in the theoretical realm**

In the macroeconomic paradigm innovation is a key to economic growth and welfare. Looping innovation discourse, creativity acts as significant ingredient for innovation, as coined by Schumpeter. It is a process of “creative destruction” – new ways using existing means, materials and methods. Something new can be created not from regular basis, but rather from something that is new to the existing value system of static economy. New is a new kind. It is also using and / or employing something in a new manner, thus carrying out new combinations (Schumpeter, 1911, pp. 409-410). Innovation means creativity plus exploration (O’Sullivan and Dooley, 2009, p. 8). Creativity is essential part of innovation, thus implying growing needs to determine needs to determine methods, which could be used to generate more and better ideas, which then could be commercialised, thus turning into innovations (von Stamm, 2008, p. 2). To utilise creativity for innovations, there is a need to locate and utilise it within the process, i.e. ideation, development and commercialisation, innovation being an output thereof. The creative process goes further than the simple production of visual outputs, as design is inserted into many areas of management decision-making. Design is an internal management process that integrates market research, marketing strategy, branding, engineering, new product development, production planning, distribution and corporate communication policies (de Mozota, 2003, p. 18). Much more, design process can facilitate innovation potential of a conceptual solution with a set of elements, so-called innovation vectors and improve the decision-making process for a given design problem (de Bassi Padilha et al., 2017,

p. 59) and reveal avenues for companies to consider and integrate preferences of customers and experts for product innovation through prioritisation and evaluation of product design factors (Yu and Li, 2021, p. 13). Indeed, the recent literature confirms that innovation is an outcome of scientific activity and creativity, and that the combination thereof is a key to innovation (Cerisola, 2019; Chapain and Strykiewicz, 2017; Rodriguez-Pose and Lee, 2020, p. 1).

However, the relation between CIs and other industries should be perceived through the lens of knowledge spill-overs (Bakhshi and McVittie, 2009; Caves, 2000; Santoro et al., 2020). These, in turn, emerge as an outcome of formal and informal collaborative modes between CIs and other firms, networks (Ferraris et al., 2017), strategic alliances (Chesbrough, 2006; Zollo et al., 2002) or even user-communities (Prause and Thurner, 2014). Therefore, when exchanging and transferring knowledge, methods, tools and perception of the environment from the own perspective, CIs and other sectors engage into cross-sectoral collaboration and develop a cross-innovation process (Bresciani et al., 2017; Enkel and Gassmann, 2010). A cross-innovation has numerous advantages, starting with competitive advantage and improved business performance (Almeida and Kogut, 1999; Matejun, 2018; Powell et al., 1999), higher level of innovation (Bellantuono et al. 2013; Laursen and Salter, 2006; Santoro, 2017; Stuart 1998) and a sound contribution to environmentally friendly solutions (de Medeiros et al., 2014) and eco-design (van Hemel and Cramer, 2002).

Indeed, making the case of cross-industry collaboration, which encapsulates cross-disciplinary co-work, co-creation and thus cross-sectoral collaboration is beneficial to all involved parties. It implies on the one hand and is governed by on the other hand by causality and interdependencies among nature, people and agents (companies). Likewise, these co-exist, co-create and co-evolve in the common setting geographical region, economic agglomeration and bounded micro-sphere – companies. Interdependency includes also aspects of physical and intangible assets (infrastructure), institutions, sources of knowledge, human capital interactions and spill-overs and network effects (Audretsch et al., 2016; Jackson et al., 2017). As a result, co-creation and cross-sectoral collaboration shall be reviewed from the perspective of entrepreneurial ecosystems, where people, materials, good and activities under different governance patterns reconcile (Colombo et al., 2019) and enable development and growth of dynamic, goal-driven communities, characterised by complexity, dynamism, adaption and emergence perspective (Gobble, 2014). Cross-sectoral collaboration enables

cross-innovation, since it is based on interplay of strong relations that presuppose collaboration, trust and co-creation of value and share of complementary technologies and competencies (Durst and Poutanen, 2013; Frow et al., 2015; Payne et al., 2008).

Bearing in mind the potential of CIs for regional SMEs, benefits for regional innovation and thus regional growth from cross-sectoral or cross-industry collaboration become huge. Integration of diverse perspectives might result in reciprocal benefits, strengthening inclusion, holistic perception of a problem or solution.

### **3 Methodology**

The research approach is of qualitative nature, dominated by a qualitative paradigm (Silverman, 2020). The research pinpoints the social construct's domain, as it deals with regional enterprises and innovation development. Taking the research gap under scrutiny, we might use the arguing of Creswell (2014), who contends that if a concept or phenomenon needs to be explored and comprehended, since only scant research on that has been done, then qualitative approach appears to be feasible. Additionally, qualitative research is especially useful when the researcher does not know the important variables to examine (p. 50).

Therefore, the impetus of inductive reasoning and thus aimed conceptualisation supports the use of the overall methodological approach (Gioia et al., 2013). An action research approach was employed throughout the entire research trajectory (Eden and Huxham, 2006; Foss and Moldenæs, 2007; Maestrini et al., 2016; Susman and Evered, 1978), as the research lasted for a longer period and the research results were recalled and reconciled in several progress phases. It is a suitable approach for the present research, since it is able to provide a way to act in a holistic and complex way. It supports a dualistic and dialectic view employed here and discussed above and opens up opportunities to bridge both science and practice. Furthermore, it enables to intertwine different research methodology categories (Zhang et al., 2015, p. 151). This is also the case in the present research. Action results is applicable, since the researchers of this paper were directly involved in the ongoing projects as innovation brokers – creative brokers – and undertook an observation and assessment of a real-time innovation prototyping within and with local and regional SMEs. Learning cycles in the frame

of the action research that were integrated in the upcoming research activities constituted also an important research component (Gustavsen, 2005, p. 281). The aggregated research trajectory can be summarised in the following way:

Table 1: Research Trajectory Overview

<b>Research scope</b>	<b>Interreg VA project CTCC – Creative Traditional Companies Cooperation</b>
Geographical coverage	South Baltic Sea Region – Danish, German, Lithuanian, Polish and Swedish coastal regions
Research scale	33 prototypes developed for 32 traditional SMEs
Research approach	Inductive
Research methods	Shadowing, co-creation, expert interviews
Research data	Qualitative
Research techniques	Data analysis, coding, decoding, explanation building
Research validation	external validity by innovation experts and policy makers in the frame of pitching ideas

Wrapping up the research journey we claim that we underpin the qualitative research methodology by integrating the so-called actor's approach (Arbnor and Bjerke, 2008). The research deals with reality and real challenges of SMEs addressed within the applied research project. The reality is socially constructed including and integrating stakeholders, participating and constructing sense-making and understanding (Lincoln et al., 2011).

The researchers disclosed their bias through the participation in the project as leading researchers and encountered this through involvement of experts in validation of the results as well as presentation of the intermediate results to direct target groups – regional SMEs.

## 4 Results

At the core of the CTCC project, there is cross-border and cross-sectoral collaboration across disciplines, industry sectors, institutions, performance areas, geographical regions and socio-economic contexts. Indeed, this bears higher success for the project, as cross-sectoral, interdisciplinary and cross-institutional cooperation might lead to higher innovation outputs, where all possible different perspectives are merged together to deliver the value to customers and users, thus meeting their expectations and avoiding any unpredicted effects or negative implications on environmental, technological, market and social levels. In

particular, the project delivers 33 tangible innovation solutions – innovation prototypes in product, service, marketing / branding and organisational level. This is achieved within the innovation development project – the so-called “Creative Auditing” that is done in the frame of minimum 17-month lasting project phase by interdisciplinary teams, where traditional sector SMEs cooperate and engage in innovation development together with start-ups, SMEs and freelances from the mentioned Creative Industries.

Figure 1: Creative Audit Tool for Cross-Sectoral Innovation in Traditional Industry SMEs  
(Source: Laima Gerlitz, 2020)

Creative Audit Tool (Figure 1) was applied during the innovation prototype development phase that took place more than 17 months out of 36-month project length. In synopsis, the project applied a holistic and multidisciplinary approach, where several key tools and methods from the innovation development, creativity and design management were applied. The Creative Audit Tool supports contribution towards development of specific mechanisms and tools that stand behind innovation processes (EC, 2010, p.17). Indeed, current research shows only a very limited record when it comes to practical tools for

SMEs, e.g. design audit tool by Moultrie et al. 2007. Yet, also existing, these tools mostly concern new product development, does not consider recent industry and transformation trends, i.e. digital transformation and Industry 4.0, as they were developed before industrial changes occurred. In addition, scrutinised approaches remain too theoretical and provide only auditing strategies without any specification of practical implications (Gabl et al., 2016), static tools without a process orientation that deliver status quo (Baumgarth et al., 2016) or are oriented towards organisational culture only, i.e. on branding and brand audits (Marrs et al., 2011; Wallström et al., 2008).

By contrast, at the core of the CTCC the delivered Creative Audit Tool there is a traditional SME that by bypassing specific steps and applying given appropriate methods is able to arrive and solid, tested and sustainable innovation output – would it be product, service, organisational improvement, e.g. change management or application of new organisational procedures and methods which optimise SME performance, or a business model aiming at improving SME's positioning, differentiation and diversification efforts through targeted marketing and branding activities. Significantly, it differs from other similar tools, as it underpins innovation character. Innovation is regarded as a key towards transformation. The tool is universal, it can be used for any kind of innovation development, a problem / challenge solving or company idea maturing. Creative brokers act within the innovation process as "owners" of the Creative Audit Tool, who are responsible for guidance, counselling between creative and traditional sectors, monitoring the progress in innovation, control and evaluation. Since innovation is a process that requires high complexity, the tool serves also as facilitator and bridge of diverse processes, actors and stakeholders meeting in innovation development. In particular, having an external source of innovation – Creative Broker – a new perspective outside of SME is integrated.

In the following, the research summarises how Creative Brokers support innovation development in selected SMEs from Germany, Lithuania and Poland, and thus contribute toward Blue and Green Growth in the region and in the EU (Table 2). The selected cases display balanced geographical coverage (Germany, Lithuania and Poland), followed by the principles of cross-sectoral balance and balance regarding innovation output (product, service, business model, organisational innovation). Finally, the balance was kept when revealing contribution for both – Blue and Green Growth in the innovation paradigm of the EU. The present paper showcases only results of nine selected SMEs based on the

fact that by the finalisation of this research, that was hampered by the COVID-19 pandemic outbreak, only these nine prototypes were fully fledged and the prototype development cycle closed. For the purpose of presentation, SMEs names were anonymised in order to safeguard confidentiality and data protection. This does not affect research results.

Table 2: Selected Cases of Creative Audit Tool Application & Collaboration with Creative Brokers for Blue Growth Innovation in Traditional SMEs (Source: CTCC project, 2020)

Organisational Level		Creative Audit Tool Application (process level)			
Traditional Sector SME	Traditional SME Expertise Field	Product Innovation	Service Innovation	Organisational Innovation	Marketing & Branding (Business Model) Innovation
<b>SME 1</b> <b>Neustrelitz,</b> <b>Germany</b>	Sustainable agriculture	Online platform			Digital business model (pricing & service components for digital marketing)
<b>SME 2</b> <b>Rostock,</b> <b>Germany</b>	Sustainable food		Online platform for customers pre-ordering products and picking them up in the physical store)		
<b>SME 3</b> <b>Rostock,</b> <b>Germany</b>	Small wind energy plants		Online information tool as part of overall strategy		Improved communication strategy
<b>SME 4</b> <b>Klaipeda,</b> <b>Lithuania</b>	Food industry, production			Development of identity & communication channels for a start-up	Presentation of SME for exhibitions
<b>SME 5</b> <b>Klaipeda,</b> <b>Lithuania</b>	Maritime transport & shipbuilding	Smart catamaran using solar	Sustainable ride sharing solution on the water		

Organisational Level		Creative Audit Tool Application (process level)			
Traditional Sector SME	Traditional SME Expertise Field	Product Innovation	Service Innovation	Organisational Innovation	Marketing & Branding (Business Model) Innovation
		power	(rental service)		
<b>SME 6</b> <b>Klaipeda,</b> <b>Lithuania</b>	Maritime transport & shipbuilding				Open innovation space for creative industries
<b>SME 7</b> <b>Elblag,</b> <b>Poland</b>	Heat pump manufacturer		Heat pump packaging	Development of corporate identity & communication channels	
<b>SM8</b> <b>Elblag,</b> <b>Poland</b>	Sport kayaks for kids	Three visually differing kayaks			Customisation of product
<b>SME 9</b> <b>Elblag,</b> <b>Poland</b>	Solar energy installations on roofs				Animated video showcasing product for potential customers

Taking a closer look on the selected nine SMEs that were engaged in cross-sectoral development, it can be concluded that most innovations occur in the organisation and service dimension. Though, some SMEs enter also into cross-sectoral innovation to develop novel products not existing on the market – either in the blue or green sector, e.g. SME 1 in Germany, SME 5 in Klaipeda or SME 8 in Poland. In all participating regions, concerned SMEs were engaged in product development, despite regional dimension, i.e. urban agglomeration (Rostock, Klaipeda) or remote regional surroundings (Elblag). The necessity to develop new products results from any missing alternatives, as SMEs producing them enter the new arena and act as first movers. In addition, SMEs developing products engaged into the project as a result of missing resources, either human or financial, or limited capacity and capabilities to apply creative tools. With the

CTCC project, manufacturing SMEs were mainly supported by providing them with creative human resources (e.g. designers), creative tools applications (visualisation, aesthetic appearance) and user-driven approaches (customer / user engagement, tracking of their buying behaviour, engagement).

With creativity potential utilised, traditional SMEs are able to better build up their competitive position with new products and strengthen it by accompanied service or business modelling orientation, thus paving the way for an expansion of their market positioning and reaching out new customer groups. Such companies use cooperation with Creative Industries to increase their productivity, resource efficiency, integrity of products with social, environmental and technological dimensions. Interestingly, by aiming at introducing innovations, such SMEs set out also at enhancing their business portfolio with new business models or branding activities in the experience field on the one hand, i.e. how SMEs can better deliver the offerings to customers and users and represent them via different channels, e.g. networks, exhibitions, etc. On the other hand, this group of SMEs concentrate on services that accompany their products, e.g. online digital tools to use, test the product, or functionality improvement, e.g. when changing the product packaging. As a result, manufacturing SMEs do not longer focus solely on product development itself, but treat innovation development as a bundle of outputs, residing in organisational (business performance, differentiation, positioning and branding) and market (customer / user engagement) fields, going beyond the operational internal business system.

When it comes to SMEs aiming at developing new business models or enhancing their marketing capacity and brand building, such SMEs tend mostly utilise creative potential in order to better understand and integrate their customers and users, e.g. SME 3 from Rostock, SME 6 from Klaipeda or SME 8 from Elblag. SMEs capitalise from creativity, since it enables "translation" of SMEs products and services into the language that is understandable for its customers and users (visual, interactive and user experience driven design utilisation). In this light, the current research confirms the available research outputs highlighting that so far maritime and green industry tend to engage into cooperation with Creative Industries for the purpose of design and capitalisation of marketing instruments for traditional SMEs (e.g. Innobarometer, 2016). In spite of the number of scrutinised SMEs in the following table, the current research is optimistic about the expanding boundaries of traditional business cooperation with Creative Industries, where design becomes an integral process of an SME, a

strategic resource that streamlines SME performance, the mushrooming thereof visible with SME 6 in Klaipeda that acknowledge the role of design and creativity for maritime industry and uses them as a driver for new spin-offs, industry settling and similar. In this, design is used not only for aesthetical appearance and visualisation, but for strategic management purposes. Overall, the development of new products is the most predominant innovation type, followed by service and business modelling innovation. This insight bears a huge potential for the regional economy growth, since SMEs are open to innovation. The majority of start-ups and small enterprises concentrate on product development or its improvement, whereas those who have products aim at better customer / user satisfaction, strengthening market positioning and value generation. Indeed, this is mainly achieved through product servitisation and opening up new horizons with tailored made business models. With this, Creative Industries are able to support traditional manufacturing SMEs in engaging new partnerships and providing with opportunities for collaboration (EC, 2018; EU, 2016).

## **5 Discussion and concluding remarks**

Indeed, as the current project results showcase, innovation development and capacity building in traditional sector SMEs deliver multiple effects and are in line with some relevant key trends on scientific and policy discourses. In particular, by enhancing product portfolio with business models SMEs increase their competitive edge and customer satisfaction. With that, SMEs are more flexible to move on the market and / or adapt to the changing market conditions – transformations, in particular, when digital services are at the core of SMEs' business portfolio. These potentials have been recently highlighted by the topical policy papers on CIs (European Commission, 2019, p. 49; European Commission, 2019, p. 7; COM(2018) 267; European Parliament, 2016). In this line, development of product-related services strengthens SMEs performance, in particular long-term profitability, brand development, their differentiation and positioning on the market. With their improved innovation capacity in the service product and portfolio, regional SMEs are capable also to improve their organisational culture, which is crucial in transformation, as the recent research shows (Bustinza et al., 2017; Gerlitz, 2017) as well as underpins marketing and brand building through customer loyalty to an organisation and its system of values. Indeed, the recent European reports on clusters and industrial change pinpoint CIs as being one of

the ten future emerging industries, which are better equipped to response to uncertainty, potential utilisation, employment growth (European Union, 2020). In addition, regional SMEs learn to engage in new business partnerships with Creative Industries and benefit from application of sector-wide tools and methods within the innovation development. Importantly, SMEs get access to knowledge and information, which is not residing in-house, which makes them stronger in their performance, as pinpointed in the study implemented by the KEA (European Commission, 2019, p. 49).

In sum, the CTCC platform and network has seen so far positive results from cross-sectoral collaboration and innovation development on a short-term, where innovation prototypes are developed with SMEs. It was clearly demonstrated that, although not simple, cross-sectoral collaboration leads to success – tangible solutions, improved capacity building, absorbed knowledge and toolkits from other industries leading towards new business portfolio diversifications, differentiation and better value proposition for customers and users, thus strengthening competitive edge of our regional SMEs on macro-regional, national and international arenas, supported by better visualisation and emotional presentation of their innovation products, services, business models or processes. In addition, the CTCC project supports internationalisation of SMEs as well as strengthening of cross-sectoral and cross-border relationships. As this project demonstrates, co-working for innovation purpose, exchanging of practices via trainings and study visits, changing the perspective and stepping out of own comfort zone, thus leaving geographical, cultural and social proximity, open up new horizons for both Creative Industries and traditional SMEs to cooperate, facilitate transition towards sustainability and market their products.

As a result, this underpins synergy effects for Blue and Green Growth. Significant contribution to sustainable Blue and Green Growth by regional SMEs that develop sustainable and user-driven products includes also recognition and manifestation of the given environmental, social and other concerns of society and searches for the ways to better respond to the given challenges Baltic Sea and its region is facing. With this, the project not only support recent policy trends on capitalisation of CIs potential, but also support research on Responsible Innovation, in which design and creativity play crucial role (Prause et al., 2018). The dovetailing of different sectors' experts, actors of different institutions and governance structures, like quintuple-helix approach stands for, within the innovation prototyping project facilitates market entry and capitalisation of the

developed innovation outputs, as they tend to comply with any environmental regulations and any policy expectations, fulfil the market needs through involvement of customers and users as well as deliver knowledge and skills demanded on the market through involvement of higher education and research institutions. Next to this, innovations delivered as a result of cross-sectoral collaboration integrates within the natural and social ecosystem by supporting preservation of natural resources, reusing existing resources and saving resources that are rare in the Baltic Sea Region.

Future research avenues will need to focus on more informal cross-sectoral collaboration modes and in particular examining social and cultural aspects that might either amplify or hamper cross-sectoral collaboration. In addition, more in-depth research is needed on the inception of cross-sectional collaboration for innovation and what principals, activities and methods could facilitate engagement of both sides. Likewise, succeeding research should increase scale of the present research by analysing and evaluating all 33 prototypes and their outputs.

### **Abstract**

The recent pandemic has changed the reference context of companies and imposed significant changes on them to react to the crisis and contain its effects.

The paper aims to investigate the managers' contribution to overcoming the crisis both in managing internal production processes and through the networks and relationships that they can activate or use. This research contributes to the literature highlight the contribution of relationships to companies' value and managers' role. The results show that managerial skills are drivers of critical success factors for the manager's professional qualities and the ability to manage and implement solid formal relationships in the reference territory and through networks.

**Keywords** – Knowledge Management, Wine Sector, Relational Capital, Manager, Covid-19

**Paper type** – Academic Research Paper

## 1 Introduction

The economic crises characterised the economic and social scenario of recent decades changed and made more complex how people, businesses and territories operate to survive, innovate, explore and organise (Rullani, 2011). The crises have forced companies to identify new paths for growth and development. Companies operate according to the logic of creating a competitive advantage, structuring a series of activities envisaged in the value chain. Still, the territory's functioning that surrounds them and acts according to different logics should not be overlooked. While the company is a production system, the territory must be interpreted as an exchange system in which individuals are at the same time economic operators, family members, institutional members, consumers. The result is a new company vision that includes relations with the external environment (Paoloni, 2021; Paoloni *et al.*, 2019; Tseng, 2014). Thus the company value should reflect the economic-financial performance and those feed the collective well-being (Paoloni *et al.*, 2018; Iaia *et al.*, 2019; Cosentino, 2020).

Intangible resources, such as trust, relational systems, reputation, legitimacy, consensus, combine to constitute the so-called territorial social capital (Manning, 2015; de Castro *et al.*, 2004) while skills (Pérez-Salazar *et al.*, 2019; Belso-Martinez and Diez-Vial, 2018), the attitudes and skills of human resources, the level of social cohesion, the quality of life, the vitality of economic and social exchanges are the basis of the harmonious development of the territory (Boedker *et al.*, 2005; St Pierre and Audet, 2011) and the performance of Italian companies. The territory is not the physical and geographical place where the company operates but represents a strategic resource. Thus, it becomes the space where intangible resources are developed. These resources are knowledge, creativity, culture, art, and a context characterised by its identity, its economic, social and environmental development is defined (Barzotto *et al.*, 2016). Finally, in the territory, relations between the various actors are born and developed, which can encourage a harmonious development process, including technological ones.

In this context, the health emergency, which humanity has faced since the early months of 2020, requires scholars to investigate its effects on companies (Mullins, 2020; Lucchese and Pianta, 2020). In this way, scholars can give visibility to the current conditions of the productive world and propose concrete suggestions that help businesses recover more quickly from the crisis.

In the changed environmental context, investigating managers' contribution to the productive world becomes central. This aspect is less investigated by recent literature. We aim to fill the gap paying particular attention to the role played by managers in the Covid-19 era. More precisely, we aim to *investigate the managers' contribution to overcoming the crisis both in managing internal production processes and through the networks and relationships that they can activate or use*.

The remainder of the paper is organised as follows: Section 2 examines the relevant literature on relational capital and knowledge management. Section 3 outlines the research methodology. Section 4 presents the findings and discussion from the pilot case study. Lastly, section 5 shows the conclusions of the paper and future research directions.

## **2 Relational capital and knowledge management**

Companies necessitate identifying new growth and development paths takes on specific implications during unforeseen shocks (He and Harris, 2020; Mora Cortez and Johnston, 2020), such as that caused by the Covid-19, which is plaguing the entire planet, as revealed by the leading economic indicators (Eurostat, 2021; Istat, 2021).

Scholars have underlined what happens when sudden situations occur, including those caused by catastrophic events, and investigated resilience as a survival factor in the face of threats from the external environment (Van Der Vegt *et al.*, 2015).

The so-called "organisational resilience" (OR) can be included in this stream of research, defined as the aptitude of an organisation to prevent actual occurrences and adapt to unexpected interruptions (proactive aspect). Organisational resilience also includes organisation promptness to adopt random measures reacting to aforementioned interruptions, guaranteeing business continuity (reactive factor) (Jia *et al.*, 2020). In the analysis of OR in states of emergency, Prasad *et al.* (2019) emphasised how relational capital shows its functionality as a value driver due to its capability of allowing organisations access to salient information and resources achieving proactive and reactive OR (Bode & Macdonald, 2016; Johnson *et al.*, 2013).

The attention paid to relational capital and the management's willingness to care about the relationships and implements contacts with stakeholders help

open communication and share information by building behavioural transparency more sought-after during disasters and natural calamities (Villena *et al.*, 2011; Lengnick-Hall *et al.*, 2011). Recent studies emphasised companies' collaborative strategies in the time of Covid-19 (Crick and Crick, 2020; Bapuji *et al.*, 2020) and hypothesised a difficulty in maintaining existing ones (Obal and Gao, 2020).

A crucial aspect to inquire about is relationships as development drivers (Palmatier, 2008) because they can become evaluative factors of resilience and business development in Covid-19 (Eggers, 2020).

In companies' growth processes and their resilience to economic crises, the relationships between organisations and the environment encourage the harmonious development of firms. By adopting this perspective, the economic development of businesses becomes an objective realisable if joined with the other purposes of the territory, such as quality of life, conservation of the landscape, enhancement of available resources and social growth (Cantino *et al.*, 2019; Cillo *et al.*, 2019).

Scholars have recognised the possession of unique and rare knowledge as the leading resource for creating business value (Belso-Martinez and Diez-Vial, 2018). The preservation of knowledge and its application grounded the basis of economic growth and well-being. The organisation's capability to innovate is closely related to its endowments of intellectual capital and its capacity to use knowledge resources (Guthrie *et al.*, 2001).

The development of this approach led to the relationship-based vision (Dyer and Singh 1998). The value created by companies derives from the keeping and dissemination of knowledge and the relationships that the company fosters, the so-called relational capital (Johansson, 2007). Thus, the knowledge incorporated in customers, suppliers and consumers, and the organisation's internal and external relationships (Boedker *et al.*, 2004) represent the relational capital (Johansson, 2007; de Castro *et al.*, 2004). Relational capital is also defined as part of a company's strategy to obtain competitive advantages (Subramaniam and Youndt, 2005; Paoloni, 2021), even in times of crisis (Crick and Crick, 2020; Bapuji *et al.*, 2020).

Scholars emphasised knowledge generation and sharing as a primary intangible resource in generating a competitive advantage (Baum *et al.*, 2001; Dyer and Nobeoka, 2000) by reducing costs (Cepeda-Carrion *et al.*, 2019).

Kamaluddin and Rahman (2009) focused on IC's constituents (relational capital (RC), organisational capital (OC), and human capital (HC)) as value creators (Cavicchi, 2017).

HC concerns the organisation's human aspect and is represented by blending human skills, qualifications, and expertise (Bontis, 1998; Bontis *et al.*, 1999). In this vein, HC refers to the value of the knowledge and talent that is encompassed in people who make up an organisation, conveying intangible resources as know-how, capacities, knowledge, skill, competence, attitude, intellectual agility, creativity (Edvinsson and Malone, 1997; Kaplan and Norton, 1996; Marr and Schiuma, 2001; Hamzah *et al.*, 2018).

Youndt *et al.* (2004) define OC as the knowledge, skills, experience and information institutionalised, codified, and used by patents, systems, databases, routines and processes and includes other not evaluable intangible assets (Edvinsson and Malone, 1997). Paoloni (2021) stressed the RC as formed by the internal and external relationships of the organisations.

Started from previous studies (Tell *et al.*, 2016), this study aims to deepen the research on the relational capital of companies operating in the agro-food sector (Fernandez-Olmos *et al.*, 2021; Paoloni *et al.*, 2020; Cosentino *et al.*, 2021).

The agro-food sector represents an integral part of the European and Italian economy in particular. Companies operate in a highly competitive market due to various factors such as increasing globalisation, the progressive reduction of entry barriers, the presence of large multinationals (Franceschelli *et al.*, 2018; Wilkinson, 2009). Faced with essential constraints, such as slowing demand and strengthening the food retail sector, agro-food companies have developed new sector strategies, especially in Western countries. They have expanded their markets towards emerging economies where the firms fight for leadership positions. All these strategies lead to a greater concentration of capital and highlight the main trends of the world food oligopoly (Tozanli, 1998 Gumbert & Fuchs, 2018; Caiazza *et al.*, 2014).

The changed context during Covid19 has prompted the authors to deepen the behaviour analysis of agro-food companies in response to the crisis. Notably, we observe what impact Covid19 has had on companies' strategies, activities, tools, and results in the agro-food sector, especially concerning resilience strategies. Particular attention was paid to the contribution that knowledge management and formal and informal relations, external and external to the company, gave

both during the critical phase of the lockdown and later, given the persistence of the pandemic and its impact on global economic systems.

### **3 Research methodology**

To comply with the paper aim, we used a qualitative research investigation methodology based on the analysis of the case study (Yin, 2014), particularly suitable for understanding complex phenomena according to a holistic approach (Flynn *et al.*, 1990).

The research was structured based on the following research protocol (Yin, 2014):

i) industry choice: started from recent studies (Paoloni *et al.*, 2020; Fernandez-Olmos *et al.*, 2021; Cosentino *et al.*, 2021), we compared the same context in two different phases: ante and post Covid-19. Notably, we selected an agro-food company operating in the wine sector.

ii) case study choice: we chose a case study that would allow for a broader framework of observation, albeit indirectly. Thus, we investigated a cooperative in the wine sector, active in the centre of Italy. The choice of an agricultural cooperative, whose members are the holders of the raw material (grapes), allows for a comprehensive view of the entire territory. Italian legislation requires members to cultivate land within 40 kilometres of the cooperative's headquarters. In this case, the exchanges of materials are considered contributions rather than trading.

To identify the connections between the relevant aspects, we selected three variables: a) company size, b) company longevity, c) territory (Stake and Schwandt, 2006):

a) company size: we analysed a medium/large cooperative, of which over 200 agricultural entrepreneurs are members;

b) company longevity: we observed a mature enterprise, which would allow us to reach conclusions of general validity;

c) territory: the research protocol provided for on-site visits. To avoid interruptions to the research protocol due to restrictions on free movement, we have chosen a company active in the Roman territory, easily accessible to researchers with national relevance, capable of offering an observation area extended to the Italian region.

iii) strong propensity of management to change.

Based on the points above, we investigated a cooperative in the wine sector, with a long tradition, firmly rooted in Italy's centre for over a century. Despite the territorial connotation, it is a company that operates throughout the national territory and abroad, to a minimal extent.

Data sources are summarised in Table 1.

Table 1: Data source

Database	Typology	Subjects	Interview code
Primary data	Interviews	<ul style="list-style-type: none"> <li>– Director of Quality Sistem</li> <li>– Cooperative President</li> <li>– Professional Accountant</li> </ul>	l <sub>1</sub> l <sub>2</sub> l <sub>3</sub>
Secondary data	Documents, site visits and virtual tours	<ul style="list-style-type: none"> <li>– Scientific literature</li> <li>– Social media</li> <li>– Specialised newspapers</li> <li>– Web sites</li> <li>– Accounting system</li> </ul>	

The interviews were carried out from April 2020 to June 2021 to capture the various phases faced by the company during the last year. The sessions lasted a total of 600 minutes and guaranteed the anonymity of the interviewees. The interviews were recorded and transcribed. The data were analysed using in-vivo coding in NVivo (Miles *et al.*, 2013), and each author performed reliability checks. The results achieved were discussed among the authors and with the interviewees (Yin, 2014).

## 4 Results and discussion

### 4.1 From birth to development

The company was founded in 1945 by farmers moved by the desire for aggregation. The winery was born on the rubble of a public enopoly, innovative and self-sufficient.

As Cooperative President told:

*"Since its inception, the cooperative has always followed the ambition of innovation. The lines, the packaging have observed over time following the taste and style."*

In 2005, the management team prompt to start a new production line. The oenologists and the chemical managers tested it for over a decade, and recently a new line of wine is launched on the market to conquer Ho.re.ca. Italian and beyond.

*"We intended to give a strong image, not only of innovation but also of quality. We had an image in our mind: that of 'millions of hands' that reach the shelves of large-scale distribution to take our quality wines." (I<sub>2</sub>).*

The skills of old and new managers and operators have been used in the continuous search for quality. The arrival in the company of a new manager, with high expertise in the oenological field, has determined a turning point in the production process and the corporate image.

*"Structured production processes, stringent internal quality controls, automation of the production chain have made it possible to obtain essential quality certifications." (I<sub>1</sub>)*

A continuous process of updating and modernisation was undertaken, which required a careful assessment of the available resources (the vineyards of our members) to be addressed with technical choices, first in the production (vines and types of farming) and then in the cellar, with differentiated collections (hand and mechanical).

*"Each process was subjected to a technical-economic evaluation and required shared choices with the cellar technicians and the producers in the countryside" (I<sub>1</sub>).*

#### **4.2 Knowledge management through technological innovation**

Love for tradition and link with the territory do not hinder the technological innovations into the company. Thus, in 2011, improve the quality of the product and efficiency of the production chain led realisation of essential investments aimed at the structural and technological modernisation of the main plant. To date, this plant has become a cutting-edge complex in the oenological sector, respectful of the environment and the safeguarding of the wine product.

The cooperative has made critical investments over the last decade and planned for the near future, thanks to the grants provided by Italian and European legislation to encourage the agro-food sector development. As underlined I<sub>1</sub>:

*"Investments are a fundamental strategic variable for us. We would not have given up on carrying out the planned technological innovations. Non-repayable*

*grants have given us some breathing room and have allowed us to improve the quality of planned investments."*

Table 2 - Investments and technological innovations introduced before Covid-19 (completed)

Year	Value	Typology	Public coverage
2011	3,000,000	Bottling machines and point of sale	RDP <sup>1</sup>
2011	150,000	Construction of a photovoltaic system and reclamation of the structure	INAIL <sup>2</sup>
2013	250,000	Furniture and Fencing Establishment	CMO <sup>3</sup>
2013-2014	300,000	Vitrification of cellar tanks, laser	CMO
2016	200.000	China / Canada / Switzerland	CMO Third countries <sup>4</sup>
2018	290.000	Laboratory and canteen	CMO

Table 3 - Investments in technological innovations introduced before Covid-19 (in progress)

Public coverage	Value	
	Requested	Obtained
RDP	783,117.65	313,247.06
RDP	794,437.56	317,775.02
CMO Third countries 2018 (Switzerland )	130,306.00	65,153.00
RDP	206,143.40	118,279.00

<sup>1</sup> Rural development programmes (RDPs) represent the primary operational tool for programming and financing interventions in the agricultural, forestry and rural sectors funding by European Union. The contribution of the European Union to the EU's rural development objectives.

<sup>2</sup> INAIL is an Italian public body that manages compulsory insurance against accidents at work and occupational diseases.

<sup>3</sup> Common market organisations (CMOs) provide a safety net to agricultural markets through the use of market-support tools, exceptional measures and aid schemes for specific sectors (in particular fruit and vegetables, and wine), to encourage producer cooperation through producer organisations and particular rules on competition and to lay down marketing standards for certain products.

<sup>4</sup> The CMOs for third countries are aimed at strengthening the internationalisation of companies.

### 4.3 The measures adopted during the pandemic

#### 4.3.1 Knowledge management and distribution channels

Various strategies have been adopted to respond promptly to the collapse in sales of the Ho.Re.Ca. channel (Hôtellerie, Restaurant and Café/Catering) or the purchases decrease of high-end wines from large-scale distribution. Firstly, the company had to reinvent the local visibility channel quickly but straightforwardly, which has always represented an important strategic development factor.

*"We had to face a challenging moment, and we got activated immediately." (I<sub>1</sub>)*

The closure of the store during the first lockdown forced the adoption of various commercial solutions. In particular: i) improved the online shop on the site (introduced before the pandemic); ii) entered a 'WhatsApp Business' number on the site for customer care, with the possibility of a direct order; iii) launched a Facebook Ads campaign with the objective of 'conversions' and 'call to action' (entitled " chat on WhatsApp ") in Italy with a focus on the region; iv) increased the number of couriers for deliveries throughout Italy.

#### 4.3.2 Relational capital and formal relationships

The health emergency has pushed the company to strengthen formal relations with institutions. To support measures provided by ordinary legislation, the Italian Government added others to support businesses during the pandemic. The health emergency and the lockdown made it necessary to resort to the subsidies provided by the Government to contain the effects of the pandemic on businesses. Table 4 summarises the measures used by the cooperative and the extent of acceptance to date.

Table 4 - Facilitation and support measures that the company resorted to during Covid-19

Facilitation and support measures provided by the Lazio Region			
Typology	Status of the request	Value	
		Requested	Obtained
CMO 2020	Admissible but not financeable due to lack of funds	273.932,00	//
Facilitation and support measures provided by the Italian Government			
Typology	Status of the request	Value	

		Requested	Obtained
Disinfection	Admissible	7,850.00	7,850.00
Smart Working 2020	Admissible	15,000.00	15,000.00
Mortgage moratorium	Admissible	600,000.00	600,000.00
Replacement and new liquidity	Under evaluation	2,000,000.00	

In this context, the formal relationship ability of the Director of Quality Systems (DRS) favoured the achievement of various results: i) obtaining loans and facilities; ii) adoption of advanced software for the management of production processes; iii) improvement of relationships with the PA and banks. The close relationships with external stakeholders made it possible to contain the crisis's effects. Some of these stakeholders are institutional (banks, Italian Government, Lazio Region).

*"The cooperative was able to access subsidised bank loans for over 3 billion Euros, provided for by the subsidy measures arranged by the Italian Government. It also obtained various non-repayable loans to encourage digitalisation and smart working" (I<sub>3</sub>).*

Different stakeholders are consortia and other wineries spread throughout the Italian territory. The partnerships with them have favoured innovative software to manage production processes and quality control.

*'Existing relationships were consolidated to obtain the necessary support for choosing the most appropriate and efficient software (...).I trusted large consortia in central Italy, who suggested advanced software to improve the product's internal control system' (I<sub>1</sub>).*

The interviews revealed a further role of DQS's skills and attitude in fostering the company's resilience under investigation.

*"Over the past year, the board of directors and I have let QM lead and strengthen relationships with banks and public administrations" (I<sub>2</sub>).*

At the same time, I<sub>1</sub> points out: *"I noticed an increase in trust in me, which has favoured both the relationships between the company and external stakeholders and my career within the company. I recently obtained the qualification of quality director, thanks to the results achieved in relationships with institutions and external lenders".*

## 5 Conclusions

During Covid19, all companies were severely hit by the freezing of activities and reduced consumption. The agro-food sector, particularly in the wine sector, struck this effect due to the closure of the Ho.Re.Ca channel, the sharp contraction in exports and the changed propensity to consume.

The analysis of the sector conducted through the case study allowed us to have an extended vision of the Roman territory, focusing on typical productions, viticulture, established and with a long tradition.

The results show that knowledge management through technological innovations is a critical success factor for companies (Belso-Martinez and Diez-Vial, 2018; Guthrie *et al.*, 2001; Baum *et al.*, 2001; Dyer and Nobeoka, 2000). Thus, the support measures must be strengthened to encourage the increase in investments in the entire sector.

The technological innovations introduced to improve the performances in terms of efficiency and productivity unfold their effects in multiple ways: i) improving the product quality, ii) enhancing the quality system (traceability of flows from the entry of the material before bottling, up to distribution), iii) reducing penalties as a result of non-compliance with health safety conditions, iv) facilitating consumer protection, thanks to a more effective control system.

In general, in the agro-food sector, wine in particular, the "quality control" area, plays a central role in the entire production process, especially in doc production, as in our case study (Youndt *et al.*, 2004; Cepeda-Carrion *et al.*, 2019).

The observation of reality in this last year has shown that the management of knowledge and technological and digital innovations produces at least two effects (Edvinsson and Malone, 1997; Kaplan and Norton, 1996; Marr and Schiuma, 2001; Hamzah *et al.*, 2018).

First of all, it makes production flexible and able to adapt to unexpected market changes. The dematerialisation of some company functions and implementing new business models (virtual trade versus traditional trade, for example) act as a driving force in periods of production shock. However, there remains the need for personal relationships based on trust and the urgency of human confrontation, which must be valued, even if they can occur in different ways than traditional ones.

The company's ability to innovate and to face the challenges of innovation in advance, concerning market demands or the changed environmental context, is confirmed as a critical factor for business success.

The aforementioned results contribute to the emerging literature on successful strategies used by companies to face the crisis, offering an original enrichment to the literature and practice on knowledge management and relational capital contribution to company resilience (Fernandez-Olmos *et al.*, 2021; Paoloni *et al.*, 2020; Cosentino *et al.*, 2021). Our research analysed a medium-sized company with extensive connections with other companies in the area, operating in the wine sector, which has been seriously affected by the pandemic crisis. Our findings offer general validity conclusions on the need for companies to develop authentic and virtual relationships with external stakeholders.

Less definitive are the conclusions on women managers' roles in guiding and promoting these processes (second research question). To obtain more general results, the future phases of the research foresee comparing the case study analysed with another case study, homogeneous by sector of activity, size and the territorial context characterised by male management.
